We investigate the passivity-driven flocking transition in a dense mixture of self-aligning active particles and passive particles, using a minimal model of active polar disks. We show that anisotropic damping leads to a discontinuous flocking transition as a function of the fraction of passive components, whereas isotropic damping produces a smooth transition where the final ordered state can display sustained oscillations and remain trapped in a metastable state, depending on the exact spatial arrangement of the passive particles. We also explore in detail the emergence of metastable oscillatory ordered states and their relation to the spatial distribution of passive particles and interstitial voids. Our findings demonstrate that heterogeneous activity and mobility anisotropy can result in a rich variety of self-organized states in various biological systems, synthetic active materials, and robotic swarms.

Topological transition in filamentous cyanobacteria: from motion to structure — •Marco Mazza — Loughborough University, Loughborough, UK

Many active systems are capable of forming intriguing patterns at scales significantly larger than the size of their individual constituents. Cyanobacteria are one of the most ancient and important phyla of organisms that has allowed the evolution of more complex life forms. Despite its importance, the role of motility on the pattern formation of their colonies is not understood. Here, we investigate the large- scale collective effects and rich dynamics of gliding filamentous cyanobacteria colonies, while still retaining information about the individual constituents' dynamics and their interactions. We investigate both the colony's transient and steady-state dynamics and find good agreement with experiments. We furthermore show that the Péclet number and aligning interaction strength govern the system's topological transition from an isotropic distribution to a state of large-scale reticulate patterns. Although the system is topologically non-trivial, the parallel and perpendicular pair correlation functions provide structural information about the colony, and thus can be used to extract information about the early stages of biofilm formation. Finally, we find that the effects of the filaments' length cannot be reduced to a system of interacting points. Our model proves to reproduce both cyanobacteria colonies and systems of biofilaments where curvature is transported by motility.

DY 17.9 Mon 17:30 ZEU/0160

Novel Phase Coexistence in a Multi-Species Vicsek Model — •Eloise Lardet[1], Letien Chen[1,2], and Thibault Bertrand[1] — [1]Imperial College London, UK — [2]University of Edinburgh, UK

A hallmark in natural systems, self-organization often stems from very simple interaction rules between individual agents. While single-species self-propelled particle (SPP) systems are well understood, the behavior of mixtures of self-propelled particles with general alignment interactions remains largely unexplored with a few scattered results hinting at the existence of a rich emergent phase behavior. Here, we first present a generalization of the two-species Vicsek model with reciprocal intra- and interspecies (anti-)alignment couplings, un-

covering a rich phenomenology of emergent states. Notably, we show that rather than destroying polar order, anti-aligning interactions can promote phase separation and the emergence of global polar order. Secondly, we derive a kinetic theory for the system, finding good agreement between theoretical predictions and particle simulations. This includes a novel mechanism for microphase separation, as predicted by a Turing instability. We finally show that these coexistence patterns can be generalized to multi-species systems with cyclic alignment interactions.

DY 17.10 Mon 17:45 ZEU/0160

Flocking in weakly nonreciprocal mixtures — •Charlotte Myin — Max Planck Institute for Dynamics and Self-Organization (MPI-DS), 37077 Goettingen, Germany

We show that weakly nonreciprocal alignment leads to large-scale structure formation in flocking mixtures. By combining numerical simulations of a binary Vicsek model and the analysis of coarse-grained continuum equations, we demonstrate that nonreciprocity destabilizes the ordered phase formed by mutually aligning or anti-aligning species in a large part of the phase diagram. For aligning populations, this instability results in one species condensing in a single band that travels within a homogeneous liquid of the other species. When interactions are anti-aligning, both species self-assemble into polar clusters with large-scale chaotic dynamics. In both cases, the emergence of structures is accompanied by the demixing of the two species, despite the absence of repulsive interactions. Our theoretical analysis allows us to elucidate the origin of the instability, and show that it is generic to nonreciprocal flocks.

DY 17.11 Mon 18:00 ZEU/0160

Collective behavior in nonreciprocal multi-species Vicsek model with permutation symmetry — •Jae Dong Noh[1], Chul-Ung Woo[2], and Heiko Rieger[2] — [1]Department of Physics, University of Seoul, Seoul 02504, Korea — [2]Department of Theoretical Physics and Center for Biophysics, Saarland University, Saarbrücken, Germany

Nonreciprocal systems are typically built upon asymmetric roles among interacting agents, such as a pursuer-evader relationship. We propose a multi-species nonreciprocal active matter model that is invariant under permutations of the particle species. The nonreciprocal, yet symmetric, interactions emerge from a constant phase shift in the velocity alignment interactions, rather from an asymmetric coupling matrix. This system displays rich collective behaviors, including a species-mixed chiral phase with quasi-long-range polar order and a species-separated vortex cell phase. We present numerical evidence for these phases using particle-based Monte Carlo simulations and analytic evidence using continuum Boltzmann and hydrodynamic equations. Our work demonstrates that multi-species chiral fluids can be realized by a nonreciprocal but symmetric alignment interaction, where the rich collective behavior is a consequence of the interplay between nonreciprocity and permutation symmetry.

DY 17.12 Mon 18:15 ZEU/0160

Flocking with random non-reciprocal interactions — •Jiwon Choi[1], Jae Dong Noh[2], and Heiko Rieger[1] — [1]Department of Physics & Center for Biophysics, Saarland University, Campus E2 6, 66123 Saarbrücken, Germany — [2]Department of Physics, University of Seoul, Seoul, 02504, Korea

Flocking is ubiquitous in nature and emerges from alignment interactions among self-propelled agents. Two species that anti-align or interact non-reciprocally exhibit complex collective phenomena, ranging from parallel and anti-parallel flocking and run-and-chase behavior to chiral phases. Whether such behavior survives in the presence of many species with random non-reciprocal interactions has remained unclear. As a first step, we study a continuous-time Vicsek-like model with fully random non-reciprocal interactions between particles. For infinite-range interactions, flocking emerges once the alignment bias becomes comparable to the non-reciprocal interactions, and deep inside this phase random non-reciprocity can still support slow global chiral and oscillating states. For short-range interactions, even without alignment bias, self-organized cliques form, where medium-sized clusters with predominantly aligning interactions remain stable over long times. We further investigate the robustness of clique formation and the coexistence phase under angular noise using a discrete-time Vicsek model with random non-reciprocal interactions. These results provide a basis for studying multi-species flocking with complex non-reciprocal interactions.

DY 18: Active Matter III (joint session BP/CPP/DY)

Time: Tuesday 9:30–12:45 Location: BAR/SCHÖ

DY 18.1 Tue 9:30 BAR/SCHÖ

inertia-driven re-entrant coil-Globule transition of active ring polymers — •Sunil P Singh[1], Roland G Winkler[2], Rakesh Palariya[1], and Arindam Panda[1] — [1]Indian Institute of Science Education and Research Bhopal, India — [2]Theoretical Physics of Living Matter, Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Germany

The role of inertia in the collective dynamics of active systems has been a subject of increasing interest in recent studies. The present study investigates the inertial effects on active agents. We present the conformational and dynamical characteristics of an active Brownian ring polymer using Langevin dynamics simulations. We show that a long active ring polymer shrinks into globular-like structures even in the absence of attractive interactions. This transition becomes sharper and the structures more compressed as the reduced moment of inertia of the monomers increases, particularly in the intermediate range of activity. We demonstrate that the ring polymer undergoes a coil-globule-coil transition, which is modulated by both activity and rotational inertia. The coil-to-globule transition is mapped in the inertial parameter space (J-M) using the radius of gyration. Additional physical quantities, including bond-bond correlations, scaling behavior in the compressed state, monomer contact probability, geometric distances, coordination number, and effective temperature, further elucidate the physical mechanism driving the collapse. Finally, we show that the effective diffusivity of the ring polymer increases with the reduced moment of inertia as $D_p \sim \sqrt{J}$.

DY 18.2 Tue 9:45 BAR/SCHÖ

Shape selectivity by complex buckling dynamics in poroelastic active gels — •Kinjal Dasbiswas[1], Subhaya Bose[1], Arnab Roy[1], Michael Vennettilli[1], and Anne Bernheim[2] — [1]University of California, Merced, USA — [2]Ben Gurion University, Israel

Shape change in animal cells is prototypically driven by active forces, generated by myosin molecular motors bound to the actin cytoskeleton. Inspired by experiments on disc-shaped extracts of crosslinked actomyosin gels, we aim to show how a family of 3D shapes can arise from buckling caused by non-uniform active stresses. Although synthesized with identical composition of actin, myosin and the crossliker fascin, these gels contract and buckle into different shapes depending on the initial aspect ratio of the disc: thinner gels tend to wrinkle, while thicker gels tend to form domes. By incorporating active stresses, actin alignment, and stress-dependent myosin binding kinetics into a 2D poroelastic gel model, we qualitatively capture trends in gel contraction dynamics observed from quantitative particle image velocimetry (PIV). Next, we carry out numeric simulations of a geometric elastic model for thin sheets to obtain 3D buckled shapes from the strain rates predicted by the poroelastic model. Our results show that the coupling of elasticity to solvent flow, motor binding and fiber alignment play an important role in shape changes in living matter. Our studies have implications for shape changes during tissue morphogenesis and cell migration.

DY 18.3 Tue 10:00 BAR/SCHÖ

The energy cost to build a spindle — •Dongliang Zhang[1], Xingbo Yang[4], Jan Brugués[2,1,3,4], and Frank Jülicher[1,3,4] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [3]Center for Systems Biology Dresden, Dresden, Germany — [4]Physics of Life, Cluster of Excellence, TU Dresden, Dresden, Germany

Spindle is a structure actively build from microtubules (MTs), and plays an important role for chromosome segregation during cell cycle. It's observed in experiments that the spindle size and shape depends on the cell level metabolic rate. In this work, we developed a minimal model that captures the active, energy-consuming processes such as MT turnover and active stress generation, which shows the energy cost for spindle mass maintenance and spindle-shape formation. We show that a spindle can be self-organized through these active processes. We aim to predict how the size and shape of the spindle depends on the energy input, and explain relative experimental phenomena, e.g. spindle shrinkage when the metabolism level is reduced.

DY 18.4 Tue 10:15 BAR/SCHÖ

Cytoskeletal oscillations drive large-scale flows and nuclear organization in early embryonic systems. — •Lara Koehler, Elissavet Sandaltzopoulou, and Jan Brugués — Physics Of Life, TU Dresden

Synchronization drives early embryonic development, enabling simultaneous cell divisions and the spatial organization of nuclei within the embryo. In organisms such as Xenopus, Drosophila, and zebrafish, mitotic waves coordinate cell cycles across distances that exceed diffusion limits, guided by a chemical oscillator. At the same time, global cytoplasmic flows in these syncytial tissues contribute to the large-scale self-organization of nuclei, yet the coupling between biochemical signaling and cytoskeletal mechanics that underlies these directed flows remains poorly understood. Here, we relax the geometric constraints of

the embryo and investigate nuclear dynamics in Xenopus egg extracts and complementary simulations. We show that the periodic polymerization and depolymerization of microtubule asters are sufficient to generate robust large-scale directed flows, even though the asters are intrinsically isotropic. Furthermore, we demonstrate that cell division stabilizes short-range order in a global synchronized system. Together, these findings reveal a minimal physical mechanism by which cytoskeletal dynamics and biochemical oscillations jointly organize flows and patterns, with implications for understanding the emergent principles that shape early development across species.

DY 18.5 Tue 10:30 BAR/SCHÖ

Geometric control of cell migration in disordered porous media — •Laeschkir Würthner[1] and Frederik Graw[2] — [1]European Molecular Biology Laboratory, Heidelberg, Germany — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany

Cell migration is a dynamic process that plays a central role in development, wound healing, and immune responses. Active cell movement is controlled by several biochemical and mechanical cues, including chemokine gradients and the mechanical properties of the extracellular matrix (ECM). Although the biochemical pathways underlying directed cell motion are increasingly well understood, the influence of the porous structure of the ECM on active cell motion remains largely unexplored. Using a combination of computational modeling and theory, we investigate how active cells move through 3D disordered porous environments. We show that cell migration in disordered porous media can be understood as a generalized random walk among "traps", with the effective diffusivity determined by the geometry of the microenvironment. A key implication of our work is that spatial heterogeneities in porosity effectively direct cell motion, revealing a guidance mechanism that we refer to as porotaxis. Overall, our work connects geometry with cell motility and underscores the microenvironment as a key regulator of cell migration.

DY 18.6 Tue 10:45 BAR/SCHÖ

Motility-induced mixing transition in exponentially growing multicellular spheroids — •Torben Sunkel[1,2], Lukas Hupe[1,2], and Philip Bittihn[1,2] — [1]MPI for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

Growth drives cellular dynamics in various dense aggregates, but its effects on other relevant activities have only received limited attention. Here, we investigate the interplay of unconstrained growth, steric repulsion and motility in a minimal agent-based model of exponentially growing, three-dimensional spheroids. Our results reveal a diverging mixing time scale at a critical motility threshold, below which mixing of cells is completely suppressed. Above the threshold, large-scale mixing is enabled. Using an effective phenomenological model parameterized from full simulations, we identify two fundamental mechanisms governing this transition: On the cell scale, weak motility-induced active motion is locally suppressed by growth-induced steric repulsion, consistent with an Active Brownian Particle type description of single-cell dynamics. Beyond this, the expanding nature of the system inhibits global mixing purely geometrically by limiting the exploration range of diffusive cell motion. Both mechanisms naturally scale with the growth rate, highlighting the nature of the transition as an interplay between proliferation and motility. The results provide a baseline for identifying additional biological mechanisms in experiments and could be relevant for competition, heterogeneous tumor evolution and other manifestations of motile proliferating active matter.

DY 18.7 Tue 11:15 BAR/SCHÖ

Fluctuation-Response Theory of Non-Equilibrium Complex Fluids — •Ryota Takaki[1] and Frank Jülicher[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Center for Systems Biology Dresden, Dresden, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany

Active soft materials such as cytoplasm and tissues are constantly driven by chemical reactions and often retain long-lived mechanical memory. In this work, we develop a generalized hydrodynamic framework applicable to non-equilibrium fluids with memory at finite wavevectors and frequencies. Our approach is based on exact correlation-function identities, leading to a fluctuation-response relation for steady states, including non-equilibrium. Applying the theory to chemically driven active fluids, we uncover Active Viscoelastic Memory, in which reaction cycles dynamically renormalize the viscous response and can generate negative storage moduli at finite frequency, absent in conventional viscoelastic materials. Our results provide a first-principles basis for modeling memory-dependent dynamics in a broad class of biological and synthetic active systems, and suggest concrete rheological signatures of chemical driving that can be tested experimentally.

DY 18.8 Tue 11:30 BAR/SCHÖ

Chemically Active Liquid Bridges Generate Repulsive Forces — •Noah Ziethen — DAMTP, University of Cambridge, UK

Intracellular droplets help organize cells by compartmentalizing biomolecules and mediating mechanical interactions. When such droplets bridge two structures, they generate capillary forces that depend on the surface properties and the separation between the structures. While the forces exerted by passive liquid bridges are well understood, the impact of active chemical reactions, ubiquitous in biological condensates, remains unclear.

Here, we investigate a single liquid bridge with continuous chemical turnover, in which the production and degradation of droplet material maintain a non-equilibrium steady state. In this active bridge, the reactions dynamically set the bridge radius, thereby controlling the force-distance relation. In striking contrast to passive systems, we find that activity can generate purely repulsive forces over a broad range of separations. These results show that chemical activity can qualitatively alter capillary forces generated by liquid bridges, suggesting a potential route for cells to actively regulate mechanical coupling via droplets.

DY 18.9 Tue 11:45 BAR/SCHÖ

Shared Laws of Pattern Formation in Reaction-Diffusion and Phase Separation — •Daniel Zhou[1] and Erwin Frey[1,2] — [1]Arnold Sommerfeld Center for Theoretical Physics — [2]Max Planck School Matter to Life

Many nonlinear field theories generate a strikingly similar repertoire of patterns: arrested coarsening, traveling waves, and spatiotemporal chaos appear both in phase-separating systems and in classical reaction-diffusion models. These descriptions have different physical origins, yet recent studies on Turing mixtures and foams in protein systems [1] and on chemotaxis-driven phase separation in cell populations [2] have already highlighted unexpected connections between these ostensibly different mechanisms, linking foam-like, phase-separating, and reaction-diffusion-type patterns. The present work revisits the relation between kinetic and phase-separating descriptions from a more general viewpoint. A unifying perspective is developed that places different modeling frameworks on comparable footing, identifies the conditions under which they yield effectively equivalent patterns, and suggests how stability criteria and design principles can be translated between them. This points toward a more systematic classification of pattern-forming dynamics that cuts across traditional divides between reaction-diffusion, chemotactic, and phase-separating systems.

DY 18.10 Tue 12:00 BAR/SCHÖ

Spatial self-organization of enzymes in complex reaction networks — •Vincent Ouazan-Reboul[1,2], Ramin Golestanian[2,3], and Jaime Agudo-Canalejo[2,4] — [1]LPTMS, CNRS, Université Paris-Sud, 91400, Orsay, France — [2]Max Planck Institute for Dynamics and Self-Organization, Am Fassberg 17, D-37077, Göttingen, Germany — [3]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, OX1 3PU, Oxford, UK — [4]Department of Physics and Astronomy, University College London, WC1E 6BT, London, UK

Living systems contain intricate biochemical networks whose structure is closely related to their function and allows them to exhibit robust behavior in the presence of external stimuli. Such networks typically involve catalytic enzymes, which can have non-trivial transport properties, in particular chemotaxis-like directed motion along gradients of substrates and products. Here, we find that taking into account enzyme chemotaxis in models of catalyzed reaction networks can lead to their spatial self-organization in a process similar to biomolecular condensate formation. We develop a general theory for arbitrary reaction networks, and systematically study all closed unimolecular reaction networks involving up to six chemicals. Importantly, we find that network-wide propagation of concentration perturbations can be key to enabling self-organization, in a manner which is highly sensitive on the global network structure.

DY 18.11 Tue 12:15 BAR/SCHÖ

Spatial organisation of the cell's metabolic power plant via phase separation — •Kathrin S. Laxhuber[1,2] and Frank Jülicher[1,2] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck School Matter to Life

Cell metabolism is the power plant that fuels the active processes essential to life. Recent experimental results show that glycolytic enzymes, central to sugar metabolism, phase-separate to form foci under energetic stress and can localise to sites of demand. To understand this phenomenon, we build and study a minimal theoretical model. We show that droplet formation can act as a metabolic switch that enables the system to maintain energetic homeostasis at higher output power. Notably, the metabolic droplets that emerge from this switch can self-organise to colocalise with demand. We discuss the non-equilibrium features and spatial energetic profiles in this system.

DY 18.12 Tue 12:30 BAR/SCHÖ

Emergent interactions lead to collective frustration in robotic matter — •Onurcan Bektas[1,3], Adolfo Alsina[2,3], and Steffen Rulands[1,3] — [1]Arnold-Sommerfeld-Center for Theoretical Physics and Center for NanoSciences, Ludwig-Maximilians-Universität München, Theresienstr. 37, 80333 München, Germany — [2]GISC, Universidad Rey Juan Carlos, Tulipán, 28933, Móstoles, Spain — [3]Max-Planck-Institute for the Physics of Complex Systems, Noethnitzer Str. 38, 01187 Dresden, Germany

Current artificial intelligence systems show near-human-level capabilities when deployed in isolation. Systems with intelligent agents are deployed to perform tasks collectively. This raises the question of whether robotic matter, where many learning and intelligent agents interact, shows emergence of collective behaviour. And if so, what kind of phenomena would such systems exhibit? Here, we study a paradigmatic model for robotic matter: a system composed of a large collection of stochastic interacting particles where each particle is endowed with a deep neural network that optimizes its transitions based on the particles' environments. For a 1D model, robotic matter exhibits complex phenomena arising from emergent interactions, including transitions between long-lived learning regimes, the emergence of particle species, and frustration. We also find an abrupt, density-dependent change in the behaviour of particles. Using active matter theory, we show that this phenomenon is a reflection of a phase transition with signatures of criticality. Our model captures key phenomena observed in more complex forms of robotic systems.

DY 19: Franco-German Session on Granular Matter I

Granular media exhibit rich collective behavior arising from simple interactions such as friction, collisions, elasticity, and confinement. This session brings together experimental, numerical, and theoretical studies addressing key transitions in granular systems, including jamming, viscous-to-inertial regimes, clustering, gas cooling, and impact dynamics, highlighting the links between microscopic mechanisms and macroscopic responses.

Organized by Baptiste Darbois Texier (Paris) and Franco Antonio Tapia Uribe (Dresden)

Time: Tuesday 9:30–12:45 Location: HÜL/S186

Invited Talk DY 19.1 Tue 9:30 HÜL/S186

Mechanics of entangled fibers — •Olivier Pouliquen[1], Aubin Archambault[1], Ignacio Andrade[2], Jerome Crassous[3], Henri Lhuissier[1], and Joël Marthelot[1] — [1]IUSTI, CNRS-Aix Marseille University, Marseille, France — [2]Departamento de Física, Universidad de Chile, Santiago, Chile — [3]CNRS - ESPCI Université PSL/Sorbonne Université/Université de Paris, paris, France

When long, flexible fibers are densely packed, they form cohesive structures, such as those found in bird*s nests, cotton balls, or fibrous insulation materials. These peculiar granular assemblies exhibit complex mechanical behaviors: they can be compacted and sustain tensile stress, despite the absence of adhesive bonds. Through experiments on model materials and discrete-element simulations, we investigate the interplay between elasticity and friction that governs the mechanics of entangled, non-bonded fiber networks.

DY 19.2 Tue 10:00 HÜL/S186

Rheology of suspensions of non-Brownian spheres across the jamming and viscous-to-inertial transition — •Franco Tapia[1,2], Olivier Pouliquen[2], Chong-Wei Hong[2], Pascale Aussillous[2], and Elisabeth Guazzelli[3] — [1]Institute of Urban and Industrial Water Management, TU Dresden, Dresden, Germany — [2]Aix-Marseille Université, CNRS, IUSTI, Marseille, France — [3]Université Paris Cité, CNRS, Matiére et Systèmes Complexes (MSC) UMR 7057, Paris, France

We study the rheology of suspensions of non-Brownian hard and soft particles across the jamming transition and within both viscous and inertial flow regimes, using a custom-built pressure- and volume-imposed rheometer. Our results, expressed in terms of the effective friction coefficient and packing fraction, demonstrate that suspensions of hard spheres exhibit continuous shear thickening when inertia becomes significant at a transitional Stokes number of 10, independent of the packing fraction. These findings can be extended to a Soft Granular Rheology model by renormalizing the volume fraction and friction coefficient to pressure-dependent values, incorporating both viscous and inertial stress scales. SGranR successfully captures the rheological behavior, showing an approximate collapse into two branches through power-law scaling relative to the distance from the jamming point: (i) above the jamming transition, where the behavior is described by a generalized Herschel-Bulkley law with yield stress and shear thinning, and (ii) below the jamming point, where the behavior follows a critical power law, with shear thinning near the jamming point.

DY 19.3 Tue 10:15 HÜL/S186

granular drag towards zero gravity — •tianhui liao[1], tivadar pongo[1], jinchen zhao[1], simeon vöelkel[2], valentin dichtl[2], raúl c. hidalgo[3], and kai huang[1,2] — [1]Collective Dynamics Lab, Division of Natural and Applied Sciences, Duke Kunshan University, 215306 Kunshan, Jiangsu, China — [2]Experimentalphysik V, Universität Bayreuth, 95440 Bayreuth, Germany — [3]Department of Physics and Applied Mathematics, University of Navarra, 31009 Pamplona, Spain

The role of gravity on the drag force F_d acting on a projectile impacting granular media is investigated experimentally using embedded inertial measurement unit (IMU) sensor and numerically with discrete element method (DEM) simulations. As gravity approaches zero, the inertial drag plays a dominating role, leading to qualitatively different scaling laws and cavity dynamics. Similarly to fluid dynamics, we define a dimensionless granular drag coefficient C_{gd}, which yields a constant of $\approx 1.2 \pm 0.2$ under microgravity, and a term inversely proportional to the impact velocity v_0 is added in the presence of gravity. This connection to fluid drag sheds light not only on a wide range of applications of granular media in space exploration, but also on drag force in non-Newtonian fluids from a first principle perspective.

DY 19.4 Tue 10:30 HÜL/S186

Impact of Roughness on Packing Fraction — •Adrien Luyckx and Eric Opsomer — GRASP Institute, Liege University, Belgium

This study investigates the impact of particle rugosity on the mechanical properties of piles using computational methods. We focus on smooth, non-convex particles (rod, cross, and star shapes) approximated via multisphere approach. Our research introduces the concepts of macro-rugosity, which increases as we progress from rod to cross to star shapes, and meso-rugosity, which is adjusted by varying the number of spheres composing the particles. Key findings include: (1) A limited meso-rugosity is sufficient to capture the mechanical properties of a pile, such as its height. (2) As macro-rugosity increases, the required meso-rugosity decreases. These results demonstrate that particle representation can be optimized by balancing meso-rugosity with the imposed macro-rugosity, significantly reducing computational demands. Our findings contribute to the ongoing efforts in enhancing the efficiency and accuracy of discrete element methods (DEM) in modeling complex particle systems.

DY 19.5 Tue 10:45 HÜL/S186

Tangential forces govern viscous-inertial transition in dense frictional granular suspensions — •Sudarshan Konidena[1], Franco Tapia[1], Alireza Khodabakhshi[1], Élisabeth Guazzelli[2], Pascale Aussillous[3], and Bernhard Vowinckel[1] — [1]Institute of Urban and Industrial Water Management, Technische Universität Dresden, 01062 Dresden, Germany — [2]Université Paris Cité, CNRS, Matière et Systèmes Complexes (MSC) UMR 7057, Paris, France — [3]Aix Marseille Université, CNRS, IUSTI, Marseille, France

Using pressure-imposed rheology, we carry out particle-resolved simulations to study dense suspensions of frictional suspensions as they move from a viscous regime into an inertial one. By independently tuning the liquid viscosity, the shear rate, and the confining granular pressure, we determine that the onset of this transition always appears at a Stokes number near 8 and does not depend on the volume fraction. A key outcome is that the shear stress evolves toward its inertial behavior more slowly than the particle pressure. This delayed response arises from the combined influence of tangential contact forces and lubrication interactions, which govern how frictional particles gradually switch from predominantly rolling motions to predominantly sliding ones. Although the Stokes number dictates the overall shift, the degree of proximity to jamming also plays a role. We further explore how stronger inter-particle friction alters the characteristics of the viscous*inertial transition.

DY 19.6 Tue 11:15 HÜL/S186

Rheology of Granular Sediment Beds from Dense to Creeping Regimes — •Bernhard Vowinckel[1], Pascale Aussillous[2], and Élisabeth Guazzelli[3] — [1]Institute of Urban and Industrial Water Management, Technische Universität Dresden, 01062 Dresden, Germany — [2]Aix Marseille Université, CNRS, IUSTI,

Marseille, France — [3]Université de Paris, CNRS, Matière et Systèmes Complexes (MSC) UMR 7057, Paris, France

We investigate the rheology of sheared sediment beds using grain-resolved direct numerical simulations supported by experimental data. Poiseuille and Couette configurations are examined, extending monodisperse systems to polydisperse beds with diameter ratios up to 10. The simulations provide depth-resolved stress profiles, fluid-particle momentum exchange, particle volume fraction, and granular pressure. For monodisperse beds, shear and normal viscosities and the effective friction coefficient follow established correlations, with a critical particle volume fraction of about 0.3 marking the transition from dense to dilute regimes. In the dilute transport layer, hydrodynamic interactions are screened and the effective viscosity approaches the Einstein relation. For polydisperse mixtures, we generalize $\mu(J)$-rheology by linking its parameters to the maximum packing fraction, achieving good agreement with reference data. Access to very low viscous numbers shows that the friction coefficient in the creeping regime tends to a finite quasi-static value, reducing the critical friction coefficient by a factor of three. These findings refine closure relations for two-phase sediment transport models.

DY 19.7 Tue 11:30 HÜL/S186

Elastic Soft-Shell Packings — •Eric Opsomer and Nicolas Vandewalle — University of Liege, Liege, Belgium

The evolution of pressure at the bottom of a two-dimensional pile of thin elastic rings is investigated for increasing filling height of the system. Due to the soft nature of the particles, contact forces are only weakly deviated which causes a delay of the pressure saturation that is commonly observed in hard grain system. More importantly, for large fillings, an abrupt transition within the structure of the granular pile is encountered once the surrounding pressure leads to the buckling of the rings composing the bottom layers of the pile. The latter transition can be predicted based on the mechanical properties of the thin rings and the global evolution of pressure can be modeled by extending Janssen's model to an effective two-phase granular media.

DY 19.8 Tue 11:45 HÜL/S186

Rheology of dense suspension: the effects of wall-boundaries on viscous-inertial transition — •Alireza Khodabakhshi, Sudarshan Konidena, Franco Tapia, and Bernhard Vowinckel — Institute of Urban and Industrial Water Management, TU Dresden, Dresden, Germany

The transition from the viscous to the inertial regime in dense suspensions is still not fully clarified. Volume-imposed rheometers with fixed-gap walls offer valuable information by reporting shear and normal stress as functions of shear rate, yet the influence of confining boundaries, especially in narrow-gap configurations relevant to industrial and natural flows, remains insufficiently explored. In this study, we perform particle-resolved Direct Numerical Simulations (pr-DNS) of dense non-Brownian suspensions sheared between rough walls in a confined volume-imposed rheometer. The simulations capture the overall viscous-inertial trend reported in recent experiments and reproduce the observed weakening of the effective friction coefficient during the transition. We analyze multiple cases by varying wall roughness and rheometer height, showing that both parameters strongly affect stress levels by altering particle layering. All configurations develop pronounced layering, but the case with the roughest wall and weaker confinement enhances inter-layer mixing, producing higher stress levels. After sufficient strain, this configuration evolves toward a more ordered, low-mixing state, reducing stress to values similar to the other cases. Despite variations in stress magnitude, all cases follow a consistent viscous-inertial transition.

DY 19.9 Tue 12:00 HÜL/S186

Two time scales drive the formation of transient networks in a ferrogranular experiment - and how to control them — •Ali Lakkis[1], Matthias Biersack[1], Oksana Bilous[2], Sofia Kantorovich[2], and Richter Reinhard[1] — [1]Experimentalphysik 5, Universität Bayreuth — [2]Fakultät für Physik, Universität Wien

We are reporting experiments on the aggregation dynamics in a horizontally confined granular mixture composed of glass and magnetized steel spheres under vertical vibration. Upon a sudden decrease of the shaking amplitude, magnetized particles undergo a transition from a dispersed to an aggregated state. For deep quenches, a transient, percolating network of magnetized spheres rapidly emerges and gradually coarsens into compact clusters. In contrast, moderate amplitude reductions lead directly to dense cluster formation without intermediate networking. Using structural and network metrics such as coordination number and its mean value, we identify two characteristic timescales: a fast one governing the head-to-tail chaining typical of dipolar hard spheres (DHS), and a slower one corresponding to the restructuring into compact aggregates [1]. This progression is driven by the intrinsic susceptibility of the beads but is challenged by inter-sphere-friction. Thus, the employed susceptible dipolar hard spheres (SDHS) are a minimal model for phase separation with two intrinsic time scales in only one constituent.

DY 19.10 Tue 12:15 HÜL/S186

CT-resolved flow-induced particle migration in pipe bends during concrete pumping — •Daniil Mikhalev[1], Moritz Kluwe[2], Rüdiger Schwarze[2], and Viktor Mechtcherine[1] — [1]TU Dresden, Institute of Construction Materials, 01187 Dresden — [2]TU Bergakademie Freiberg, Institute for Mechanics and Fluid Dynamics, 09599 Freiberg

In this study, we investigate how the granular microstructure of pumped fresh concrete evolves as the suspension passes through a 90° pipe bend. The material is pumped under realistic operating conditions and allowed to harden in situ. To identify shear-dominated regions, a dyed low-viscosity premix is introduced as a passive tracer. Hardened bend sections are then analysed using high-resolution X-ray computed tomography. Segmentation of individual grains, voids, and tracer regions enables spatial statistics of solid volume fraction, grain-size distributions, air-void patterns, and shear-zone geometry along the inflow-bend-outflow transition.

Preliminary results reveal measurable deviations from the symmetric plug - lubrication-layer structure known from straight pipe flow, including radial and azimuthal segregation and restructuring of both solid and air phases. The combined tracer-based and tomographic approach provides a foundation for linking experimentally resolved microstructure with continuum suspension models and particle-migration theories in complex geometries.

General Discussions

DY 20: Focus Session: Water – from Atmosphere to Space I (joint session CPP/DY)

Water plays a vital role in diverse Earth processes across multiple scales, from atmospheric cycles and aerosol chemistry to geological porous media and nanoscale biological functions of hydrated proteins. Despite its fundamental importance and numerous anomalous properties, such as the diverging heat capacity of supercooled water, pure bulk water remains poorly understood. Key phenomena like evaporation and crystallization are relevant not only on Earth but also in extraterrestrial environments. In Germany, molecular water research is flourishing across prestigious centers, exemplified by the new BlueMat cluster at Hamburg University of Technology, the renewed RESOLV cluster at Ruhr-University Bochum, and the Max Planck Society's expanding Liquid Initiative in Mainz. The 2025 inauguration of the Centre for Molecular Water Science (CMWS) at Hamburg's DESY campus further strengthens a Europe-wide interdisciplinary network, uniting 47 founding members from 12 countries to advance water science across disciplines and methods. Within this focus session the state of molecular water research shall be discussed and interactions between the physical sub-fields shall be fostered.

Organized by Alexander Schlaich, Katrin Amann-Winkel, Mischa Bonn.

Time: Tuesday 9:30–11:00 Location: ZEU/LICH

Topical Talk DY 20.1 Tue 9:30 ZEU/LICH

Surface adsorption and protonation equilibrium of atmospheric organics at the aqueous surface — •Nønne Prisle — Center for Molecular Water Science, Deutsches Elektronen-Synchrotron DESY, Notkestrasse 85, D-22607 Hamburg, Germany — Institute of Inorganic and Applied Chemistry, University of Hamburg, Martin-Luther-King-Platz 6, D-20146 Hamburg, Germany — Center for Atmospheric Research, University of Oulu, P.O. Box 4500, FI-90014, Oulu, Finland

Atmospheric aerosols comprise a significant fraction of organic species which frequently exhibit both surface activity and Brönsted acidity or basicity in aqueous solutions. The high surface area to bulk volume ratios of nano- and microscopic aerosols and droplets further favor surface-specific states, affecting both bulk-phase and heterogeneous chemistry.

We used X-ray Photoelectron Spectroscopy (XPS) in combination with high-brilliance synchrotron radiation to directly observe the protonation state of atmospheric acids and bases at the surfaces of aqueous aerosol and droplet models. We found that for each acid-base pair, the neutral species is enhanced in the surface, consistent with its higher surface activity, compared to the charged conjugate. This introduces a shift in the protonation equilibrium at the aqueous surface corresponding to an apparent change in pKa of 1-2 pH units, depending on the concentration, acidity, and surface activity of the conjugate acidic and basic species.

DY 20.2 Tue 10:00 ZEU/LICH

The Effect of pH on the Structure of Model Sea Spray Aerosol Surfaces — •Clara M. Saak, Lars Höhner, and Ellen H.G. Backus — Institute of Physical Chemistry, Faculty of Chemistry, University of Vienna, Währinger Straße 42, 1090 Vienna, Austria

Aerosols play a key role in the global climate due to their ability to scatter and reflect solar radiation and to act as cloud condensation nuclei (CCN), exerting a pronounced cooling influence on the global climate. In particular, the surface availability of ions and organic compounds is known to affect the hygroscopicity of the particle and thereby its ability to act as a CCN [1]. While the surface propensity of individual compounds has been studied widely, much less is known about more complex systems. Here we focus on the impact of bulk pH on the architecture of mixed aqueous interfaces. In atmospheric systems the pH has been shown to range from roughly pH 8 to 2 [2]. Using sum-frequency-generation (SFG) spectroscopy in conjunction with surface tension data we study the surface composition and structure of short and long chain organic acids at different protonation stages, obtained by varying the pH. Using this approach, we find pronounced changes in the structuring of the aqueous sub-surface layers depending on the specific composition and pH, and in the Gibbs free energy of adsorption of the studied organics. Our results show that it is feasible for subtle environmental changes to considerably affect structure and composition of the aqueous interface, which is known to play a key role in aerosol hygroscopicity. DY 20.3 Tue 10:15 ZEU/LICH

Crystallization behaviour of nanoparticle suspensions — •Isabell Zick[1,2], Eduard Edel[2], and Katrin Amann-Winkel[1,2] — [1]Institut für Physik, Johannes Gutenberg-Universität, Staudinger Weg 7, 55128 Mainz, Germany — [2]Max-Planck-Institut für Polymerforschung, Ackermannweg 10, 55128 Mainz, Germany

Water is one of the most abundant substances in the world and due to this in close contact with many materials including micro- and nanoplastic particles. Those have been detected not only in sea but also in the atmosphere, where the particles can interact with water and act as cloud condensation nuclei or ice-nucleating particles. Emerging evidence suggests that nanoparticles with increased surface roughness or chemical functionalities may promote heterogeneous ice nucleation through different processes like, e.g., contact- and immersion-freezing. Such a behaviour affects cloud properties with significant implications for Earth*s radiative balance and the hydrological cycle.

We investigate atmospherically relevant nanoparticles dispersed in water to investigate their influence on the ice crystallization. Our experiments include calorimetry (DSC) as well as X-ray diffraction measurements (XRD). Our measurements show that the crystallization temperature depends on the particle size, concentration, and the chemical surface of the particles. Using XRD, we investigate the restructuring of the water molecules during supercooling, observed by a shift in the characteristic main diffraction peak of water and the subsequent crystallization process.

DY 20.4 Tue 10:30 ZEU/LICH

Laser-Excited X-ray Reflectivity of Aqueous SrCl2 at the Air-Water Interface — •Ali Ashtiani Abdi[1,2], Julia Kobus[1,2], Svenja C. Hövelmann[1,2], Philipp Jordt[1,2], Nicolas Hayen[1,2], Prashant Hitaishi[1,2], Ajay Ajay[1,2], Rabia Qamar[1,2], Otto Lippmann[1,2], Chen Shen[3], Florian Bertram[3], and Bridget M. Murphy[1,2] — [1]IEAP, CAU Kiel University, Kiel, Germany — [2]Ruprecht Haensel Laboratory, DESY, Hamburg, Germany — [3]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

Understanding aqueous interfaces is essential for describing chemical processes in atmospheric, marine, and geochemical environments. While monovalent salts have been widely studied, the interfacial behavior of divalent ions is less understood, despite their relevance in seawater aerosols and reactive brines. SrCl2 is a representative divalent electrolyte whose interfacial structure may show alteration by laser illumination.

We investigate aqueous SrCl2 solutions at different concentrations using X-ray reflectivity (XRR) at the liquid-air interface. Measurements were performed at the LISA setup at beamline P08, PETRA III (DESY), where controlled laser illumination can be applied directly to the X-ray footprint, following the instrumentation concept of Warias and Hovelmann et al. (J. Synchrotron Rad. 2024). Reflectivity curves were recorded with and without laser exposure. The data demonstrate the suitability of SrCl2 surfaces for laser-assisted XRR and the sensitivity of the method to potential changes in interfacial structure, including indications of near-surface layering.

DY 20.5 Tue 10:45 ZEU/LICH

Monitoring Uptake, Release and Reaction of Gases at the Liquid-Vapor Interface — •Tillmann Buttersack[1], Shirin Gholami[1], Clemens Richter[1], Daniela Torres-Diaz[1], Bernd Winter[1], Pavel Jungwirth[2], Stephen Bradforth[3], Markus Ammann[4], Ruth Signorell[5], Ivan Gladich[6], Remi Dupuy[7], Philip Mason[2], and Hendrik Bluhm[1] — [1]Fritz Haber Institute, Max Planck Society, Berlin, GER — [2]IOCB, Czech Academy of Sciences, Prague, CZ — [3]University of Southern California, Los Angeles, USA — [4]Paul Scherrer Institut, Villigen, CH — [5]EZH Zürich, CH — [6]University of Urbino, Urbino, I — [7]Sorbonne Université, Paris, F

Multiphase reactions are omnipresent in nature, industrial applications. The direct observation of reactions at the liquid-vapor interface requires spectroscopic techniques that are surface specific and chemically sensitive to detect low concentrations, e.g., photoelectron spectroscopy (XPS). Furthermore, the sample delivery method must allow sufficient time for an interface reaction to proceed. These complex challenges require individual approaches for each system of interest. One example for a multiphase process is the reaction between liquid alkali metal and water vapor, which is extremely fast. We used a slow droplet train of NaK in a wet atmosphere and observed the formation of golden aqueous solutions with metallic properties with XPS. An example with relevance for atmospheric chemistry is the formation and the release of sulfur dioxide (SO2) from aqueous sulfite solutions due to acidification. We demonstrated that dissolved gases can be detected with XPS even though their concentration is only about 1 mM.

Thermodynamic bounds and error correction for faulty coarse graining — •Jann van der Meer and Keiji Saito — Department of Physics No. 1, Graduate School of Science, Kyoto University, Kyoto 606-8502, Japan

At the nanoscale, random effects govern not only the dynamics of a physical system but may also affect its observation. This work introduces a novel paradigm for coarse graining that eschews the assignment of a unique coarse-grained trajectory to a microscopic one. Instead, observations are not only coarse-grained but are also accompanied by a small chance of error. Formulating the problem in terms of path weights, we identify a condition on the structure of errors that ensures that the observed entropy production does not increase. As a result, the framework of stochastic thermodynamics for estimating entropy production can be extended to this broader class of systems. As an application, we consider Markov networks in which individual transitions can be observed but may be mistaken for each other. We motivate, derive, and illustrate thermodynamic bounds that relate the error sensitivity of the observed entropy production to the strength of the driving and are valid for arbitrary network topologies. If sufficiently many transitions in the network can be observed, redundancies in the coarse-grained trajectories can be used to detect and correct errors, which potentially improves naive estimates of entropy production. We conclude with an outlook on subsequent research on thermodynamic bounds for erroneous coarse graining.

DY 21.2 Tue 9:45 ZEU/0114

Between heat engine and information engine, characteristics of the entropy production rate in a Brownian ratchet. — Adrien Meynard, Marc Lagoin, Caroline Crauste-Thibierge, and •Antoine Naert — Univ Lyon, Ens de Lyon, Univ Claude Bernard, CNRS, Laboratoire de Physique, F-69342 Lyon, France

A two-state device such as a Brownian ratchet can be regarded as a *heat engine* or an *information engine*. Our experiment, at the centimeter scale, gives access to long time series of all observables of interest, resolved in time. These are the

heat flux $\dot{q}_1(t)$ supplied by the hot (athermal) bath, at an (effective) temperature kT_1, and the work produced per unit time $\dot{w}(t)$.

Taking advantage of the discreet operation of such 1-bit elementary information device, an example of a Maxwell's demon, we can measure the rate of entropy production. We infer a comprehensive characterization of the rate of entropy produced by this device, in the Boltzmann sense. Our findings are compatible with a Poisson point process.

In steady state operation, this entropy is to be released as heat into the surrounding, at ambient temperature $k_B T_2$. (Note that $\dot{q}_2(t)$ is distinct from the various losses.) The heat over temperature ratios of the exchanges with the hot and cold baths are of the same order of magnitude:

$$\frac{\langle \dot{q}_1 \rangle}{kT_1} \simeq \frac{\langle \dot{q}_2 \rangle}{k_B T_2}. \quad (2)$$

We confirm that, within the limit of experimental uncertainties, entropy is conserved in a lossless heat engine, just like energy is.

Minimum Action Principle for Entropy Production Rate of Far-From-Equilibrium Systems — •Atul Tanaji Mohite and Heiko Rieger — Department of Theoretical Physics and Center for Biophysics, Saarland University, Saarbrücken, Germany

The Boltzmann distribution connects the energetics of an equilibrium system with its statistical properties, and it is desirable to have a similar principle for non-equilibrium systems. Here, we derive a variational principle for the entropy production rate (EPR) of far-from-equilibrium discrete state systems, relating it to the action for the transition probability measure of discrete state processes [1,2]. This principle leads to a tighter, non-quadratic formulation of the dissipation function, speed limits, the thermodynamic-kinetic uncertainty relation, the large deviation rate functional, and the fluctuation relation, all within a unified framework of the thermodynamic length [2]. Additionally, the optimal control of non-conservative transition affinities using the underlying geodesic structure is explored, and the corresponding slow-driving and finite-time optimal driving exact protocols are analytically computed [1,3]. We demonstrate that discontinuous endpoint jumps in optimal protocols are a generic, model-independent physical mechanism that reduces entropy production during finite-time driving of far-from-equilibrium systems [3].

DY 21.4 Tue 10:15 ZEU/0114

Asymptotic limit laws of projected empirical currents — •Felix Tippner and Aljaz Godec — Mathematical Physics and Stochastic Dynamics, Institute of Physics, University of Freiburg (GER)

Most experimental measurements capture only a restricted subset of a system's degrees of freedom at any given time. As a result, the higher-dimensional stochastic process that describes the full physical system, such as the high-dimensional conformational dynamics of proteins, can typically be observed only in terms of low-dimensional projections, which are also subject to experimental and sampling constraints. These projections inevitably give rise to non-Markovian behaviour and typically obscure key features of the underlying dynamics, including irreversible probability currents that distinguish driven from reversible systems. The main result of the present work is an asymptotic limit law, i.e., a sharpening of the central limit theorem, for empirical currents of projected observables.

DY 21.5 Tue 10:30 ZEU/0114

Nonlinear Response Theory for Nonequilibrium Biochemical Networks — Ruicheng Bao[1] and •Shiling Liang[2,3,4] — [1]University of Tokyo, Tokyo, Japan — [2]MPI-PKS, Dresden, Germany — [3]MPI-CBG, Dresden, Germnay — [4]CSBD, Dresden, Germany

Living cells process information through biochemical networks operating far from equilibrium. Understanding how these systems respond to finite perturbations, such as changes in enzyme concentrations or metabolic fluxes, is essential, yet the fluctuation-dissipation theorem applies only near equilibrium.

This talk introduces a framework that fills this gap. We derive an exact identity that links nonlinear responses to linear ones through a physically meaningful scaling factor, based on a connection between steady-state responses and mean first-passage times. This provides bidirectional inference: predicting global responses from local biochemical changes, and inferring metabolic costs from measurable observables. We also establish a universal response-resolution limit, a strong-perturbation analogue of the fluctuation-dissipation theorem, which sets fundamental bounds on signal detectability.

Using transcriptional regulation as an example, we show how these parameter-independent bounds constrain the computational expressibility of gene networks. Reliable detection of transcription factor changes requires fold-changes above a universal threshold. Overall, this framework defines general physical limits on cellular information processing, with implications for metabolic control and signal transduction.

Compensating random transition-detection blackouts in Markov networks — •Alexander Maier, Benjamin Häsler, and Udo Seifert — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

In Markov networks, measurement blackouts with unknown frequency compromise observations such that thermodynamic quantities can no longer be inferred reliably. In particular, the observed currents neither discern equilibrium from non-equilibrium nor can they be used in extant estimators of entropy production. Our strategy to eliminate these effects is based on formally attributing the blackouts to a second channel connecting states. The unknown frequency of blackouts and the true underlying transition rates can be determined from the short-time limit of observed waiting-time distributions. A post-modification of observed trajectory data yields a virtual effective dynamics from which the lower bound on entropy production based on thermodynamic uncertainty relations can be recovered fully. Moreover, the post-processed data can be used in waiting-time based estimators. Crucially, our strategy does neither require the blackouts to occur homogeneously nor symmetrically under time-reversal. Reference: Alexander M. Maier, Benjamin Häsler and Udo Seifert, arXiv:2511.14679 (2025)

Why Life Is Hot — •Tanja Schilling[1], Patrick Warren[2], and Wilson Poon[3] — [1]Institute of Physics, University of Freiburg, Hermann-Herder-Straße 3, D-79104 Freiburg, Germany — [2]The Hartree Centre, STFC Daresbury Laboratory, Warrington, WA4 4AD, United Kingdom — [3]School of Physics and Astronomy, The University of Edinburgh, Peter Guthrie Tait Road, Edinburgh EH9 3FD, United Kingdom

Biological organisms use strongly driven cycles to optimize the output of chemical reactions. This mechanism is versatile, it is employed to meet a large variety of cost functions such as robustness, precision, or sensitivity to external stimuli. However, the improvements over the equilibrium behaviour come at the cost of increased production of heat. We show that the heat generated by this mechanism constitutes a large part of the total heat produced by living organisms. Further we demonstrate that the effect saturates and that nature operates near saturation. Hence we conclude that the heat production of living organisms is consequence of their need to function accurately and to adapt flexibly to varying demands.

DY 21.8 Tue 11:45 ZEU/0114

Optimal Localisation against a Flow — •Till Welker and Patrick Pietzonka — School of Physics and Astronomy, University of Edinburgh, United Kingdom

How much work does it cost for a propelled particle to stay localised near a stationary target, defying thermal noise and a constant flow that would carry it away? We study the control of such a particle in finite time and find optimal protocols for time-dependent propulsion speed and diffusivity, without feedback. Accuracy, quantified via the mean squared deviation from the target, and energetic cost turn out to be connected by a trade-off relation, which complements the one between precision and cost known in stochastic thermodynamics. We show that accuracy better than a certain threshold requires active driving , which comes at a cost that increases with accuracy. The optimal protocols have discontinuous propulsion speed and diffusivity, switching between a passive drift state with vanishing diffusivity and an active propulsion state. If the initial position is fixed, an initial jump of the particle, enabled by a sudden burst of propulsion, can be optimal. This study highlights how a time-dependent diffusivity enhances optimal control and sets benchmarks for artificial self-propelled particles navigating noisy environments.

DY 21.9 Tue 12:00 ZEU/0114

Thermodynamic optimal control out of equilibrium: insights from active and driven systems — •Kristian Olsen[1], Rémi Goerlich[2,1], Yael Roichman[2,3], and Hartmut Löwen[1] — [1]Institut für Theoretische Physik II - Weiche Materie, Heinrich-Heine-Universität Düsseldorf, D-40225 Düsseldorf, Germany — [2]Raymond & Beverly Sackler School of Chemistry, Tel Aviv University, Tel Aviv 6997801, Israel — [3]Raymond & Beverly Sackler School of Physics & Astronomy, Tel Aviv University, Tel Aviv 6997801, Israel

Optimal control far from equilibrium raises intriguing questions in stochastic thermodynamics and offers a route to design microscopic engines that operate out of equilibrium. We study thermodynamically optimal protocols for a harmonically trapped particle driven by arbitrary time-dependent forces, including those from active matter or external fields [1]. The resulting protocols are able to harness non-equilibrium forces to extract a net work. We provide exact solutions for the optimal protocol and associated work for arbitrary forces and protocol duration. We also derive a quasistatic work bound that splits into three parts: an information-geometric term capturing energy stored in an initial non-equilibrium state, the work extracted from time-averaged forces, and extra work from fast dynamical modes. Finally, we analyze the energetic cost of

adding boundary constraints, giving insights into the cost of precision in these protocols.

1. Harnessing non-equilibrium forces to optimize work extraction, Kristian Stølevik Olsen, Rémi Goerlich, Yael Roichman and Hartmut Löwen, In press Nature Communications, arXiv: 2504.07049, 2025.

Searching with Memory: Experiments on Stochastic Resetting in Complex Fluids — •Felix Ginot and Clemens Bechinger — University of Konstanz, 78457 Konstanz, Germany

Many natural and technological search processes, from molecular reactions to robotic exploration, benefit from occasionally resetting and trying again. This mechanism, known as stochastic resetting (SR), is well understood in simple memoryless environments, but real systems often exhibit complex relaxation dynamics that retain information about recent motion.

We experimentally investigate SR in a viscoelastic fluid by tracking a colloidal particle undergoing controlled resets. The fluid's delayed elastic response creates restoring forces that oppose each reset and reduce search efficiency. We show that these memory effects can be tuned: holding the particle at the trap center allows the fluid to relax and erase residual memory. With a target present, this control significantly lowers the mean passage time, with optimal performance at intermediate resetting rates. In this regime, memory induces temporal correlations that bunch target encounters and speed up repeated hits.

These results demonstrate that environmental memory can both hinder and enhance search, and they point to new strategies for optimizing transport in non-Markovian media.

DY 21.11 Tue 12:30 ZEU/0114

Information as a Thermodynamic Resource in Non-Markovian Stochastic Systems — •Lokesh Chinnakanna Muruga, Felix Ginot, and Clemens Bechinger — Fachbereich Physik, Universität Konstanz, Konstanz, Germany

The interplay between information and thermodynamics lies at the core of modern stochastic physics. Classical thermodynamics links quantities such as entropy, temperature, and free energy solely to the physical state of a system. Contemporary developments from Maxwell demon and Szilard engine led to fluctuation theorems which revealed that information itself acts as a thermodynamic resource. The acquisition, storage, and use of information can reshape energy landscapes, enable work extraction, and modulate entropy production without violating the second law. In this work, we explore how information stored in unobserved degrees of freedom affects work extraction and equilibrium dynamics in stochastic systems. Using time-resolved position measurements of an optically trapped Brownian particle in a non-Markovian fluid, we show that correlations in the measurement encode memory effects that reveal multiple hidden configurational states. We introduce a new protocol to distinguish these information-bearing states experimentally and quantify their influence on relaxation and work extraction efficiency. Our results highlight how information, whether explicit or hidden can be leveraged as a functional resource for energy extraction and control at the microscale.

DY 22: Pattern Formation

Unexpected wave patterns observed within an extended parameter range of the Barkley model — Vladimir Zykov and •Eberhard Bodenschatz — Max Planck Institute for Dynamics and Self-Organization, D-37077 Goettingen, Germany,

The Barkley model is a widely accepted example of reaction diffusion systems demonstrating different self-organization processes including a creation of self-sustained spiral waves. Recently the study of the spiral wave dynamics performed within the extending parameter region of the Barkley model allowed us to reveal some unexplored features of these processes [1]. The latest computational results performed under a further expansion of the parameter range demonstrate the existence of spiral wave under completely unexpected conditions in monostable and bistable regions. These spirals exhibit absolutely unusual instability, which should be investigated. In parallel to spiral waves self-supported wave segments remaining critical fingers have been observed, which also demonstrated a similar unusual instability.

[1] V. S. Zykov and E. Bodenschatz, Unexplored aspects of the spiral wave dynamics in the Barkley model within an extended parameter range, Phys. Rev. E. 110, 064209 (2024).

DY 22.2 Tue 9:45 ZEU/0118

Dynamics of localized states in a weakly dissipative Korteweg-de Vries-Kuramoto-Sivashinsky Equation — •Justus Keussen[1], Daniel Greve[1], Julien Javaloyes[2], and Svetlana V. Gurevich[1,2,3] — [1]Institute for Theoretical Physics, University of Münster, Münster, Germany — [2]Universitat de les Illes Balears, Palma, Spain — [3]Center for Data Science, University of Münster, Münster, Germany

We are interested in the dynamics of localized solutions in a weakly dissipative Korteweg de Vries Kuramoto Sivashinsky equation, using a combination of analytical, numerical, and path-continuation methods. We show that a traveling solitary soliton exists and is stable over a certain parameter range, even though the homogeneous state is linearly unstable. Furthermore, we employ a variational ansatz to analytically determine the selected velocity of the localized state. Finally, path continuation in the domain size reveals that the corresponding bifurcation points on both the homogeneous and solitary branches follow a power-law scaling with the system length, implying that each domain size admits a finite interval of parameter values in which a stable solitary wave exists.

DY 22.3 Tue 10:00 ZEU/0118

Pattern formation and route to chaos in a two-species reaction-diffusion model with one conservation law — •Simon Navia Rafide[1] and Uwe Thiele[2] — [1]University of Münster, Münster Germany — [2]University of Münster, Münster Germany

In many intracellular reactions, the total amount of a substance remains constant. For example, in reactions involving proteins that can adopt different conformations, it is possible to observe spatio-temporal concentration patterns that differ in their behaviour from those in systems without such constraints. We explore a relatively simple two-species reaction-diffusion model with a single mass conservation law governing cell polarisation [1, 2]. Here, we investigate the bifurcation behaviour of the model in detail and, using numerical continuation and time simulations, show that time-periodic patterns follow a period-doubling route to chaos, which appear in two different flavours. Moreover, we propose an approximate model based on the first two instability modes that allows us to understand the underlying mechanisms behind the first steps of pattern formation.

The 3-Components Problem — •Davide Toffenetti[1], Beatrice Nettuno[1], Henrik Weyer[2], and Erwin Frey[1] — [1]Ludwig Maximilian University of Munich (LMU), Munich, Germany — [2]KITP, UC Santa Barbara, USA

Our work develops a general framework that connects reaction-diffusion systems with active-matter theories. Earlier studies showed that two-component mass-conserving reaction-diffusion (2cMcRD) systems can be mapped onto Model-B-type dynamics [1], which leads to the coarsening of patterns. We extend this idea by introducing a minimal three-component mass-conserving reaction-diffusion (3cMcRD) model. Using adiabatic elimination, we derive an effective active description for the total-mass dynamics, reminiscent of the well-known AMB+ theory. We validate the mapping through extensive numerical simulations.

Only 3cMcRD systems and their associated effective active theory produce finite-wavelength patterns such as dots, stripes, and foam-like structures, in contrast to the coarsening dynamics of 2cMcRD models. Employing a local quasi-steady-state approximation, we further determine the thresholds separating distinct pattern-forming regimes. In particular, we analyze how fingering instability emerges from an initially flat interface, marking the transition to foam-like patterns.

Our approach naturally generalizes to systems with more than three components and and to more general active-matter theories.

DY 22.5 Tue 10:30 ZEU/0118

Coarsening dynamics and interface instabilities in coupled conserved pattern-forming systems — Benjamin Winkler[1], Sergio Alonso[2], and •Markus Bär[3] — [1]RKI and FU Berlin, Germany — [2]UPC Barcelona, Spain — [3]PTB and TU Berlin, Germany

We investigate the coarsening dynamics of non-variationally coupled, mass-conserved pattern-forming systems. Our main example is a model describing multiscale pattern formation via the interaction of membrane binding proteins with a multicomponent lipid membrane. We find that the coupling of a reaction-diffusion system for a protein species to an equation describing the phase composition of a lipid membrane exhibiting active phase separation leads to arrested coarsening for strong enough coupling. In addition, inverse coarsening is found if simulations start from large domains. We show that these phenomena are

closely connected with interface instabilities and an exceptional point in the linear properties of the spatially homogeneous state both of which emerge for strong-enough non-variational coupling. Similar phenomena are also found in a version of the non-reciprocally coupled Cahn-Hilliard equations, which have similar linear behavior and instabilities, and in a qualitative model for a compressible active polar fluid. The nonlinear evolution of the interface instability and the emerging complex patterns depend, however, on the specific form of the chosen model. This is demonstrated with a survey of possible dynamical evolutions in different models.

DY 22.6 Tue 10:45 ZEU/0118

Leading mechanisms of defibrillation: A computational approach to study the differences between monophasic and biphasic waveforms — •Daniel Frühwald[1] and Thomas Lilienkamp[1,2] — [1]Nuremberg Institute of Technology Georg Simon Ohm, Computational Physics for Life Science, Nuernberg, Germany — [2]Max Planck Institute for Dynamics and Self-Organization, Biomedical Physics Group, Goettingen, Germany

Sudden cardiac death caused by, for example, malignant ventricular arrhythmia, results in an estimated 600,000 deaths per year in the European Community alone. In addition, atrial fibrillation is the most common cardiac arrhythmia worldwide, affecting worldwide more and more people with around 33.5 million in 2010 and 59 million people in 2019. In both diseases, the heart can be reset to sinus rhythm by cardioversion: The application of a high-energy defibrillation shock delivered either from an external device, or from implantable cardioverter defibrillators (ICDs). In both cases, patients suffer from significant side effects due to this treatment, including additional tissue damage and post-traumatic stress. The introduction of biphasic waveforms, instead of monophasic ones enabled a significant reduction in energy leading to mitigated side-effects. While many hypotheses for the increased efficiency of biphasic waveforms exist, the underlying mechanisms are not entirely understood. In a statistically driven multi-scale study, we use numericalsimulations to investigate the influence of different cardiovascular structures on the success rate of defibrillation.

Travelling waves of invasion in ecological communities with phenotypic variation — •Pierre A. Haas — Max Planck Institute for the Physics of Complex Systems — Max Planck Institute of Molecular Cell Biology and Genetics — Center for Systems Biology Dresden

Bacterial populations can switch to slowly growing "persister" subpopulations that are resilient to competition. Here, I will present a minimal model for the effect of this phenotypic variation on the spatial competition of two species. One of these species switches, both randomly and in response to the other, competitor species, to such a persister phenotype. One would expect this phenotypic switching to slow down the travelling wave by which the competitors invade the first species.

Combining exact results and numerical calculations, I will show that, surprisingly, this expectation does not hold true: phenotypic switching does not affect the speed of this wave. Somewhat conversely, I will demonstrate that phenotypic switching can speed up the reverse wave by which this species invades the competitors. This suggests that, counterintuitively, persisters can be an offensive, rather than defensive ecological strategy.

DY 22.8 Tue 11:30 ZEU/0118

How spatial patterns can lead to less resilient ecosystems — •David Pinto-Ramos and Ricardo Martinez-Garcia — Center for Advanced Systems Understanding (CASUS), Helmholtz-Zentrum Dresden-Rossendorf, Görlitz D-02826, Germany

Several theoretical models predict that spatial patterning increases ecosystem resilience. However, these predictions rely on simplifying assumptions, such as assuming isotropic and infinitely large ecosystems, and empirical evidence directly linking spatial patterning to enhanced resilience remains scarce. We introduce a unifying framework, encompassing existing models for vegetation pattern formation in water-stressed ecosystems, that relaxes these assumptions. This framework incorporates finite vegetated areas surrounded by desert and anisotropic environmental conditions that lead to non-reciprocal plant interactions. Under these more realistic conditions, we identify a novel desertification mechanism, known as nonlinear convective instability in physics but largely overlooked in ecology. These instabilities form when non-reciprocal interactions destabilize the vegetation-desert interface and can trigger desertification fronts even under stress levels where isotropic models predict stability. Importantly, ecosystems exhibiting periodic vegetation patterns are more susceptible to nonlinear convective instabilities than those with homogeneous vegetation, suggesting that spatial patterning may reduce, rather than enhance, resilience. These findings challenge the prevailing view that self-organized patterning enhances ecosystem resilience.

DY 22.9 Tue 11:45 ZEU/0118

Time-crystals in actively mode-locked lasers — Elias Koch[1], Ruiling Weng[2], Jesús Yelo-Sarrión[2], Josep Batle[2], Julien Javaloyes[2], and •Svetlana V. Gurevich[1,3] — [1]Institute for Theoretical Physics, University of Münster, Wilhelm-Klemm-Str.9 48149 Münster, Germany — [2]Departament de Física and IAC3, Universitat de les Illes Balears, Campus UIB 07122 Mallorca, Spain — [3]Center for Data Science and Complexity (CDSC), University of Münster, Corrensstrasse 2, Münster, 48149, Germany

We propose a time-delayed model for the study of active mode-locking that is devoid of restriction regarding the values of the round-trip gain and losses. There, we report the occurence of discrete time-crystal phases and crystallites. By tuning either the bias current or the modulation frequency, the system undergoes a spontaneous symmetry-breaking transition from the harmonically mode-locked state towards robust, highly coherent time-crystal states that persist indefinitely. Two equivalent time-crystal configurations, shifted by one driving period, can coexist as domains separated by sharp, long-lived boundaries analogous to domain walls. Additionally, we present recent experimental results that are in good quantitative agreement with the theoretical predictions. Our findings demonstrate that mode-locked semiconductor lasers offer a readily accessible platform to explore and control non-equilibrium phases of light, enabling practical implementations of time-crystal physics in photonic systems.

DY 22.10 Tue 12:00 ZEU/0118

Unified Simulation Framework for Multi-Soliton Dynamics in Femtosecond Lasers — •Julia A. Lang[1], Julien Javaloyes[2], Svetlana V. Gurevich[3], and Georg Herink[1] — [1]University of Bayreuth, Germany — [2]University of the Balearic Islands, Spain — [3]University of Münster, Germany

Ultrafast lasers exhibit a rich variety of multi-pulse dynamics, strongly influenced by the underlying laser architecture and system-specific nonlinear effects.

In this contribution, we present a novel simulation approach that flexibly integrates diverse effects into a single, unified framework. A key feature of our model is the inclusion of full gain dynamics. This enables us to reproduce a wide range of experimentally observed soliton interactions, including harmonic mode-locking in erbium fiber lasers [1], the formation of soliton molecules via delayed feedback [2] or Raman-induced soliton molecules in Ti:sapphire lasers [2].

We introduce a classification of characteristic inter-soliton trajectories by attributing hierarchies of critical weights to nonlinear effects. The resultant classification provides deeper insights into the origins of multi-pulse interactions and enables novel approaches for harnessing multi-soliton applications.

Process-Directed Self-Assembly of Copolymer Blends: Micro- and Macrophase Separation — •Jiayu Xie and Marcus Müller — Institute for Theoretical Physics, Georg August University Göttingen, 37077 Göttingen, Germany

The equilibrium phase behavior of binary diblock copolymer blends involves a complex interplay between microphase and macrophase separation. We investigate blends of linear diblock copolymers, A_1B_1 (cylinder-forming) and A_2B_2 (cylinder- or lamella-forming), using a combination of self-consistent field theory (SCFT) and single-chain-in-mean-field (SCMF) simulations. When the chain-length asymmetry between the A_1B_1 and A_2B_2 copolymers becomes large, the equilibrium phase diagram exhibits a wide macrophase-separation channel. Strikingly, our simulations reveal a strong pathway dependence within this region: rapid quenching yields a spatially homogeneous structure with narrow cylinder-size distributions and strong hexagonal order, whereas gradual annealing promotes local demixing, resulting in bimodal domain sizes and weaker order. We demonstrate that this process-dependent nonequilibrium behavior can be explained by the distinct evolutions of the system state and free-energy landscape of the blends under quenching or annealing. These findings highlight how different processing conditions can direct nanostructure formation in block copolymer blends, and establish a mechanistic link between processing pathway and the final morphology, thus offering insights into rational design of targeted nanostructured materials.

DY 23.2 Tue 9:45 ZEU/0160

Topological defect engineering enables size and shape control in self- assembly — Lara Koehler[1,3], Markus Eder[2], Vincent Ouzan-Reboul[3], Christoph Karfusehr[2], Andrey Zelenskiy[3], Pierre Ronceray[4], Friedrich Simmel[2], and •Martin Lenz[3] — [1]MIPPKS, Dresden, Germany — [2]TU Munich, Germany — [3]U. Paris-Saclay, Orsay, France — [4]Aix-Marseille-Université, Marseille, France

Equilibrium self-assembly is a powerful way to build nano- and microscale structures out of interacting subunits. The size and shape of such structures must be controlled in many biological and technological functions, posing significant practical challenges as current strategies require multiple subunit types or the precise control of their shape and mechanics. Here we introduce an alternative approach that circumvents these obstacles. Our method uses subunits whose interactions promote crystals, but also favor crystalline defects. We show theoretically that the magnitude of these interactions, which is well controlled in experiments, governs the self-assembly through topological restrictions on the scope of the defects. Using DNA origami, we demonstrate both size and shape control in two-dimensional disk- and fiber-like assemblies. Our basic concept of defect engineering operates well beyond these examples, and provides a broadly applicable framework to control self-assembly.

DY 23.3 Tue 10:00 ZEU/0160

Soft colloidal monolayers under drying conditions — •Kai Luca Spanheimer[1], Maret Ickler[2], Julian Ringling[3], Nicolas Vogel[2], Matthias Karg[4], and Hartmut Löwen[1] — [1]Insitut für Theoretische Physik II, Heinrich-Heine-Universität, 40225 Düsseldorf, Germany — [2]Institute of Interfaces and Particle Technology, Friedrich-Alexander University, Erlangen, Germany — [3]Physikalische Chemie I: Kolloide und Nanooptik Heinrich-Heine-Universität, 40225 Düsseldorf, Germany — [4]Institut für Chemie, Martin-Luther-Universität Halle-Wittenberg, 06099 Halle, Germany

Langmuir-Blodgett deposition is a well established technique in research and industry. Even though, there still are effects in this process that are not yet explored from a theoretical standpoint. It is usually assumed that the deposited pattern is identical with the one appearing at the water-air interface. In recent experimental studies, strong reorganization during the drying of soft colloidal monolayers has been observed [1]. Capillary forces during drying are known to change nanoscopic structures, sometimes even leading to their destruction. To model these processes we propose a combination of overdamped particle dynamics coupled to dewetting dynamics of an evaporating liquid film. The patterns produced by this model fit those observed in experiment. This theoretical approach allows exploration of the drying dynamics. Thereby we gain new insights into the drying process and makes experimental results produced with Langmuir-Blodgett deposition more reliable.

Mechanical assessment of microfluidically-generated poroelastic microgel particles — Aude Sagnimorte[1,2], Anke Lindner[2], and •Joshua McGraw[1] — [1]Gulliver-CNRS, ESPCI-PSL, 10 rue Vaquelin, 75005 Paris — [2]PMMH-CNRS, ESPCI-PSL, 10 rue Vaquelin, 75005 Paris

Soft microgels have numerous applications in diverse fields,such as tissue engineering, drug delivery systems, soft robotics, or as model systems for suspensions or colloids. Among these, photopolymerized hydrogels such as poly(ethylene glycol) diacrylate (PEGDA) are commonly used due to their highly tunable mechanical properties. However, proper characterisation of these properties is challenging, in part due to their small scale, on the order of tens of microns, and in particular the lack of assessment of their time-dependent properties. Here we provide a comprehensive mechanical characterisation of individual photopolymerised microgels particles using atomic force microscopy (AFM) for precise local measurements. In particular, we performed indentation-relaxation tests on PEGDA microdisks immersed in water. By varying indentation depth and probe diameter, we changed the contact area and observed relaxation responses which are indicative of poroelastic behaviour. In particular, larger contact areas resulted in longer relaxation times. Our results also show that increasing the amount of solvent increased the relaxation time. Our collected results are consistent with a simple, Herzian poroelastic model giving good agreement with both the approach and relaxation phases of the experiments.

DY 23.5 Tue 10:30 ZEU/0160

Nonlinear Viscoelastic Response and Stress Shielding in Driven Bistable Spring Chains — •Sven Pattloch[1,2] and Joachim Dzubiella[1,2] — [1]Applied Theoretical Physics-Computational Physics, Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, D-79104 Freiburg, Germany. — [2]Cluster of Excellence livMatS@FIT-Freiburg Center for Interactive Materials and Bioinspired Technologies, Albert-Ludwigs-Universität Freiburg, D-79110 Freiburg, Germany

Bistable micromodules are a promising route to design adaptive mechanical metamaterials with tunable viscoelastic response. Here, a driven one-dimensional chain of bistable springs is studied in which both the mechanical deformation and the internal excitation states evolve dynamically under time-dependent forcing. Their coupling produces rich nonlinear viscoelastic behaviour, including frequency-dependent susceptibilities, delayed deformation, and pronounced hysteresis in cyclic loading.

Using analytical linear response theory complemented by numerical simulations, the model quantifies how microscopic parameters and driving protocols control effective stiffness, loss, and phase lags. A key result is a strong attenuation ('shielding') of stress propagation along the chain that is already present for monostable springs but is markedly amplified by excitation switching in bistable modules. These findings provide simple design principles for tailoring nonlinear viscoelasticity, hysteresis, and stress shielding in driven soft matter and mechanical metamaterial systems.

DY 23.6 Tue 10:45 ZEU/0160

Euler buckling on curved surfaces — •Shiheng Zhao[1,2,3] and Pierre A. Haas[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems — [2]Max Planck Institute of Molecular Cell Biology and Genetics — [3]Center for Systems Biology Dresden

Nearly three hundred years ago, Euler showed that an inextensible straight elastic line in the plane buckles under compression when the compressive force F reaches a critical value $F_* > 0$. But how does such an elastic line buckle within a general curved surface? Here [1], we reveal that the classical instability changes fundamentally: By weakly nonlinear analysis of the buckling of an asymptotically short elastic line, we show that the critical force for the lowest buckling mode is $F_* = 0$ and discover a new bifurcation structure in which the modes of classical Euler buckling split into pairs. For long elastic lines, we numerically find an additional bifurcation by which the second of these new modes becomes the lowest mode and show that, at sufficiently large F, they undergo discontinuous snap-through to higher end-to-end compression. We explain these bifurcations in terms of the general unfolding of a pitchfork. This constitutes the foundations for a class of mechanical instabilities within curved surfaces from which, for example, biological shape emerges in development.

Linking molecular dynamics and experimental FORCs in multicore magnetic nanoparticles — Ekaterina Novak[1], •Malika Khelfallah[2], Andrey Kuznetsov[3], Deniz Mostarac[4], Claire Carvallo[2], Amélie Juhin[2], and Sofia Kantorovich[3] — [1]Ekaterinburg, Russia — [2]Sorbonne Université, Paris, France — [3]University of Vienna, Vienna, Austria — [4]University of Edinburgh, Edinburgh, United Kingdom

Multicore magnetic nanoparticles - clusters of several magnetic grains embedded in a nonmagnetic matrix - exhibit collective behaviour distinct from single-core particles and are promising candidates fro drug targeting and magnetic hyperthermia. Their magnetic cores possess finite anisotropy, and the multicore assemblies range from near-spherical to elongated ellipsoids, features that strongly affect their response to external fields. To study these effects, we use molecular dynamics simulations [1] to model internal structure, anisotropy distribution, and collective switching. As a key diagnostic, we employ First Order Reversal Curves [2], which experimentalists routinely measure for immobilised multicore particles, enabling direct comparison between simulations and experiments. FORC diagrams reveal coercivity distributions and magnetic interactions between grains, offering detailed insight into interaction mechanisms and domain processes.

Hydrodynamics substantially affects induced structure formation in magnetic fluids — •Henning Reinken and Andreas M. Menzel — Otto-von-Guericke-Universität Magdeburg, Germany

Magnetorheological fluids consist of micrometer-sized magnetic particles suspended in a carrier liquid [1]. Sufficiently strong external magnetic fields lead to the formation of string-like particle aggregates, which results in complex magnetorheological behavior. This mechanism can further be used in the production of magnetic elastomers during the polymerization process when the carrier medium is still fluid and particulate structure formation still possible [2]. Using numerical simulations that spatially resolve both fluid flows and magnetization, we demonstrate that hydrodynamic interactions play a substantial role during structure formation. Hydrodynamics supports the emergence of string-like aggregates, while magnetic interactions align them. Considering besides this fundamental insight the enormous technical importance and potential of magnetic fluids, our results are substantial also from an application perspective.

Near-surface colloidal dynamics in jammed and slipping microgel suspensions — •Masoodah Gunny[1], Frédérick Caetano[2], Matilde Bureau[2], Alexandre Vilquin[1], Marie Le Merrer[2], Catherine Barentin[2], and Joshua McGraw[1] — [1]Gulliver - CNRS, ESPCI-PSL 10 Rue Vauquelin 75005 Paris, France — [2]ILM - CNRS, Claude Bernard University, 16 Enrico Fermi 69100 Villeurbanne, France

Jammed suspensions of soft microgel particles exhibit wall slip along smooth boundaries. The direct observation of dynamics within a supposed depletion layer near the wall were difficult to achieve as a result of the layers' supposed sub-micrometric dimensions. We use total internal reflection fluorescence microscopy (TIRFM) to observe colloidal-particle dynamics near the interface between glass and microgel suspensions. Remarkably, microgel suspensions display nanoscale velocity profiles with a slope rupture; particle velocity increases with distance near the wall, and tends to a constant beyond a distance which is characteristic of the ones predicted previously. Beyond velocimetry, we also study the statistical particle altitude distributions near the wall in TIRFM measurements. These distributions are strongly pressure dependent, with nanoparticles more likely found near the solid/liquid interface when the fluid is transported faster near the wall. This high-velocity particle enrichment, not seen for the Newtonian case, is consistent with the development of a depletion layer under such conditions. Taken together, our observations give strong support for the existence of a depletion layer being responsible for wall slip.

Random close packing as a conserved directed percolation transition — •Thomas Axmann and Michael Schmiedeberg — Theoretical Physics: Lab for Emergent Phenomena, Soft Matter Theory Group, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

In studying quenches in soft sphere systems O'Hern et al. related the onset of overlaps to isostaticity [1], and consequently to the random close packing scenario. The conditions that lead to the avoidance of overlaps between spheres can be studied with the random organization model [2], which was initially introduced to investigate self organization in sheared colloids. Modifications of this model, which dynamically reduce interparticle overlaps, were used to characterize the random close packing problem as the critical point of a dynamic absorbing state transition in the $d+1$ dimensional conserved directed percolation universality [3,4].

We aim to deepen the understanding of this connection by demonstrating that the configuration change at each time step can be chosen with a fully deterministic strategy while retaining the features of the transition. We clarify difficulties in the treatment of percolating clusters and find that the median overlap depth proves to be a more useful order parameter.

Rescaled mode-coupling scheme for dynamics in binary mixtures of highly charged colloids — •Daniel Weidig and Joachim Wagner — University of Rostock, Rostock, Germany

We investigate dynamic processes in binary mixtures of highly charged colloidal particles by means of Brownian dynamics and multi-component mode-coupling theory (MCT). As input for MCT, thermodynamically consistent, static structure factors from integral equations with Rogers-Young closure are used which are in quantitative agreement to Fourier transforms of static pair correlation functions resulting from simulations.

MCT based on partial structure factors in many-particle systems predicts dynamic properties such as long-time self-diffusion coefficients in qualitative agreement to simulation trajectories. Using instead structure factors from systems with slightly reduced number of effective charges as input, a quantitative agreement of MCT with simulations is achieved. In mixtures of identically charged particles with different short-time mobilities, this rescaled MCT scheme accurately predicts coupling effects in long-time dynamics observed in Brownian dynamics simulations.

Electric double layers - the software package capDFT — Fabienne Dressler and •Andreas Härtel — Institute of Physics, University of Freiburg

Electric Double Layers are used to store electric energy, they can be utilized to harvest energy from waste heat or steps in concentrations, and they stabilize colloidal systems. In all cases, mobile ions arrange themselves to screen surface charges, resulting in sometimes densely packed regions of microscopic particles far from bulk states that dominate the macroscopic physical properties of the system. Modeling these complex systems has theoretical and numerical limitations, but good although expensive solutions exist. We present an open-source software package to treat the described modeling utilizing classical density functional theory [1]. The package has been used successfully in studies of underscreening [2] and allows to go beyond the standard mean-field approximation of primitive models [3]. We will demonstrate the package by discussing an example, where we study capacities of structured electrodes.

Microscopic diffusion and reactivity in aqueous solutions: photogenerated nascent halogen atoms, solvated electrons and subsequent dihalide formation — •Zhangatay Nurekeyev[1,2], Hyein Hwang[1,2], Fernando Rodriguez Diaz[1], Mei Bai[3], Michael Thorwart[3], Michaela Schäfer[4], Carmen Herrmann[4], and Christian Bressler[1,2,5] — [1]Inst. of Exp. Physics, Universität Hamburg — [2]The Hamburg Centre of Ultrafast Imaging (CUI) — [3]I. Inst. of Theor. Physics, Universität Hamburg — [4]Dept of Chemistry, Universität Hamburg — [5]European XFEL, Schenefeld

The solvent plays an important role in the assembly, stability and reactivity of (bio)chemical molecules. Small changes of the caging solvent can alter the reaction outcome, but little is known about the atomic-scale solvation shell dynamics. Our approach utilizes aqueous mono-atomic halide solutes, which are transformed into nascent neutral halogen atoms upon femtosecond optical excitation together with a separated solvated electron. Combining X-ray absorption with transient optical absorption spectroscopies we monitor the subsequent diffusion-driven atom-electron recombination, each focusing on the halogen atom and on the solvated electron, respectively. We also monitor the appearance of dihalides on the tens of picosecond time scale. Using all x-ray and laser observables we deliver a new picture of the ensuing dynamics, for which the existence of the long-lived (X:e) contact pair is not required. Next steps aim to trace more complex guest-host scenarios towards functional proteins in solution.

DY 24.2 Tue 11:30 ZEU/LICH

Surface Propensity of Halide Ions in Water: New Evidence from LJ-XPS — •Daniela Torres-Díaz[1], Shirin Golami[1], Tillmann Buttersack[1], Qi Zhou[1], Rémi Dupuy[2], Bernd Winter[1], Chistophe Nicolas[3], and Hendrik Bluhm[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Laboratoire de Chimie Physique - Matière et Rayonnement (Sorbonne Université, CNRS), Paris, France — [3]Synchrotron SOLEIL, Saint-Aubin, France

The surface propensity of halide ions in water is still a matter of debate. While the famous Onsager&Samaras model indicates that charged species should avoid the interface, more recent Molecular Dynamics simulations that take into account the polarizability of the ions indicate notably that iodide and bromide prefer the interface while chloride and fluoride avoid it. Different models, however, differ in how strong this effect is, while experimental studies have reported contradictory results. Here I will discuss recent results obtained using Liquid-Jet X-Ray Photoemission Spectroscopy on water interfaces for potassium halide solutions. In particular, the measurement of the photoelectron angular distributions allow for a higher spatial resolution than classic XPS measurements.

DY 24.3 Tue 11:45 ZEU/LICH

Ion Correlations Drive Collective Adsorption of Hydronium Ions at the Air-Electrolyte Interface — •Elena Köhler Ruiz, Maximilian Becker, Louis Lehmann, and Roland Netz — Fachbereich Physik, Freie Universität Berlin, Germany

Acids exhibit distinct interfacial behavior at the air-water interface compared to simple monoatomic salts. While monoatomic ions are largely repelled from the interface, hydronium ions preferentially reside at the interface due to formation of an interfacial hydrogen-bond network. To investigate these contrasting behaviors, we perform molecular-dynamics simulations with thermodynamically optimized force fields, analyzing ionic distributions at the interface as well as resulting surface tensions and potentials. The simulated surface potentials reproduce the concentration-dependent trends observed in SFG experiments: At high concentrations, interfacial hydronium promotes co-adsorption of counterions, which results in a decrease of the surface potential with rising concentration,

consistent with experimental observations. These findings highlight the critical role of ion-ion correlations at interfaces, which are not accounted for by modified Poisson-Boltzmann models.

DY 24.4 Tue 12:00 ZEU/LICH

Calcium-amino acid complexation in water probed by Intermolecular Coulombic Decay — •Michele Pugini, Nicolas Velasquez, Harmanjot Kaur, Florian Trinter, Qi Zhou, Lukas Tomaník, Uwe Hergenhahn, and Bernd Winter — Fritz-Haber-Institut, Berlin

The Ca2+ ion is the most abundant metal ion in the human body, playing essential roles in numerous biological processes, many of which involve interactions with proteins. Gaining molecular-level insight into the nature of the interaction between Ca2+ ions and solvated amino acids is therefore crucial for understanding calcium's biological function. Intermolecular Coulombic decay (ICD), a non-local autoionization process, offers unique sensitivity to the local chemical environment and can selectively probe interactions within the first solvation shell of solvated Ca2+ ions.

Here, we demonstrate the sensitivity of resonant ICD3 to the chemical composition of the solvation shell, enabling the identification of Ca2+ associations with specific amino acids. Our model system is the amino acid proline. The interaction, if present, is revealed via the ICD electrons resulting from the ionization of the biomolecule upon the 2p to 3d excitation of Ca2+.

Our results unequivocally identify Ca2+-proline interactions, indicating substitution of water molecules in the ion's coordination shell by proline. These findings establish ICD as a sensitive probe of metal-biomolecule interactions and highlight its potential as a powerful spectroscopic tool for investigating biomolecular structure in solution.

DY 24.5 Tue 12:15 ZEU/LICH

Distinguishing cavity and non-cavity solvation structures of the hydrated electron — •Sy Dat Ho and Benjamin Philipp Fingerhut — Department of Chemistry and Centre for NanoScience, Ludwig-Maximilians-Universität München, 81377 München, Germany

Solvated electrons in water are prototypical low-dimensional quantum systems that are coupled to a fluctuating, many-body environment. However, their hydration structure is still a matter of debate, with both cavity and non-cavity models having been suggested. First-principles molecular dynamics simulations are performed of excess-electron localization in liquid water, using hybrid-meta-GGA and hybrid-GGA density functionals that accurately reproduce bulk water structure. Perturbations to the local hydrogen bond structure of water due to interaction with the excess charge are identified, giving rise to specific signatures in transient radial distribution functions. These patterns are then compared with preliminary liquid-phase MeV-UED data obtained during an early science campaign at SLAC. In order to distinguish the structural changes induced by excess electrons in the diffraction patterns, long-time simulations at an unprecedented level of theory are required in order to minimise statistical noise. Our results clarify the coupling of hydrated electrons to solvent fluctuations and provide microscopic insight into polaron formation in disordered condensed phases.

DY 24.6 Tue 12:30 ZEU/LICH

Mesoscopic Structures in Water/HFIP based Electrolytes — •Sophie Zeilinger[1,2] and Markus Mezger[1] — [1]Center for Nano Structure Research, Faculty of Physics, University of Vienna, AT-1090 Vienna — [2]Institute of Physical Chemistry, Faculty of Chemistry, University of Vienna, AT-1090 Vienna

Previous studies have shown that binary water/hexafluoroisopropanol (HFIP) mixtures exhibit nanoscale heterogeneties that strongly affect properties such as reaction rates. The complex hydrogen bonding network of the binary mixture together with the amphiphilic character of the HFIP molecule provides a sensitive environment in which subtle changes in interactions can generate nanoscale heterogeneties. Here, we study the structure formation in water/HFIP under the influence of hydrophilic and hydrophobic ions by Small Angle X-Ray Scattering (SAXS). Depending on water content, pH, salt concentration and temperature we observe monotonous and oscillatory density correlations with structural parameter on the nanometer length scale. These structures are explained by the coupling of coulombic interactions between charged hydrophilic and hydrophobic ions vs. local fluctuations in water/HFIP concentrations.

DY 25: Franco-German Session on Granular Matter II

Granular media exhibit rich collective behavior arising from simple interactions such as friction, collisions, elasticity, and confinement. This session brings together experimental, numerical, and theoretical studies addressing key transitions in granular systems, including jamming, viscous-to-inertial regimes, clustering, gas cooling, and impact dynamics, highlighting the links between microscopic mechanisms and macroscopic responses.

Avalanches of a granular medium reinforced with flexible fibres — •Baptiste Darbois Texier, Georges Gauthier, and Ladislas Wierzchalek — FAST, CNRS UMR 7608, University Paris-Saclay

Debris flows and landslides are catastrophic geophysical events that typically occur on sloped terrains and involve a large amount of granular materials in motion. At the laboratory scale, such events can be studied by observing avalanches of granular materials flowing down a slope and analyzing the factors that influence their initiation and cessation. In this study, we explore the effect of incorporating flexible fibres into granular media as a strategy to attenuate avalanches and stabilize granular piles. While fibre reinforcement has been shown to enhance the mechanical strength of soils, its influence on avalanche dynamics remains largely unexplored. We perform rotating-drum experiments at low rotation speeds using mixtures of grains and flexible fibres with varying volume fractions and aspect ratios. We measure the angles at which avalanches start and stop, as well as the relaxation dynamics following individual events. Increasing the fibre content or aspect ratio systematically raises both start and stop angles and broadens their distributions, accompanied by a marked rise in the number of small-amplitude avalanches. Analysis of relaxation curves further shows that fibres enhance dissipation, leading to slower, more gradual avalanche decay compared with pure grains. These findings provide quantitative evidence of the stabilizing effects of fibres on granular slopes and their role in dissipating energy during avalanches.

DY 25.2 Tue 14:15 HÜL/S186

Magnetic-Field Controlled Self-Diffusion and Clustering in Ferrogranular Mixtures — •Oksana Bilous[1], Kirill Okrugin[1], Ali Lakkis[2], Richter Reinhard[2], and Sofia Kantorovich[1] — [1]Computational and Soft Matter Physics, University of Vienna, Vienna, Austria — [2]Experimental Physics 5, University of Bayreuth, Bayreuth, Germany

We investigate self-diffusion in ferrogranular mixtures of magnetic and glass beads via Langevin/molecular dynamics of quasi-2D Stockmayer spheres mixed with repulsive non-magnetic ones, complemented by mm-scale experiments. We vary out-of-plane magnetic induction and total area fraction. The field aligns dipoles and reduces in-plane aggregation by inducing repulsion, while dipole-dipole interactions and central attractions (or susceptibility in experiments) drive chain-like and compact clustering. Increasing area fraction counteracts field-induced suppression and stabilizes larger clusters. Single magnetic particles and glass beads remain mostly diffusive, with diffusion only weakly concentration dependent, whereas particles embedded in clusters show persistent subdiffusion. The field also alters diffusion type: cluster-bound particles exhibit robustly non-Gaussian dynamics that amplify with area fraction and field. At sufficiently high induction and crowding, the glass component becomes non-Gaussian, revealing field-driven dynamical freezing of the non-magnetic species. Simulations and experiments consistently show how external fields, dipolar self-assembly, and crowding govern transport in ferrogranular layers.

DY 25.3 Tue 14:30 HÜL/S186

Angular Velocity of Spherical Particles in a Granular Gas under Microgravity during Granular Cooling — •Mahdieh Mohammadi[1], Raúl Cruz Hidalgo[2], Dmitry Puzyrev[3], Ralf Stannarius[1,3], and Kirsten Harth[1,3] — [1]Department of Engineering, Brandenburg University of Applied Sciences, Magdeburger Str. 50, 14770 Brandenburg an der Havel, Germany — [2]Departamento de Física y Matemática Aplicada, Facultad de Ciencias , Universidad de Navarra, Pamplona, Spain — [3]MARS and MTRM, Otto von Guericke University Magdeburg, Universitätsplatz 2, 39106 Magdeburg, Germany

We investigate the rotational dynamics of spherical particles in a granular gas in microgravity, which allows a clean realization and observation of collisional kinetics. The system starts in a highly excited state and undergoes dissipative collisional cooling (loss of mean kinetic energy). Patterned spheres were tracked from video data using two cameras, their 3D trajectories and velocities were extracted. Surface markers enable 3D orientation reconstruction via feature-based and projection-consistent analysis. Continuous angular trajectories are obtained by interpolating missing orientation data. From these, we extract angular veloc-

ities and analyze their evolution across different cooling intervals.

Our studies are funded within by the German Aerospace Center (DLR) projects PARADYSE, KORDYGA and EVA-II (50WM2542, 50WM2242, 50WK2348).

DY 25.4 Tue 14:45 HÜL/S186

Granular gas mixtures: Experiments and numerical simulations — •Dmitry Puzyrev[1], Kirsten Harth[2,1], Torsten Trittel[2,1], Raúl Cruz Hidalgo[3], and Ralf Stannarius[2,1] — [1]Otto von Guericke University, Magdeburg, Germany — [2]Brandenburg University of Applied Sciences, Brandenburg an der Havel, Germany — [3]University of Navarra, Pamplona, Spain

Granular gases are ensembles of free-moving macroscopic particles which collide inelastically, which leads to effects like unusual heating (gain of mechanical energy from external sources) and cooling (dissipative loss of mechanical energy), clustering, and spontaneous collective movement. Such systems can exist in different dynamical regimes depending on filling fraction, particle shapes and material properties, as well as external energy input. Our investigation is focused on 3D microgravity experiments with ensembles of non-spherical, rod-shaped particles [1] and their mixtures [2]. Machine learning-aided software used for particle detection, 3D matching and tracking is available as an open-source package [3] and can be applied to other multiparticle tracking problems. In addition to previously published results for a mixture of thinner and thicker rods [2], we present the initial results for a short/long rods mixture. Our studies are funded within by the German Aerospace Center (DLR) projects EVA-II, VICKI, KORDYGA and PARADYSE (50WK2348, 50WM2252, 50WM2242, 50WM2542). [1] K. Harth et al., Rev. Lett., 120, 214301 (2018) [2] Puzyrev et al., npj Microgravity, 10, 36 (2024) [3] A. Niemann et al., github.com/ANP-Granular/ParticleTracking, JOSS 10(109), 5986 (2025)

DY 25.5 Tue 15:00 HÜL/S186

Granular gases of non-convex particles: Experiments and numerical simulations — Torsten Trittel[1,2], Mohammad Enezz[1], Dmitry Puzyrev[2], Kirsten Harth[1], Raúl Cruz Hidalgo[3], and •Ralf Stannarius[1,2] — [1]Brandenburg University of Applied Sciences, Brandenburg an der Havel, Germany — [2]Otto von Guericke University Magdeburg, Magdeburg, Germany — [3]University of Navarra, Pamplona, Spain

Granular gases are dilute ensembles of macroscopic particles that are not in permanent contact. Owing to the low packing fraction, they interact only by random inelastic collisions. Consequences are permanent dissipative loss of mechanical energy (granular cooling) and spontaneous clustering. Most experiments and numerical simulations so far considered spheres. The present study investigates spatial crosses (hexapods). They add more complexity in the particle interactions, and alter the role of the collisions in the exchange of translational and rotational kinetic energies. We present experiments performed in microgravity on a suborbital rocket flight [1], demonstrate particle tracking from the optical video data [2], and show results of DEM simulations of these systems. The study is funded within by DLR within projects EVA-II and JACKS (50WK2348, 50WM2340).

General Discussion

DY 26: Focus Session: Water – from Atmosphere to Space III (joint session CPP/DY)

Time: Tuesday 14:00–15:30 Location: ZEU/LICH

Topical Talk DY 26.1 Tue 14:00 ZEU/LICH

Why water in plants survives negative pressure — Marin Šako[1,2], Emanuel Schneck[3], Roland Netz[4], and •Matej Kanduč[1] — [1]Jožef Stefan Institute, Ljubljana, Slovenia — [2]University of Ljubljana, Faculty of Mathematics and Physics, Ljubljana, Slovenia — [3]Physics Department, Technische Universität Darmstadt, Darmstadt, Germany — [4]Fachbereich Physik, Freie Universität Berlin, Berlin, Germany

It may seem surprising that we can lower the pressure in a liquid to negative values, far below the saturated vapor pressure at which a vapor phase should form. In water, such deeply metastable states are possible only when it is exceptionally pure and free of nucleation sites. It is therefore even more striking that plants transport water at negative pressures down to −100 atm without cavitation, even though xylem sap is anything but pure: it contains dissolved ions, sugars, lipids, and other organic molecules. How is this possible?

In this talk, I will show how molecular simulations and theory can explain this surprising behavior. We find that amphiphilic molecules such as lipids can adsorb onto hydrophobic surface crevices — places that would normally trap nanobubbles. Once coated, these surface defects can no longer stabilize bubbles, which allows water to stay intact even under strong tension. This mechanism offers a molecular-level explanation for how trees transport water to heights of over 100 meters without cavitation. More broadly, it illustrates how soft-matter physics and interfacial molecular organization can control the mechanical stability of liquids under extreme conditions.

DY 26.2 Tue 14:30 ZEU/LICH

Cholesterol Controlled Photo-Switching Activity of Azobenzene Glycoconjugates in Lipid Membranes — •Prashant Hitaishi[1,2], Svenja C. Hövelmann[1,2], Michael Röhrl[3], Nicolas Hayen[1], Ella Diebell[1], Ali Ashtiani[1], Carlotta Mager[1], Thisbe Lindhorst[3], and Bridget M. Murphy[1,2] — [1]Institute of Experimental and Applied Physics, Kiel University, Leibnizstraße 19, Kiel, 24118, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, Hamburg, 22607, Germany — [3]Otto Diels-Institut für Organische Chemie, University of Kiel, Germany

Reversible photo-switchable molecules enable precise optical control of soft interfaces and are attractive for smart surfaces and light-triggered drug delivery. Azobenzene glycoconjugates (Azo) undergo reversible trans-cis isomerization under alternating UV and visible illumination, thereby modulating their conformation and interactions with lipid membranes. Here, Azo is incorporated into DPPC monolayers containing 0, 15, or 30 mol% cholesterol to mimic biologically relevant membrane compositions. Langmuir monolayer isotherm studies combined with time-resolved illumination cycles and X-ray measurements are used to quantify Azo-induced changes in membrane structure and relaxation kinetics. Increasing cholesterol slows Azo photo-switching, indicating a more constrained, rigid nanoenvironment, and shows that membrane composition can be used to tune light responsiveness in lipid interfaces for designing azobenzene-based responsive biomaterials.

DY 26.3 Tue 14:45 ZEU/LICH

Photoelectron Angular Distributions of Ions Influenced by Surfactants at the Solution-Vapor Interface — •Shirin Gholami[1], Tillmann Buttersack[1], Clemens Richter[2], Rémi Dupuy[3], Daniela Torres-Díaz[1], Christophe Nicolas[4], Uwe Hergenhahn[1], and Hendrik Bluhm[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]SPECS Surface Nano Analysis GmbH, Berlin, Germany — [3]Sorbonne Université, CNRS, Paris, France — [4]Synchrotron SOLEIL, Paris, France

Aqueous liquid-vapor interfaces play key roles in atmospheric and oceanic processes. The ocean-air boundary forms the largest aqueous-vapor interface, covering over 70 % of Earth's surface. In addition to Na^+ and Cl^-, Mg^{2+} and SO_4^{2-} are the most abundant ions in ocean water.

Here, we investigate how Mg^{2+} and SO_4^{2-} ions behave at the aqueous solution-vapor interface in the presence of charged surfactants. Using sub-monolayer coverages of octylamine $-CNH_3^+$ and octanoate $-COO^-$, we examine how these surfactants modify the distance of the ions from the interface. Liquid-jet X-ray photoelectron spectroscopy in combination with photoelectron angular distributions provides Å-scale depth sensitivity, enabling us to quantify ion-surfactant interactions.

Our results show that differently charged surfactants shift the interfacial positioning of Mg^{2+} and SO_4^{2-}, and that specific ion-ion interactions influence their interfacial propensity.These findings reveal how surfactants govern the depth distribution of ions, providing insight into oceanic and atmospheric processes.

DY 26.4 Tue 15:00 ZEU/LICH

Contact line dynamics on moving fibers measured by X-ray holography — •Louisa E. Kraft[1,2], Jens Lucht[3], Fiona Berner[1,2], Hannes P. Hoeppe[3], Tobias Eklund[1,2], Yizhi Liu[1], Markus Osterhoff[3], Tim Salditt[3], Hans-Jürgen Butt[1], and Katrin Amann-Winkel[1,2] — [1]Max Planck Institute for Polymer Research, Mainz, Germany — [2]Johannes Gutenberg University, Institute for Physics, Mainz, Germany — [3]Georg-August-University, Institute of X-ray Physics, Göttingen, Germany

The wetting properties of solid surfaces are important for many natural and industrial processes, especially with respect to dynamic wetting. The wetting dynamic of solid surfaces, in particular the quantitative description of the dynamic contact angles, is still under debate. Dynamic contact angle variations connect macroscopically measured quantities with microscopic processes. Most studies rely on optical or confocal microscopy which limits the experimental access to the sub-microscopic region where these processes take place. We present data from X-ray holography experiments, imaging the three-phase contact line on moving glass fibers with an improved spatial resolution of about 450 nm combined with a temporal resolution of 10 Hz. We used the GINIX nanofocus-

ing setup at the P10 beamline at PETRA III (DESY, Hamburg). The used glass fibers were pulled out of a liquid bath filled with varying aqueous solutions while changing the lateral velocity. We could clearly observe a decrease of the receding dynamic contact angle with increasing fiber velocity confirming the predictions of dynamic wetting theory.

DY 26.5 Tue 15:15 ZEU/LICH

Properties of micrometre-sized supercooled water droplets — Claudia Goy[1], •Frédéric Caupin[2], Felix Lehmkühler[1], and Robert E. Grisenti[3,4] — [1]Deutsches Elektronen Synchrotron DESY, Hamburg, Germany — [2]Université Claude Bernard Lyon 1, Villeurbanne, France — [3]GSI, Darmstadt, Germany — [4]J. W. Goethe-Universität, Frankfurt am Main, Germany

Water displays a wide range of anomalous behaviors, many of which become particularly pronounced in the supercooled state, where its properties deviate strongly from those of other liquids. A prevailing hypothesis suggests that, at low temperatures, water may locally adopt two distinct structural motifs. This presentation will discuss results from temperature-dependent experiments that probe the physical and chemical properties of liquid water. The studies employ evaporatively cooled liquid jets in vacuum, investigated with techniques such as Raman spectroscopy and X-ray spectroscopy. These approaches enable a detailed examination of inter- and intramolecular vibrational modes, providing insight into the molecular dynamics of cooling water and optical properties, including the refractive index. Together, these experimental methods offer a comprehensive view of the temperature-dependent behavior of water, shedding light on the complex interactions that drive its anomalies. Through these studies, we aim to elucidate the mechanisms governing water's unique behavior in the supercooled regime and contribute to a deeper understanding of its structural transformations and physical properties.

DY 27: Statistical Physics far from Thermal Equilibrium II

Time: Tuesday 14:00–15:30 Location: ZEU/0114

DY 27.1 Tue 14:00 ZEU/0114

Efficiency of Carnot-like engine for intracellular diffusivity fluctuations and diffusing diffusivity — •Yuichi Itto — Aichi Institute of Technology, Japan — ICP, Universität Stuttgart, Germany

In contemporary physics of intracellular diffusion, much attention is paid to understanding how environmental conditions affect the diffusivity [1], the change of which is crucial, e.g., for tuning the rates of biochemical reactions. Recently, the heat-like engine for local diffusivity fluctuations, which slowly vary and obey a universal exponential law, has been constructed to extract the diffusivity change in a cycle realized by compression/expansion of cells and temperature change [2]: it has the Carnot-like efficiency determined by the average diffusivity.

Here, the effect of slowly varying fluctuation on the efficiency [3] is discussed based on "diffusing diffusivity" [4] that describes the dynamics of the fluctuation distribution by an advection-diffusion equation, the stationary solution of which is of the exponential type. The entropy of the fluctuations, which gives the exponential law at its maximum, takes positive production rate under the dynamics. The tendency to approach the (stationary) average diffusivity is dominantly governed by the factor characterizing the diffusion term in its square root, showing its peculiar role in view of the fact that the exponential law is due to the advection term.

DY 27.2 Tue 14:15 ZEU/0114

Relaxation speed in quenched-random force fields — •Jan Meibohm and Sabine H.L. Klapp — Technische Universität Berlin, Institut für Physik und Astronomie, Fachgruppe Theoretische Physik, Hardenbergstraße 36, 10623 Berlin, Germany

We determine the asymptotic relaxation speed of a Brownian particle in quenched-random force fields with a harmonic background in dimensions $d \geq 2$. For random forces derived from a potential, we show that relaxation is generally slower than in the unperturbed case when the background is isotropic. By contrast, for strongly anisotropic backgrounds, where the background is stiffer in all directions except one, we find a crossover between slow and fast relaxation, similar to the one-dimensional case discussed in [1]. Allowing for non-potential forces changes this picture and leads to generally faster relaxation. In the limits of small and large correlation length of the random force, we identify universal regimes in which the relaxation speed becomes independent of of the details of the random forces. Finally, we analyse a scaling limit for quasi-isotropic backgrounds at weak disorder, where the change in relaxation speed becomes anomalously large.

DY 27.3 Tue 14:30 ZEU/0114

Mpemba effect for a particle in a bistable potential: classical versus quantum — •Jannis Michael Melles[1], Hartmut Löwen[1], Benno Liebchen[2], and Alexander Antonov[1] — [1]Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany — [2]Institut für Physik der kondensierten Materie, Technische Universität Darmstadt, Darmstadt, Germany

An anomalous cooling behavior where initially hot systems cool faster than initially warm ones is referred to as the Mpemba effect and clearly goes beyond quasi-static thermodynamics. For classical particles, such a cooling behavior has been thoroughly studied for a simple paradigmatic set up involving a single classical colloidal particle in a bistable optical potential [1]. We quantize this model and consider a quantum particle coupled to an external bath with the Lindblad damping [2]. The Mpemba effect does occur during the cooling of this quantum system; however, the origin of the anomalous cooling is qualitatively massively different from that of its classical counterpart for temperatures close to or at zero. Additionally, we identify a doubled inverse quantum Mpemba effect when the system is heated instead. Our results are amenable for an experimental verification with an ultracold atom in a suitable laser-optical trap potential.

Brownian gyrators: from mono- to quadrupolar gyration — •Iman Abdoli and Hartmut Löwen — Institut für Theoretische Physik II - Soft Matter, Heinrich-Heine-Universität Düsseldorf, Universitätsstraße 1, D-40225 Düsseldorf, Germany

Thermally anisotropic Brownian systems-where different spatial directions are coupled to different effective temperatures-break detailed balance and generate circulating probability currents, exemplified by the Brownian gyrator. Such systems provide a minimal framework for studying nonequilibrium energy conversion and the emergence of directed motion and torques driven purely by fluctuations. We demonstrate how these anisotropic fluctuations can be harnessed as a microscopic heat engine, whose efficiency can approach Carnot performance at maximum power when appropriately loaded with external mechanical forces [1]. Furthermore, we show that confining a thermally anisotropic particle to a narrow ring produces quadrupolar steady-state gyration, a symmetry-protected circulation pattern arising solely from anisotropic noise [2]. These results highlight the rich flux structures and energetic functionalities enabled by thermal anisotropy.

DY 27.5 Tue 15:00 ZEU/0114

Role of kinetics in mesoscopic dynamics of a driven Potts model — •Maciej Chudak[1], Massimiliano Esposito[2], and Krzysztof Ptaszyński[1] — [1]Institute of Molecular Physics, Polish Academy of Sciences, Mariana Smoluchowskiego 17, 60-179 Poznań, Poland — [2]Department of Physics and Materials Science, University of Luxembourg, 30 Avenue des Hauts-Fourneaux, L-4362 Esch-sur-Alzette, Luxembourg

The Potts model is a generalization of the Ising model, where spins can take more than two states. We study a driven three-state non-equilibrium Potts model with homogeneous all-to-all coupling. At a macroscopic level, this model exhibits complex behavior such as synchronization and persistent oscillations (limit cycles). In the mean-field limit the model dynamics is described via deterministic equations of motion. Choice of the transition rate function can reshape the phase diagram of the model. We identified seven distinct dynamical phases separated by seven bifurcation types. Beyond the mean-field analysis, we characterize the effect of rare fluctuations on the model behavior. We determine the coherence lifetime of the oscillations and compare it to a thermodynamic bound given by the entropy production per cycle. The trade-off between coherence lifetime and entropy production can be fine-tuned. We characterize the rare stochastic transitions among the coexisting mean-field attractors using the instanton approach. Such transitions tend to relax the system to a single attractor that determines the macroscopic behavior of the model. In case of multistability, the ordered state is usually the most likely.

DY 27.6 Tue 15:15 ZEU/0114

Continuous-time multifarious systems — •Jakob Metson[1], Saeed Osat[1,2], and Ramin Golestanian[1,3] — [1]Max Planck Institute for Dynamics and Self-Organization (MPI-DS), 37077 Göttingen, Germany — [2]Institute for Theoretical Physics IV, University of Stuttgart, 70569 Stuttgart, Germany — [3]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

Multifarious assembly models consider multiple structures assembled from a shared set of components. We explore Gillespie simulations of lattice-based assembly models, comparing these to Monte Carlo simulations. We start with an equilibrium model, in which detailed balance is obeyed. However, due to the rough energy landscape, the systems often end up in long-lived metastable states. Despite this, the Gillespie and Monte Carlo simulations are largely consistent. We present physical arguments to predict the state boundaries, which also reconciles a small discrepancy between the two simulation methods. We furthermore study an explicitly non-equilibrium model, the non-reciprocal multifarious self-organisation model. Here, non-reciprocal interactions between the building blocks break detailed balance. Also in this case, the Gillespie and Monte Carlo simulations demonstrate the same range of behaviours. Additionally, we explore the timescales of shape-shifting present in this model, developing analytical calculations to compare with simulations. Overall, these results demonstrate that both Gillespie and Monte Carlo simulations can be relied on to explore such systems, even when the dynamics are far from equilibrium.

DY 28: Fluid Physics and Turbulence

Time: Tuesday 14:00–15:15 Location: ZEU/0118

Invited Talk DY 28.1 Tue 14:00 ZEU/0118

Geometry of turbulent mixing in thermal convection — •Jörg Schumacher — Institut für Thermo- und Fluiddynamik, TU Ilmenau, Germany

Thermal convection flows, which are driven by buoyancy forces, are ubiquitous in nature and technology ranging from atmospheric dynamics to heat transfer in blankets of nuclear fusion devices. They are mostly connected to further physical processes, such as phase changes, radiation or magnetic fields, but the paradigm to all these turbulent flows is the plane Rayleigh-Bénard convection layer that is uniformly heated from below and cooled from above. In my talk, I will review some recent numerical investigations, both in the Eulerian and Lagrangian frames of reference, which shed new light on geometric aspects of these flows. This comprises the organization of thermal plumes in hierarchical and self-affine near-wall networks, the large-scale organization of the flow structures, and the organization of tracer particle tracks to extreme swirling events. Consequences for the turbulent transport of heat and momentum across the convection layer and their necessary modeling will be discussed.

DY 28.2 Tue 14:30 ZEU/0118

Compression, simulation, and synthesis of turbulent flows — •Stefano Pisoni[1,2], Raghavendra Peddinti[2], Siddhartha Morales[2], Egor Tiunov[2], and Leandro Aolita[2] — [1]TUHH, Hamburg, Germany — [2]TII Abu, Dhabi, UAE

Numerical simulations of turbulent fluids are paramount to real-life applications. However, they are also computationally challenging due to the intrinsically nonlinear dynamics, which requires a very high spatial resolution to accurately describe them. A promising idea is to represent flows on a discrete mesh using tensor trains (TTs), where the values of the velocity field are encoded as a product of matrices (also known as Matrix Product States). This representation features an exponential compression of the number of parameters, under the assumption of low inter-scale correlations. However, it is yet not clear how the achieved compression of TTs is affected by the complexity of the flows. In fact, no TT fluid solver has been extensively validated in a fully developed turbulent regime yet. We fill this gap by analyzing TTs as an Ansatz to compress, simulate, and generate 3D snapshots with turbulent-like features. We first investigate the effect of TT compression on key turbulence statistical signatures. Second, we present a TT solver to time evolve a 3D fluid fields according to the incompressible Navier-Stokes equations. Third, we develop a memory-efficient TT algorithm to generate artificial snapshots displaying turbulent-like features. In all three cases we observe that the memory-efficient TT representation captures the relevant features of turbulent flows, offering a powerful quantum-inspired toolkit for their computational treatment.

DY 28.3 Tue 14:45 ZEU/0118

Physics-based reduced order modeling of complex chemical reactors — •Lisanne Gossel[1], Leon L. Berkel[2], Maira Gauges[2], Paul Brand[1], Mathis Fricke[1], Christian Hasse[2], Alessandro Stagni[3], Hendrik Nicolai[2], Dieter Bothe[1], and Tiziano Faravelli[3] — [1]Mathematical Modeling and Analysis, Technical University of Darmstadt, Darmstadt, Germany — [2]Simulation of Reactive Thermo-Fluid Systems, Technical University of Darmstadt, Darmstadt, Germany — [3]CRECK Modeling Group, Politecnico di Milano, Milan, Italy

Understanding and predicting observables in complex reacting flows is crucial for many applications related to the clean energy transition. We are interested in describing chemical reactors with detailed, often multiphase chemistry including thousands of reactions. While detailed understanding of the fluid physics can be gained by highly-resolved numerical models of the reactors, i.e., different types of Computational Fluid Dynamics (CFD) simulations, these usually rely on strongly simplified chemistry models to retain computational tractability. On the other hand, we use a physics-based reduced order method that allows to complement CFD by detailed chemistry computations. This is achieved by describing the reactor by a network of modeling components representing certain states of the reactor. The talk will focus on recent achievements in the development of algorithms for creating these network models based on prior CFD results. We discuss the roles of model consistency and defining proper trade-offs between model ac- curacy and complexity.

DY 28.4 Tue 15:00 ZEU/0118

Numerical investigation of surface wind veer in a transitional Atmospheric Boundary Layer — •Maharun Nesa Shampa, Heiko Schmidt, and Marten Klein — Brandenburgische Technische Universität Cottbus-Senftenberg, Cottbus, Germany

The Atmospheric Boundary Layer (ABL) is defined as the lower part of the atmosphere that dynamically couples the free atmosphere and Earth's surface. Transitional features and strong variability in boundary layer thickness due to surface heating and cooling pose a challenge for modeling atmospheric dynamics, placing a burden on flow profile and surface-flux parameterizations. This study addresses the mentioned challenge by investigating an idealized ABL, the so-called Ekman Boundary Layer (EBL) using a stochastic One-dimensional Turbulence (ODT) model as standalone tool. The EBL is characterized by absence of stratification such that a statistically stationary force balance between the pressure-gradient, Coriolis and drag forces is reached asymptotically for a prescribed synoptic pressure gradient. A single non-dimensional parameter, the Reynolds number, characterizes the flow regime and reflects the range of the turbulent scales participating in the flow. It is demonstrated that ODT is capable of capturing surface properties (like friction velocity, wind-turning angle) compatible with reference data and appropriate parameterization for transitional Reynolds numbers. In addition, the model offers additional insight into the boundary layer structure and statistical flow properties, which are likewise discussed. By constraining the stochastic sampling of turbulent length scales, an outlook to cut-off mechanisms is given.

DY 29: Active Matter IV (joint session DY/BP/CPP)

Time: Tuesday 14:00–15:30 Location: ZEU/0160

DY 29.1 Tue 14:00 ZEU/0160

Automated decision-making by chemical echolocation in active droplets — •Aritra K. Mukhopadhyay[1], Ran Niu[2], Linhui Fu[2], Kai Feng[2], Christopher Fujta[1], Qiang Zhao[2], Jinping Qu[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, Darmstadt, Germany. — [2]Huazhong University of Science and Technology, Wuhan, China.

Motile microorganisms like bacteria and algae combine self-propulsion, cooperation, and decision-making at the micron scale. Inspired by these biological systems, synthetic microswimmers are emerging as human-made counterparts capable of self-propulsion. Recent breakthroughs provide a platform to integrate additional functionalities, bridging the gap between biology and synthetic systems. We propose and experimentally demonstrate a mechanism that enables synthetic microswimmers, including autophoretic colloids, droplet swimmers, and ion-exchange-driven modular swimmers, to make autonomous navigational decisions. These swimmers generate chemo-hydrodynamic signals that interact with boundaries, producing echoes that encode structural information about

the environment. These echoes trigger automatic responses, such as synthetic chemotaxis, allowing swimmers to avoid dead ends and autonomously find paths through complex mazes. We show the mechanism remains robust across different maze geometries, ensuring reliable navigation without external cues. Our findings illustrate how simple physical principles can endow synthetic systems with advanced navigation functionalities.

DY 29.2 Tue 14:15 ZEU/0160

Dead or alive?—Probing scale-dependent liveliness in multiscale active matter — •Joscha Mecke[1] and Klaus Kroy[2] — [1]Institute for Advanced Study, Shenzhen University, Shenzhen, China — [2]Institut für Theoretische Physik, Universität Leipzig, Leipzig, Germany

If you have ever watched live and dead trouts swimming upstream, side by side, you may have wondered how closer inspection of their mesoscale activity might help to tell them apart. But probing spatially heterogeneous activity in living matter is a major challenge. We demonstrate the emergence of multiple effective ("active") temperatures in nonequilibrium molecular- and Brownian-dynamics simulations of an active polymer. Energy injection at different length scales leads to mode coupling, inter-modal energy transfer, and entropy production. We put forward a generalised Langevin equation for a labelled monomer, which, by application of a harmonic potential, can serve as a spectroscopic device. Upon varying the trap stiffness, we can selectively scan through the emergent effective temperatures and thereby resolve the scale-dependent activity. Our approach thus provides a minimally invasive spectroscopic tool to generate quantitative maps of liveliness, across multiple scales.

DY 29.3 Tue 14:30 ZEU/0160

Tuning the velocity of thermophoretic microswimmers with thermo-sensitive polymers — Franziska M. Braun, Aritra K. Mukhopadhyay, Samad Mahmoudi, Benno Liebchen, and •Regine von Klitzing — Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstrasse 8, 64289 Darmstadt

Understanding and controlling the motion of self-propelled particles in complex fluids is crucial for applications in targeted drug delivery, microfluidic transport, and the broader field of active matter. Here, we investigate the thermophoretic self-propulsion of partially gold-coated polystyrene Janus particles (Au-PS) in temperature-responsive linear Poly(N-isopropyl acrylamide) (PNIPAM) solutions across various PNIPAM concentrations and temperatures. Particle velocities are examined at three representative temperatures: far below, near but below and above the LCST. In pure water, Au-PS Janus particles propel with the PS hemisphere leading, driven by their intrinsic thermophoretic response. Conversely, the positive Soret coefficient of PNIPAM results in depletion forces that induce motion of the Janus particle towards the hot Au side. The experiments reveal a non-monotonic dependence of particle velocity on temperature, with a maximum near the LCST. Interfacial processes like ion movement in the electric double layer and PNIPAM adsorption at the Au-PS particles are separated from processes that are coupled to the bulk solution. Theoretical calculations are in good agreement with the experimental findings and are essential for the understanding of the complex interplay of microswimmers with thermoresponsive polymers.

DY 29.4 Tue 14:45 ZEU/0160

Non-reciprocal multifarious self-organization — •Saeed Osat[1] and Ramin Golestanian[2] — [1]Institute for Theoretical Physics IV, University of Stuttgart, Heisenbergstraße 3, 70569 Stuttgart, Germany — [2]Max Planck Institute for Dynamics and Self-Organization (MPI-DS), 37077 Goettingen, Germany

Biological systems exhibit a unique ability to design diverse structures from a shared set of building blocks, with a plethora of proteins made from a limited set of amino acids as a prime example. Furthermore, these systems often use building blocks efficiently by introducing transformations between different structures. A structure might undergo structural transformations to form a new structure with different functional purposes, without the need to discard the current structure and start anew. To unravel this mystery, one must examine the underlying non-equilibrium processes that make this shape-shifting behavior feasible.

Here, we leverage non-reciprocal interactions between building blocks to provide a foundation for designing dynamic structures. We used a multifarious self-assembly (MSA) model, which is the molecular counterpart of the Hopfield associative memory. By upgrading the MSA model to its non-equilibrium counterpart with non-reciprocal interactions, we introduce the ability to not only self-assemble different structures on demand but also facilitate shifts and transformations that lead to shape-shifting behavior.

Invited Talk DY 29.5 Tue 15:00 ZEU/0160

Designing topological edge states in bacterial active matter — Yoshihito Uchida[1], Daiki Nishiguchi[2,1], and •Kazumasa A. Takeuchi[1] — [1]The University of Tokyo, Tokyo, Japan — [2]Institute of Science Tokyo, Tokyo, Japan

Besides its potential relevance to the life sciences, active matter also manifests as a novel, intrinsically non-equilibrium kind of matter, endowed with characteristic transport properties distinguished from conventional matter. A challenge is how to control and design transport in active matter. A potentially useful, emerging concept here is topological transport developed in condensed matter physics, which was extended to active matter successfully, but experimental realizations have thus far relied on the chirality of the active particles, which limits design capabilities.

Here we report a controlled realization of topological edge states in dense bacterial suspension, induced by microfabricated geometry instead of the bacteria's chirality. First we demonstrate that we can rectify bacterial collective motion by a channel with asymmetric shape. Then we construct networks made of asymmetric channels and show that we can control the emergence of topological edge states through the network design. Through modelling and experiments, we discuss what properties of the network and the bacterial flow are crucial to the observed topological phenomenon. We expect our results may pave the way for establishing a control and design principle of topological transport in such active matter systems.

DY 32.1 Wed 9:30 HÜL/S186

Compression of Floquet random circuits — •Francesca De Franco[1,2], David Luitz[3], Dante Kennes[4], Matteo Rizzi[1,5], and Markus Schmitt[1,2] — [1]FZ Juelich, Institute of Quantum Control (PGI-8) — [2]University of Regensburg — [3]University of Bonn — [4]RWTH Aachen University — [5]University of Cologne

Current quantum computing hardware suffers from significant dissipation due to the coupling to the environment. This limits the depth of unitary quantum circuits which can be applied with high fidelity and hence the physical timescales reachable by digital quantum simulation. Here, we show that the reachable timescale in practice depends strongly on the physics of the many-body system under investigation: For systems deep in a many-body localized phase, we can find shallow circuit representations of the evolution operator U to late times, while in a chaotic regime this is not possible. The associated compressibility of the late time evolution operator is hence associated with the accessibility of long times on noisy quantum hardware. Moreover, we compare the performance of these compressed, variationally obtained circuits to tensor-network simulations, which allow us to compute quantum-information-spreading diagnostics such as entanglement entropy and out-of-time-ordered correlators.

DY 32.2 Wed 9:45 HÜL/S186

Spectral pairing statistics in Floquet time crystals — Alexander-Georg Penner[1], •Harald Schmid[1,2,3], Leonid I. Glazman[4], and Felix von Oppen[1] — [1]Dahlem Center for Complex Quantum and Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany — [2]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [4]Department of Physics, Yale University, New Haven, Connecticut 06520, USA

Floquet time crystals are characterized by the subharmonic behavior of temporal correlation functions. Studying the paradigmatic time crystal based on the disordered Floquet quantum Ising model, we show that its temporal spin correlations are directly related to spectral characteristics and that this relation provides analytical expressions for the correlation function of finite chains, which compare favorably with numerical simulations. Specifically, we show that the disorder-averaged temporal spin correlations are proportional to the Fourier transform of the splitting distribution of the pairs of eigenvalues of the Floquet operator, which differ by pi to exponential accuracy in the chain length. We find that the splittings are well described by a log-normal distribution, implying that the temporal spin correlations are characterized by two parameters. We discuss possible implications for the phase diagram of Floquet time crystals.

DY 32.3 Wed 10:00 HÜL/S186

Spin-Spin Correlations and Multifractality in 1D disordered $SU(2)$-Invariant Heisenberg Spin Chains — •Debasmita Giri, Julian Siegl, and John Schliemann — Institute for Theoretical Physics, University of Regensburg, Regensburg, Germany

Disorder and interactions in one-dimensional quantum spin chains give rise to rich non-ergodic phenomena that lie beyond the conventional eigenstate thermalization hypothesis (ETH). In the presence of sufficiently strong quenched disorder, many-body localization (MBL) can emerge: transport is frozen, entanglement growth is logarithmically slow, and local operators retain memory of their initial conditions even at infinite temperature. On the contrary, studies on models with non-Abelian symmetries have demonstrated that continuous symmetries, such as $SU(2)$, can obstruct the construction of local integrals of motion and thus hinder full localization. We investigate spin correlations in one-dimensional $SU(2)$-invariant Heisenberg chains with exchange disorder for spin lengths $S = 1/2$ and $S = 1$. In the weak-disorder regime, the eigenmodes of the spin-spin correlation matrix are delocalized, consistent with ergodic behavior. Under strong disorder, the system enters a quasi-localized multifractal phase characterized by exponentially decaying, dimer-like spin correlations. Finite-size scaling of the inverse participation ratios of the correlation-matrix eigenmodes yields a correlation dimension, $D_2 \approx 0.37-0.39$, confirming the presence of a multifractal regime that is distinct from both the ergodic limit ($D_2 = 1$) and the fully localized limit ($D_2 = 0$).

DY 32.4 Wed 10:15 HÜL/S186

Timescales for Deep and Full Thermalization — •Tabea Herrmann[1], Felix Fritzsch[2], and Arnd Bäcker[1] — [1]TU Dresden, Institut für Theoretische Physik, Dresden, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Isolated quantum systems typically approach thermal equilibrium as described by the Eigenstate Thermalization Hypothesis (ETH). Going beyond this involves either higher order correlators (full ETH) or the approach of moments of the reduced density matrix towards thermal equilibrium (deep thermalization). In this talk we compare these two types of thermalization using extensive numerical studies within a paradigmatic model for chaotic many-body quantum dynamics. For this we find exponential relaxation for both types: For deep thermalization all moments relax with the same rate, which approximately equals the relaxation rate of two-point correlation functions within full ETH. In contrast, all higher order correlation functions approach equilibrium twice as fast.

DY 32.5 Wed 10:30 HÜL/S186

Free Cumulants and Full Eigenstate Thermalization from Boundary Scrambling — •Felix Fritzsch, Gabriel O. Alves, Michael A. Rampp, and Pieter W. Claeys — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Out-of-time-order correlation functions (OTOCs) represent important probes of quantum information dynamics and scrambling. We introduce a solvable many-body quantum circuit model, which we term boundary scrambling, for which the full dynamics of OTOCs is analytically tractable. These dynamics support a decomposition into free cumulants and unify recent extensions of the eigenstate thermalization hypothesis (full ETH) with predictions from random quantum circuit models. We moreover obtain exact expressions for higher-order correlations between matrix elements as predicted by the full ETH. The solvability is enabled by the identification of a higher-order Markovian influence matrix, capturing the effect of the full system on a local subsystem.

DY 32.6 Wed 10:45 HÜL/S186

Mechanism of Eigenstate Thermalization Breakdown — •Rafał Świetek[1,2,3] and Lev Vidmar[2,3] — [1]Institut für Theoretische Physik, Georg-August-Universität Göttingen, D-37077 Göttingen, Germany — [2]Department of Theoretical Physics, J. Stefan Institute, SI-1000 Ljubljana, Slovenia — [3]Department of Physics, Faculty of Mathematics and Physics, University of Ljubljana, SI-1000 Ljubljana, Slovenia

Establishing a common framework for ergodicity-breaking transitions has many potential applications and provides insight into the nature of non-ergodic phases. In this work, we show that the softening of fluctuations within the recently established fading ergodicity framework can be derived directly from the emergence of the Fermi Golden Rule (FGR), ultimately classifying fading ergodicity as manifestation of FGR physics in quantum many-body systems. We show that this framework identifies the width of the local density of states and the fractal nature of eigenstates in the unperturbed basis as building blocks for fading ergodicity. Furthermore, we argue that our theory can be also applied to integrability-breaking transitions, where the critical point drifts exponentially with system size to a singular point, providing a common framework for ergodicity breaking in RMT models and integrability-breaking in local Hamiltonians.

DY 32.7 Wed 11:15 HÜL/S186

Entanglement in bipartite systems with symmetry: coupled chaotic kicked Bose-Hubbard systems — •Jan Himmelsbach[1], Maximilian F.I. Kieler[1,2], and Arnd Bäcker[1] — [1]TU Dresden, Institut für Theoretische Physik, Dresden, Germany — [2]CESAM research unit, University of Liège, B-4000 Liège, Belgium

We study the eigenstate entanglement of a time-periodically driven Bose-Hubbard system in a bipartite setting with a tunable coupling between two subsystems. By incorporating the symmetry of the particle conservation and employing perturbation theory we find that the entanglement transition for varying coupling strength is described by a universal transition parameter. It turns out that the entanglement transition is governed by localization for the particle conservation symmetry and a thermalizing process between the subsystems.

DY 32.8 Wed 11:30 HÜL/S186

Dynamical Pictures for Growth of Entanglement and Decay of Correlators in U(1) Conserving Random Circuits — •Marco Lastres[1,2], Olexei I. Motrunich[3], and Sanjay Moudgalya[1,2] — [1]Technical University of Munich, School of Natural Sciences, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [3]Department of Physics, Caltech, Pasadena, CA, USA

We study the dynamics of random circuit models with a global $U(1)$ charge conservation law. Prior work showed that systems without conservation laws exhibit linear growth of entanglement, linked to domain wall dynamics in an effective ferromagnetic model. In contrast, rigorous upper bounds for $U(1)$-conserving systems indicate that diffusive charge transport constrains Rényi entropies to grow only diffusively as $\sqrt{t}$. We study the second Rényi entropy in $U(1)$-conserving random circuits by mapping its dynamics onto the low-energy physics of an effective interacting Hamiltonian. This approach explicitly demonstrates the microscopic mechanism which produces diffusive growth of entanglement in the effective replica model. We also show that the same effective model naturally captures the recently discovered subexponential decay of non-hydrodynamic correlations through a closely related mechanism. Further, we demonstrate that in a different regime this model can also describe the dynamics of entanglement in noisy free-fermion systems, which also exhibit diffusive entanglement growth, but through a different mechanism. Finally, we discuss extensions to other continuous symmetries and to higher Rényi entropies.

DY 32.9 Wed 11:45 HÜL/S186

Correspondence principle, dissipation, and Ginibre ensemble — •David Villaseñor, Hua Yan, Matic Orel, and Marko Robnik — CAMTP - Center for Applied Mathematics and Theoretical Physics, University of Maribor, Mladinska 3, SI-2000 Maribor, Slovenia, European Union

The correspondence between quantum and classical behavior has been essential since the advent of quantum mechanics. This principle serves as a cornerstone for understanding quantum chaos, which has garnered increased attention due to its strong impact in various theoretical and experimental fields. When dissipation is considered, quantum chaos takes concepts from isolated quantum chaos to link classical chaotic motion with spectral correlations of Ginibre ensembles. This correspondence was first identified in periodically kicked systems with damping, but it has been shown to break down in dissipative atom-photon systems [Phys. Rev. Lett. 133, 240404 (2024)]. In this contribution, we revisit the original kicked model and perform a systematic exploration across a broad parameter space, reaching a genuine semiclassical limit. Our results demonstrate that the correspondence principle, as defined through this spectral connection, fails even in this prototypical system. These findings provide conclusive evidence that Ginibre spectral correlations are neither a robust nor a universal diagnostic of dissipative quantum chaos.

DY 32.10 Wed 12:00 HÜL/S186

Quantum Mpemba effect from Stark localization — •Nico Albert[1], Masudul Haque[1], and Shovan Dutta[2] — [1]TU Dresden, Dresden, Germany — [2]Raman Research Institute, Bangalore, India

In the Mpemba effect a system prepared at a higher temperature cools down faster to a target equilibrium state than the same system prepared at a lower temperature. We investigate how quantum effects can influence the occurence of such an effect. As an example we consider a bosonic chain subject to a suitable onsite potential that is dissipatively cooled to its ground state, and find that Stark localization significantly enhances the Mpemba effect compared to analogous classical systems.

DY 32.11 Wed 12:15 HÜL/S186

Robustness of interference-caged QMBS under real-space local perturbations: analysis through the Fock-space local interference pattern — •Tao-Lin Tan[1] and Yi-Ping Huang[1,2,3] — [1]Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan — [2]Physics Division, National Center for Theoretical Sciences, Taipei 10617, Taiwan — [3]Institute of Physics, Academia Sinica, Taipei 115, Taiwan

Quantum many-body scars (QMBS) represent a notable violation of the eigenstate thermalization hypothesis (ETH), hosting non-thermal eigenstates embedded in an otherwise thermal spectrum. Despite recent progress, a systematic understanding of their stability under real-space local (r-local) perturbations remains lacking. Building on recent insights of interference-caged quantum many-body scars (ICQMBS), protected by exact many-body destructive interference on Fock-space graphs, we develop an interference-based diagnostic to assess the robustness of ICQMBS in various lattice Hamiltonians. Applying this framework to quantum link models (QLM) and quantum dimer models (QDM), we analyze how r-local perturbations deform the underlying Fock-space local (f-local) interference structure, thereby identifying heuristic mechanisms that stabilize or destabilize ICQMBS. Our results broaden the applicability of the interference-based perspective beyond previously studied models and provide practical criteria for evaluating the persistence of ICQMBS in experimentally relevant Hamiltonians.

DY 32.12 Wed 12:30 HÜL/S186

Scrambling and Scarring in Topological Materials — •Nicholas Sedlmayr, Dominik Szpara, and Szczepan Głodzik — Institute of Physics, M. Curie-Skłodowska University, 20-031 Lublin, Poland

Topological insulators and superconductors have recently attracted considerable attention, and many different theoretical tools have been used to gain insight into their properties. Here we investigate how perturbations can spread through exemplary one-dimensional topological insulators and superconductors using out-of-time ordered correlators. Out-of-time ordered correlators are often used to consider how information becomes scrambled during quantum dynamics. The wavefront of the out-of-time ordered correlator can be ballistic regardless of the underlying system dynamics, and here we confirm that for topological free fermion systems the wavefront spreads linearly at a characteristic butterfly velocity. We pay special attention to the topologically protected edge states, finding that information can become trapped in the edge states and essentially decoupled from the bulk, surviving for relatively long times - a form of scarring. We further investigate what happens due to the chiral and helical edge modes of two dimensional topological models. The information travels around the edge, carried by the edge mode, but again is not scrambled over very long time scales.

DY 33: Statistical Physics of Biological Systems I (joint session DY/BP)

DY 33.1 Wed 9:30 ZEU/0114

Metastability in the mixing/demixing of two species with reciprocally concentration-dependent diffusivity — •Benjamin Lindner[1,2], Alexander B. Neiman[3,4], and Xiaochen Dong[2] — [1]Department of Physics, Humboldt University Berlin, Berlin, Germany — [2]Bernstein Center for Computational Neuroscience Berlin — [3]Department of Physics and Astronomy, Ohio University, Athens, OH, United States — [4]Neuroscience Program, Ohio University, Athens, OH, United States

It is known that two species of diffusing particles can separate from each other by a reciprocally concentration-dependent diffusivity: the presence of one species at a certain location amplifies the diffusion coefficient of the respective other one in this location, causing the two densities of particles to separate spontaneously. In a minimal model, Schimansky-Geier et al. (2021) observed this with a quadratic dependence of the diffusion coefficient on the density of the other species. Here, we consider a sigmoidal dependence in the form of a logistic function on the other particle's density averaged over a finite sensing radius. The sigmoidal dependence leads to a new regime in which a homogeneous disordered (well-mixed) state and a spontaneously separated ordered (demixed) state coexist, forming two long-lived metastable configurations. In systems with a finite number of particles, random fluctuations induce repeated transitions between these two states. By tracking an order parameter that distinguishes mixed from demixed phases, we measure the corresponding mean residence in each state.

DY 33.2 Wed 9:45 ZEU/0114

Phase separation in a mixture of proliferating and motile active matter — Lukas Hupe[1], Joanna M. Materska[2], David Zwicker[1], Ramin Golestanian[1,3], Bartlomiej Waclaw[2,4], and •Philip Bittihn[1] — [1]MPI for Dynamics and Self-Organization, Göttingen, Germany — [2]Dioscuri Centre for Physics and Chemistry of Bacteria, Institute of Physical Chemistry, Warsaw, Poland — [3]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, United Kingdom — [4]School of Physics and Astronomy, The University of Edinburgh, United Kingdom

Proliferation and motility are ubiquitous drivers of activity in biological systems. Here, we study a dense binary mixture of motile and proliferating particles with exclusively repulsive interactions, where homeostasis in the proliferating subpopulation is maintained by pressure-induced removal. Using large-scale simulations, we show that this heterogeneous active matter undergoes spontaneous phase separation at high density and weak enough self-propulsion. We recapitulate this behavior using an effective Active Brownian Particle model that incorporates the emergent effects of the proliferating matrix on motile particles: enhanced diffusion, renormalized self-propulsion, reduced persistence, and an effective attraction between motile particles. Our results establish a new type of phase transition and reveal how mechanical activity from growth can mediate non-equilibrium interactions and fluctuations. This mechanism provides a conceptual framework to reinterpret the physics of dense pattern-forming cellular populations, such as bacterial colonies or tumors, as systems of mixed active matter.

DY 33.3 Wed 10:00 ZEU/0114

Reentrant phase separation and critical behaviour in cellular aggregates — •Subhadip Chakraborti[1,2] and Vasily Zaburdaev[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany

We study pili-mediated bacterial colonies as a paradigm for attractive cellular aggregates. The interplay between inherent motility and intercellular attraction leads to a reentrant phase separation between attraction-induced and motility-induced phase separation separated by a homogenous state. Using finite-size scaling of the largest cluster we characterise these two transitions and thereby determine the associated critical lines in terms of the control parameters - density, pili lifetime and attraction strength. We further evaluate critical exponents corresponding to two transitions in the parameter space and from their relations determine the respective universality classes.

DY 33.4 Wed 10:15 ZEU/0114

Phase separation with non-local interactions — Filipe C. Thewes, Yicheng Qiang, Oliver W. Paulin, and •David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

Phase separation takes place in many complex systems, notably biological cells. While simple theories predict coarsening until only macroscopically large phases remain, concrete models often exhibit patterns with finite length scales, e.g., caused by chemical reactions, elasticity, membrane interactions, or charge. To unify such models, we here propose a field theory that combines phase separation with non-local interactions. If these interactions are long-ranged, they generally suppress coarsening, whereas systems with non-local short-range interactions additionally exhibit a continuous phase transition to patterned phases. Only the latter system allows for the coexistence of homogeneous and patterned phases, which we explain by mapping to the conserved Swift–Hohenberg model. Taken together, our generic model provides a framework that unifies similar phenomena observed in many complex phase-separating systems.

DY 33.5 Wed 10:30 ZEU/0114

Motile response of bacterial swimmers towards competing chemical signals — •Agniva Datta[1], Robert Grossmann[1], and Carsten Beta[1,2] — [1]Institute of Physics and Astronomy, University of Potsdam, Germany — [2]Nano Life Science Institute (WPI-NanoLSI), Kanazawa University, Kakuma-machi, Kanazawa 920-1192, Japan

Understanding how bacteria navigate in bulk fluid has gained significant interest in the field of active matter and random transport processes in the last few decades. We use the soil bacterium *Pseudomonas putida* as our model organism, the motility pattern of which is characterized by persistent runs, interrupted by

random reorientation events (turns). In addition to this, bacteria sense chemical signals and adapt their motility pattern accordingly. Recent experiments show that bacteria can change the frequency of turns (duration of runs) depending on the concentration of nutrients as well as auto-inducer molecules that they themselves produce in the medium. This complex interplay of the dynamics of nutrients, auto-inducers and bacterial density may lead to dynamic instabilities. Combining experiments and theory, we are elucidating the dynamics of bacteria in the presence of these two competing signaling factors.

DY 33.6 Wed 10:45 ZEU/0114

Anisotropic hierarchy decides the fate of an amorphous droplet — •Andrey Zelenskiy, Pietro Caracciolo di Torella, and Martin Lenz — LPTMS, CNRS, Orsay, France

The classical description of ordering, from theories of phase transitions to classical nucleation, typically emphasizes a direct transition from disorder to order. Yet, the majority of systems in nature deviate from this simple description, and often choose indirect pathways to ordering. In particular, complex structures often form via disordered or partially ordered intermediates – the amorphous precursors.

We present a model of self-assembling patchy particles, where the interactions are characterized by a hierarchy of geometric competitions. By tuning the anisotropy, we can stabilize a variety of aggregate morphologies, including crystals, gels, lamellar sheets, and fibers. However, due to geometric frustration, self-assembly proceeds via a dense amorphous intermediate, where the anisotropic interactions are largely averaged out. Our simple framework based on an anisotropic hierarchy sheds light on this non-classical mechanism of particle assembly, and provides a platform for new experimental principles of complex structure design.

DY 33.7 Wed 11:15 ZEU/0114

Improving neuronal information transmission with pathway splitting — •Kolja Klett[1,2] and Benjamin Lindner[1,2] — [1]Humboldt University, Berlin — [2]Bernstein Center for Computational Neuroscience, Berlin

In many organisms sensory information can take different neuronal paths from sensory cells to destinations in the brain. These paths can be made up of neurons serving distinct functions. Often, pathways consisting of neurons coding the increase (ON) or decrease (OFF) of a signal are observed which have be found to improve the transmission static signals. Here, we consider a simple network of spiking ON and OFF neurons to study the effects of pathway splitting on the transmission of dynamic signals. To that end, we use the coherence function as a frequency-resolved measure of informations transmission. We relate the information transmission of the whole network to that of the constituting neurons by employing response theory leading to approximate relations for the coherence function. For a simple white noise driven integrate-and-fire model of spiking neurons, we find an optimal mixture of ON and OFF neurons which maximizes the coherence function over a broad frequency range. The effect can be attributed to the nonlinear response of the neurons that only becomes relevant for sufficiently strong stimuli.

DY 33.8 Wed 11:30 ZEU/0114

Population sparseness in recurrent spiking neural networks — •Jakob Stubenrauch[1,2], Naomi Auer[3], Richard Kempter[2,3,4], and Benjamin Lindner[1,2] — [1]Physics Department HU Berlin — [2]Bernstein Center for Computational Neuroscience Berlin — [3]Institute for Theoretical Biology HU Berlin — [4]Einstein Center for Neurosciences Berlin

It is long known that in association tasks for neural networks, the fraction of active neurons in patterns to be associated plays an important role. Specifically, the number of patterns that can be simultaneously remembered grows when the information content per pattern is decreased. In binary networks, this content can be constrained by the population sparseness (one minus fraction of active neurons). For neurons with graded activity, population sparseness can be quantified by the Treves-Rolls measure or by the Gini coefficient. Here, we present results on the spontaneous and evoked population sparseness in different variants of recurrent neural networks of integrate-and-fire neurons. We find that the type of competition between neurons plays an important role and discuss that neurons in fully disordered networks can, in a mean field limit, only compete across a low-dimensional effective inhibition hub. We showcase the relevance of our findings for association tasks in spiking neural networks.

DY 33.9 Wed 11:45 ZEU/0114

Minority-triggered reorientation yields macrocscopic cascades and maximal responsiveness in a Vicsek swarm — •Simon Syga[1], Chandraniva Guha Ray[2,3,4], Josué Manik Nava Sedeño[5], Fernando Peruani[6], and Andreas Deutsch[1] — [1]Technische Universität Dresden, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [3]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [4]Center for Systems Biology Dresden, Germany — [5]Universidad Nacional Autónoma de México, Mexico City, Mexico — [6]CY Cergy Paris Université, Paris, France

Collective motion in animals and cells often exhibits bursty reorientations and scale-free velocity correlations associated with criticality. This ensures that information, like the presence of predators, quickly spreads through a group, ensuring an adequate response. To explain this phenomenon, we introduce a simple, biologically plausible mechanism, a minority-triggered reorientation rule: when local order is high, agents sometimes follow a strongly deviating neighbor instead of the majority. This generates heavy-tailed cascades of reorientations and macroscopic spatial correlations over broad parameter ranges, without fine-tuning. Our mechanism preserves cohesion while markedly enhancing collective responsiveness: localized directional cues elicit amplified, group-level reorientation. Our results provide a parsimonious, biologically interpretable route to critical-like fluctuations and high susceptibility in collective motion.

DY 33.10 Wed 12:00 ZEU/0114

Noise structure shapes transitions in cell differentiation processes — •Sara Oliver-Bonafoux[1], Javier Aguilar[1,2], Tobias Galla[1], and Raúl Toral[1] — [1]Institute for Cross-Disciplinary Physics and Complex Systems IFISC (CSIC-UIB), Campus UIB, Palma de Mallorca, Spain — [2]Laboratory of Interdisciplinary Physics, Department of Physics and Astronomy "G. Galilei", University of Padova, Padova, Italy

Stochastic differential equations provide a natural framework to describe dynamical systems influenced by random fluctuations, but they require specifying the structure of the noise term (e.g., additive, demographic, or environmental). In biological systems, the choice of an appropriate noise description remains a matter of debate. Understanding how stochastic fluctuations shape biological dynamics is a central challenge in biophysics and systems biology.

We address this question in the context of a model of cell differentiation, the process by which an unspecialised cell commits to a specialised cell type with a specific structure and function. Both the undifferentiated state and differentiated states are stable, and transitions between them are induced by noise. A recent study has provided theoretical evidence that different noise structures can give rise to substantially distinct differentiation paths. Here, we use stochastic bridges to sample differentiation paths under different types of noise and for varying noise intensity.

DY 33.11 Wed 12:15 ZEU/0114

Darwin's paradox of the peacock tail: a stochastic perspective on sexual selection — •Ian Magalhaes Braga — CASUS, Gorlitz, Germany

Many species show male traits that are extravagant, costly, and seemingly disadvantageous, yet they evolve and persist. Classical explanations especially deterministic versions of Fisher's runaway struggle to fully account for this pattern, mostly because they ignore the inherent randomness of evolutionary processes. In this work, I propose that stochasticity is not a secondary detail but the key element that reshapes the dynamics of trait preference coevolution. Treating sexual selection at the microscopic, probabilistic level reveals a simple but unexpected idea: in finite populations, a costly trait can actually support the evolution of female preference. I refer to this effect as the cost advantage. The basic picture is that stochastic fluctuations change the timing of fixation events, creating conditions under which preference benefits from the very cost that penalizes the trait. Using large-scale simulations across multiple evolutionary architectures, I show that this behavior is general and does not depend on specific modelling choices. The results suggest that costly ornaments are not paradoxical after all they may simply reflect the true stochastic nature of evolutionary change.

DY 33.12 Wed 12:30 ZEU/0114

Local equations for the generalized Lotka-Volterra model on sparse asymmetric graphs — •David Machado Pérez[1,2,3], Pietro Valigi[1], Tommaso Tonolo[4,5], and Maria Chiara Angelini[6] — [1]Physics Department, Sapienza University of Rome, Rome I-00185, Italy — [2]Department of Theoretical Physics, Physics Faculty, University of Havana. CP10400, Havana, Cuba — [3]CNR-NANOTEC, Rome Unit, Rome I-00185, Italy — [4]Gran Sasso Science Institute, 67100 L'Aquila, Italy — [5]INFN-Laboratori Nazionali del Gran Sasso, 67100 Assergi (AQ), Italy — [6]INFN, Sezione di Roma I, 00185 Rome, Italy

Real ecosystems are characterized by sparse and asymmetric interactions, posing a major challenge to theoretical analysis. We introduce a new method to study the generalized Lotka-Volterra model with stochastic dynamics on sparse graphs. By deriving local Fokker-Planck equations and employing a mean-field closure, we can efficiently compute stationary states for both symmetric and asymmetric interactions. We validate our approach by comparing the results with the direct integration of the dynamical equations and by reproducing known results and, for the first time, we map the phase diagram for sparse asymmetric networks. Our framework provides a versatile tool for exploring stability in realistic ecological communities and can be generalized to applications in different contexts, such as economics and evolutionary game theory.

DY 34: Focus Session: Fluids with Broken Time-Reversal Symmetry – Odd/Hall Viscosity Between Active Matter and Electron Flows

Viscosity is a fundamental property of fluids and an important physical quantity characterizing resistance to flow and energy dissipation. While time-reversal symmetry holds in conventional fluids, its violation can lead to striking phenomena, one of which is the emergence of a dissipationless transport coefficient called odd viscosity. Odd viscosity, also known as Hall viscosity, was originally proposed by Avron et al., as a quantized observable in electron fluids with a magnetic field. Since this seminal work, odd viscosity has been studied in various systems, such as 2D electron fluids, fractional Hall fluids, and ionic crystals. Although odd viscosity was also known in plasma physics, it was largely overlooked in fluid dynamics, mainly due to the technical challenges involved in its experimental realization. In recent years, however experiments in driven colloidal systems led to a surge of interest in odd viscosity in the active matter community. In parallel, our understanding of odd phenomena was advanced by continuum theories with many novel exact solutions. Major open questions in the field include the microscopic mechanisms that lead to odd viscosity, its experimental manifestations, the transition from two- to three-dimensional systems, and the effect of odd viscosity on hydrodynamic phenomena at different length scales, ranging from microrheology to turbulent flows. This Focus Session will connect the wider condensed matter and active matter physics communities with recent theoretical advances in odd viscosity. It is organized along with a Symposium on the same topic.

Organized by Yuto Hosaka (Göttingen) and Ewelina M. Hankiewicz (Würzburg)

Time: Wednesday 9:30–12:30 Location: ZEU/0160

Invited Talk DY 34.1 Wed 9:30 ZEU/0160

Active turbulence and odd viscosity in a colloidal chiral active system in bulk and in patterned environments — Joscha Mecke[1,2], Yongxiang Gao[1], and •Marisol Ripoll[2] — [1]Institute for Advanced Study, Shenzhen University, Shenzhen, China — [2]Institute for Advanced Simulation, Forschungszentrum Jülich, Jülich, Germany

Experiments for a chiral active fluid composed of a carpet of standing and spinning colloidal rods are compared with simulations for synchronously rotating hard discs in a hydrodynamic explicit solvent [1]. The emergence of multi-scale eddies, with features of self-similar dynamics, indicates the existence of active turbulence, while the particles accumulation in the centre of the vortices allows the quantification of the system odd viscosity. The existence of a non-negligible substrate friction can be shown to be responsible of the truncation of the energy spectra and the related reduction of the vortex size [2], and the interaction with fixed obstacles shows to originate a flow opposite to the rotation direction which induces a pinning vortex effect [3].

From Gels to Rotors: Tunable Chiral Phases in Odd Colloidal Fluids — •Dennis Schorn[1], Stijn van der Ham[2], Suvendu Mandal[1], Benno Liebchen[1], and Hanumantha Rao Vutukuri[2] — [1]Institute for Condensed Matter Physics, Technische Universität Darmstadt, 64289 Darmstadt, Germany — [2]MESA+ Institute, University of Twente, 7500 AE Enschede, The Netherlands

Starfish embryos aggregate into chiral crystals exhibiting odd elasticity (Tan *et al.* Nature **607**, 287 (2022)). Similar structures have been recently observed in externally driven magnetic colloids. In this talk, I present experiments and simulations of binary mixtures of magnetic spinners and passive colloids. We develop a model to predict the phase diagram of the system, which comprises four distinct phases that can be systematically reproduced in experiments. In particular, our simulations and experiments reveal a phase in which the passive particles form a gel-like network, with significant holes filled with self-organized, rotating chiral clusters composed of spinners. This phase can be reversed by changing the system's composition and magnetic field strength, resulting in a spanning spinner phase with embedded counter-rotating chiral clusters made of passive colloids. Both phases exhibit odd viscosity and diffusivity, whose magnitudes depend sensitively on spinner fraction and magnetic field strength. Our system may open the route towards a new type of viscoelastic active chiral matter involving nonreciprocal interactions between both species.

Odd Droplets: Fluids with Odd Viscosity and Highly Deformable Interfaces — •Hugo França and Maziyar Jalaal — Van der Waals-Zeeman Institute, Institute of Physics, University of Amsterdam, Science Park 904, Amsterdam, 1098XH, The Netherlands

Flows with deformable interfaces are commonly controlled by applying an external field or modifying the boundaries that interact with the fluid, but realizing such solutions can be demanding or impractical in various scenarios. Here, we demonstrate that fluids with broken symmetries can self-control their mechanics. We present a continuum model of a viscous fluid with highly deformable interfaces subject to capillary stresses. Our model features odd viscosity, a parity-violating property that emerges in chiral fluids. Using direct numerical simulations, we focus on the impact of an odd droplet on a superhydrophobic surface. By numerically solving the full conservation equations, we are able to study this highly non-linear problem hardly accesible through analytical methods. We demonstrate that odd viscosity dramatically disrupts conventional symmetric spreading by inducing asymmetric deformations and chiral flow patterns. Our analysis reveals a variety of dynamic regimes, including leftward and rightward bouncing, as well as rolling, depending on the relative strength of the odd viscosity. Our work illustrates that regulating odd viscosity provides a promising framework for controlling multiphase flows and designing functional metamaterials with tailored fluidic properties.

DY 34.4 Wed 10:30 ZEU/0160

The notion of dissipation in three-dimensional fluids with odd viscosity — •Jeffrey Everts[1,2], Laura Meissner-Oszer[1], and Bogdan Cichocki[1] — [1]Institute of Theoretical Physics, Faculty of Physics, University of Warsaw, Pasteura 5, 02-093 Warsaw, Poland — [2]Institute of Physical Chemistry, Polish Academy of Sciences, 01-224 Warsaw, Poland

Odd viscosity is a transport coefficient that occurs in fluids where the constituent particles carry a non-trivial spin angular momentum. Exemplary realisations in this context are chiral active fluids and electronic systems in an external magnetic field. Due to the symmetry properties of the resulting viscosity tensor it is often stated in the literature that odd viscosity does not contribute to viscous dissipation. In this talk, I will explicitly demonstrate that this statement is incorrect for incompressible odd viscous fluids in three spatial dimensions. In this case, the fluid flow velocity can be affected by odd viscosity, which gives a non-trivial contribution to the dissipated power. As an example, we will show by explicit calculation how odd viscosity contributes to viscous dissipation for a spherical (colloidal) particle immersed in an odd viscous fluid. Furthermore, we will make general statements for viscous dissipation by generalising the Helmholtz minimum dissipation theorem -which is well known for ordinary Stokesian fluids - to fluids with odd viscosity.

DY 34.5 Wed 10:45 ZEU/0160

Exact flow patterns in systems with odd viscosity — •Laura Meissner-Oszer[1], Bogdan Cichocki[1], and Jeffrey Everts[1,2] — [1]nstitute of Theoretical Physics, Faculty of Physics, University of Warsaw, Pasteura 5, 02-093 Warsaw, Poland — [2]Institute of Physical Chemistry, Polish Academy of Sciences, 01-224 Warsaw, Poland

Chiral active fluids are composed of self-spinning particles with a non-trivial spin-angular momentum that is maintained through a continuous injection of energy at the microscopic scale. Due to this property, there are antisymmetric contributions in the viscosity tensor, which are called odd viscosity. In the low Reynolds-number regime we show that there is a uniqueness theorem for such flows akin to ordinary Stokesian fluids. In order to analyse the effect of odd viscosity on flow patterns of a three-dimensional incompressible fluid in the creeping flow regime, we focus on a simple model of a chiral active fluid described by one shear viscosity and one odd viscosity. By considering the Green's function of the linear momentum-balance equation in the presence of a point force, we derive exact closed-form analytical expressions for the velocity and pressure field of the fluid around a translating and rotating spherical particle. Furthermore, we highlight specific features of such flows due to the presence of odd viscosity

and we demonstrate how the direction of spin momentum affects the qualitative features of the streamlines.

DY 34.6 Wed 11:15 ZEU/0160

Resonances in Odd Viscoelastic Materials — •Julius Kiln and Alexander Mietke — Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford, United Kingdom

Active matter describes materials that are powered by microscopic sources of energy. This injection of energy can lead to a wide variety of phenomena and unconventional material properties, including odd elasticity and odd viscosity. Despite recent analytical examination of these systems, a widely applicable method for solving force balance equations for odd materials on finite domains was so far not available.

The Papkovich-Neuber (PN) ansatz, introduced almost a hundred years ago, has proved an invaluable method for solving the force balance equation of a Stokes fluid and of a passive linearly elastic solid. We generalise this idea and find an ansatz for odd solids and fluids that reduces to the known PN solutions in the limit of vanishing odd material parameters. Altogether, this provides a new and versatile method for finding analytical solutions to this class of problems. Using this result, we construct the displacement field for an odd elastic material in circular domain under both displacement and stress boundary conditions. Further extending this method to write displacement and flow solutions of an odd viscoelastic material explicitly, we study the response to oscillatory forcing at the boundary, finding resonances at certain forcing frequencies even in an overdamped system. Finally, based on these new PN solutions, we propose rheological protocols for measuring odd material properties.

DY 34.7 Wed 11:30 ZEU/0160

Edge currents shape condensates in chiral active matter — •Boyi Wang[1,2], Patrick Pietzonka[4], and Frank Jülicher[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Center for Systems Biology Dresden, Dresden, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, Germany — [4]SUPA, School of Physics and Astronomy, University of Edinburgh, Edinburgh, United Kingdom

Chiral active matter, which breaks both parity symmetry and detailed balance, is widespread in living systems. Here, we introduce a minimal two-dimensional chiral active Ising model by incorporating stochastic, biased local rotations. At low temperatures, the system coarsens into condensates with chiral orientations and faceted, crystal-like shapes rather than circular ones observed under Kawasaki dynamics. The interfaces align at characteristic angles to the lattice axes and support persistent, unidirectional, angle-dependent edge currents.

To generalise these results, we develop a continuum theory by adding an active edge-current term to Model B. An edge current with n-fold symmetry produces condensates with corresponding n-fold polygonal shapes. In the sharp-interface limit, we construct an effective active surface potential that predicts the steady-state condensate geometry, consistent across both the lattice model and the continuum description.

Our results reveal how local chiral activity generates global edge currents and demonstrate their fundamental role in governing phase separation and interfacial dynamics in chiral active systems.

DY 34.8 Wed 11:45 ZEU/0160

A mobility based approach to self diffusion in odd-mobile systems — •Filippo Faedi and Abhinav Sharma — University of Augsburg

Odd-diffusive systems, defined by antisymmetric diffusion tensors, display unusual dynamics including enhanced self-diffusion due to interactions, oscillatory force autocorrelation functions in over-damped systems, and reversal of particle mobility. This work introduces a mobility-based approach by externally driving particles with constant forces, uncovering profound transport anomalies. We demonstrate an inverted density wake around a driven tracer, where increasing oddness reverses collision effects, reducing effective friction and enhancing mobility. Using fluctuation-dissipation, mobility-derived self-diffusion confirms prior findings, providing a unified view of interaction-induced anomalous dynamics in chiral media.

DY 34.9 Wed 12:00 ZEU/0160

Exceptional points, chirality and entropy production in nonreciprocal polar active matter — Kim L. Kreienkamp and •Sabine H. L. Klapp — Institut für Physik, Technische Universität Berlin, Germany

Non-reciprocal couplings significantly impact the collective dynamics of mixtures. A particularly striking consequence of such couplings is the spontaneous emergence of time-dependent phases that break parity-time symmetry. Here, we study a paradigmatic model of a non-reciprocal polar active mixture by combining field-theoretical analyses and particle-based simulations. When different species have opposing alignment tendencies, flocking states with spontaneously broken rotational symmetry transform into chiral states characterized by a rotating polarization direction. At the field-theoretical level, the transition to these parity-time-symmetry-breaking chiral states is indicated by so-called exceptional points. We demonstrate that these theoretical concepts have clear counterparts in particle-based systems [1]: we observe chimera-like states with coexisting locally synchronized and disordered regions, and find that both the spontaneous chirality and the entropy production rate [2] peak at coupling strengths corresponding to the exceptional points. Our results highlight the diverse effects of non-reciprocity across different scales.

The chiral random walk: A model for odd transport on the lattice — Jan Wójcik[1] and •Erik Kalz[2] — [1]Institute of Theoretical Physics and Astrophysics, University of Gdánsk, 80-308 Gdánsk, Poland — [2]Institute of Physics and Astronomy, University of Potsdam, 14476 Potsdam, Germany

We present a model for an isotropic chiral random walk on a lattice. Inspired by the quantum random walk framework, we equip the walker with an internal degree of freedom representing chirality and show, both numerically and analytically, that this model resembles odd transport properties on the continuum level. Chirality further acts as a control parameter, and the model resembles unitary transport in the strong-chirality regime. Building on established results from Quantum Random Walk theory, we analyse features such as topologically protected transport in this limit. We find that this qualitative persists also into the dissipative regime, allowing us to theoretically ground edge-transport phenomena, characteristics of dissipative odd systems. We illustrate our approach in spatially confined geometries and in systems with random chirality.

DY 35: Focus Session: Water – from Atmosphere to Space IV (joint session CPP/DY)

Time: Wednesday 9:30–10:45 Location: ZEU/0260

Topical Talk DY 35.1 Wed 9:30 ZEU/0260

Synchrotron X-Ray Studies on Structural Transitions in Water and Alcohol containing Ice Analogues — •Christina M. Tonauer — Institute of Physical Chemistry, University of Innsbruck, Austria — Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany

To this date, 21 different crystalline and at least 3 distinct amorphous forms of water ice have been discovered. In addition to the structural versatility of pure water ice phases, water forms solid guest-host systems, so-called 'clathrate hydrates' where water builds cage-like structures around guest molecules of various sizes (e.g., Ar, CO2, methane, ethanol).

Ices in space are exposed to various forms of (external) stress, e.g., impacts, cosmic rays, UV/Vis radiation as well as endogenous thermal fluctuations, thereby undergoing structural changes. By studying such structural transitions in ice analogues upon heating (and/or radiation), conclusions can be drawn about the conditions at various extraterrestrial environments.

Therefore, we here present temperature-resolved wide- and small-angle synchrotron X-ray scattering data of vapor-deposited water-ethanol mixtures of various concentrations, collected at PETRA 3/DESY. While the SAXS data allows for monitoring of changes of the morphology of the microporous sample, the WAXS data reveals the formation sequence of two different hydrates, offering new insights into the crystallisation of astrophysical ices.

Water in exoplanetary atmospheres: from molecular spectra to Water Worlds — •Sergey Yurchenko — Department of Physics and Astronomy, University College London, Gower Street, WC1E 6BT London, United Kingdom

Water vapour is one of the key tracers of atmospheric physics and chemistry on exoplanets, from hot Jupiters to temperate sub-Neptunes and so-called Water Worlds. In this contribution I will give an overview of the role of H_2O across this diversity of atmospheres, focusing on how we infer its presence from transmission and emission spectra. I will review both low-resolution transit spectroscopy and high-resolution cross-correlation techniques, and show how they are applied to data from space- and ground-based facilities, including JWST, Hubble and VLT, as well as future observations with the ELT and ESA's Ariel mission. Special emphasis will be placed on the way clouds and hazes imprint themselves on the observed spectra.

I will summarise the current observational status of water detections and non-detections – including recent and sometimes controversial claims for habitable-

zone planets. A central theme of the talk will be the importance of accurate laboratory and theoretical data for water and related species. I will highlight how comprehensive molecular line lists and cross sections from the ExoMol and HITRAN databases, together with other laboratory measurements, underpin the modelling and retrieval of exoplanet spectra over a wide range of temperatures, pressures and compositions, thereby linking detailed molecular physics to the emerging picture of water in exoplanetary atmospheres.

Water dynamics in conductive PEDOT:PSS/cellulose nanocomposite films in dependence of relative humidity and temperature — •Lucas Kreuzer[1], Marie Betker[2], Marcell Wolf[1], Jacques Ollivier[3], Daniel Söderberg[4], and Stephan V. Roth[2,4] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), TUM, Garching, Germany — [2]Deutsches Elektronen Synchrotron, Hamburg, Germany — [3]Institut Laue-Langevin, Grenoble, France — [4]Department of Engineering Mechanics, Royal Institute of Technology KTH, Stockholm, Sweden

PEDOT:PSS is a conductive and water-soluble polymer blend widely used in organic electronics. However, pure PEDOT:PSS films absorb significant amounts of water, causing swelling, degradation, and eventually a decrease in conductivity. Integrating PEDOT:PSS with cellulose nanofibrils (CNFs) overcomes these issues by limiting water absorption and enhancing mechanical stability. However, a minor amount of water is still absorbed, leading to a change in film morphology: high humidity induces de-wetting of PEDOT:PSS from the CNFs, reducing conductivity, whereas drying generally leads to a re-wetting of PEDOT:PSS, thereby restoring conductivity. To investigate further the role of water, quasi-elastic neutron scattering is applied, which reveals two water species in the films: mobile bulk water and slower hydration water. Upon drying, bulk water is released completely, while hydration water remains in the films, supporting the re-wetting of PEDOT:PSS. Moreover, at higher temperatures, different diffusive behavior was found for bulk and hydration water.

Scalable Machine Learning Model for Energy Decomposition Analysis in Aqueous Systems — •Thomas Kühne — CASUS/HZDR, Görlitz, Germany

Energy decomposition analysis (EDA) based on absolutely localized molecular orbitals provides detailed insights into intermolecular bonding by decomposing the total molecular binding energy into physically meaningful components. Here, we develop a neural network EDA model capable of predicting the electron delocalization energy component of water molecules, which captures the stabilization arising from charge transfer between occupied absolutely localized molecular orbitals of one molecule and the virtual orbitals of another. Exploiting the locality assumption of the electronic structure, our model enables accurate prediction of electron delocalization energies for molecular systems far beyond the size accessible to conventional density functional theory calculations, while maintaining its accuracy. We demonstrate the applicability of our approach by modeling hydration effects in large molecular complexes, specifically in metal-organic frameworks.

DY 36.2 Wed 11:15 ZEU/0260

Advances in absolute-scale electronic structure measurements of liquid water and aqueous solutions — •Florian Trinter — FHI Berlin, Germany

Recent advances in liquid-jet photoelectron spectroscopy (LJ-PES) have enabled the precise determination of absolute electronic energetics of liquid water and aqueous solutions, both in the bulk and at interfaces. By implementing refined vacuum and Fermi-level referencing procedures, rooted in condensed-matter concepts, vertical ionization energies (VIEs) and solution work functions can now be measured with high accuracy. We show that binding energy determinations near the ionization threshold are strongly influenced by quasi elastic electron scattering and indirect ionization processes. Vibrational excitation and autoionization via super-excited states lead to spectral distortions at electron kinetic energies below ~14 eV, necessitating careful data interpretation to extract intrinsic properties. Applying these methods to neat water and aqueous solutions of sodium iodide (NaI) and tetrabutylammonium iodide (TBAI), we reveal solute-specific effects: NaI primarily alters water's bulk structure, increasing the $1b_1$ binding energy with concentration, while TBAI affects surface potentials through interfacial dipole formation, leading to an apparent binding energy decrease. Additionally, we determine the work function of neat water as 4.73 ± 0.09 eV and quantify its reduction in TBAI solutions. These findings establish a framework for quantitative studies of molecular interactions and electronic-structure modifications in aqueous systems, with implications for electrochemical and interfacial science.

DY 36.3 Wed 11:30 ZEU/0260

Liquid-vapor critical behavior of the TIP4P/2005 water model: Effects of NaCl solutes and hydrophobic confinement — •Mayank Sharma and Peter Virnau — Institute of Physics, Johannes Gutenberg University Mainz, Germany

The liquid-vapor critical behavior of water is strongly influenced by both ionic solutes and confinement. Molecular dynamics simulations of aqueous NaCl solutions using the TIP4P/2005 water model and the Madrid-2019 ion parameters reveal a systematic increase in the liquid-vapor critical temperature and pressure with salt concentration, consistent with experimental trends. In contrast, confinement between parallel hydrophobic plates leads to a depression of the critical point. The critical temperature was determined using the Binder cumulant crossing in the NVT ensemble, based on a recently developed method originally applied to an active Brownian particle system [1]. The reliability of this approach was verified through complementary NPT simulations using histogram reweighting. We further demonstrate the pronounced sensitivity of the estimated critical point to the van der Waals cutoff distance, underscoring the importance of properly accounting for long-range interactions. The present results capture qualitative shifts in the critical point of water arising from ionic interactions and confinement, and the Binder-cumulant framework used here is readily extendable to other critical phenomena, including the putative liquid-liquid critical point of water.

DY 36.4 Wed 11:45 ZEU/0260

Cooperative molecular dynamics and nuclear quantum effects in bulk water — •Margarita Russina — Helmholtz-Zentrum Berlin for Materials and Energy, Berlin, Germany

The cooperative dynamics in water remain difficult to access due to the lack of long-range order and the short lifetimes of molecular correlations. Neutron scattering is well suited to probe such phenomena on the nanoscale but has been hindered by the weak coherent signal of H2O. Using a novel neutron polarization-analysis approach, we directly measure the coherent scattering in H2O and D2O with high accuracy [1]. Beyond self-diffusion and molecular rotation, we identify a picosecond cooperative process in liquid water, likely associated with rearrangements of several neighboring molecules and the reorganization of hydrogen bonds. This process may act as a precursor to large-scale molecular transport. In the intermediate wave-vector range Q < 1 1/Å, the coherent signal in H2O is enhanced compared to the expectation for rigid, noninteracting, randomly oriented molecules. Since this Q-range corresponds to distances of several molecular spacings, our results provide evidence that intermolecular correlations in water extend beyond short-range correlations and involve more distant neighbors, giving rise to cooperative dynamical fluctuations. Such an enhancement can be rationalized by correlated preferential molecular orientations, hydrogen-bond rearrangements, and nuclear quantum effects. In contrast, D2O follows a more hydrodynamic behavior consistent with reported differences in the molecular bonding and symmetry of H2O and D2O. [1] M. Russina et al., J. Phys. Chem. Lett. (2025).

DY 37: Glasses and Glass Transition (joint session DY/CPP)

Time: Wednesday 11:15–12:45 Location: ZEU/0118

Invited Talk DY 37.1 Wed 11:15 ZEU/0118

Topological defects in 2D amorphous ensembles — •Peter Keim — Heinrich-Heine-Universität Düsseldorf

Topological defects are key to understand melting of crystals in two dimensions. A dilute gas of bound thus virtual pairs of dislocations cause the softening of a crystal in the vicinity of melting. If thermal energy is high enough to unbind dislocation pairs, translational order is destroyed and the crystal to melts due to the lack of shear resistance. In an amorphous solid, the concept of topology seems useless for the first glance due to the absence of order. Here, we discuss, how the definition of virtual dislocations can be generalized for a two-dimensional glass. Based on positional data of a binary colloidal monolayer we determine the fugazity of generalized virtual dislocations and measure elasticity close to the glass transition: Youngs modulus gets 16π at melting in surprisingly close analogy to Kosterlitz-Thouless-Halperin-Nelson-Young (KTHNY) - theory for melting of 2D crystals.

DY 37.2 Wed 11:45 ZEU/0118

Glass transition and universal scaling in ultra-low crosslinked microgels — Alessandro Martinelli[1], Rajam Elancheliyan[1], Andrea Scotti[2], Alexander V. Petrunin[3], •Domenico Truzzolillo[1], and Luca Cipelletti[1,4] — [1]Laboratoire Charles Coulomb (L2C), UMR 5221 CNRS-Universitè de Montpellier, F-34095 Montpellier,France — [2]Division of Physical Chemistry, Lund University, SE-22100 Lund, Sweden — [3]Institute of Physical Chemistry, RWTH Aachen University, Landoltweg 2, 52074 Aachen,Germany — [4]Institut Universitaire de France, F-75231 Paris, France

We investigate the glassy dynamics of Ultra-Low Crosslinked (ULC) poly(N-isopropylacrylamide) (PNIPAM) microgels. The glass transition is reached by varying either the temperature (modulating microgel swelling) or the colloidal number density. Our Dynamic Light Scattering (DLS) measurements confirm that the dynamic slowdown is solely governed by the effective volume fraction (φ), with ULC microgels behaving as fragile glass formers. Small-Angle X-ray Scattering data further indicates that the center-to-center inter-microgel distance is insensitive to temperature, scaling geometrically with mass fraction, while the height of the first peak of the static structure factor decreases with increasing concentration, suggesting structural melting above glass transition. We finally we report on the striking emergence of a universal dynamic behavior for the relaxation time (τ_α) dependence on the scattering vector (q) across the entire supercooled and glass regimes, allowing the data to collapse onto a master curve, whose features will be discussed.

DY 37.3 Wed 12:00 ZEU/0118

Strain-rate dependent rheological memory in a model glass former — •Monoj Adhikari and Jürgen Horbach — Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, 40225 Düsseldorf, Germany

We investigate the shear response of deeply supercooled liquids far below the mode coupling critical temperature of a model glass former. Our system is based on the Kob-Andersen binary Lennard-Jones mixture (KABLJM) model but incorporates polydispersity, allowing us to combine SWAP Monte Carlo (MC) with Molecular Dynamics (MD) simulations. This hybrid approach enables equilibration at temperatures far below the Mode-Coupling critical temperature, T_{MCT}, while maintaining an equation of state similar to the original binary KABLJM model. We examine the response of these equilibrated samples to shear deformation at finite temperature and strain rate. By combining MD with SWAP MC during shear, we demonstrate that states with stress far below the yield stress can be accessed, making Newtonian fluid behavior observable even at temperatures well below T_{MCT}. To characterize the Newtonian fluid states obtained from this hybrid approach, as well as the solid-like states from standard MD, we employ a strain-rate switching protocol on the steady states. When applying this protocol to the stationary states, we observe intriguing memory effects. In the transient regime, stress overshoots appear when increasing the strain rate, whereas a striking stress undershoot emerges when decreasing it, mirroring recent experimental observations in polymer glasses.

DY 37.4 Wed 12:15 ZEU/0118

An Analytical Relation between Thermodynamics and Dynamics in a Trap-like Model of Supercooled Liquids — •Simon G. Kellers, Anshul D. S. Parmar, and Andreas Heuer — Institute of Physical Chemistry, University of Münster, Corrensstraße 28/30, 48149 Münster, Germany

Recent studies on 2D non-network glass formers, enabled by the million-fold acceleration of Swap Monte Carlo, have revealed clear deviations from Gaussian behavior in the inherent-structure (IS) density of states and linked these features to the fragile-to-strong crossover (FSC) and the emergence of a low-energy depletion regime.

Here, we establish such a connection by introducing a direct analytical relation between thermodynamic PEL statistics and dynamical properties within a trap-like description of supercooled liquids. We illustrate this relation using a binomial distribution of IS states and show that it naturally yields a characteristic trap size for polydisperse systems. This trap size reflects the effective number of degrees of freedom that collectively determine the depth and barrier of a metabasin participating in an activated relaxation event, thereby offering a physically transparent measure of cooperativity.

By combining this analytical framework with simulation data for a polydisperse 2D glass former, we obtain a coherent and quantitatively consistent landscape-based interpretation of the FSC.

Single particle vs. collective diffusion dynamics in a glassforming ternary Lennard-Jones mixture — •Anna Pini and Jürgen Horbach — Institut für Theoretische Physik II: Soft Matter, Heinrich Heine-Universität Düsseldorf, Universitätsstraße 1, 40225 Düsseldorf

Ternary fluid mixtures exhibit a rather complicated diffusion dynamics compared to their binary counterparts. Apart from three self-diffusion coefficient, there are three interdiffusion coefficients. In this work, we study a ternary ABC Lennard-Jones mixture using molecular dynamics computer simulation. It is based on the Kob Andersen binary Lennard-Jones mixture (KABLJM) [1] to which we have added a third C component. While C-C and A-C interactions are respectively identical to A-A and A-B interactions, B-C interactions are different from those between A and B particles. We study the glassy dynamics of this system at a high density of $\rho = 1.2$ and compare it to that of the original KABLM. While the self-diffusion coefficient show a similar temperature dependence for the binary and the ternary system, the behavior of the interdiffusion coefficients in the ternary system is significantly different from that in the binary one; in particular, unlike the binary system, the Darken equation does not hold in the ternary one. [1] W. Kob and H. C. Andersen, Phys. Rev. Lett. **73**, 1376 (1994).

Learning the statistical folding of bacterial chromosomes — •Chase Broedersz — Vrije Universiteit, Amsterdam, Nertherlands

The physical organization of bacterial chromosomes is inherently variable, with large conformational fluctuations both from cell to cell and over time. Yet, chromosomes must also be structured to facilitate processes such as transcription, replication, and segregation. A physical description of this dynamic statistical folding of bacterial chromosomes remains largely elusive. Hi-C experiments probe chromosome organization by measuring average contact frequencies of chromosomal loci pairs. I will present a principled approach to infer and analyze the dynamic and statistical organization of chromosomes. In particular, we developed a rigorous and fully data-driven 4D Maximum Entropy approach to extract a generative model for the dynamic organization of a replicating bacterial chromosome directly from time-course Hi-C and microscopy data. This data-driven approach aims to unravel the dynamic statistical folding of chromosomes - and its impact on functional processes - in growing and replicating bacteria. Finally, I will discuss how these data-driven inferences can be used to develop mechanistic insights into the contributions of various chromosome segregation mechanisms, including ParABS and loop-extruding SMC complexes. Together, our results illustrate how changes in the geometry and topology of the polymer, induced by DNA-replication and loop-extrusion, impact the organization and segregation of bacterial chromosomes.

A freely jointed chain with two-state hinges — •Minsu Yi and Panayotis Benetatos — Department of Physics, Kyungpook National University, Daegu, South Korea

We discuss aspects of the stretching and bending elasticity of a freely jointed chain, where the hinges can be open or closed in a random fashion. This two-state-hinge model captures a specific degree of freedom associated with the local bending stiffness of the polymer, and its variation can be due to internal changes or to the attachment of ligands from the environment. In this presentation, we focus on comparing the effects of two different types of disorder on the hinges: annealed (reversible Freely Jointed Chain, rFJC) or quenched (quenched Freely Jointed Chain, qFJC). It turns out that, as expected, those different types of disorder yield qualitatively different behaviors. For finite-size systems, we obtain a recurrence relation, which allows us to calculate the exact force-extension relation numerically for an arbitrary size of the system for both systems. In the thermodynamic limit, when the contour length is much larger than the persistence length, we obtain an exact expression for the force-extension relation. The difference between the two systems still exists in the thermodynamic limit.

Impact of cytosine methylation on the diffusion of charges along DNA: a quantum perspective — •Mirko Rossini, Dennis Herb, Paul Raschke, and Joachim Ankerhold — Institute for Complex Quantum Systems, University of Ulm, Ulm, Germany

We develop a coarse-grained tight-binding (TB) framework that treats electrons and holes on equal footing. TB parameters, required to characterize the model, are derived from an ab-initio molecular scheme (linear-combination-of-atomicorbitals (LCAO)) that includes all valence orbitals. Simulations address unmethylated vs. methylated CpG-rich and regulatory sequences sensible to DNA methylation, enabling us to investigate the impact methylation has on the charge diffusion along models of critical relevance in epigenetics and shedding new light on possible undiscovered mechanisms for epigenetic regulation in cells.

Methylation substantially lowers cytosine charge energies (~150 meV) while leaving the opposite guanine nearly unchanged (<20 meV), thereby introducing site-selective energetic shifts that redesign diffusion pathways. Statistical investigations, such as time-averaged populations and Inverse Partecipation Ratio (IPR) analyses, show enhanced electron localization at methylated cytosines, contrasted by increased hole delocalization: these dual trends suppress electron-hole co-localization (localization at same sites) and reduce recombination probability, leading to higher trapping times of excess charges along the DNA. Consistently, modelled excitations lifetimes increase upon cytosine methylation.

Efficient control of F_1 molecular motor — •Deepak Gupta — Institut für Physik und Astronomie, Technische Universität Berlin, Germany

Designing low-dissipation control driving protocols for small-scale systems is an active field of research. In this talk, I will specifically discuss designing efficient driving procedures for a biomolecular motor-the F_1ATPase. In general, designing such protocols is challenging due to the spatial nonlinearity of the systems and the presence of environmental thermal fluctuations. Nonetheless, a near-equilibrium (linear response) framework is found to apply to a broad class of small-scale systems. We follow this framework to design non-trivial protocols to drive the F_1's γ-shaft to synthesize ATP at low-dissipation cost. Our analysis reveals that the designed protocols, based on the linear response approach, dissipate lower energy as compared to the constant velocity driving protocol for a wide range of protocol durations[1]. In the second part of my talk, I will show our recent experimental results on the F_1 ATPase motor, where we compared the dissipation of driving this motor using two experimentally viable protocols: angle clamp and torque clamp. Our experimental results (supported by analytical findings) suggest that angle clamp driving requires less work than that of the torque clamp[2].

Elementary spectrum for the dissonance curve: from biophysics to number theory of musical harmony — •Alexandre Guillet — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Musical harmony, as the ancient problem of finding tunings and scales based on the commensurability of sound waves, has been approached by Helmholtz in terms of a dissonance curve in the frequency domain. This model is here recast in an elementary form related to number theory and a thermodynamical formalism for musical intervals and frequency ratios. The idea of the pioneer of biophysics connects with Riemann's zeta function along the critical line, and Minkowski's question mark measure. The former models rational relationships resulting from the acoustics of a harmonic timbre, while the latter models the probability distribution of the neurocognitive effort to assess the commensurability of frequency pairs. The spectrum of the resulting fractal curve predicts the quasi-periods of widely used musical scales, from the pentatonic division of the octave to microtonal ones, thus constituting a biophysical and mathemusical common ground to harmony across musical genres and cultures.

DY 41: Poster: Nonlinear Dynamics, Granular Matter, and Machine Learning

Time: Wednesday 15:00–18:00 Location: P5

DY 41.1 Wed 15:00 P5

Dynamics of Root Growth in Granular Media — Tianhui Liao[1,3], Jiayun Huang[1], Shihe Pan[1], Matthias Schroeter[1,4], and •Kai Huang[1,2] — [1]Collective Dynamics Lab, Division of Natural and Applied Sciences, Duke Kunshan University, 215306 Kunshan, Jiangsu, China — [2]Experimentalphysik V, Universität Bayreuth, 95440 Bayreuth, Germany — [3]Department of Physics, School of Science, Westlake University, Hangzhou, China — [4]Max-Planck-Institut für Dynamik und Selbstorganisation, Am Faßberg 17, 37077 Göttingen, Germany

Since the pioneering work of C. Darwin, the dynamics of growing plants and its interactions with the surrounding environment have been a topic of interest over centuries. As more frequent flooding and drought arise along with global climate change, it is essential to develop ecological models based on first principle understanding of the 'microscopic' interactions between plant roots and surrounding environment. Given the complex rheological behavior of granular media, it is intuitive to understand how plant roots navigate through granular media with heterogeneous stress distributions. By means of X-ray computer tomography, we measure the local packing density of individual 'soil' particles using (Set-)Voronoi tessellation, along with the morphological changes of plant roots. Our goal is to map temporal changes in packing fraction, displacement fields, and strain fields to reveal how roots actively adapt to the surrounding environment.

DY 41.2 Wed 15:00 P5

Diffusion in a Ferrogranular Pinball Machine — Ali Lakkis[1], Matthias Biersack[1], Oksana Bilous[2], Sofia Kantorovich[2], and •Richter Reinhard[1] — [1]Experimentalphysik 5, Universität Bayreuth — [2]Fakultät für Physik, Universität Wien

We experimentally investigate the diffusion of millimeter-sized glass and steel beads in a vessel under vertical vibration. At high amplitudes of an applied vertically oriented magnetic induction B, the magnetization of the steel beads aligns with the field direction. This causes the magnetized steel spheres to become nearly pinned in a hexagonal lattice due to dipole-dipole repulsion. As a result, they act as obstacles that hinder the diffusion of the glass beads, similar to the pins in a pinball machine. When B is reduced, the hexatic lattice of steel spheres becomes more fluid-like. We track both the glass and steel beads and estimate their mean square displacement (MSD) for different values of B. These results are compared to Molecular Dynamics simulations of a quasi-2D thermalized Stockmayer-glass mixture [1].

Analysis and optimization of power grid stability for rising feed-in of wind energy — •Jean-Luc Schnipper and Philipp Maass — Universität Osnabrück, Institut für Physik, Germany

On the basis of the swing equations for power flow in electricity grids and heterogeneous test grid structures, we analyse the impact of wind-power feed on grid stability. The stability is quantified by the exceedance, that is the fraction of time the network frequency exceeds thresholds triggering primary control measures. Wind farms are incorporated into test grids by replacing conventional generators. They are represented by stochastically driven single turbines with mean power output equal to that of the replaced conventional generator. We find that that the exceedance per unit of installed wind power can vary substantially depending on which generators are substituted and to which extent wind fluctuations are correlated at different locations of wind power injection. This offers strategies for maintaining best power grid stability by optimized spatial allocation of wind farms.

DY 41.4 Wed 15:00 P5

On Uncertainty Quantification in Parameter Estimation of Ordinary Differential Equation Initial Value Problems — •Oliver Strebel — Angelstr. 17, 75392 Deckenpfronn

Parameter estimation tasks for ordinary differential equation initial value problems (ODE-IVP) arise, when solution data for the ODE-IVP are given and for a given model the parameters and initial values are estimated. From the mathematical definition of the ODE-IVP it follows that uncertainty due to noise in the data and from a misfit of the model is reflected in the parameters and initial values alone. This uncertainty determines the uncertainty in the solution curves of the ODE-IVP. It is shown that simple Monte Carlo simulations, using the standard nonlinear regression measure, are well-suited for uncertainty quantification (UQ) in ODE-IVPs. This approach also uncovers practical identifiability issues related to the parameters and initial conditions. Additionally, the limitations of the method, such as its sensitivity to initial conditions and computational feasibility, are discussed.

DY 41.5 Wed 15:00 P5

Transition to Turbulence via Synchronization and Interacting Wakes — •Urantuya Batsuuri[1,2], Michael Hölling[1,2], Matthias Wächter[1,2], and Joachim Peinke[1,2] — [1]School of Mathematics and Science, Institute of Physics, Carl von Ossietzky Universität Oldenburg, 26129 Oldenburg, Germany — [2]ForWind - Center for Wind Energy Research, Küpkersweg 70, 26129 Oldenburg, Germany

The study investigates the dynamics of wake interactions under periodic perturbations using an active grid with two independently driven shafts, which are excited with different frequencies. Downstream velocity field is measured with constant-temperature anemometry to resolve the flow response.

For the single-shaft excitation case, a nonlinear synchronization effect is observed: the wake meandering synchronizes to the small-amplitude shaft motion, and this synchronized behavior grows downstream until it collapses into turbulence. Through this synchronization mechanism, the transition to turbulence appears to be accelerated.

For the two-shaft excitation case, an incipient interaction of the vortices leads to a low-dimensional quasi-periodic state. Further downstream, increasing nonlinear dynamics generate enhanced higher harmonics and interharmonics (mixing components). Eventually, the spectrum broadens into a fully turbulent state that follows the classical -5/3 power-law decay.

DY 41.6 Wed 15:00 P5

BHD In semi-chaotic phasespace — •Nico Fink — RPTU Kaiserslautern Landau; Kaiserslautern; Erwin Schrödinger Straße 46, Germany

The previous project showed a realisation of breaking of time reversal symmetry in a system with one degree of freedom, leading to the "rediscovery" of what was coined the Krystal-Neistadt-henrard-Theorem. This project extends the system to a nonlinear System with 1,5 degrees of freedom, displaying the rise of chaos around the separatrix widening and splitting of ensembles. Tje aim is to explore the macroscopic behaviour of ensembles by a bottom up approach.

DY 41.7 Wed 15:00 P5

Laminar chaos in systems with state-dependent delay — •David Müller-Bender — Institute of Physics, Chemnitz University of Technology, 09107 Chemnitz, Germany

Laminar chaos, an extremely low-dimensional form of chaotic dynamics, was originally discovered in time-delay systems with large, periodically time-varying delays [Phys. Rev. Lett. 120, 084102 (2018)]. In contrast, the same systems with constant delay exhibit high-dimensional turbulent chaos. Laminar chaos therefore provides a clear example of how temporal modulation of the delay can drastically change the dynamics of a time-delay system. While turbulent chaos is characterized by strong high-frequency oscillations, laminar chaos shows nearly constant laminar phases, whose intensity levels follow the dynamics of a chaotic one-dimensional iterated map.

Following a bottom-up approach, we subsequently investigated systems with quasiperiodic [Phys. Rev. E 107, 014205 (2023)], random, and chaotically time-varying delays [Phys. Rev. E 112, 064203 (2025)], thereby stepwise increasing the generality of the delay variation and building on insights from the preceding cases. In the present work, we consider the case of state-dependent delays and present first results, demonstrating that laminar chaos can also be observed in such systems.

DY 41.8 Wed 15:00 P5

Mesoscopic interface laws in patterns formed by non-equilibrium cell polarity models — •Tobias Alexander Roth[1], Henrik Weyer[2], and Erwin Frey[1,3] — [1]Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, Ludwig-Maximilians-Universität München — [2]Kavli Institute for Theoretical Physics, UCSB — [3]Max Planck School Matter to Life

Inspired by minimal models for protein-based polarization of living cells, we investigate the dynamics of interfaces in quasi-stationary patterns generated by two-component mass-conserving reaction-diffusion systems. These models describe two density fields that diffuse and interconvert through chemical reactions. Simulations reveal that for fast reactions sharp interfaces emerge, that separate high- and low density regions, which coarsen over time and eventually become a single patch. To quantitatively describe this process, we derive reduced descriptions for the motion of these interfaces, which are strikingly similar to what is found in crystal growth processes with dynamic heat deposition. Our derivation allows for a diffusio-chemical version of surface tension and kinetic drag and explains a cross-over in coarsening exponents. Taken together, we put non-equilibrium two-component models in context to classical thermodynamic models and give insight into biological self organization.

DY 41.9 Wed 15:00 P5

Nonlinear pulse dynamics in harmonic active mode-locking — •Shakiba Khajenooriranjbar[1], Elias R. Koch[1], Julien Javaloyes[2], and Svetlana V. Gurevich[1,2,3] — [1]Institute for Theoretical Physics, University of Münster, Wilhelm-Klemm-Str. 9, Münster 48149, Germany — [2]Departament de Física & IAC-3, Universitat de les Illes Balears, Cra. de Valldemossa, km 7.5. E-07122 Palma, Spain — [3]Center for Data Science and Complexity, Corrensstr. 2, 48149 Münster, Germany

Active mode-locking (AML) is a prominent technique for generating ultra-short laser pulses and frequency combs, finding applications in fields such as medicine and laser metrology. We employ a time-delayed model to study the multipulse dynamics in AML that is valid for large values of the round trip gain and losses. It allows us to access the typical regimes encountered in semiconductor lasers and to perform an extended bifurcation analysis. Close to the harmonic resonances and to the lasing threshold, we recover the Hermite-Gauss solutions. However, we also discover a global bifurcation scenario in which a single pulse can jump, over a slow time scale, between the different minima of the modulation potential. There, a periodic orbit terminates at an homoclinic limit point of the solution branch, where not all potential slots occupied with the pulses, forming a so-called time-crystal state. Next, we analyzed the interaction between pulses by analyzing their phase relations. Numerical path continuation reveals the existence of multistable splay states and the laser may wander between them under the influence of stochastic forces.

DY 41.10 Wed 15:00 P5

Dynamic Models for Two Nonreciprocally Coupled Fields: A Microscopic Derivation for Zero, One, and Two Conservation Laws — Kristian Blom[1], •Uwe Thiele[1], and Aljaz Godec[2] — [1]Institute of Theoretical Physics, University of Münster, Wilhelm-Klemm-Strasse 9, 48149 Münster, Germany — [2]Mathematical bioPhysics group, Max Planck Institute for Multidisciplinary Sciences, Am Faßberg 11, 37077 Göttingen, Germany

Dynamical field theories form a cornerstone of statistical and soft matter physics, providing continuum descriptions of complex systems through a coarse-grained order parameter field. These theories can be derived either by explicit coarse-graining of microscopic dynamics or by top-down symmetry and conservation arguments.

An intriguing class of such models are nonreciprocal field theories, including the nonreciprocal Allen-Cahn and Cahn-Hilliard models, which describe the

spatiotemporal evolution of two fields coupled through interactions that violate Newton's third law. Depending on the underlying microscopic dynamics, two interacting fields may exhibit zero, one, or two conservation laws associated.

In this poster, we demonstrate how the evolution equations for each of these scenarios can be systematically derived from a single microscopic framework: the nonreciprocal Ising model. After obtaining the corresponding field-theoretic descriptions, we briefly discuss their linear and nonlinear behavior, and finally show how distinct combinations of kinetic modes give rise to a set of sixteen different nonreciprocal field theories.

Competing instabilities in electroferrofluids via non-variationally coupled Swift-Hohenberg equations — •Emil Stråka[1], Max Phillip Holl[1], Maria Sammalkorpi[1], and Mikko Haataja[2] — [1]Aalto University, Finland — [2]Princeton University, USA

Recent experiments in charged ferrofluids, so called electroferrofluids, have shown that they can exhibit Rosensweig-like patterns with non-equilibrium activity [1]. The observed activity rises from the competition of an magnetic and electric field induced instabilities. In this work, we study the phenomenon via two non-reciprocally coupled Swift-Hohenberg equations analytically and numerically [1,2]. In addition to the propagating patterns predicted by theory, the model equations reveal a wide range of dynamics, including irregular, active motions [2].

Our findings demonstrate how competing instabilities in a simplified model system can generate new, nontrivial pattern dynamics. These results suggest that similar active dynamics may arise broadly in complex fluids with competing instability mechanisms.

Mitigating Degradation in Anion Exchange Membrane Water Electrolysis: Repurposing Shutdowns to Probe Cell Health — •Limei Jin[1], Violeta Karyofylli[2], Karsten Reuter[1], and Christoph Scheurer[1,2] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]IET-1, Forschungszentrum Jülich

The reliable integration of Anion Exchange Membrane Water Electrolysis (AEMWE) into renewable energy systems is hampered by rapid cell degradation, a challenge exacerbated by variable loads and frequent, safety-mandated shutdowns. This performance loss has been attributed to cell reversal: when the cell's potential drops below a critical inflection point, an acute negative current excursion occurs.

To address this challenge, we present an effect analysis of key shutdown parameters on the inflection point of the potential, using this operational signature as a critical indicator to correlate with long-term aging. We base the analysis on our comprehensive COMSOL multiphysics model to accurately simulate dynamical processes governing the shutdown and reversal phenomena in detail. Data generated from these simulations are integrated into an AI-driven optimization framework to identify ideal operating parameters. It will be used to design an optimal pulse sequence for an active online control to suppress reversal events and mitigate degradation.

DY 41.13 Wed 15:00 P5

TANGO and Machine Learning Enhanced Experimentation for Real Time Tracking of Actively Steered Magnetic Particles. — •Nikita Popkov[2,3], Nikolai Weidt[1,2], Yahya Shubbak[1,2], Rico Huhnstock[1,2], Kristina Dingel[2,3], Bernhard Sick[2,3], and Arno Ehresmann[1,2] — [1]Institute for Physics and CINSaT, University of Kassel, Heinrich-Plett-Str. 40, 34132 Kassel, Germany — [2]AIM-ED, Joint Lab of Helmholtzzentrum für Materialien und Energie, Berlin (HZB) and University of Kassel, Hahn-Meitner-Platz 1, 14109, Berlin, Germany — [3]Intelligent Embedded Systems, University of Kassel, Wilhelmshöher Allee 71-73, 34121, Kassel, Germany

This work presents an AI-driven closed-loop framework for automating experimental tasks, demonstrated for the remote-controlled on-chip transport of magnetic particles. The system integrates machine learning models for particle detection, tracking, and classification, enabling dynamic feedback control during experiments. It autonomously adjusts experimental parameters to improve data quality and align outcomes with research objectives. The TANGO controls modular design allows adaptation to different experimental setups and hypotheses. Overall, it emphasizes how autonomous systems could iteratively optimize experiments, advancing the field of next-generation laboratory automation and, specifically for our experiments, the development of novel lab-on-a-chip devices.

Machine Learning of a Classical Density Functional for 2D Hard Rods — •Paul Bitzer, Jens Weimar, and Martin Oettel — Eberhard Karls University of Tübingen, Tübingen, Germany

Obtaining phase diagrams and density distributions via Grand canonical Monte Carlo simulations (GCMC) for classical fluids still requires substantial computational resources. Here, classical density functional theory (cDFT) is more efficient if the excess functional for the free energy is known. Recently, machine learning (ML) methods have become popular to learn such functionals (which are broadly applicable) from a limited amount of training data obtained in random, inhomogeneous external potentials [1]. We discuss an extension of an ML scheme to lattice fluids and apply it to the case of hard rods in two dimensions (2D). This model shows demixing between majority phases of vertically resp. horizontally oriented rods. This is typical of demixing in a binary, continumm fluid whose phase diagram has been learned recently in [2] employing only training data inhomogeneous in 1D. The use of explicit 2D training data allows applications to more general inhomogeneous situations [3].

Neural-Network-Driven Sequential Quasi Monte Carlo Sampling for Bayesian Inference with Complex Posteriors — •Andreas Panagiotopoulos[1], Javed Mudassar[2], Jens-Uwe Repke[2], Georg Brösigke[2], and Sebastian Matera[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Technische Universität Berlin

Bayesian inference has seen an increasing popularity in recent years, because it overcomes some of the limitations of classical parameter fitting. The price is the need to sample the potentially high-dimensional parameter space, which can become computationally demanding for complex forward models. This is enhanced when faced with uninformative priors but accurate data in conjunction with highly sensitive and nonlinear models. Posteriors will be sharply localized and of complex nature resulting in challenging sampling problems. To address this, we have developed a sequential importance sampling approach which utilizes neural network normalizing flows to exploit the superior sampling properties of Quasi Monte Carlo (MC) techniques. An initial sampling from a simple distribution is employed to learn the first layer of the normalizing flow, i.e. a first coarse approximation of the posterior distribution. Using this flow to quasi MC sample from that distribution provides the data to learn the next layer and so on. As at early stages appropriate sampling of the posterior is intractable, a tempering strategy is employed to make this strategy more robust. We demonstrate the approach on a realistic problem with complex posteriors stemming from the field of chemical kinetics.

DY 41.16 Wed 15:00 P5

Computational modeling and design of self-stratifying colloidal materials — •Mayukh Kundu and Michael Howard — Auburn University, Auburn, United States

Mixtures of colloidal particles suspended in a solvent can spontaneously form layered structures during fast solvent drying. This process, called self-stratification, can be leveraged to fabricate multilayered colloidal materials in a single processing step. Existing models for simulating self-stratification are computationally expensive or inaccurate. I have developed a better model for simulating the phenomena using dynamic density functional theory (DDFT). DDFT is a continuum model that is systematically formulated from particle-level interactions and dynamics. As such, it incorporates physics that would be present in particle-based simulations but can access much larger length scales and longer time scales. DDFT has two key inputs: a thermodynamic model (free-energy functional) and a dynamics model (mobility tensor). DDFT model can be made faster using the simplest approximations of these inputs that give the desired accuracy. I systematically investigated approximations of both inputs to develop an accurate, efficient DDFT model for drying suspensions. I also coupled these drying simulations to an optimization strategy based on surrogate modeling to inverse design self-stratified coatings with targeted thickness and particle distribution. This work has the potential to reduce the time and resources required to create these novel materials in the laboratory.

DY 42: Poster: Quantum Dynamics and Many-body Systems (joint session DY/TT)

Time: Wednesday 15:00–18:00 Location: P5

DY 42.1 Wed 15:00 P5

Operator spreading through the lens of the information lattice — •Luca Gawalleck[1,2], Maxime Debertolis[1], Jens H. Bardarson[3], and David J. Luitz[1] — [1]Institut of Physics, University of Bonn, Nußallee 12, 53115 Bonn, Germany — [2]Institute for Functional Matter and Quantum Technologies, University of Stuttgart, Pfaffenwaldring 57, 70550 Stuttgart, Germany — [3]Department of Physics, KTH Royal Insititute of Technology, Stockholm, 106 91 Sweden

We study the entanglement growth during Heisenberg time evolution by extending the framework of the information lattice to operators using the operator entanglement entropy. We focus on one-dimensional quantum spin chains and work in the tensor network formalism. The generalization of the information lattice to matrix product operators allows us to observe the spreading of initially local operators in a way that is not biased by the choice of a probing operator. We demonstrate that the operator information lattice we introduce contains all information typically provided by the out-of-time-order correlator with the additional ability to resolve the correlations on different scales. This method provides a good way to analyze systematically the time dependence of entanglement and can seamlessly be integrated into existing information-lattice-based algorithms.

Non-Perturbative Out-Of-Equilibrium Dynamics with Initial Four-Point-Correlations — Jürgen Berges, Louis Jussios, and •Cosima Schmitt — ITP Heidelberg

We investigate how initial correlations affect the equilibration dynamics of closed systems in quantum field theory. For interacting scalar fields with N components, we derive nonequilibrium evolution equations from a self-consistent large-N expansion to next-to-leading-order. By going beyond conventional Gaussian initial conditions, we point out the role of initial four-point correlations for the propagator evolution at early times and in the late-time approach to thermal equilibrium.

DY 42.3 Wed 15:00 P5

Nonequilibrium Green Function Simulations for Large Systems — •Erik Schroedter, Jan-Philip Joost, and Michael Bonitz — Christian-Albrechts-Universität zu Kiel, Kiel, Germany

Nonequilibrium Green Functions (NEGF) provide a powerful framework for accurately simulating the dynamics of correlated many-body systems. A major limitation of standard NEGF approaches is the cubic scaling of computational cost with the number of time steps. Recently, the G1-G2 scheme [1] overcame this limitation, achieving linear scaling. However, it introduces its own challenges, such as numerical instabilities at strong coupling and large memory requirements, which have so far restricted simulations to small systems with fewer than 150 basis states. Here, we introduce a NEGF-based quantum fluctuations approach (NEGF-QF)[2] that builds on earlier works [3] to efficiently factorize the two-particle Green function. This method drastically reduces computational costs for advanced self-energy approximations, including GW and T-matrix, while enabling straightforward parallelization. As a result, NEGF-QF allows simulations of systems with up to ten thousand basis states. We demonstrate the approach for large Hubbard clusters and graphene nanoribbons, illustrating its effectiveness for large, strongly correlated systems.

This work was funded by the Deutsche Forschungsgemeinschaft (DFG), Project No. 464370560.

Quantum Chaos in a Classical Counterpart to the Fermi-Hubbard model through an exact Path-Integral Formalism — •Louis Renck[1], Wolfgang Hogger[2], Juan Diego Urbina[2], and Peter Schlagheck[1] — [1]IPNAS, CESAM research unit, Université de Liège, Belgium — [2]Institut für Theoretische Physik, Universität Regensburg, Germany

Understanding quantum chaos in interacting many-fermion systems remains challenging : unlike many-bosons systems - where quantum-classical correspondence can be established using semiclassical tools such as the van Vleck-Gutzwiller propagator [1] -, most interacting fermions models still lack a sensible classical limit where Hamiltonian chaos can be defined.

We propose a candidate to the first classical Hamiltonian for the Fermi-Hubbard model with integrability broken by a random onsite potential. Starting from the fermionic Hamiltonian, we apply a Jordan-Wigner transformation and switch to the Schwinger-boson representation to obtain a bosonic form. A recently developed exact bosonic path-integral formalism [2] then provides a classical Hamiltonian symbol defined over a symplectic phase space. We investigate the resulting quantum-classical correspondence by comparing the effective dynamics with the quantum evolution, and we present quantitative checks of chaos based on spectral properties and out-of-time ordered correlators.

Adaptive Fermion Circuits with chiral transport — •Markus Siegl and Michael Buchhold — Department of Theoretical Physics, Universität Innsbruck, Austria

Nonequilibrium quantum transport, where coherent many-body dynamics coexist with directional motion remains a central challenge in modern quantum physics. This project investigates transport phenomena in two coupled fermionic chains designed to break chiral symmetry. Using fermionic adaptive circuits and measure-ment-feedback protocols, we aim to control nonequilibrium dynamics and induce directional motion in an other-wise symmetric quantum system. By linking classical universality, quantum many-body effects, and information transport, the research seeks to uncover new mechanisms for controlled, symmetry-broken quantum transport, establishing a model system for genuinely nonequilibrium quantum matter.

DY 42.6 Wed 15:00 P5

Absorbing-State Dynamics and Feedback Control in Quantum Many-Body Scar Systems — •Lara Schorr — University of Innsbruck

We look at quantum many-body scar states, which are special excited states in non-integrable systems that do not thermalize. To better understand their non-equilibrium dynamics, we translate the problem to a measurement-based quantum circuit equipped with feedback control. Focusing on a spin-1/2 chain with SU(2) symmetry, we show that local unitary feedback enables controlled manipulation of non-local charges, allowing the system to relax into highly entangled dark states. By analyzing the convergence towards the target state, we find that the dynamics resembles an emergent absorbing-state process, in which non-local charges diffuse and annihilate over time. Studying the scaling of convergence times allows us to identify conditions under which the dynamics may exhibit an absorbing-state phase transition.

Floquet-Magnus expansion for driven quantum systems and spin dynamic mean-field theory in NMR — •Antonia Joëlle Bock — TU Dortmund University, Germany

An accurate and reliable theoretical description of periodically driven quantum systems is highly relevant to many applications, such as for magic-angle spinning (MAS) in nuclear magnetic resonance (NMR) and ultracold atoms in driven optical lattices. Typically, the first step in capturing the dynamics is to determine an effective time-independent Hamiltonian, for which one can choose from a broad range of slightly different, hence often confusing, theories. Thus, I specifically investigated two widely used theories: Average Hamiltonian theory (AHT) and the Floquet-van Vleck approach (secular averaging). I was able to quantify the importance of the kick operator for the equivalence between perturbative and numerically exact approaches. This was achieved through analytical calculations and numerical evaluations of exemplary spin systems. These crucial insights then build the foundation for the second step of my project: a dynamic mean-field theory for dense spin ensembles applicable to complex couplings between three or more spins (MAS-DMFT). The recently developed spinDMFT (cp., e.g., Gräßer et al., 2024) has proven to be efficient, accurate and applicable to large spin systems yielding 2-particle interactions.

Phonon mediated indirect spin interaction — •Pablo Reiser and Habib Rostami — University of Bath, Bath, United Kingdom

Due to the lack of inversion symmetry in the hBN monolayer, circular polarized vibration in solids, or chiral phonons, with nonzero angular momentum are allow. These chiral phonons can couple to spins of different nature through their angular momentum. Within this context, we explored the coupling of chiral phonons with non-zero angular momentum to two impurities spins in hBN. Using field theory methods, we obtained the spin susceptibility and studied it*s properties like the mass dependence of the coupling, frequency of oscillation and rate of decay. The momentum transfer due to this coupling may opens the door for non-trivial thermal or spin transport effects.

DY 42.9 Wed 15:00 P5

Dynamical Phases and Instabilities in Periodically Driven Bogoliubov-de Gennes Superconductors — •Subhadip Chakraborty, Animesh Panda, and Ferdinand Evers — Institute of Theoretical Physics, University of Regensburg, D-93040 Regensburg, Germany

We investigate the nonequilibrium dynamics of a superconductor subjected to a periodic modulation of the interaction strength starting with Bogoliubov-de Gennes (BdG) mean field Hamiltonian. Using numerical solutions of the time-dependent Bogoliubov-de Gennes equations, we first explore several dynamical superconducting regimes. Our analysis reveals a rich variety of phases, including Rabi-Higgs oscillations, synchronized Higgs dynamics, and time-crystalline responses, and shows how their stability varies across driving parameters. In some regions of parameter space, infinitesimal initial seeds of finite momentum pairing grow exponentially during our driving protocol. By computing the momentum-resolved pairing response, we identify the instability bands associated with these finite-momentum modes, quantify their growth rates, and determine their dependence on driving frequency and drive amplitude. These results provide a comprehensive numerical characterization of the dynamical phases and instabilities that arise in periodically driven superconductors before the final steady state is reached.

DY 42.10 Wed 15:00 P5

Higher order Magnus expansion for two-level quantum dynamics — •Chen Wei and Frank Grossmann — Institut für Theoretische Physik, 01062 Dresden, Germany

This study investigates the Magnus expansion[1] for a generic time-dependent two-level system. By using its convergence condition[2], we find that elementary unitary transformations significantly extend the validity of the Magnus expansion. Furthermore, higher order terms admit particular physical interpretations. By virtue of su(2) Lie algebra, the expansion is decomposed into a commutator-free form. To illustrate its usefulness, we study the Landau-Zener[3] model, which displays a special case of non-adiabatic transitions. Using agian the Magnus expansion, Hermitian and non-Hermitian versions of the semiclassical Rabi model are systematically treated by determining the Floquet quasienergy[4] and Bloch-Siegert shift[5]. As a noteworthy by-product, the Magnus expansion provides a quantitative characterization of the adiabatic theorem[6].

Distribution of complex amplitudes of chaotic resonance states — •Jan Möseritz-Schmidt and Roland Ketzmerick — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

Resonance states of chaotic scattering systems have complex amplitudes in the position representation. Naively, one would expect that the phase of the complex amplitude is uniformly distributed, however, we observe significant deviations. We find that part of this is a finite-size effect which is already present in the random wave model. It is enhanced by the multifractal structure of chaotic resonance states, which follows from the factorization conjecture. We quantify these deviations using the phase rigidity and analyze its scaling behavior in the semiclassical limit. Numerically, this is demonstrated for the paradigmatic three-disk scattering system.

DY 42.12 Wed 15:00 P5

Complex dynamics and particle-wave correspondence in anisotropic mesoscopic cavities — •Silvan Stopp, Samuel Schlötzer, Lukas Seemann, and Martina Hentschel — Technische Universität Chemnitz, 09107 Chemnitz, Germany

Mesoscopic billiard systems with different geometries are well-known model systems for investigating complex dynamics and quantum chaos. While the breaking of spatial cavity symmetries is typically considered to be the origin of chaotic dynamics, we show that anisotropies, i.e., broken symmetries in momentum space, can also cause chaotic particle dynamics. To this end, we investigate bilayer graphene systems (BLG) [1] and birefringent optical microcavities [2], both of which have preferred propagation directions. Anisotropy prevent angular momentum to be a conserved quantity, and consequently, the angles of incidence and of reflection of a particle trajectory deviate. Therefore, we implementing an advanced ray tracing algorithm that we apply to BLG and birefringent cavities. We show that the presence of anisotropies induces chaotic dynamics even in circular cavities. We investigate the interplay of the cavity shape and the Fermi line geometry and illustrate how it affects the cavity dynamics. In particular, we find that certain trajectories can be stabilized by matching the symmetry in real and momentum space. In addition, we use Kwant and transformation optics to demonstrate ray/particle-wave correspondence in real space as well as in phase space using the Husimi function.

Periodic orbit theory approach for a non-Hermitian Riemann operator — •Sebastian Hörhold, Andreas Hötzinger, Juan Diego Urbina, and Klaus Richter — Institut für Theoretische Physik, Universität Regensburg, Germany

The Riemann Hypothesis (RH) is one of the most important open problems in mathematics. Among the various approaches toward its proof is the Hilbert-Pólya (HP) conjecture, stating that there should exist a Hermitian operator whose eigenvalues t_n are given by the zeros of the Riemann zeta function $\zeta(1/2 + it_n)$. The RH would then follow from the reality of these eigenvalues.

In a recent contribution toward a proof of the RH, a non-Hermitian Hamiltonian has been introduced, referred to as a Riemann operator, whose spectrum contains the t_n, and from which one can construct an HP operator [1]. Our work focuses on a similar Hamiltonian, and we intend to make use of semiclassical tools to support earlier work by Berry and Keating, who obtained a formal asymptotic expression for the counting function of the nontrivial Riemann zeros [2]. Their results suggest a strong connection between the spectral statistics of these zeros and classically chaotic systems.

In this poster contribution, we show the emergence of the Riemann zeros within the spectrum of our non-Hermitian Hamiltonian and discuss how periodic orbit theory can be applied.

Echo state network prediction of billiard dynamics — •Anna Skopnik, Lukas Seemann, and Martina Hentschel — Institut für Physik, TU Chemnitz, Germany

Machine Learning has attracted a lot of interest recently. Here, we apply an Echo State Network (ESN) algorithm to two mesoscopic billiard systems in order to explore its usability in the prediction of the internal dynamics of ballistic cavities. First, we study the well-known Limaçon system with chaotic dynamics. Second, we study the more complex dynamics in an anisotropis system inspired by bilayer graphene (BLG) representing a mixed space dynamics with regular and chaotic trajectories. Here, we present preliminary results on the training and hyperparameter optimization for both systems, Limaçon and BLG.

DY 42.15 Wed 15:00 P5

Anomalous Dynamics in Complex Quantum Systems — •Irina Petreska[1], Pece Trajanovski[1,2], Ervin Kaminski Lenzi[3], and Trifce Sandev[1,2,4] — [1]Ss. Cyril and Methodius University in Skopje, Macedonia — [2]Macedonian Academy of Sciences and Arts, Skopje, Macedonia — [3]Universidade Estadual de Maringá, Maringá, Brazil — [4]Korea University, Seoul, Korea

We will give an overview of our recent works related to some generalizations of the Schrödinger equation. Special attention will be paid to the fractional Schrödinger equation, pointing out physical examples where the time-fractional Schrödinger equation naturally emerges under certain geometric constraints. Additionally, we include a long-range interaction term, modeled by an integral operator, which captures spatial nonlocalities. Using the Green's function approach, we derive analytical solutions and explore their implications in the time-space domain. Our findings reveal anomalous behavior arising from the interplay of fractional dynamics, nonlocal potentials and memory effects.

DY 43.1 Wed 15:00 P5

Extended classical nucleation theory for active phase separation in the reversed Ostwald regime — •Wanja Becker[1], Cesare Nardini[2,3], and Michael te Vrugt[1] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany — [2]Service de Physique de l'Etat Condensé, CEA, CNRS Université Paris-Saclay, CEA-Saclay, 91191 Gif-sur-Yvette, France — [3]Sorbonne Université, CNRS, Laboratoire de Physique Théorique de la Matière Condensée, 75005 Paris, France

Classical nucleation theory (CNT) is a model to describe how rare fluctuations lead to nucleation and thus describes the kinetics of phase transitions. In Ref. [1], CNT was extended to describe phase separation in Active Model B+ - a scalar field theory for active matter - for the case of positive active surface tension. Here, we further extend the theory to be applicable for negative active surface tensions. In this regime a stable fixed-point radius is expected to be found. Droplets smaller than this radius grow and droplets larger than this radius shrink, i.e. reverse Ostwald ripening. In Ref. [1], the theory was formulated by expanding the

order parameter in powers of 1/R, up to order 1/R. Here, terms of order 1/R^2 are included to describe nucleation for negative surface tension. In doing this the effective potential acquires an additional linear contribution. We calculate the prefactor of the linear contribution numerically to determine whether it suffices to capture the nucleation of droplets at negative surface tension that afterwards grow by reversed Ostwald processes.

Classical fractionally charged quasiparticles in kagome lattices and at interfaces — •Jannis Waldmann, Malte Grunert, and Erich Runge — Theoretical Physics I, Institute of Physics, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Interacting systems of charged particles can show fractionally charged excitations, as is well known from the Fractional Quantum Hall Effect of electrons in a magnetic field. Fractionally charged excitations have also been predicted in the absence of magnetic fields for certain lattices with geometric frustrations, e.g., for quantum mechanical models of spinless fermions on the criss-crossed checkerboard lattice [1,2]. Here, we present results on the transport properties of classical particles with nearest-neighbor repulsion on a kagome lattice including Andreev-like reflection at interfaces between frustrated and 'normal', i.e., non-frustrated matter. This involves a coupling between kagome lattice and an infinite particle reservoir via transport channels. Through kinetic Monte Carlo simulations, we study the transition from classical hopping at high temperatures and electric fields to transport dominated by half-charged quasiparticles at low temperatures and special filling factors.

DY 43.3 Wed 15:00 P5

Non-markovian master equation for Thioacetylacetone Coupled to bosonic bath — •Zahra Sartipi[2], Richard Gundermann[1], Janet Anders[2,3], and Peter Saalfrank[1] — [1]University of Potsdam, Institute of Chemistry, Theoretical Chemistry, Karl-Liebknecht-Str. 24-25, D-14476 Potsdam, Germany — [2]University of Potsdam, Institute of Physics and Astronomy, Karl-Liebknecht-Str. 24-25, 14476 Potsdam, Germany — [3]Physics and Astronomy, University of Exeter, Exeter EX4 4QL, United Kingdom

The Canonically Consistent Quantum Master Equation (CCQME) is used to address intramolec-ular proton transfer in thioacetylacetone , with an N -level quantum system coupled to an organic solvent. In this setup, the solvent is modeled as a harmonic bath (a continuum of oscillators) characterized by a Drude-cutoff Ohmic spectral density.

The results highlight that while the Redfield and CCQME (canonical consistent quantum master equation) approaches agree in the weak-coupling regime, they diverge at stronger couplings. Redfield incorrectly drives the system toward the canonical Gibbs state of the bare system Hamiltonian, neglecting the influence of correlations, and may thus yield thermodynamically inconsistent predictions. By contrast, CCQME incorporates the bath's effect on the system's energy landscape, ensuring relaxation toward the correct mean-force Gibbs state. This guarantees both positivity and consistency with statistical mechanics, even at stronger coupling.

DY 43.4 Wed 15:00 P5

An O(logN) Kinetic Monte Carlo Algorithm for Transport Simulation with Long-Range Interactions — •Bat-Amgalan Bat-Erdene, Roya Ebrahimi Viand, Karsten Reuter, and Sebastian Matera — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin

When transport is controlled by activated events, kinetic Monte Carlo (kMC) simulation is the method of choice. However, a characteristic of charge transport is the presence of long-range Coulomb interactions, leading to a complexity of $O(N)$ in the system size N for the updates of the transition rates. In contrast, kMC with only short-range interactions can be made to scale as $O(\log N)$ per step, and thus Coulomb interactions cause a significant computational overhead. We address this issue by a novel time discretization approach. Starting with exact values for the rates, the approach conducts fast incremental updates ($O(\log N)$) in every step based on a truncated short-range potential. Inevitably, this leads to a deviation of the rates from their true values as simulation proceeds. Therefore, a full $O(N \log N)$ recalculation is conducted once every $O(N)$ steps, resulting in an average cost of $O(\log N)$ per step. We demonstrate the scheme for charge transport on a cubic lattice using our in-house kMC framework. Special emphasis is placed on the balance between discretization error and efficiency, as well as the influence of the truncation radius on both.

DY 43.5 Wed 15:00 P5

Quantifying stochastic resonance in bistable systems: a new measure based on passive observation — •Christian Muñoz[1], Bart Vos[1], Till Münker[1], Dorian Marx[1], Matthias Krüger[2], and Timo Betz[1] — [1]Third Institute of Physics - Biophysics, Georg August University Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — [2]Institut für Theoretische Physik, Georg August University Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Stochastic resonance (SR) is a noise-assisted phenomenon of broad relevance whose complexity motivates its study in simple and controllable systems. In this work, SR is investigated using a single Brownian particle confined in a bistable potential created with optical tweezers. In such a system, SR emerges from the interplay between thermal fluctuations and the periodic modulation of the potential landscape. First, several well-established approaches from literature are revised to determine under which conditions SR is enhanced. In particular, the strength of the first peak of the residence time distribution displays a clear maximum. Additionally, we propose a new protocol to quantify SR based on the novel quantity of the mean back relaxation (MBR). The new quantifier, which measures the amplitude of the oscillations that MBR displays, shows quantitative agreement with the average work done by the system. Our findings may provide a new approach for analyzing the stochastic energetics of a system by mere passive observation.

DY 43.6 Wed 15:00 P5

Random Organization in a Many-Body Reaction System — •Mishael Derla and Michael Schmiedeberg — Soft Matter Theory Group, Theoretical Physics: Lab for Emergent Phenomena, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen

Random organization refers to certain simplified simulation protocols of the reversibility-irreversibility transition in sheared colloid suspensions. It displays an absorbing state transition believed to be in the conserved directed percolation universality class. We present a related analytical time-continuous many-body reaction-diffusion model. It features two species of spherical grains (of diameter σ): diffusing active grains A (with diffusion constant D), and motionless inactive grains I. A spontaneously decay $A \to I$ with rate μ and overlapping grains react with $A + I \to 2A$ and $I + I \to 2A$, respectively at rate λ. When $\lambda \gg \mu \gg D\sigma^{-2}$ overlapping grains are almost certainly active and non-overlapping ones almost certainly inactive and hence a time-continuous (or small step-size) version of random-organization is recovered.

DY 43.7 Wed 15:00 P5

Stochastic Simulation Algorithm for Spatiotemporal Chemical Master Equations — •Fatemeh Tavakkoli, Roya Ebrahimi Viand, Bat-Amalgam Bat-Erdene, Karsten Reuter, and Sebastian Matera — Fritz-Haber-Institut der MPG, Berlin

Spatiotemporal chemical master equations (SCME) have a number of applications ranging from biochemistry to sociodynamics, and have gained interest in mathematical physics. Describing high-dimensional Markov jump processes, SCMEs are typically not solvable, neither analytically nor numerically, but need to be addressed by stochastic simulation using kinetic Monte Carlo methods. We present a software framework for this purpose based on the Berlin Extended Stochastic Simulation Software (BeESSS). A simple to use Python frontend allows to define an SCME model and the software generates efficient backend C++ code (controllable by the Python frontend). The sparse nature of BeESSS allows to exploit the local nature of SCMEs where space is decomposed into compartments and only neighboring compartments interact. We demonstrate the tool on Lottka-Volterra-type predator-prey models and use it to evaluate the time complexity and memory limitations of our simulation approach.

DY 43.8 Wed 15:00 P5

Bottom-Up DPD Thermostat Parameterization for Coarse-Grained Molecular Liquids — •Karan Venkatesh and Nico F. A. van der Vegt — Technische Universität Darmstadt

Coarse-grained (CG) models substantially accelerate molecular dynamics simulations but often yield dynamical properties that diverge from those of fine-grained (FG) systems. We introduce a dynamic coarse-graining framework that bottom-up parameterizes a Markovian Dissipative Particle Dynamics (DPD) thermostat in conjunction with a CG model of liquid cyclohexane, enabling more consistent reproduction of FG dynamical behavior. We determine the Markovian friction for the DPD thermostat by extracting its distance dependence from the fluctuations of pair forces measured in the FG simulations. The resulting distance-dependent friction is subsequently scaled by an amplitude optimized through an iterative procedure to match the long-time diffusion coefficient[1]. Compared to standard DPD[2], our bottom-up parameterized model significantly improves the reproduction of velocity autocorrelation functions (VACFs) on all time scales. It also yields a closer match to the frequency-dependent viscosity. Overall, this method offers a physically grounded, systematic route to parameterizing DPD thermostats for molecular liquids, preserving the efficiency of single-site coarse-graining while delivering improved dynamics across all time scales.

DY 43.9 Wed 15:00 P5

Reduction of interaction order in hard combinatorial optimization through conditionally independent degrees of freedom — •Alexandru Ciobanu[1], David Dahmen[1], John Paul Strachan[2], and Moritz Helias[1] — [1]Forschungszentrum Jülich, Jülich, Germany — [2]Peter Grünberg Institut (PGI-14), Aachen, Germany

Combinatorial optimization problems have a broad range of applications and map to physical systems with complex dynamics. Among them, the 3-SAT problem is prominent due to its NP-complete nature. In physics terms, its solution corresponds to finding the ground state of a disordered Ising spin Hamiltonian with third-order, or tensor, interactions. The large growth of the number of third-order interactions with number of variables poses technical difficulties for the physical implementation of minimizers. In this work, we employ the renormalization group to create a pairwise interacting system from the original third-order system while preserving the free energy. Our procedure utilizes additional degrees of freedom that now exhibit conditional independence. A step-wise trace of the extra variables while running the minimization is therefore computable, yielding a state-dependent effective interaction. We use the effective interaction to reconstruct the original third-order energy spectrum.

DY 43.10 Wed 15:00 P5

From Gradients to Flux: Towards A General Strategy for Non-Equilibrium Molecular Dynamics Simulations — •Daniel Padilla-González, Diego Veloza-Diaz, Mauricio Sevilla, Kurt Kremer, and Robinson Cortes-Huerto — Max Planck Institute for Polymer Research, Mainz, Germany

The numerical simulation of molecular systems under external gradients is crucial for understanding processes in which local solvation and diffusion play a central role, common to applications in nanofluidics and biological transport. Few computational methods can handle the stationary non-equilibrium, open-boundary conditions present in reality while consistently sampling the grand canonical (GC) ensemble in equilibrium. The Hamiltonian Adaptive resolution simulation (AdResS) provides a framework for this purpose by coupling a fully atomistic region to a coarse-grained reservoir that acts as a thermodynamic bath. AdResS can be combined with particle insertion (PI) steps [1] to reproduce GC conditions and to impose controlled gradients by connecting the atomistic region to multiple reservoirs at different state points [2]. This strategy enables the study of non-equilibrium situations in which particle fluxes appear across the system. In this project, by considering simple liquids and mixtures, we aim to evaluate the applicability of the AdResS+PI methodology to the study of stationary flows generated by temperature, density, and concentration gradients.

DY 43.11 Wed 15:00 P5

Coexistence in chemically driven mixtures — •Ellen Meyberg[1], Joshua Robinson[2,3], and Thomas Speck[1] — [1]Institute for Theoretical Physics IV, University of Stuttgart, Stuttgart, Germany — [2]STFC Hartree Centre, Sci-Tech Daresbury, Warrington, United Kingdom — [3]H. H. Wills Physics Laboratory, University of Bristol, United Kingdom

Underlying virtually any biological function is the organization of proteins and other molecules in time and space. A current challenge in statistical physics is to uncover universal principles governing the self-organization of macromolecules in crowded environments and driven away from equilibrium. Usually, Ostwald ripening leads to the macroscopic phase separation. In contrast, aggregates of proteins in living cells typically show "size control" and are stable over an extended time without coarsening, which can be rationalized in terms of reverse Ostwald ripening. We study a thermodynamically consistent, chemically driven two component reaction-diffusion system in which particles of one species attract each other. Combining insights from stochastic thermodynamics and active field theories, we aim to understand how phase coexistence is modified by the chemical activity.

DY 43.12 Wed 15:00 P5

Coarsening in the $1D$ XY model with long-range interactions — •Dustin Warkotsch, Fabio Müller, and Wolfhard Janke — Institut für Theoretische Physik, Universität Leipzig, 04103 Leipzig, Germany

We investigate the phase-ordering kinetics of the $1D$ XY model with long-range interactions using a simplified version of the recently established fast, hierarchical Metropolis algorithm. Owing to the sparse predictions concerning the nonequilibrium dynamics of this model in one dimension, we seek to close this gap via Monte Carlo simulations with our highly efficient method. Regarding the scaling behavior of correlation function $C(r,t)$, the structure factor $S(k,t)$ and the characteristic length scale $\ell(t)$, we find consistent behavior for all studied growth exponents $\sigma \leq 1$.

DY 43.13 Wed 15:00 P5

Strong coupling phases of conserved growth models are crumpled — •Debayan Jana and Abhik Basu — Saha Institute of Nuclear Physics (SINP), Kolkata, India

We show that stochastically driven nonequilibrium conserved growth models admit generic strong coupling phases for sufficiently strong nonlocal chemical potentials underlying the dynamics. The models exhibit generic roughening transitions between perturbatively accessible weak coupling phases satisfying an exact relation between the scaling exponents in all dimensions d, and strong coupling phases. In dimensions below the critical dimension d_c, the latter phases are unstable and argued to be crumpled, and thus distinct from the well-known strong coupling rough phase of the Kardar-Parisi-Zhang equation in dimensions $d \geq 2$. At d_c, conventional spatio-temporal scaling in the weak coupling phase is logarithmically modulated and are exactly obtained.

DY 43.14 Wed 15:00 P5

Universality of shocks in conserved driven single-file motion with bottlenecks — •Sourav Pal and Abhik Basu — Theory Division, Saha Institute of Nuclear Physics, a CI of Homi Bhabha National Institute, Kolkata, India

Driven single-file motion, in which particles move unidirectionally along one-dimensional channels, sets the paradigm for wide variety of one-dimensional directed movements, ranging from intracellular transport and urban traffic to ant trails and controlled robot swarms. Motivated by the phenomenology of these systems in closed geometries, regulated by number conservation and bottlenecks, we explore the domain walls (DWs) or shocks in a conceptual one-dimensional cellular automaton with a fixed particle number and a bottleneck. For high entry and exit rates of the cellular automaton, and with sufficiently large particle numbers, the DWs formed are independent of the associated rate parameters, revealing *universality* in their *shapes*, which are however enclosed by nonuniversal boundary layers. In contrast, the DWs do depend upon these parameters, if they are small, and hence have nonuniversal shapes, but without boundary layers. Nonuniversal delocalized DWs can be formed by additional tuning of the control parameters. Experimental verification of our theoretical predictions can be performed via high-resolution ribosome profiling on mRNA loops with slow codons, or video imaging of vehicular flow, ant trails, and robotic swarms on confined tracks.

DY 43.15 Wed 15:00 P5

Dynamics of dense phase separation — •Bibhut Sahoo[1] and Peter Sollich[1,2] — [1]Institut für Theoretische Physik, Georg-August-Universität Göttingen, 37077 Göttingen — [2]Department of Mathematics, King's College London, London

Phase separation in mixtures is a ubiquitous phenomenon in nature. In dense systems, it involves an intriguing interplay of phase separation dynamics with slowing down due to crowding effects. We investigate such systems by encoding the approach to dynamic arrest in the kinetic coefficient at the level of a continuum description. We predict the phase behaviour of such kinetically constrained multicomponent mixtures, including density and composition of both mobile and arrested phases, using a suitable constrained free energy minimization. We probe the coarsening dynamics numerically and find, for the baseline one-component case, a crossover between two distinct domain growth power laws. For binary mixtures with three equilibrium phases (one gas and two demixed liquids), we see a Warren-like scenario where collective diffusion first leads to gas-liquid phase separation without fractionation, before the mixture components eventually start to demix. Surprisingly, this demixing dynamics is interface-induced, i.e. it begins at the interfaces of the initial gas-liquid domains. We rationalize this by controlled numerical experiments starting from constrained (without demixing) gas-liquid equilibria and by theoretical analysis of the local spinodal growth rates.

DY 43.16 Wed 15:00 P5

Linear coupling reduces entropy production in nonequilibrium multicomponent systems — •Vansh Kharbanda[1,2], Anton Burnet[1,2], and Benedikt Sabass[1,2] — [1]Faculty of Physics and Center for NanoScience, Ludwig-Maximilians-Universität München, 80752 Munich, Germany — [2]Fakultät Physik, Technische Universität Dortmund, 44227 Dortmund, Germany

Many biological and synthetic systems operate far from equilibrium and pay an energetic cost quantified by the steady-state entropy production rate (EPR). We investigate how linear coupling between subsystems modifies this dissipation in a class of Hurwitz-stable Langevin dynamics. For networks of diffusively coupled Ornstein-Uhlenbeck processes, we derive closed-form expressions for the EPR of n-coupled two-dimensional units and show that any attractive symmetric coupling reduces the EPR, which monotonically approaches the single-unit value in the strong-coupling limit. This behaviour is traced to a suppression of probability currents, driving the collective closer to detailed balance. We then generalize to higher dimensions and arbitrary symmetric coupling topologies and conjecture a structural criterion: commuting coupling and diffusion matrices together with negative semidefinite coupling are sufficient for a monotonic EPR decrease. Violating this criterion generates mismatch-induced irreversible currents, which can increase EPR. Finally, we illustrate this mechanism in nonlinear biological models of bacterial chemotaxis and inner-ear hair bundles, where coupling substantially lowers dissipation without hindering performance metrics.

DY 43.17 Wed 15:00 P5

Energetics of coupled stochastic circular limit-cycle oscillators — •Anton Francis Burnet[1,2], Vansh Kharbanda[1,2], David Tobias[1], and Benedikt Sabass[3,1,2] — [1]Faculty of Physics and Center for NanoScience, Ludwig-Maximilians-Universität München, 80752 Munich, Germany — [2]Department of Veterinary Sciences, Ludwig-Maximilians-Universität München, 80752 Munich, Germany — [3]Fakultät Physik, Technische Universität Dortmund, 44227 Dortmund, Germany

Stochastic oscillations serve important functions in many biological systems, including hair-cell bundles of the inner ear and neuronal activity. Sustaining coherent cycles in noisy environments requires continuous energy dissipation, quantified by the steady-state entropy production rate (EPR). We study an idealized, analytically tractable model of a stochastic circular limit cycle and examine how mutual diffusive coupling in pairs and populations alters dissipation. Three factors contribute to the EPR: intrinsic frequency asynchrony, tangential velocity fluctuations, and mean tangential velocity. The dynamics are characterized by an effective temperature, which depends on diffusion and intrinsic relaxation timescales. For radial (amplitude), phase (Kuramoto-like), and Cartesian couplings, we derive analytical expressions for the EPR and confirm them numerically. Varying the effective temperature and system size strongly influences how the EPR depends on coupling strength and, in some cases, results in qualitatively distinct behaviors. Moreover, the coupling types affect the tangential velocity distributions differently.

DY 43.18 Wed 15:00 P5

Localized Driving of the Jamming Transition in a Quasi-2D Colloidal Platform — •Jordan D. Groh, Timo Betz, and Bart Vos — Drittes Physikalisches Institut, Göttingen, Deutschland

The jamming transition marks the abrupt emergence of rigidity when a dense assembly of particles is compressed beyond a critical packing fraction. Decades of experiments and simulations have identified its static signatures, a sharp rise of the shear modulus and contact-network percolation, for globally driven systems. What remains largely unexplored is how a jammed material reacts to localized perturbations and whether they can steer the system into new metastable states.

We therefore construct a reproducible quasi-2D colloidal chamber that confines a binary mixture of polyacrylamide hydrogel beads (elastic stress sensors) and polystyrene beads (optically addressable active centres). A small fraction of temperature-responsive pNIPAm beads allows us to tune the effective packing fraction; cooling below the LCST swells them, thereby raising the global packing fraction with high precision. High-speed confocal microscopy provides particle trajectories, from which we locate the jamming point and perform contact-network analysis.

The platform enables calibrated optical forces on single beads and local heating-induced volume changes, yielding full spatiotemporal maps of displacement and stress fields. This testbed will allow us to map a local-driving jamming phase diagram, study force-propagation lengths, and ultimately design amorphous metamaterials with programmable mechanical heterogeneity.

Critical behaviour of ferroelectrics with divergence-free polarization — •Svitlana Kondovych[1], Asle Sudbø[2], and Flavio S. Nogueira[1] — [1]Institute for Theoretical Solid State Physics, Leibniz Institute for Solid State and Materials Research Dresden, Helmholzstr. 20, D-01069 Dresden, Germany — [2]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway

Unconventional phase transitions often display unusually large anomalous dimensions, often attributed to fractionalization and emergent gauge fields [1]. Here we show that similar behaviour can arise without fractionalization when the order parameter is constrained to be divergence-free, as occurs in ferroelectrics where the polarization $\vec{P}$ remains locally charge-neutral, div$\vec{P}$=0 [2]. This constraint forces polarization into loop-like textures and reshapes the critical behaviour.

Our analysis reveals a new universality class in which internal symmetry becomes intrinsically linked to spatial dimensionality [3]. The resulting critical point exhibits strongly enhanced fluctuations and a remarkably large anomalous dimension. These findings show that conventional ferroic materials can exhibit non-Landau criticality driven by local conservation laws. This reveals a new conceptual pathway for unconventional critical phenomena and suggests nanoscale ferroelectrics as experimentally accessible platform for exploring these ideas.

Nonequilibrium phase transition in single-file transport at high crowding — •Annika Vonhusen[1], Sören Schweers[1], Artem Ryabov[2], and Philipp Maass[1] — [1]Universität Osnabrück, Institut für Physik, Germany — [2]Charles University, Faculty of Mathematics and Physics, Czech Republic

In driven single-file Brownian motion across periodic energy landscapes, fast particle transport can occur for potential barriers orders of magnitude larger than the thermal energy. The fast transport is mediated by solitary cluster waves forming at high crowding of interacting particles [1]. Cluster waves were first predicted theoretically for hard spheres [2] and shortly after confirmed in experiments [3]. Here we show that persistent cluster wave propagation sets in at a critical density and gives rise to a nonequilibrium phase transition that manifests itself in a singular point of the current-density relation [4]. The critical density varies in a complex manner with the particle size and temperature, which can be understood from a simple geometric principle.

Sampling of ground states for the bimodal random-field Ising model — •Jana Lukin, Tony Albers, and Martin Weigel — Institut für Physik, TU Chemnitz, 09107 Chemnitz, Germany

The Gaussian random-field Ising model (RFIM) is well understood, largely because its ground state is non-degenerate and can therefore be computed efficiently using polynomial-time optimization methods. In contrast, the bimodal RFIM exhibits degenerate ground states, which has hindered precise numerical investigations of its critical behavior. Here, we introduce a perturbation to lift this degeneracy. This approach enables the application of a max-flow algorithm to obtain exact ground states and thereby allows a more accurate characterization of the phase transition in the bimodal RFIM.

DY 43.22 Wed 15:00 P5

Critical behaviour of non-reciprocal Ising models — •Max Haessler and Martin Weigel — TU Chemnitz Institut für Physik, Chemnitz, Germany

Equilibrium statistical physics is based on symmetric, Hamiltonian interactions fulfilling Newton*s Third Law. On the other hand, active matter like bacteria or bird flocks, predator-prey relations in nature and social systems violate time-reversal symmetry due to non-reciprocal interactions, hence they are non-equilibrium systems.

We try to investigate the fundamental mechanisms that govern such systems by investigating non-reciprocal modifications of the Ising model.

We especially focus on investigating the impact of the non-reciprocal interactions on the critical behaviour of those models.

DY 43.23 Wed 15:00 P5

Analysis of phase transitions in the random-field Blume-Capel model via exact ground state calculations — •Tony Albers, David Müller-Bender, and Martin Weigel — Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany

The random-field Blume-Capel model is a generalization of the well-known Ising model, where spin variables can take three values (-1,0,1) corresponding to three orientations of the spins with respect to an external field. We perform exact ground-state calculations of this 3-label problem using a suitable transformation to a 2-label problem [1] and an advanced graph-cut method called generic cuts [2]. The obtained ground states can be used to study phase transitions in dependence on the zero-field splitting parameter and the strength of the random field resulting in a phase diagram which is compared to the one obtained by a mean-field approximation [3]. Preliminary results suggest the presence of first- and second-order phase transitions. With the help of a finite-size scaling analysis, we obtain a set of critical exponents for the latter and compare them with the exponents of related universality classes.

Shear-driven diffusion process and its generalizations — •Trifce Sandev — Macedonian Academy of Sciences and Arts, Skopje, Macedonia — Ss. Cyril and Methodius University in Skopje, Macedonia — Korea University, Seoul, Korea

We consider different generalizations of the shear-driven diffusion process, which represents a two-dimensional Brownian motion in presence of a linear shear flow. One possible generalization is the shear-driven anomalous diffusion motion which occurs due to the long-tailed waiting time of the particle, effect described by a two-dimensional Fokker-Planck equation with memory kernel. Another possible generalization is the shear-driven finite-velocity diffusion, that is a shear-driven motion, but now, at random times, the walker changes its direc-

tion to the opposite one. The corresponding process can be described by a two-dimensional telegrapher's-like equation. We also explore the corresponding processes under stochastic resetting and find that the systems reach non-equilibrium stationary states in the long time limit that also result in saturation of the evolution of the corresponding mean squared displacement, variance, skewness and kurtosis.

DY 44.1 Wed 15:00 P5

Directed autonomous motion of active Janus particles induced by wall-particle alignment interactions — •Poulami Bag — Presidency University Kolkata

We propose a highly efficient mechanism to rectify the motion of active particles by exploiting particle-wall alignment interactions. Through numerical simulations of active particles' dynamics in a narrow channel, we demonstrate that a slight difference in alignment strength between the top and bottom walls or a small gravitational drag suffices to break upside-down symmetry, leading to rectifying the motion of chiral active particles with over 60% efficiency. In contrast, for achiral swimmers to achieve rectified motion using this protocol, an unbiased fluid flow is necessary that can induce orbiting motion in the particle's dynamics. Thus, an achiral particle subject to Couette flow exhibits spontaneous directed motion due to an upside-down asymmetry in particle-wall alignment interaction. The rectification effects caused by alignment we report are robust against variations in self-propulsion properties, particle's chirality, and the most stable orientation of self-propulsion velocities relative to the walls. Our findings offer insights into controlled active matter transport and could be useful to sort artificial as well as natural microswimmers (such as bacteria and sperm cells) based on their chirality and self-propulsion velocities.

DY 44.2 Wed 15:00 P5

Emergent Interaction in Attractively Coupled Active Particles — •Ritwick Sarkar and Urna Basu — S. N. Bose National Centre for Basic Sciences, India.

We investigate the dynamics of N pair-wise harmonically coupled active Brownian particles (ABPs) in the presence of thermal fluctuations. The harmonic coupling and the bounded nature of the active noise ensure that the relative distance between each pair of particles eventually reaches a stationary state. Depending on the interplay between the active time-scale and the relaxation time-scale associated with the harmonic coupling, three regimes emerge: strong, moderate, and weak coupling. We analytically show that in the strong coupling regime, an effective short-range repulsion emerges between ABP pairs with speed heterogeneity, both in the presence and absence of thermal fluctuations. The short-range repulsion also persists when the ABP pairs are coupled by a generic long-range attractive potential.

AMEP: Analyzing Active and Soft Matter Simulations — •Kay-Robert Dormann[1], Lukas Hecht[1], Kai Luca Spanheimer[2], Aritra K. Mukhopadhyay[1], Mahdieh Ebrahimi[1], Suvendu Mandal[1], and Benno Liebchen[1] — [1]Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Darmstadt, Germany — [2]Institut für Theoretische Physik II, Heinrich-Heine-Universität, Düsseldorf, Germany

AMEP [1] is a Python library that focuses on the fast and user-friendly analysis of active and soft matter simulations. It can natively analyze data from molecular dynamics, Brownian dynamics, and continuum simulations from software such as LAMMPS, HOOMD-blue, and GROMACS. With a plethora of methods for calculating observables and visualizing results, AMEP is suitable for calculating complex observables equally for advanced studies of active and soft matter, as well as for beginners in the field. Computationally expensive methods are parallelized to run on any system from laptops and workstations to high-performance computing clusters.

The methods range from correlation functions and order parameters to cluster detection and coarse-graining methods. Due to the Python-based implementation, the methods can be easily extended and individualized. Information and examples are available at https://amepproject.de. AMEP can be installed via pip and conda.

DY 44.4 Wed 15:00 P5

Environmental Control of Self-Aligning Chiral Bristlebots — •Timo Wagner, Thomas Ihle, and Horst-Holger Boltz — University Greifswald, Institute for Physics, Greifswald

The subject of our work is the interplay of two very topical aspects of active matter systems, self-alignment and chirality, with complex environments. Chirality refers to a handedness of the dynamics manifesting itself in circular trajectories and self-alignment is a specific realization of physical memory in which the direction of the actual velocity and that of the self-propulsion are not identical, but are coupled. We present experimental results of an implementation of self-aligning chiral dynamics by custom augmentation of commercial toy bristlebots (Hexbugs) and extend the accessible parameter range by inferring a numerical model capable of reproducing the observable data. In particular, we study the control of edge currents (cf. Caprini et al, arXiv:2509.05053) by chiral environments. Additionally, we show that this simple system is sufficient to observe mode-switching between collectively moving and arrested states in active solids (cf. Hernandez-Lopez et al, PRL 132, 238303 (2024)).

DY 44.5 Wed 15:00 P5

Stochastic Path Integral for the Active Brownian Particle in a Harmonic Potential — •Mike Brandt[1], Carsten Littek[2], and Falko Ziebert[1] — [1]Institut für Theoretische Physik Philosophenweg 19, D-69120 Heidelberg, Germany — [2]Institut für Theoretische Physik Philosophenweg 12, D-69120 Heidelberg, Germany

We present a path-integral approach for the motion of active particles in harmonic traps, developed in our recent preprint [arXiv:2509.26296]. We apply the Martin-Siggia-Rose formalism to the overdamped Langevin equations of an active Brownian particle (ABP). The associated action can be separated into an exactly solvable passive reference motion and an "activity operator" to be treated perturbatively. This method allows for the calculation of the exact, time-dependent correlation functions for the ABP in a harmonic potential. Furthermore, the probability density can be perturbatively expanded in a series, which already captures important qualitative features of the system at low orders. This is exemplified by discussing the transition between a ring-shaped distribution for a weak potential and a peaked distribution for a strong potential in the long-time limit. Finally, we present full time-dependent expressions for the mean-square displacement of the Brownian circle swimmer (BCS), along with comparisons to simulations.

DY 44.6 Wed 15:00 P5

Continuum models for active matter: Derivation and overview — •Juliette Wegner and Sebastian Heidenreich — Physikalisch-Technische Bundesanstalt Braunschweig und Berlin, Abbestr. 2-12, 10587 Berlin, Germany

Turbulence and collective motion in active matter provide an interesting insight into non-equilibrium systems. Many different models have been suggested to describe the prevalent dynamics, mainly including polar and nematic systems. Each of these systems is developed under different assumptions considering different systems, but their similarities and differences are often not obvious.

In our poster we start from a simple micro-swimmer model to derive a general continuum model incorporating both nematic and polar order parameter equations, following the procedure from [1]. To this general continuum model, we then systematically introduced further restrictions and assumptions to derive more specific models which are in line with popular continuum models from literature. Specifically, we obtain models with nematic and polar symmetries similar to those studied by Saintillan and Shelley, as well as active Nematics, and active Polar suspension. Finally, we also consider theories that only incorporate the overall bacterial motion, such as the Toner Tu equation or the hydrodynamic approach of Slomka and Dunkel.

DY 44.7 Wed 15:00 P5

Active Brownian ellipsoids in three spatial dimensions — •Sebenzile Tsabedze and Michael te Vrugt — Institut für Physik, Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany

We investigate ellipsoidal active Brownian particles with alignment interactions in three spatial dimensions that are propelled orthogonal to their symmetry axis. Their propulsion direction makes the particles biaxial, implying that their dynamics is considerably more complex than in the usually considered case of particles being propelled along their symmetry axis. We use Brownian dynamics simulations and assume the particles to interact via a Gay-Berne potential (for the ellipsoidal repulsion) and a Heisenberg potential (for the interaction).

DY 44.8 Wed 15:00 P5

Dynamics of Aligning Active Matter: Mapping to a Schrödinger Equation and Exact Diagonalization — •Tara Steinhöfel, Horst-Holger Boltz, and Thomas Ihle — University Greifswald, Institute for Physics, Greifswald

We investigate models of Viscek-like particles with long-ranged interactions subject to noise and alignment interactions of polar and nematic symmetries. It is shown how the relevant N-particle Fokker–Planck equation can be mapped onto a Schrödinger equation in imaginary time for arbitrary particle numbers. Focusing on the minimal case of $N = 2$, we construct a complete eigenbasis by exact diagonalization of the corresponding self-adjoint Hamiltonian. In a treatment formally equivalent to standard quantum mechanics, this yields the fully time-resolved relaxation of the N-particle-probability density from arbitrarily correlated initial conditions into the stationary state. By marginalization, the one-particle angular modes which include the usual hydrodynamic modes are obtained; we discuss their relaxation backed by agent-based simulations and give comparisons for the resulting exact relaxation rates to mean-field and to predictions from approximate field theories (G. Spera, C. Duclut, M. Durand, J. Tailleur, PRL 132, 078301 (2024)). Furthermore, we discuss possible extensions of the method to $N \geq 3$ particles, as well as modifications due to non-reciprocal interactions.

DY 44.9 Wed 15:00 P5

Absence of chiral long-range order in the 2d non-reciprocal Vicsek model — •Chul-Ung Woo[1], Heiko Rieger[1], and Jae Dong Noh[2] — [1]Department of Theoretical Physics and Center for Biophysics, Saarland University, Saarbrücken, Germany — [2]Department of Physics, University of Seoul, Seoul, Korea

Nonreciprocal interactions in active matter have been predicted to generate homogeneous chiral phases, in which the polarization order parameter rotates at a constant frequency as a result of a nonreciprocal phase transition. Here we revisit the non-reciprocal Vicsek model in two space dimensions with short-range interactons and ask whether the putative chiral phase survives in the thermodynamic limit. Using large-scale simulations, we show that a spatially homogeneous chiral state, while long-lived in small systems, is generically unstable to the spontaneous nucleation of spiral defects that invade the system and drive it into spatio-temporal chaos. The global chiral order parameter, τ exhibits a robust finite-size scaling $\tau(J_-; L) = J_-\tau_r(LJ_-)$, where $J_{=}J_{AB} - J_{BA}$ is the anti-symmetric part of the interaction matrix, with the asymptotic behavior $\tau_r(x) \sim x^{-1}$ at large x, implying that global chirality vanishes in the thermodynamic limit. Controlled droplet-seeding experiments and a Boltzmann kinetic description support the droplet nucleation and growth scenario for the breakdown of chiral order. Our results demonstrate that paradigmatic non-reciprocal flocking models display chiral long-range order only in mean-field, whereas it is only metastable in two space dimensions and replaced there by spatio-temporal chaos.

DY 44.10 Wed 15:00 P5

Phase properties of constant density interacting flocks — •Astik Haldar and Heiko Rieger — Center for Biophysics & Department of Theoretical Physics, Universität des Saarlandes, Saarbruecken 66123, Germany

We present a field-theoretic study of a mixture of two polar Malthusian species in two dimensions with distinct aligning and propulsion strengths. The system exhibits rich phase behavior, including oriented flocking states (both parallel and anti-parallel) and a coherently rotating chiral phase. We map the parameter regions for these phases and characterize their universal properties.

DY 44.11 Wed 15:00 P5

Influence of shape on dynamic properties of magnetic active particles — •Ekaterina Novak[1], Elena Pyanzina[1], Tatyana Belyaeva[1], and Sofia Kantorovich[2] — [1]Ekaterinburg, Russia — [2]University of Vienna, Vienna, Austria

This study investigates the influence of shape on the dynamic properties of active magnetic particles. The focus is on ellipsoidal particles of two variations and spherical particles, aiming to understand the relationship between particle shape and motion characteristics. The research is motivated by the need to improve the control and efficiency of active particles, which have significant potential in medical and technological applications, such as precise drug delivery.

Active particles, inspired by natural systems like bacteria, can convert chemical energy into directed motion. However, challenges arise in maintaining precise control over their orientation and direction over time. By introducing a rigidly fixed permanent dipole moment and utilizing a strong external magnetic field, it is possible to minimize thermal fluctuations and achieve precise control.

The study also explores the anisotropic properties of ellipsoidal particles, which can have two possible orientations of the magnetic moment depending on the material. This behavior is analogous to magnetic cubes with integrated nanomotors. The findings from this research contribute to the development of optimal particle shapes for effective transportations, opening new possibilities in various fields.

The work was financially supported by the RSF grant No. 25-22-00327.

DY 44.12 Wed 15:00 P5

Order and shape dependence of mechanical relaxation in proliferating active matter — Jonas Isensee[1,2], •Finn Albrecht[1,2], Lukas Hupe[1,2], and Philip Bittihn[1,2] — [1]MPI for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

The collective behavior of dense, proliferating anisotropic active matter, such as elongated cells or bacteria, arises from an interplay between growth, division, and mechanical interactions, often mediated by particle shape. In classical models of prolate, rod-like growth, flow-induced alignment and division geometry reinforce one another, leading to robust nematic order under confinement. Here we introduce a complementary regime by considering smooth convex particles whose geometry can be oblate for part or all of their growth cycle, creating a tunable competition between these two alignment mechanisms. Using agent-based simulations of particles with tunable curvature profiles in both channel and open-domain geometries, we systematically vary particle shapes to span regimes of cooperation and competition between ordering cues. We find that oblate growth can reverse classical flow-alignment, destabilize microdomain formation in intermediate regimes, and, in combination with variations in curvature, lead to entirely new global order patterns. These findings are then reconciled using an order- and shape-dependent mechanical relaxation interpretation that is supported by explicit measurements.

DY 44.13 Wed 15:00 P5

The impact of particle shape for self-diffusiophoresis — •Leif Peters[1], Benjamin J. Walker[2], and Christina Kurzthaler[1,3,4] — [1]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Straße 38, 01187 Dresden, Germany — [2]Department of Mathematics, University College London, WC1H 0AY London, UK — [3]Center for Systems Biology Dresden, Pfotenhauerstraße 108, 01307 Dresden, Germany — [4]Cluster of Excellence, Physics of Life, TU Dresden, Arnoldstraße 18, 01062 Dresden, Germany

Self-diffusiophoretic micron-sized particles are paradigmatic examples of synthetic microswimmers where the swimming behavior depends not only on the patterning of the chemically active surface, i.e., the activity and phoretic mobility, but also on the particle shape itself. Accounting for the governing chemical and hydrodynamic equations we investigate how the particle shape influences the self-propulsion velocity and the agent's chemotactic behavior. To derive analytical expressions for anisotropic and curved particles we employ slender body theory and the Lorentz reciprocal theorem. Furthermore, we corroborate our results with a boundary element method. Our numerical framework allows going beyond the slender-particle limit and lays the foundation for addressing the physics of hydro-chemically interacting active agents and the emergent collective phenomena.

DY 44.14 Wed 15:00 P5

Dynamics of thermophoretic Janus particles in homogeneous light fields — •Samad Mahmoudi, Franziska Michaela Braun, and Regine von Klitzing — Institute of Condensed Matter Physics,TU Darmstadt, Hochschulstraße 8 64289 Darmstadt

We study the thermophoretic motion and orientational dynamics of individual Au-polystyrene Janus particles under uniform laser illumination. Light-driven Janus colloids serve as a model system for active Brownian motion and non-equilibrium transport in soft matter. The particles are illuminated by a defocused, approximately homogeneous laser spot and observed with dark-field microscopy. Image-processing routines in Python yield long-time trajectories, center-of-mass positions and in-plane orientations of the gold cap. From the mean-squared displacement we extract effective self-propulsion velocities and compare them with active Brownian particle models and simple expectations for thermophoretic motion. Our first measurements show that the tracking procedure resolves both translational and rotational motion of single Janus particles and yields thermophoretic velocities in the expected range for micrometer-sized swimmers. In future work, we will use this analysis to study how light gradients and cap design can create transient barriers for Janus particles and control their thermophoretic motion.

DY 44.15 Wed 15:00 P5

Static and dynamic states of compound drops on heated substrates — •Dominik Thy, Jan Diekmann, and Uwe Thiele — Institute of Theoretical Physics, University of Münster, Wilhelm-Klemm-Str. 9, 48149 Münster, Germany

We present a mesoscopic thin-film model for interface dominated compound drops including a vertical temperature gradient [1]. Starting with established findings for the passive case, i.e., (isothermal) gradient dynamics that show relaxation to equilibrated compound drops of different configurations [2], we then drive the system out of equilibrium. To this end, we introduce a vertical temperature gradient that renders the system active by introducing thermal Marangoni flows. We discuss different static and dynamic states.

Evaporation Induced Salt Precipitation in Porous Media: A Lattice Boltzmann Approach — •Alexander Reinauer[1], Louis Oberer[1], Alexander Schlaich[2], and Christian Holm[1] — [1]Institute for Computational Physics, Stuttgart, Germany — [2]Institute for Physics of Functional Materials, Hamburg University of Technology, Hamburg, Germany

We present a lattice Boltzmann model for simulating coupled evaporation and salt precipitation in porous media. The approach integrates Shan-Chen multiphase flow with a volume-based discretization of salt transport and incorporates a precipitation rule, which converts fluid cells into solid crystals once the local concentration exceeds a crystallization threshold.

The model is validated by reproducing analytical predictions for crystal growth. Besides, it features a tunable evaporation rate, enabling pore-scale studies of evaporation-induced salt precipitation. Investigations of the wettabilities of both the salt and the porous matrix reveal a pronounced impact on precipitation patterns. The simulations show distinct shifts in pore-clogging behavior depending on the relative wetting properties, with highly wetting crystals causing the strongest clogging and the slowest evaporation, arising from how wetting influences the spatial distribution of precipitation.

DY 44.17 Wed 15:00 P5

Power-Law to Maxwell Transition in Soft Glassy Materials under Large Amplitude Oscillations — •Raffaele Mendozza[1], Shanay Zafari[1], Sarah Köster[1], and Peter Sollich[1,2] — [1]Institute for Theoretical Physics, University of Göttingen, Göttingen, Germany — [2]Department of Mathematics, King's College London, London, United Kingdom

Soft glassy materials, such as colloidal suspensions and biological networks, exhibit complex rheological behaviour. We present a modified version of the Soft Glassy Rheology (SGR) model, introducing an upper cutoff on the yield rate that prevents unphysical yield rate increases at large strains. In the nonlinear response to step strains, the modified model exhibits a crossover from short-time exponential (Maxwell-like) relaxation to the power law relaxation obtained in the original model. This qualitatively reproduces results from strain-ramp experiments on actin networks. Under large amplitude oscillatory strain (LAOS) we similarly find Maxwell-like viscoelastic spectra at higher frequencies, crossing over to the original SGR power-law spectrum at low frequencies. We demonstrate that this can be rationalized qualitatively by Fourier transforming the nonlinear step strain results. The nonlinear spectra break the usual phase angle relations for power law (linear) response, however, which we explain using a quasistatic approximation. The stress response to LAOS at fixed frequency becomes more anharmonic for increasing strain amplitudes up to a critical value; beyond this point, harmonicity is eventually restored due to the crossover to Maxwell behavior.

DY 44.18 Wed 15:00 P5

Gelation versus bundling in parallel-aligned directed polymers — •Panayotis Benetatos and Minsu Yi — Department of Physics, Kyungpook National University, Daegu, South Korea

In many soft-matter and biological systems, bundles of similarly charged parallel-aligned filaments form when a short-range attraction overcomes the longer-range electrostatic repulsion. It is also known that permanent cross-links in parallel-aligned directed polymers can yield a directed gel with a finite in-plane shear modulus. Because permanent cross-links effectively act as a short-range attraction, we are motivated to investigate the interplay of gelation versus bundling in such a system. Using the theoretical tools of replica field theory, where the cross-links are treated as quenched disorder following the Deam-Edwards distribution, we show that the effective attraction due to spring-like permanent cross-links is too weak to induce bundling before the gelation transition.

DY 44.19 Wed 15:00 P5

Thermoresponsive liquid-liquid phase behaviour of biomolecular condensates in programmable thermal landscapes — •Ilona Kundi[1], Falko Schmidt[1], Rasmus Krogh Norrild[2], Alexander Kai Büll[2], and Frank Cichos[1] — [1]Peter Debye Institute for Soft Matter Physics, Leipzig University, 04103 Leipzig, Germany — [2]Department of Biotechnology and Biomedicine, DTU, 2800 Kgs. Lyngby, Denmark

Liquid-liquid phase separation (LLPS) of biomolecules drives the formation of membraneless organelles in cells. The LLPS behavior of the intrinsically disordered N-terminal region of the DEAD-box helicase DDX4 (DDX4N) is examined under precisely controlled and reconfigurable local temperature fields.

Locally tunable thermal landscapes are generated by scanning a focused laser beam over an absorbing metal thin film, creating microscale temperature profiles around DDX4N condensates. Here, the spatiotemporal evolution of condensate nucleation, growth, coarsening, and dissolution is tracked, linking local thermal forces to mesoscale LLPS dynamics.

By repeatedly cycling the temperature across the LLPS boundary, kinetic and thermodynamic parameters of the DDX4N phase transition are measured, revealing switching thresholds, hysteresis, and condensate material properties. Controlled microthermal perturbations thus provide a powerful means to probe and program protein LLPS, establishing a versatile platform for testing models of thermoresponsive intrinsically disordered proteins.

DY 44.20 Wed 15:00 P5

Rheology of Semi-Flexible Polymer Networks — •Sanjay Bhandarkar[1] and Peter Sollich[1,2] — [1]Institute for Theoretical Physics, University of Göttingen, Germany — [2]Department of Mathematics, King's College London, London

Semiflexible polymers, both in solution and organized into networks, continue to be a major focus in biological physics owing to their critical relevance to the structural and mechanical functions of living systems. The mechanics of the cytoskeleton emerges from the collective properties of semiflexible biopolymers such as actin filaments, microtubules, and intermediate filaments [1,2]. We investigate the rheology of semiflexible polymer networks using molecular dynamics simulations, performing Small-Amplitude Oscillatory Shear (SAOS) tests on permanently cross-linked systems to demonstrate how filament stiffness and monomer density control the frequency dependence of the complex shear modulus G*. In addition, we examine the connection between power-law rheology and the self-similar structural features observed in biopolymer networks and gels [3,4]. We further analyze how crosslinking dynamics and activity-induced stresses modify the network mechanics. Together, this rheological framework lays the groundwork for future models that incorporate more detailed structural and biochemical complexity.

Dynamic magnetic susceptibility of magnetic elastomers taking into account the internal magnetic anisotropy of particles — •Alla Dobroserdova[1] and Sofia Kantorovich[2] — [1]Ekaterinburg, Russia — [2]University of Vienna, Vienna, Austria

Magnetic elastomers are non-magnetic elastic matrices with embedded magnetic particles. These systems can be controlled using an external magnetic field, which provides the basis for their practical applications in both industry and medicine.

The aim of this study is to investigate the dynamic magnetic response of magnetic elastomers. Two previously developed elastomer models suitable for molecular dynamics simulations are used. This study reveals the dependence of the response on the intensity of interparticle interactions, the rigidity of the elastic non-magnetic matrix, and the internal magnetic anisotropy of the particles.

Support by RSF (project 25-22-00270) is acknowledged.

Computer simulation of the dynamic susceptibility of ellipsoidal multicore particles: the effect of inter-core interaction — •Vladimir Zverev[1], Ekaterina Novak[1], Andrey Kuznetzov[2], and Sofia Kantorovich[2] — [1]Ekaterinburg, Russia — [2]University of Vienna, Vienna, Austria

This report presents a study of the magnetic dynamic susceptibility of MNPs under the influence of a low-amplitude alternating plane-polarized magnetic field. We consider ellipsoidal MNPs modeled as a collection of spherical subparticles with fixed spatial positions relative to each other. This corresponds to a scenario where nanoparticles are embedded in a polymer or other rigid non-magnetic matrix. The modeling employs the molecular dynamics simulations using the ESPResSo software package, which accounts for magnetic anisotropy. The model is based on the concept proposed in [1]. The core idea is that the orientation of the magnetic moment in a subparticle is determined by solving the stochastic Landau-Lifshitz-Gilbert equation in a reference frame fixed to the particle body, neglecting precession and the Barnett effect. To form a single-domain-like particle assembly, their common convex hull approximates an elongated ellipsoid of revolution with a preset aspect ratio, enabling comparison with spherical particles.

The work was financially supported by the Russian Science Foundation grant No. 25-22-00338.

DY 45: Focus Session: Physics of AI – Part I (joint session SOE/DY)

The focus session is organized by Claudius Gros (Goethe-Universität Franfurt), Moritz Helias (Forschungszentrum Jülich), Peter Sollich (Georg-August-Universität Göttingen)

This focus session brings together experts in the field of physics-inspired theory of machine learning and artificial intelligence, who aim to supplement the engineering-driven success of AI by a principled theory of neural information processing. Contributions will address how statistical and dynamical perspectives explain learning in modern AI systems and how these insights support interpretability as well as prediction of performance, generalization, and the required resources.

Time: Thursday 9:30–11:15 Location: GÖR/0226

Generative AI and diffusion models: a statistical physics approach — •Giulio Biroli — Ecole Normale Superieure, Paris, France

Generative AI represents a groundbreaking development within the broader *Machine Learning Revolution,* significantly influencing technology, science, and society. In this colloquium, I will focus on the state-of-the-art *diffusion models*, which are currently used to generate images, videos, and sounds. They are very fascinating algorithms for physicists, as they are very much connected to concepts from stochastic thermodynamics, particularly time-reversed Langevin dynamics. These diffusion models start from a simple white noise input and make it evolve through a Langevin process to generate complex outputs such as images, videos, and sounds. I will show that statistical physics provides principles and methods to characterise this generation process. Specifically, I will discuss how phenomena such as the transition from memorization to generalization and the emergence of features can be understood through the lens of symmetry breaking, phase transitions, slow dynamics, and methods used to study disordered systems.

DY 45.2 Thu 10:00 GÖR/0226

Statistical Physics of Classifier-free Diffusion Guidance — •Enrico Ventura[1], Beatrice Achilli[1], Carlo Lucibello[1], and Luca Ambrogioni[2] — [1]Bocconi University, Milan, Italy — [2]Radboud University, Nijmegen, The Netherlands

Classifier-free Guidance (CFG) is a simple yet effective technique that helps diffusion models better follow a user's prompt. By combining standard unconditional diffusion with diffusion conditioned on a specific class of the data, it steers generation toward samples (e.g. images, videos or text) that more clearly reflect the intended content. We propose a description of the sampling dynamics of a diffusion model under CFG based on the statistical mechanics of disordered systems. Specifically, we study the time-dependent transformation of the diffusion potential providing a quantitative prediction of the way a complex target distribution is deformed to improve data generation. Moreover, we leverage our results to propose alternative theory-based guidance schedules that enhance such beneficial effects.

DY 45.3 Thu 10:15 GÖR/0226

Fundamental operating regimes, hyper-parameter fine-tuning and glassiness: towards an interpretable replica-theory for trained restricted Boltzmann machines — •Alberto Fachechi[1], Elena Agliari[1], Miriam Aquaro[1], Anthony Coolen[2], and Menno Mulder[2] — [1]Department of Mathematics, Sapienza University of Roma, P. le A. Moro 5, 00185 Roma, Italy — [2]Theoretical Biophysics, DCN Donders Institute, Faculty of Science, Radboud University, 6525 AJ Nijmegen, The Netherlands

Since the seminal work by Amit, Gutfreund and Sompolinsky, statistical mechanics of spin-glasses with structural disorder has acquired a crucial role in theoretical investigations of artificial neural networks, as it enables the representation of their generalization and information processing capabilities as phases within the space of parameters. We study the relaxation towards equilibrium of the training procedure of restricted Boltzmann machines with a binary visible layer and a Gaussian hidden layer with an unlabelled dataset consisting of noisy realizations of a single ground pattern. We develop a statistical mechanics framework to describe the network generative capabilities by exploiting replica theory. We outline the effective control parameters (e.g., the relative number of weights to be trained, the regularization parameter), whose tuning can yield qualitatively different operative regimes. We also provide analytical and numerical evidence for the existence of a sub-region in the space of the hyperparameters where replica-symmetry breaking occurs.

DY 45.4 Thu 10:30 GÖR/0226

Mirror, Mirror of the Flow: How Does Regularization Shape Implicit Bias? — •Tom Jacobs, Chao Zhou, and Rebekka Burkholz — CISPA Helmholtz Center, Saarbrucken, Germany

Implicit bias plays an important role in explaining how overparameterized models generalize well. Explicit regularization like weight decay is often employed in addition to prevent overfitting. While both concepts have been studied separately, in practice, they often act in tandem. Understanding their interplay is key to controlling the shape and strength of implicit bias, as it can be modified by explicit regularization. To this end, we incorporate explicit regularization into the mirror flow framework and analyze its lasting effects on the geometry of the training dynamics, covering three distinct effects: positional bias, type of bias, and range shrinking. The mirror flow framework relies on Noether style parameter symmetry preservation, the regularization controls them. Our analytical approach encompasses a broad class of problems, including sparse coding, matrix sensing, single-layer attention, and LoRA, for which we demonstrate the utility of our insights. To exploit the lasting effect of regularization and highlight the potential benefit of dynamic weight decay schedules, we propose to switch off weight decay during training, which can improve generalization, as we demonstrate in experiments.

DY 45.5 Thu 10:45 GÖR/0226

Generalization performance of narrow one-hidden layer networks in the teacher-student setting — Rodrigo Pérez Ortiz[1], •Gibbs Nwemadji[2], Jean Barbier[3], Federica Gerace[1], Alessandro Ingrosso[4], Clarissa Lauditi[5], and Enrico Malatesta[6] — [1]Alma Mater Studiorum * Università di Bologna (Unibo), Bologna, Italy — [2]International School of Advanced Studies (SISSA), Trieste, Italy — [3]The Abdus Salam International Centre for Theoretical Physics, Trieste, Italy — [4]Radboud University, Nijmegen, The Netherlands — [5]Harvard University, Cambridge, US — [6]Bocconi University, Milano, Italy

Generalization on simple input-output distributions is best studied in the teacher-student setting, but fully connected one-hidden-layer networks with generic activations still lack a complete theory. We develop such a framework for networks with a large but finite number of hidden neurons, using statistical-physics tools to obtain closed-form predictions for both Bayesian and ERM estimators through a few summary statistics. We also identify a specialization transition when the sample size matches the number of parameters. The resulting theory accurately predicts generalization errors for networks trained with Langevin dynamics or standard full-batch gradient descent.

DY 45.6 Thu 11:00 GÖR/0226

Testing generalization through tiny task switching frameworks — •Daniel Henrik Nevermann and Claudius Gros — Institut für Theoretische Physik, Goethe-Universität Frankfurt, Deutschland

With an ever-growing interest in advancing the performance and efficiency of large language models (LLMs), and therein particularly the transformer architecture, the need for tiny testing frameworks is pressing, as many researchers cannot afford to train models on large GPU clusters. We here propose a tiny testing framework, extending the recently published IARC task switching framework, that despite being trivial to implement offers suitable complexity to be non-trivial to learn for small scale transformer models with a few million parameters or less. Beyond model benchmarking, the framework is also suitable for probing phenomena relevant to problems arising in physics of AI, where controlled, interpretable testbeds are essential. The proposed training and evaluation scheme relies on integer sequences to be predicted by the model. These integer sequences are generated by simple deterministic tasks designed to abstract typical challenges arising in natural language processing, such as short and long range correlations, or context awareness. Within the sequences, tasks are randomly switched, where a switch is indicated by a control token. An important quality of LLMs is the ability to generalize at inference time. We here extend the existing task switching framework with new tasks able to probe models generalization capacities in a tiny, yet meaningful manner.

Nonequilibrium transport in adaptive fermionic circuits — •Paul Weiss[1], Karim Chahine[2], and Michael Buchhold[1] — [1]Department of Theoretical Physics, Universität Innsbruck, Austria — [2]Institute for Theoretical Physics, University of Cologne, Germany

We investigate nonequilibrium dynamics in one-dimensional adaptive fermionic circuits, where monitored fermions undergo local unitary evolution conditioned on measurement outcomes. By tuning the measurement strength and the duration of the unitary gates, the dynamics can be continuously interpolated between incoherent, classical transport and coherence-dominated quantum transport. In the classical limit, we recover the asymmetric simple exclusion process (ASEP), while in the quantum regime we uncover a coherent analogue of the Burgers equation along with coherence-enhanced Kardar-Parisi-Zhang (KPZ) transport. Our analytical approach, based on transport equations and Keldysh field theory, is supported by numerical simulations.

DY 46.2 Thu 9:45 HÜL/S186

Frustration-Free Control and Absorbing-State Transport in Entangled State Preparation — •Tobias Dörstel[1,2], Thomas Iadecola[3,4,5], Justin H. Wilson[6,7], and Michael Buchhold[1,2] — [1]Department of Theoretical Physics, University of Innsbruck, Austria — [2]Institute for Theoretical Physics, University of Cologne, Germany — [3]Department of Physics, The Pennsylvania State University, USA — [4]Institute for Computational and Data Sciences, The Pennsylvania State University, USA — [5]Materials Research Institute, The Pennsylvania State University, USA — [6]Department of Physics and Astronomy, Louisiana State University, USA — [7]Center for Computation and Technology, Louisiana State University, USA

We study frustration-free control, a measurement-feedback protocol for quantum state preparation that extends the concept of frustration-free Hamiltonians to stochastic dynamics. The protocol drives many-body systems into highly entangled target states, common dark states of all measurement projectors, through minimal local unitary corrections that realize an absorbing-state dynamics without post-selection. We show that relaxation to the target state is governed by emergent transport of nonlocal charges, such as singlet excitations in SU(2)-symmetric dynamics. While measurement-feedback annihilates compatible charge configurations, both measurement and scrambling unitaries induce charge transport and thus determine the convergence time. Mapping a baseline model of SU(N) SWAP measurements with local corrections to a solvable absorbing random walk yields a runtime scaling $t \sim L^z$ with transport exponent $z = 2$.

DY 46.3 Thu 10:00 HÜL/S186

Quantum typicality approach to energy flow between two spin-chain domains at different temperatures — Laurenz Beckemeyer[1], •Markus Kraft[1], Mariel Kempa[1], Dirk Schuricht[2], and Robin Steinigeweg[1] — [1]University of Osnabrück, Department of Mathematics/Computer Science/Physics,D-49076 Osnabrück, Germany — [2]Institute for Theoretical Physics, Utrecht University, 3584CC Utrecht, The Netherlands

We discuss a quantum typicality approach to examine systems composed of two subsystems at different temperatures. While dynamical quantum typicality is usually used to simulate high-temperature dynamics, we also investigate low-temperature dynamics using the method. To test our method, we investigate the energy current between subsystems at different temperatures in various paradigmatic spin-1/2 chains, specifically the XX chain, the critical transverse-field Ising chain, and the XXZ chain. We compare our numerics to existing analytical results and find a convincing agreement for the energy current in the steady state for all considered models and temperatures.

DY 46.4 Thu 10:15 HÜL/S186

Revisiting boundary-driven method for transport: Finite-size effects and the role of system-bath coupling — •Mariel Kempa[1], Markus Kraft[1], Sourav Nandy[2], Jacek Herbrych[3], Jiaozi Wang[1], Jochen Gemmer[1], and Robin Steinigeweg[1] — [1]University of Osnabrueck, Osnabrueck, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [3]Wroclaw University of Science and Technology, Wroclaw, Poland

Understanding transport in interacting quantum many-body systems is a central challenge in condensed matter and statistical physics. Numerical studies typically rely on two main approaches: Dynamics of linear-response functions in closed systems and Markovian dynamics governed by master equations for boundary-driven open systems. While the equivalence of their dynamical behavior has been explored in recent studies, a systematic comparison of the transport coefficients obtained from these two classes of methods remains an open question. Here, we address this gap by comparing and contrasting the dc diffusion constant $\mathscr{D}_{\mathrm{dc}}$ computed from the aforementioned two approaches. We find a clear mismatch between the two, with $\mathscr{D}_{\mathrm{dc}}$ exhibiting a strong dependence on the system-bath coupling for the boundary-driven technique, highlighting fundamental limitations of such a method in calculating the transport coefficients related to asymptotic dynamical behavior of the system. We trace the origin of this mismatch to the incorrect order of limits of time $t \to \infty$ and system size $L \to \infty$, which we argue to be intrinsic to boundary-driven setups.

DY 46.5 Thu 10:30 HÜL/S186

Synchronized Aharonov-Bohm Motifs via Engineered Dissipation — •Christopher Wächtler and Gloria Platero — ICMM-CSIC, Madrdi, Spain

The interplay between external gauge fields and lattice geometry can induce extreme localization dynamics through complete destructive interference. We show that combining this flux-induced localization with engineered dissipation leads to robust spin synchronization in rotationally symmetric spin geometries, referred to as Aharonov-Bohm motifs, with cyclic symmetries of any order. The synchronized dynamics is independent of initial conditions and features entanglement among spins within each motif. We further demonstrate that multiple motifs can fully synchronize when coupled, which is achieved by applying additional collective dissipation acting on all intra-motif spins. These results reveal a direct connection between flux-induced localization, dissipative engineering, and collective quantum synchronization.

DY 46.6 Thu 10:45 HÜL/S186

Krylov space dynamics of ergodic and dynamically frozen Floquet systems — •Luke Staszewski[1], Asmi Haldar[2], Pieter Claeys[1], and Alexander Wietek[1] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden — [2]Laboratoire de Physique Theorique - IRSAMC, Toulouse

In isolated quantum many-body systems periodically driven in time, the asymptotic dynamics at late times can exhibit distinct behavior such as thermalization or dynamical freezing. Understanding the properties of and the convergence towards infinite-time (nonequilibrium) steady states however remains a challenging endeavor. We propose a physically motivated Krylov space perspective on Floquet thermalization which offers a natural framework to study rates of convergence towards steady states and, simultaneously, an efficient numerical algorithm to evaluate infinite-time averages of observables within the diagonal ensemble. The effectiveness of our algorithm is demonstrated by applying it to the periodically driven mixed-field Ising model, reaching system sizes of up to 30 spins. Our method successfully resolves the transition between the ergodic and dynamically frozen phases and provides insight into the nature of the Floquet eigenstates across the phase diagram. Furthermore, we show that the long-time behavior is encoded within the localization properties of the Ritz vectors under the Floquet evolution, providing an accurate diagnostic of ergodicity.

Chaotic many-body quantum dynamics, spectral correlations, and energy diffusion — •Dominik Hahn and John Chalker — Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

We present results on the quantum dynamics of a minimal model with spatial structure and local interactions. The model features a time-independent Hamiltonian, in contrast to the widely studied quantum circuits, and is analytically tractable in the limit of large local Hilbert space dimension and weak intersite coupling. In this regime, we show that the energy dynamics are governed by a classical master equation exhibiting diffusive behavior. Furthermore, we demonstrate that the spectral form factor can be expressed exactly in terms of the solution to this master equation, demonstrating how the linear ramp emerges at long times, while locality gives rise to an additional enhancement at short times.

DY 46.8 Thu 11:30 HÜL/S186

Dissipative diffusion in quantum state preparation — •Tim Pokart[1], Lukas König[1], Sebastian Diehl[2], and Jan Carl Budich[1,3,4] — [1]Institute of Theoretical Physics, Technische Universität Dresden — [2]Institut für Theoretische Physik, Universität zu Köln, 50937 Cologne, Germany — [3]Würzburg-Dresden Cluster of Excellence ct.qmat, 01062 Dresden, Germany — [4]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Str. 38, 01187 Dresden, Germany

Dissipative quantum protocols that engineer a desired state as their dark state provide a powerful route to preparing quantum many-body states. We investigate a number conserving variant of such a dissipative protocol which is able to stabilize a topologically nontrivial phase. We show that the protocol admits a unique and stable dark state. Furthermore, we find that the cooling is diffusive in nature, supported by both analytical arguments and numerical simulations.

DY 46.9 Thu 11:45 HÜL/S186

First principles simulation of spin diffusion using dynamic mean-fields — •Timo Grässer[1], Matthias Ernst[1], and Götz S. Uhrig[2] — [1]Institute of Molecular Physical Science, ETH Zurich, 8093 Zurich, Switzerland — [2]Condensed Matter Physics, TU Dortmund University, 44227 Dortmund, Germany

The transfer of a globally conserved polarization among a homogeneous spin ensemble is called spin diffusion and one of the most important phenomena in the broad field of magnetic resonance. Describing spin diffusion theoretically is a notoriously difficult task due to the large number of spins involved. We use a description through dynamic mean-fields (dubbed spinDMFT [1]) to derive an effective model for spectral spin diffusion. The approach is benchmarked for two crystalline test samples, malonic acid and dipotassium α-D-glucopyranose-1-phosphate dihydrate, yielding a remarkable agreement with experimental data and requiring only little computational effort. This strongly supports the use of spinDMFT, which may be extended in future works to understand spin diffusion in dynamic nuclear polarization (DNP) experiments [2].

DY 46.10 Thu 12:00 HÜL/S186

Simulating universal long-time dynamics in integrable quantum spin chains — •Angelo Valli[1], Catalin Pascu Moca[2], Miklos Antal Werner[3], Marton Kormos[1], Doru Sticlet[6], Balazs Dora[1], Ziga Krajnik[4], Tomaz Prosen[5], and Gergely Zarand[1] — [1]Budapest University of Technology and Economics, Budapest (Hungary) — [2]University of Oradea, Oradea (Romania) — [3]Wigner Research Centre for Physics, Budapest (Hungary) — [4]New York University, New York (USA) — [5]University of Ljubljana, Ljubljana (Slovenia) — [6]National Institute for R&D of Isotopic and Molecular Technologies, Cluj-Napoca (Romania)

We introduce a novel tensor-network approach to calculate cumulants of the full counting statistics to unprecedentedly long times. We investigate spin-transfer in quantum spin chains, where the superdiffusive transport with dynamical exponent z=3/2 has been conjectured to fall within the Kardar-Parisi-Zhang (KPZ) universality class of classical interface growth. Recent experimental evidence on quantum simulators challenged this hypothesis. Our results extend far beyond the experimental timescales and provide unambiguous evidence that spin transfer in integrable quantum spin chains is indeed incompatible with KPZ universality. However, spatio-temporal fluctuations of the spin analogue of surface roughness exhibit a self-similar Family-Vicsek (FV) scaling, relating roughness, growth, and dynamical exponents in all transport regimes and across models with SU(N) symmetry. Our results shed light on how classical universal scaling laws extend to the quantum many-body realm.

DY 46.11 Thu 12:15 HÜL/S186

Few-body structures of Quantum impurity problems in the Heisenberg picture — •Maxime Debertolis — University of Bonn

Quantum impurity problems are known to exhibit a simplified representation of their ground state or for quench protocols when an optimized single-particle basis is chosen. This work extends the study of single-particle rotations taylored to operators in the Heisenberg picture. We present the concept of natural super-orbitals for many-body operators, defined as the eigenvectors of the one-body super-density matrix associated with a vectorized operator. These objects are related to measures of non- Gaussianity of operators associated to the occupations of the natural super-orbitals. We perform a numerical investigation of the natural super-orbitals corresponding to both the time-evolution operator and a time-evolved local operator in the t-V model and in a quantum impurity model using tensor network simulations. In the quantum impurity model, occupations of the natural orbitals for both operators decay exponentially at all times. More surprisingly, the non-Gaussianity of the local operator saturates in time. This indicates that only a small number of orbitals contribute significantly to quantum correlations, enabling a compact matrix-product-operator representation. This framework opens the door to future research that leverages the compressed structure of operators in their natural super-orbital basis, enabling for instance the computation of out-of-time-order correlators in large interacting systems over extended time scales.

DY 46.12 Thu 12:30 HÜL/S186

Propagating the Hierarchical Equations of Motion (HEOM) using the Multi-Configurational Time-Dependent Hartree method (MCTDH) — •Luisa R. Grether[1], Uwe Manthe[2], Samuel L. Rudge[1], and Michael Thoss[1] — [1]Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Hermann-Herder-Str. 3, 79104 Freiburg im Breisgau, Deutschland — [2]Theoretische Chemie, Fakultät für Chemie, Universität Bielefeld, Universitätsstr. 25, 33615 Bielefeld, Deutschland

The Hierarchical Equations of Motion (HEOM) are a powerful, numerically exact approach for simulating the time evolution of an open quantum system. Over the past decade, several tensor-train- and tensor-network-based approaches have been suggested and realized to make the HEOM applicable to ever larger model systems [1,2].

In this contribution, we build upon the existing twin-space formulation of the HEOM [2] and introduce a novel approach employing the Multi-Configurational Time-Dependent Hartree method (MCTDH) [3] for the time propagation of the HEOM. We demonstrate the applicability of the resulting HEOM+MCTDH method by presenting electron transport calculations for a nanojunction model, for which fully quantum results have not been available previously.

Microcanonical ensemble out of equilibrium — •Roman Belousov[1], Jenna Elliott[1,2], Florian Berger[3], Lamberto Rondoni[4,5], and Anna Erzberger[1,2] — [1]European Molecular Biology Laboratory (EMBL), Heidelberg, Germany — [2]Heidelberg University, Heidelberg, Germany — [3]Utrecht University, Utrecht, The Netherlands — [4]Politecnico di Torino, Turin, Italy — [5]Istituto Nazionale di Fisica Nucleare (INFN), Turin, Italy

The microcanonical ensemble serves as the fundamental representation of equilibrium thermodynamics in statistical mechanics by counting all possible realizations of a system's states. Ensemble theory connects this idea with probability and information theory, leading to the notion of Shannon-Gibbs entropy and, ultimately, to the principle of maximum caliber describing *trajectories* of systems—in and out of equilibrium. While the latter phenomenological generalization reproduces many results of nonequilibrium thermodynamics, its physical justification remains an open area of research. What is the microscopic origin and physical interpretation of this variational approach? What guides the choice of relevant observables? We address these questions by extending Boltzmann's method to a microcanonical caliber principle. Thereby we systematically develop generalized local detailed-balance relations, clarify the statistical origins of inhomogeneous transport, and provide an independent derivation of key equations from stochastic thermodynamics. This approach introduces a *dynamical* ensemble theory, which we verify in numerical simulations of spatially extended, driven, and active systems.

DY 47.2 Thu 9:45 ZEU/0114

Ensemble dependence of the critical behavior of a system with long range interaction and quenched randomness — •Nir Schreiber, Reuven Cohen, and Simi Haber — Department of Mathematics, Bar Ilan University, Ramat Gan, Israel 5290002

A system with long range interaction (LRI) is usually non-additive. In other words, such a system with volume V and energy E, cannot be divided into two subsystems with energies E_1, E_2 , where $E = E_1 + E_2 + o(V)$.

The canonical and the microcanonical ensembles are expected to be equivalent when describing additive systems. Conversely, non-additivity may result in peculiar microcanonical phenomena that are not observed in the canonical ensemble, such as negative specific heat or the presence of microstates that are inaccessible to the system, leading to breaking of ergodicity.

The Blume-Emery-Griffiths (BEG) model with mean-field-like interaction is a simple example of a model with LRI. We employ that model to demonstrate inequivalence of the two ensembles, without interfering with the interaction content. Specifically, we consider a hybrid system governed by the BEG Hamiltonian, where the spins are randomly quenched such that some of them are "pure" Ising and the others admit the BEG states. It is found, by varying the concentration of the Ising spins while keeping the parameters of the Hamiltonian fixed, that the model displays different canonical and microcanonical phase portraits in concentration-temperature plain. Indications that these portraits are rich and rather unusual are provided.

DY 47.3 Thu 10:00 ZEU/0114

Quasicrystals with large rotational symmetries: Amorphous-like on small but ordered at large lengths scale — Alan Rodrigo Mendoza Sosa[1,2], Atahualpa S. Kraemer[1], Erdal C. Oğuz[2], and •Michael Schmiedeberg[3] — [1]Departamento de Física, Facultad de Ciencias, Universidad Nacional Autónoma de México, Ciudad Universitaria, 04510, Mexico City, Mexico — [2]Key Laboratory of Soft Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing, 100190, China — [3]Soft Matter Theory group, Institut für Theoretische Physik, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

We study hyperuniformity in quasicrystals with large rotational symmetry. Hyperuniform systems are characterized by anomalously suppressed long-wavelength (i.e., large-length-scale) density fluctuations compared to those found in ordinary gases and fluids as well as in amorphous solids. We show that the degree to which the large-scale fluctuations are suppressed reveals a new characteristic length-scale. Below this length the patterns behave like amorphous systems while only above this length the long-ranged order becomes important leading to hyperuniformity in all cases.

DY 47.4 Thu 10:15 ZEU/0114

Emergence of mixed orientational ordering in quasi-one-dimensional superdisk and superball fluids — •Sakineh Mizani[1], Martin Oettel[1], Péter Gurin[2], and Szabolcs Varga[2] — [1]Institute for Applied Physics, University of Tübingen, Auf der Morgenstelle 10, 72076 Tübingen, Germany — [2]Physics Department, Centre for Natural Sciences, University of Pannonia, PO Box 158, Veszprém, H-8201 Hungary

We investigate the collective behavior of hard anisotropic particles confined in quasi-one-dimensional channels where particle centers are constrained to a line but particles can rotate freely. For superdisks and superballs with tunable curvature, equilibrium properties are calculated using an exact transfer-operator method. We reveal the emergence of a novel state of mixed orientational order which is characterized by a close-packing state with particles having two distinct orientations, distributed randomly over the line [1]. This ordering is highly sensitive to particle shape: small deviations from ideal spherical symmetry can stabilize or destabilize the mixed phase, demonstrating the the subtle interplay between particle geometry and confinement. Our results provide new insights into entropically driven ordering in confined systems, offering potential guidelines for designing colloidal assemblies and understanding phase behavior in narrow channels. DY 47.5 Thu 10:30 ZEU/0114

Scaling of the Mpemba effect in the Ising model — •Janett Prehl and Martin Weigel — Institute of Physics, Technisch Universität Chemnitz, Chemnitz, Germany

The Mpemba effect – originally observed by Mpemba and Osborne for water [1] – describes the counterintuitive situation in which a hotter system relaxes faster than an initially colder one when both are instantaneously brought into contact with the same (cold) reservoir. Lately this phenomenon has been identified in various systems undergoing phase transitions [2 – 4]. Here, we investigate the Mpemba effect in the 2D Ising model with a critical temperature T_c. Using Monte Carlo simulations with different update dynamics, we study how initial temperatures and different initial magnetization influence the coarsening dynamics of different structural properties while quenching below T_c. In detail we investigate observables such as the energy per spin $\langle e \rangle$ and the average domain length $\langle \ell \rangle$. While Mpemba-like curve crossings appear for several conditions, they occur in the finite-size limited regime and weaken with increasing system size L. In contrast, non-zero initial magnetization enhances the effect, producing robust inversions in relaxation behavior.

Work extraction from a single negative-temperature bath considered as a temperature gradient-driven heat flow — •Wolfgang Bauer — Dept. of Internal Medicine I, Comprehensive Heart Failure Centre, UKW, Würzburg, Germany — EPV, Institute of Physics and Astrophysics, University of Würzburg, 97074 Würzburg, Germany}

Work can dissipate as heat within a bath. The reverse, i.e. extracting work from a thermal bath without changing the state of the working system contradicts the 2nd law of thermodynamics. However, this does not hold for a bath at negative absolute temperature. Our approach reconciles the 2nd law with sole work extraction from a bath at negative temperature. We consider not only a single, but rather a large assembly of working systems. Within the assembly the working systems may exchange mutually energy by weak thermal coupling. This assembly is now assigned from Shannon entropy a canonical temperature. While this framework may seem unconventional for macroscopic working machines, it naturally becomes clear for very small, molecular-scale machines. We show for paradigmatic examples of working machines, that their initial canonical temperature is positive. Consequently, sole extraction of work from a bath at negative temperature represents simply heat flow from a hot system (bath at negative temperature) to a cool system (assembly of working machines), consistent with the 2nd law of thermodynamics.

Advancing Stochastic 3-SAT Solvers by Dissipating Oversatisfied Constraints — •Joachim Schwardt[1,2] and Jan Budich[2,1] — [1]Max Planck Institute for the Physics of Complex Systems — [2]Institute of Theoretical Physics at TU Dresden

We introduce and benchmark a stochastic local search heuristic for the NP-complete satisfiability problem 3-SAT that drastically outperforms existing solvers in the notoriously difficult realm of critically hard instances. Our construction is based on the crucial observation that well established previous approaches such as WalkSAT are prone to get stuck in local minima that are distinguished from true solutions by a larger number of oversatisfied combinatorial constraints. To address this issue, the proposed algorithm, coined DOCSAT, dissipates oversatisfied constraints (DOC), i.e. reduces their unfavorable abundance so as to render them critical. We analyze and benchmark our algorithm on a randomly generated sample of hard but satisfiable 3-SAT instances with varying problem sizes up to N = 15000. Quite remarkably, we find that DOCSAT outperforms both WalkSAT and other well known algorithms including the complete solver Kissat. The essence of DOCSAT may be seen as a way of harnessing statistical structure beyond the primary cost function of a combinatorial problem to avoid or escape local minima traps in stochastic local search.

DY 47.8 Thu 11:30 ZEU/0114

Quest for optimal quantum resetting: Protocols for a particle on a chain — •Pallabi Chatterjee, S. Aravinda, and Ranjan Modak — Department of Physics, Indian Institute of Technology Tirupati, Tirupati 517619, India

In the classical context, it is well known that, sometimes, if a search does not find its target, it is better to start the process anew. This is known as resetting. The quantum counterpart of resetting also indicates speeding up the detection process by eliminating the dark states, i.e., situations in which the particle avoids detection. In this work, we introduce the most probable position resetting(MPR) protocol, in which, at a given resetting step, resets are done with certain probabilities to the set of possible peak positions that could occur because of the previous resets, followed by uninterrupted unitary evolution, irrespective of which path was taken by the particle in previous steps. In a tight-binding lattice model, there exists a twofold degeneracy (left and right) of the positions of maximum probability(peak). The survival probability with optimal restart rate approaches zero when the particle is reset with equal probability on both sides path independently. This protocol significantly reduces the optimal mean first-detected-passage time, and it performs better even if the detector is far apart compared to the usual resetting protocols in which the particle is brought back to the initial position. We propose a modified protocol, an adaptive two-stage MPR, by making the associated probabilities of going to the right and left a function of steps. We see a further reduction of the optimal mean FDT and improvement in the search process.

DY 47.9 Thu 11:45 ZEU/0114

Quantification of correlations by Fisher matrix — •Jakub Grabarczyk and Krzysztof Byczuk — Faculty of Physics, University of Warsaw, Poland

Quantum Fisher Information (QFI) is a concept based on relative entropy used to measure the distinctiveness of the given statistical ensemble. When applied to a lattice model, it quantifies the measurable difference between two instances of the model characterized by different parameter values. In my work, I demonstrate the significance of QFI in understanding microscopic properties of correlated quantum particles. The results are verified numerically. I compare the QFI across several important lattice models including the bosonic and fermionic Hubbard models as well as the Heisenberg model. Furthermore, I discuss how QFI relates to physically measurable quantities.

DY 47.10 Thu 12:00 ZEU/0114

Universal irreversibility—an information loss paradigm — •Jürgen Stockburger — Institut for Complex Quantum Systems, Ulm University

I develop a general prescription to incorporate irreversibility into any physical dynamics governed by a reversible microscopic dynamics with interactions. A description of irreversibility is introduced from the perspective that reversibility is *infeasible* due to insufficient means, not as a fundamental alteration of any microscopic theory.

With an arbitrary partitioning into subsystems, a coupled dynamics between a projected (decorrelated) and a residual (complementary) state is formulated, still fully equivalent to the reversible dynamics. All partitions are treated equally, without designation of "system" and "bath". With a (variable) truncation of the memory of the residual state, I recognize the fact that correlations in the distant

past are undetectable in the present. The notion of irrecoverable correlation information is also implicit in current open-system approaches such as repeated interaction models [1]; the need to consider heat baths equally as a "system of interest" arises, e.g., in the context of quantum bolometry [2]. The framework of *entropy augmentation through subadditive excess* (EASE) introduces not only a universal view on irreversibility, it also provides a roadmap for actual computation [3].

DY 47.11 Thu 12:15 ZEU/0114

Temperature as joules per bit — Charles Alexandre Bédard[1], •Sophie Berthelette[2], Xavier Coiteux-Roy[3], and Stefan Wolf[2,4] — [1]École de technologie supérieure, Montreal, Canada — [2]Università della Svizzera italiana, Lugano, Switzerland — [3]University of Calgary, Calgary, Canada — [4]Facoltà indipendente di Gandria, Gandria, Switzerland

In statistical mechanics, entropy is defined as a fundamental quantity. However, its unit, J/K, involves that of temperature, which is only subsequently defined — and defined in terms of entropy. This circularity arises with the introduction of Boltzmann's constant into the very expression of entropy. The J/K carried by the constant prevents entropy from finding a unit of its own while simultaneously obfuscating its informational nature. Following the precepts of information theory, we argue that entropy is well measured in bits and coincides with information capacity at thermodynamic equilibrium. Consequently, not only is the temperature of a system in equilibrium expressed in J/bit, but it acquires a clear meaning: It is the cost in energy to increase its information capacity by 1 bit. Viewing temperature as joules per bit uncovers the strong duality exhibited by Gibbs long ago between available capacity and free energy. It also simplifies Landauer's cost and clarifies that it is a cost of displacement, not of erasure. Replacing the kelvin with the bit as an SI unit would remove Boltzmann's constant from the seven defining constants.

From Case Counts to Contact Networks: Inferring Epidemic Coupling in Space and Time — •Adrian Pelcaru and Dirk Brockmann — Center Synergy of Systems (SynoSys), TUD Dresden University of Technology, Dresden, Germany

Inferring spatio-temporal transmission structure from incidence data alone is a central problem in epidemic modelling, with implications for real-time surveillance and for how we interpret mobility and contact information. We analyse discrete-time renewal SIRS models on a network of metapopulations that incorporate infection-age structure, seasonality, mobility between regions, and time-varying local contact rates. In the analysis, these ingredients are combined into an effective spatio-temporal contact kernel that quantifies how cases in region m at a given infection age contribute to new infections in region n one day ahead. Stacking multi-region incidence histories across lags into a delay-embedded state, the renewal dynamics define a map on this reconstructed space whose local Jacobian is the convolution operator determined by the contact kernel and the susceptibles. Aggregating the kernel over infection age with suitable weights yields a time-dependent effective contact matrix and associated effective distances that summarise how infections propagate between regions. This construction provides a transparent link between mechanistic assumptions about mobility and varying infection rates and the resulting effective couplings in space and time, and identifies a natural operator that can, in principle, be compared to reconstructions from incidence data to detect systematic deviations from mobility-based expectations.

Beyond the Balance: A Minimal Model Unifying Regime Shifts, Long Transients, and Critical Transitions — •Misha Chai and Holger Kantz — Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Str. 38, D 01187, Germany

By the late 20th century, ecologists recognized that classical equilibrium views — nature is deterministic and always converges to a single, stable state — often fail to capture real-world dynamics. A nonequilibrium perspective emerged: ecological systems are frequently dominated by long transients that can persist over a super-long periods of time, with recurrent cyclic and chaotic behavior, until a sudden regime shifts changes the dynamics and transitions the system to an unpredictable new state.

However, models that integrate these key features — alternative stable states, stochastic drivers, long transients, and critical transitions — while also quantifying stability via resilience, remain rare.

We propose a minimal model that encapsulates these key properties of nonequilibrium ecology, while remaining amenable to theoretical analysis.

DY 48.3 Thu 10:00 ZEU/0118

Anticipated synchronization in systems with distributed delay — •David Ortiz, Tobias Galla, and Raúl Toral — Instituto de Física Interdisciplinar y Sistemas Complejos IFISC (CSIC-UIB), Campus UIB, 07122 Palma de Mallorca, Spain

Anticipated Synchronization (AS) describes counterintuitive situations in which a system synchronizes with the future state of another, even though the coupling between the systems is perfectly causal. Thus, the driven system 'forecasts' the driver. Common setups include two identical copies of a system, coupled with a fixed delayed interaction. AS has been reported in chaotic, excitable and spatially extended systems.

We extend AS to linear and nonlinear systems coupled with distributed delay. This models situations with uncertainty on the delay, or systems in which there are multiple distinct delay channels. The damped harmonic oscillator can be studied analytically, and shows stable AS provided the coupling strength and mean delay are not too large. We compute the anticipation time, and show that the driven system amplifies the oscillations in the driver. Our theoretical predictions are confirmed by numerical simulations. Numerically, we also investigate nonlinear chaotic and excitable systems. We confirm that AS can occur in the presence of distributed delay. Similar to the case of linear systems, we again find instances of signal enhancement.

DY 48.4 Thu 10:15 ZEU/0118

Dynamics of Temporal Localized States in an Injected Resonant Saturable Absorber Mirror — •Martin P. Szymiczek[1], Elias R. Koch[1], Julien Javaloyes[2], and Svetlana V. Gurevich[1,2,3] — [1]Institut für Theoretische Physik, Universität Münster — [2]Universitat de les Illes Balears, Palma — [3]Center for Data Science and Complexity, Universität Münster

We are interested in the dynamical behaviour of temporal localized states (TLS) and corresponding frequency combs in an injected microcavities subjected to a strong time-delayed feedback. A nonlinear optical system consist of a short injected microcavity with a thin slice of a saturable absorber, coupled to a long external cavity introducing a time delay and closed by a feedback mirror. We disclose sets of multistable bright TLSs coexisting on their respective bistable homogeneous backgrounds and show that they are mainly generated through the locking of domain walls leading to a collapsed snaking structure. The results provide insights into the control and design of emission in delay-coupled micro-resonator systems.

DY 48.5 Thu 10:30 ZEU/0118

FPGA-integrated analog simulations of time-delayed differential equations — •Matthias Hering[1], Julien Javaloyes[2], and Svetlana V. Gurevich[1,2,3] — [1]Institute of Theoretical Physics, Münster, Germany — [2]Departament de Física and IAC[3], Universitat de les Illes Balears, Spain — [3]Center for Data Science and Complexity, Münster, Germany

Real-world complex systems can be strongly influenced by time-delays due to unavoidable finite signal propagation speeds and time-delayed dynamical systems (TDSs) have proven to be a fertile framework for the modeling of nonlinear phenomena. However, they are difficult to study experimentally due to the need for precise delay elements. We present a hybrid implementation by integrating a digital feedback loop powered by an FPGA into an analog circuit to realize a damped harmonic oscillator with a piecewise nonlinear, delayed restoring force. Operating at 125 MS/s enables the FPGA to enable a clean reconstruction of the system*s dynamics up into the MHz regime without digital artifacts. The experiment not only reproduces the expected Turing bifurcation in the long delay limit, but also reveals the formation of robust localized states and square-waves patterns.

DY 48.6 Thu 10:45 ZEU/0118

Experimental realisation of thermalisation in a nonlinear non-Hermitian optical lattice — •Julia Görsch[1], Joshua Feis[1], Andrea Steinfurth[1], Sebastian Weidemann[1], Georgios G. Pyrialakos[2], Matthias Heinrich[1], Mercedeh Khajavikhan[2], Alexander Szameit[1], and Demetrios N. Christodoulides[2] — [1]Institute of Physics, University of Rostock, Rostock, Germany — [2]Ming Hsieh Department of Electrical and Computer Engineering, University of Southern California, Los Angeles, California, USA

Optical thermodynamics has emerged as an efficient framework for describing and predicting the dynamics of strongly multimode, nonlinear systems. Yet, in non-Hermitian settings, many of the theoretically predicted effects have remained experimentally unexplored. Here, we report the first experimental observation of thermalisation in a nonlinear, non-Hermitian optical lattice using a platform based on coupled optical fiber loops. This arrangement emulates light propagation in a one-dimensional lattice by coupling two fiber loops of unequal length via a beam splitter, thereby mapping pulse evolution onto a doubly discrete (1+1)D lattice. Within this system, we engineer a pseudo-Hermitian lattice whose non-Hermiticity arises from anisotropic nearest-neighbor coupling, implemented via a tunable beam-splitting ratio combined with amplitude modulation. Following excitation with a superposition of eigenmodes, the system undergoes a clear thermalisation process - despite its intrinsic non-Hermiticity - revealing a previously inaccessible regime of non-Hermitian optical thermodynamics and opening the door to further experimental investigations.

Invited Talk DY 49.1 Thu 9:30 ZEU/0160

Active memory and non-reciprocity as pathways to pattern formation in conserved scalar fields — •Supropriya Saha and Vaishnavi Gajendragad — Max Planck Institute for Dynamics and Self-organisation

Active phase separation has emerged as a field within active matter that investigates pattern formation in number-conserving scalar fields. The field has also gained momentum from developments in biological systems, where phase separation has been implicated in the formation of biological condensates. In this talk, I will explore two different paths to non-Hermiticity in number-conserving scalar fields. Non-Hermiticity, or the emergence of complex eigenvalues in the linear dynamics of scalar densities, is associated with traveling patterns that break time-reversal symmetry and parity.

The first pathway I will discuss is a feedback mechanism in which particles store and use information about their past trajectories to influence their time evolution. I will present a model in which the particle velocity acquires an active contribution that depends on its past trajectory, weighted by a memory kernel. This memory kernel is independent of the thermal noise acting on the particle, implying a microscopic violation of detailed balance. The number density of these particles is described by a modified Cahn*Hilliard equation that incorporates this non-equilibrium effect. The second pathway involves non-reciprocal interactions between two or more species. I will describe the phenomenology observed in both cases, focusing on the role of fluctuations, nonlinearities, and the stability of the resulting patterns.

DY 49.2 Thu 10:00 ZEU/0160

Self-propulsion via non-transitive phase coexistence in chemically active mixtures — •Yicheng Qiang, Chengjie Luo, and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany

Chemical activity is common in many active matter systems. For example, active reactions can lead to the self-propulsion of particles, which can finally give rise to rich collective dynamics, including phase separation, even in the absence of attractive interactions. With interactions that already favor phase separation, chemical activity and multiple coexisting phases will further intertwine. To unveil the basic effect of active reactions on coexistence, we study mixtures where solvent species interconvert while solutes segregate. We demonstrate that active reactions alter the chemical potential balance between the coexisting phases and defy the construction of pseudo-pressure balance. As a result, the transitivity of phase coexistence is broken, and the bulk compositions depend on the contact topology among all the coexisting phases. With cyclic topologies, the pressure imbalance leads to self-propelled phases and other complex dynamics such as budding and engulfment.

DY 49.3 Thu 10:15 ZEU/0160

Contraction waves in pulsating active liquids: from pacemaker to aster dynamics — Tirthankar Banerjee[1], Thibault Desaleux[1], Jonas Ranft[2], and •Etienne Fodor[1] — [1]Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg City, Luxembourg — [2]Institut de Biologie de l'ENS, Ecole Normale Supérieure, CNRS, Inserm, Université PSL, 46 rue d*Ulm, 75005 Paris, France

We propose a hydrodynamic theory to examine the emergence of contraction waves in dense active liquids composed of pulsating deformable particles. Our theory couples the liquid density with a chemical phase that determines the periodic deformation of the particles. This mechanochemical coupling regulates the interplay between the flow induced by local deformation, and the resistance to pulsation stemming from steric interaction. We show that this interplay leads the emergent contraction waves to spontaneously organize into a packing of pacemakers. We reveal that the dynamics of these pacemakers is governed by a complex feedback between slow and fast topological defects that form asters in velocity flows. In fact, our defect analysis is a versatile platform for investigating the self-organization of waves in a wide range of contractile systems. Our results shed light on the key mechanisms that control the rich phenomenology of pulsating liquids, with relevance for biological systems such as tissues made of confluent pulsating cells. Refs: arXiv:2509.19024, arXiv:2407.19955

DY 49.4 Thu 10:30 ZEU/0160

Topology of pulsating active matter: Defect asymmetry controls emergent motility — •Luca Casagrande[1], Alessandro Manacorda[2], and Étienne Fodor[1] — [1]Department of Physics and Materials Science, University of Luxembourg, Luxembourg City, Luxembourg — [2]CNR Institute of Complex Systems, Uos Sapienza, Rome, Italy

When heartbeats become irregular, spiral waves and motile defects emerge at the surface of cardiac tissues [1]. Capturing the emergence of defect motility despite the absence of any cellular flows is a theoretical challenge which has recently been tackled by models of actively deforming particles [2-4]. The interplay between individual pulsation of particles sizes, synchronization, and repulsion yields deformation waves resembling those of cardiac tissues. Combining particle-based and hydrodynamic approaches, we examine the statistics of defects in the collective deformation of particles. We rationalize defect motility as stemming from the breakdown of time-reversal and spatial symmetries, and provide predictions for the deformation profile near the defect core to quantify motility. [1] A. Karma, Annu. Rev. Condens. Matter Phys., 4, 313-337 (2013) [2] Y. Zhang, É. Fodor, Phys. Rev. Lett., 131, 238302 (2023) [3] A. Manacorda, É. Fodor, Phys. Rev. E, 111, L053401 (2025) [4] W. Piñeros, É. Fodor, Phys. Rev. Lett., 134, 038301 (2025)

DY 49.5 Thu 10:45 ZEU/0160

Avalanche statistics in dense active matter — •Vinay Vaibhav[1] and Peter Sollich[1,2] — [1]Institut für Theoretische Physik, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — [2]Department of Mathematics, King's College London, The Strand, London, UK

Reorganization processes in dense active matter remain a central open question in non-equilibrium physics. In particular, how persistent self-propulsion drives local rearrangements and triggers collective failure events is not well understood. Here, we investigate such activity-induced rearrangements, that sometimes rapidly cascade to avalanches, in a dense assembly of self-propelled particles with extremely persistent activity. These systems evolve through abrupt transitions between mechanically stable configurations, giving rise to rich intermittent behavior. Using large-scale simulations, we systematically characterize avalanche statistics across a range of system sizes and activity protocols. We quantify the scaling properties of avalanche-size distributions for two widely studied active matter models: active Brownian particles and active Ornstein-Uhlenbeck particles. By comparing these classes of dynamics, we identify how the nature of the propulsion mechanism influences the exponents associated with the avalanche size distribution. In addition, we report the frequency and temporal organization of avalanches. Our results provide a unified picture of how persistent activity drives rearrangements in dense active systems and highlight the connections between active intermittency, mechanical stability, and avalanche dynamics.

DY 49.6 Thu 11:15 ZEU/0160

Coupling intracellular processes and extracellular environment in a Cellular Potts model — •Cornelis Mense[1,2], Falko Ziebert[1,2], and Ulrich Schwarz[1,2] — [1]ITP, Heidelberg — [2]BioQuant, Heidelberg

The Cellular Potts Model (CPM) is a computationally very efficient framework to study cell dynamics, wherein cells are simulated through Hamiltonian based update rules on a discretised lattice. The model has traditionally been used to predict cell migration and shape in scenarios such as immune response, morphogenesis, cancer, and wound healing. In contrast to e.g. active gel models, however, the CPM usually does not represent subcellular processes. Here, we propose an extension to the CPM by which cells can contract their bulk to both actively transport material and strain their substrate. This model allows us to represent feedback loops between intracellular processes, cell shape and the mechanical and geometrical properties of the extracellular environment. Migration can emerge both as internal symmetry break or as response to an external gradient. We apply it to some standard situations of experimental interest, in particular 3D-printed scaffolds for cell adhesion and migration.

DY 49.7 Thu 11:30 ZEU/0160

Exact Stationary State of a d-dimensional Run-and-Tumble Particle in a Harmonic Potential — •Mathis Guéneau[1], Grégory Schehr[2], and Satya N. Majumdar[3] — [1]Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Straße 38, 01187 Dresden, Germany — [2]Sorbonne Université, Laboratoire de Physique Théorique et Hautes Energies, CNRS UMR 7589, 4 Place Jussieu, 75252 Paris Cedex 05, France — [3]LPTMS, CNRS, Univ. Paris-Sud, Université Paris-Saclay, 91405 Orsay, France

We study the stationary state of a run-and-tumble particle (RTP) confined in a harmonic potential in arbitrary dimension d. Owing to isotropy, all statistical properties of the steady state are fully encoded in the distribution of a single coordinate. This coordinate follows an effective one-dimensional dynamics with a piecewise-constant self-propulsion velocity drawn from a prescribed distribution. We obtain the exact stationary distribution by identifying a stick-breaking process and a Dirichlet process in the dynamics, and by using known results for these processes. This framework allows us to compute exactly the full radial distribution, the joint law of the coordinates, and their moments, and to extend these results to include thermal noise. We further characterize the shape transition of the stationary state, from active-like to passive-like behavior, and show that it can be analyzed for arbitrary external potentials.

DY 49.8 Thu 11:45 ZEU/0160

Jerky active particles — •Hartmut Löwen and Stephy Jose — Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine Universität Düsseldorf, Universitätsstraße 1, 40225 Düsseldorf

We introduce jerky active particles, a generalization of inertial active Brownian particles subjected to jerk, the time derivative of acceleration. These particles can be realized by feedback in active macroscopic granules or in mesoscopic colloids moving in a viscoelastic background with memory. We analytically derive their mean squared displacement (MSD) and show that there is a gigantic dynamical spreading with extremely high scaling exponent of the MSD as a function of time [1]. We also generalize jerky dynamics to a chiral active particle and demonstrate that the mean displacement shows damped and exploding Lissajous-like patterns alongside the well-known classical spira mirabilis [2]. Our work on jerky chiral active particles opens a new route to explore rich dynamical effects in active matter.

[1] H. Löwen, Physical Review E 112, 045412 (2025)

DY 49.9 Thu 12:00 ZEU/0160

Diffusion of active particles on curved manifolds — •Maxim Root[1], Lorenzo Caprini[2], and Hartmut Löwen[1] — [1]Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, 40225 Düsseldorf, Germany — [2]Physics Department, Sapienza University of Rome, 00185 Rome, Italy

Active Matter rarely exists in isolated idealized systems. In nature, it is rather typical that active particles are surrounded by complex environments and experience external forces. So far, passive Brownian motion constrained to curved surfaces [1,2] was studied extensively and similar work was done on clusters of active particles [3]. In this talk we explore the emergent effects of active particles constrained to two-dimensional curved surfaces and in presence of an external homogeneous force field, e.g., gravity. This is done for an overdamped active particle that exhibits persistent motion on a short time scale and diffusion in the long-time limit. The lateral long-time diffusion coefficient is computed for different scenarios and criteria for localization are derived.

DY 49.10 Thu 12:15 ZEU/0160

Modeling dissipation in quantum active matter — Alexander P. Antonov[1], Sangyun Lee[2], Benno Liebchen[3], Hartmut Löwen[1], Jannis Melles[1], Giovanna Morigi[4], Yehor Tuchkov[2], and •Michael te Vrugt[2] — [1]Institut für Theoretische Physik II, Weiche Materie, Heinrich-Heine-Universität Düsseldorf — [2]Institut für Physik, Johannes Gutenberg-Universität Mainz — [3]Institut für Physik der kondensierten Materie, Technische Universität Darmstadt — [4]Theoretische Physik, Universität des Saarlandes

In classical active matter systems, dissipation plays a major role. Currently, there is an increased focus in exploring quantum mechanical active matter systems, for which the question of how to model dissipation is far from obvious. In fact, for open quantum systems, a variety of quantum heat bath models have been proposed that are valid in different physical situations. Here, we compare the effects of different quantum heat baths based on a recently proposed quantum active matter model [Phys. Rev. Res. **7**, 033008 (2025)]. We find that the choice of the quantum heat bath strongly influences the dynamics at short timescales, which is the regime in which quantum effects are most relevant.

DY 49.11 Thu 12:30 ZEU/0160

Active Magnetic Particles in Magnetic Gradient Fields — •Laris Berekovic, Margaret Rosenberg, and Hartmut Löwen — Heinrich-Heine University Düsseldorf, Universitätsstraße 1, 40225 Düsseldorf

Active particles are common in nature, underlying many complex phenomena. Since the motion of active particles has no intrinsic directionality, steering the particles' motion requires an additional control parameter, such as a magnetic interaction. In this contribution, we present an analysis of the effect of magnetic vortex fields created by a current carrying wire on the ground states and motion of active Brownian particles (ABP) carrying a fixed magnetic dipole moment. We present an analytical solution for the single-particle case, compute the ground state for multiple particles via simulated annealing in the passive case and explore the activity-induced phase transition created by increasing the self-propulsion. We find new forms in the ground state, as well as a rich variety of activity-induced structures. These results can be applied to ferrofluid systems, biophysical systems of magnetotactic bacteria or form the basis of more complex industrial applications.

DY 50: Focus Session: Controlling Microparticles and Biological Cells by Ultrasound (joint session BP/CPP/DY)

Recently ultrasound has emerged as a very promising physical modality to control the behavior of microparticles and even of biological cells, which can be moved and stimulated by sound waves. For biological cells, one can further control the effect of sound through gene expression (sonogenetics), similar to the control by light (optogenetics). However, because the wavelength of sound is much larger than the one of light, one of the challenges is to localize the effect of sound waves, e.g. by using gas bubbles. Here, we bring together experimental and theoretical researchers who currently explore the potential of ultrasound to control active and passive microsystems and to develop new applications ranging from biomedicine to soft robotics.

Remote Tipping in Networks — •Philip Marszal[1], Malte Schröder[1], and Marc Timme[1,2] — [1]Chair of Network Dynamics, Center for Advancing Electronics Dresden (cfaed) and Institute of Theoretical Physics, TUD Dresden University of Technology, 01062 Dresden, Germany — [2]Lakeside Labs, Lakeside B04b , 9020 Klagenfurt, Austria

Tipping of a single unit in a complex networked system can trigger large-scale cascades that shift the system's macroscopic state. Typically, such cascades propagate diffusively, with each tipping event destabilizing adjacent units.

Here we report a novel form of tipping cascade in systems of coupled bistable oscillators, that results in the tipping of non-adjacent nodes. One node can trigger transitions in distant nodes while intermediate neighbors remain unaffected. Which nodes tip and which ones remain unaffected depends intricately on the local oscillator dynamics and the underlying network structure. We study the transition between locally spreading and non-local cascades and characterize the conditions necessary for the emergence of non-local cascades.

DY 51.2 Thu 11:30 ZEU/0118

Ponderomotive Route to Tipping in Open Networks — Seungjae Lee[1], •Marisa Fischer[1], and Marc Timme[1,2,3] — [1]Chair for Network Dynamics, Institute of Theoretical Physics and Center for Advancing Electronics Dresden (cfaed), Technische Universität Dresden, 01062 Dresden, Germany — [2]Center Synergy of Systems, Technische Universität Dresden, 01062 Dresden, Germany — [3]Lakeside Labs, Lakeside B04b, 9020 Klagenfurt, Austria

External fluctuations impact the dynamics of complex networked systems, from cells and ecosystems to engineered infrastructures. Strong external forcing may cause tipping that compromises such systems' functionality. Here, we identify a generic ponderomotive route to tipping in open, periodically driven systems. Upon increasing the driving amplitude, the time-average of the oscillatory responses persistently shifts away from the original system's operating point – a system-level ponderomotive effect. We characterize the shift as the fixed-point solution of a slow dynamics resulting from a two-time-scale analysis. A bifurcation point of the shift defines the tipping point beyond which the system settles into another collective state, diverges gradually, or exhibits finite-time blow-up. The ponderomotive shift together with its bifurcation yields the novel type of *ponderomotive tipping*. It generically emerges across disparate systems from science and engineering and is independent of their diverse post-tipping dynamics.

Linear dynamics on infinite networks — •Bernd Michael Fernengel — HIFMB, Oldenburg, Germany

Linear evolutionary equations are often used to describe the time evolution of a physical system. Their solution operator can be written in an exponential form of exp(t A), with some generator A. When the generator is a finite dimensional matrix, we can interpret its time evolution as a hopping dynamics on a finite network, where the dynamics of the network can be transferred to the dynamics of the solution operator.

In order to study special types of solution operators for non-interacting systems of countable dimensions, we construct countable, infinitely large networks using the iterated Cartesian product of finite graphs, where the dynamics is known. We discuss the possibilities to infer properties like the time evolution and the stationary solution of the infinite network from finite approximations via the thermodynamic limit. This is closely related to the question, under which conditions it is possible to approximate a countable, infinite system by finite subsystems.

DY 51.4 Thu 12:00 ZEU/0118

Localizing sparse perturbation sources in driven nonlinear networks — •Julian Luca Fleck, Jose Casadiego, and Marc Timme — Chair of Network Dynamics, Center for Advancing Electronics Dresden (cfaed) and Institute of Theoretical Physics, TUD Dresden University of Technology, 01062 Dresden, Germany

Network dynamical systems under the influence of external perturbations abound in nature and engineered systems, ranging from neural circuits to electrical power grids. The external driving can drastically change the system's operating mode and be fatal for system stability. Localizing sources of perturbations in a network is crucial to mitigate systems failure. We present a linear response approach to infer the location from a multivariate time series of a recorded subset of nodes. We employ a compressed-sensing algorithm to locate one or multiple perturbation sources utilizing the sparsity of such locations. The approach additionally yields the time series of the unmeasured nodes and the external driving. We test for random linear systems, and illustrate the applicability to electrical power grids.

DY 51.5 Thu 12:15 ZEU/0118

Elucidating structure-function relationships in physical networks via ensnarlment — •Yu Tian[1,2,3,4], Chinmayi Subramanya[1,3,4], and Carl Modes[1,3,4] — [1]Center for Systems Biology Dresden, Dresden, Germany — [2]Max Planck Institute for the Physics of Complex Systems — [3]Max Planck Institute of Molecular Cell Biology and Genetics — [4]Dresden University of Technology, Dresden, Germany

Understanding physical networks – whose structure is constrained by the physical properties of their nodes and links – is a growing interdisciplinary challenge, especially in biological systems. Physical constraints such as volume exclusion and non-crossing conditions, along with biological functionality, can drive these networks into non-optimal spatial configurations. One prominent feature is that cycles may go through each other's interior space, which may not be unraveled without removing edges, leading to an ensnarled state. Characterizing the ensnarlment in the space, and its interplay with the functional behaviours of the network, is essential for revealing structure-function relationships in such systems. In this work, we introduce a graph-theoretic framework based on the linking operator, obtained by the Gauss linking integral applied to the cycles in the network. This approach enables a multiscale analysis of entanglement, spanning local, intermediate, and global structures. Our goal is to reveal how topological complexity shapes, and is shaped by, biological functions, providing new insights into the organizational principles of physical and biological networks.

DY 51.6 Thu 12:30 ZEU/0118

Transient stability properties for transitions between stationary power flows — •Leo Heidweiler[1,2] and Frank Hellmann[2] — [1]TU Dresden — [2]Potsdam Institute for Climate Impact Research

The increasing incorporation of renewable energy sources into electrical power grids fundamentally changes their dynamical behaviour and introduces new challenges for system stability. While network expansion and operation are traditionally based on stationary power flow analysis, dynamical effects following line faults, such as loss of synchronization of a single generator or whole part of the network, may occur even when a stable post-fault power flow exists and operational constraints are fulfilled. Direct assessment of transient stability, however, requires time-resolved simulations that are computationally expensive and unsuitable for large-scale planning and real-time applications. This motivates the question of whether transient stability properties can be inferred from static characteristics of the network, such as power flow solutions and topology.

In this work, we develop stability indicators for the IEEE39 Bus power system and investigate their predictability using PowerDynamics.jl, a Julia Library for numerical Power Grid simulations. In particular, we make use of the complex oscillator formulation of Power Systems and machine learning. This helps us assess whether stability margins can be predicted from stationary quantities alone or whether intrinsically dynamical information is indispensable. If so, we can deduce what minimal dynamical information is sufficient for reliable prediction.

DY 52: Statistical Physics of Biological Systems III (joint session BP/DY)

DY 52.1 Thu 15:00 BAR/SCHÖ

Efficiency of Droplet Formation and Dissolution by Chemical Reactions — •Gerrit Wellecke[1,2], Riccardo Rossetto[1,2], Jan Kirschbaum[1], and David Zwicker[1] — [1]Theory of Biological Fluids, Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany — [2]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Droplets formed by phase separation are vital for intracellular organization, and cells often control the formation and dissolution of these droplets through chemical reactions. To understand how cells can influence droplets in space and time, we consider a ternary system that exhibits a bistability between homogeneous and phase-separated states. We use a thermodynamically consistent approach to describe the diffusive and reactive dynamics, which allows us to quantify the energy dissipation and entropy production during transitions between these states. We find that reaction-controlled droplet formation and dissolution in the

bistable regime are fundamentally different processes. While droplet formation is generally aided by relaxation to equilibrium, we find that a droplet's size determines whether it is best dissolved internally or externally. Further, our model identifies plausible mechanisms by which cells may regulate their intracellular droplets, providing insights that could guide the development of synthetic soft matter systems with tunable droplet behaviour.

DY 52.2 Thu 15:15 BAR/SCHÖ

Size control and fluctuations of chemically active droplets — •Guido Kusters and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

Biological cells use liquid-liquid phase separation to dynamically compartmentalize their environment for various applications, many of which require size control. This process is challenging because (i) large droplets tend to grow at the expense of smaller ones, and (ii) thermal fluctuations can disturb droplets since cells are typically small and soft. Chemical reactions can, in principle, control droplet sizes, but there are no clear guidelines on how to robustly achieve size control. To provide guidelines, we consider a binary fluid model driven out of equilibrium by chemical reactions. We reveal two different classes of size-controlled droplets, depending on the ratio of droplet radius to the reaction-diffusion length. Moreover, we determine parameter regimes in which droplets become small. To study fluctuations in this case, we use fluctuation-dissipation arguments to predict the size fluctuations of size-controlled droplets, consistent with our numerical simulations. Taken together, our theory allows us to predict the chemical reactions necessary for maintaining small droplets, e.g., in biological cells or synthetic applications.

DY 52.3 Thu 15:30 BAR/SCHÖ

Anomalous diffusion and directed coalescence of condensates out of equilibrium — •Andriy Goychuk — Helmholtz Centre for Infection Research, Braunschweig, Germany — Lower Saxony Center for Artificial Intelligence and Causal Methods in Medicine, Hannover, Germany

Phase separation is ubiquitous in engineered and in biological systems. For example, biomolecular condensates contribute to the organization of the cytoplasm and nucleoplasm in cells. Here, I will first extend our understanding of textbook phase separation models by showing how condensates consisting of nonpolar molecules can effectively polarize and undergo coarsening by directed coalescence when subjected to a global drift, for example due to electrostatic potential gradients, chemical concentration gradients, or gravitation. Next, to better model the intracellular solution, I will incorporate viscoelastic stress propagation and nonequilibrium fluctuations. In this context, the Brownian motion of condensates has been barely explored despite being a cornerstone of statistical and colloidal Physics. If the active stresses, for example generated by molecular motors, have a different correlation time than the viscoelastic relaxation time of the solution, then the fluctuation-dissipation theorem is broken and the mixture is driven out of equilibrium. In this case, the size-dependence of the center-of-mass diffusion coefficient of the condensates can be either suppressed or enhanced, and the droplet can show superdiffusive motion. Together, these findings improve our understanding of the dynamics of domains in viscoelastic media and conserved order parameters in general.

DY 52.4 Thu 15:45 BAR/SCHÖ

A Minimal Theoretical Framework Linking Translation Activity to Stress-Induced Condensates — •Pascal S. Rogalla[1], Alessandro Barducci[1], and Luca Ciandrini[1,2] — [1]Centre de Biologie Structurale, Université de Montpellier, CNRS, INSERM, Montpellier, France. — [2]Institut Universitaire de France

The formation of intracellular membraneless organelles, such as stress-granule-like condensates formed via liquid-liquid phase separation (LLPS), is a common response to cellular stress. RNA, including mRNA, promotes the assembly of many of these condensates, while the resulting aggregation of mRNAs reduces their availability for translation and thereby modulates ribosome loading. This establishes a feedback loop between condensate formation and translational activity. Here we develop a minimal physical model that makes this coupling explicit by combining Flory-Huggins theory for LLPS with the Totally Asymmetric Simple Exclusion Process (TASEP) for ribosomal traffic on mRNAs. This hybrid framework provides a proof-of-principle description of how LLPS and translation dynamically influence one another. Our analysis reveals that the phase behaviour of both subsystems becomes mutually dependent: a low-occupancy ribosomal phase promotes mRNA aggregation, whereas a high-occupancy phase suppresses condensate formation. These results suggest that cells may regulate condensate formation through translation modulation and, conversely, that LLPS can reshape the translatome. This provides a first proof-of-principle framework for quantifying stress-induced reorganisation of the translational landscape.

DY 52.5 Thu 16:00 BAR/SCHÖ

Optimal sensing through phase separation — •Henry Alston[1], Mason Rouches[2], Arvind Murugan[2], Aleksandra Walczak[1], and Thierry Mora[1] — [1]Laboratoire de Physique, Ecole Normale Superieure — [2]The James Franck Institute & Department of Physics, The University of Chicago

Cells are constantly tasked with making accurate measurements of their surroundings. A paradigmatic example is the sensing of signalling molecule concentrations: the work of Berg and Purcell derived limits for the precision and speed of this sensing through ligand-receptor binding. However, recent experimental work has identified the formation of condensates (liquid droplets coexisting with the cell cytoplasm through phase separation) as a potential mechanism for selectively initiating downstream processes by effectively amplifying small concentration differences between competing signalling molecules. Using a minimal model for droplet nucleation and growth in a fluid mixture, we observe that phase separation can distinguish concentration differences of 1% in minutes, a significant improvement upon well-established pathways for precise concentration sensing.

DY 52.6 Thu 16:15 BAR/SCHÖ

Thermodynamics of DNA sequence recognition by a transcription factor — •Jonas Neipel[1,2,3], Anne Schwager[1], Yahor Savich[1,2,3], Douglas Diehl[1], Anthony A. Hyman[1], Frank Jülicher[2,3], and Stephan W. Grill[1,3] — [1]Max Planck Institute for Molecular Cell Biology and Genetics, Dresden Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden Germany — [3]Center for Systems Biology Dresden, Dresden, Germany

Transcription factors (TFs) are proteins that regulate the transcription of genes by binding to specific genomic positions defined by the DNA sequence. The sequence of preference of a TF is typically characterized by a single sequence motif that maximizes binding affinity. However, eukaryotic TFs bind to a spectrum of low affinity binding sites that vastly outnumber canonical motif sequences in the genome. Here, we develop an Ising model of DNA sequence recognition that yields quantitative prediction of TF binding energies across sequence space for the human TF KLF-4. The model is parametrized by in vitro experiments, where we quantify relative binding energies for various sequences in a competitive assay using fluorescence anisotropy. Strikingly, we find that the thus fully parametrized thermodynamic model quantitatively predicts KLF-4 occupancy across the human genome. Finally, we discuss how this genomic energy landscape guides the formation of TF condensates.

DY 52.7 Thu 16:45 BAR/SCHÖ

Kinetic inference of entropy production — •Ivan Di Trelizzi — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Nonequilibrium steady states, from planetary dynamics to biological processes, constantly dissipate energy to their environment, producing entropy at a constant rate. Quantifying this dissipation is key to understanding how far systems operate from equilibrium but remains experimentally challenging. I will present a new approach to infer entropy production directly from trajectory data, using measurable kinetic quantities known as traffic and inflow rate, without requiring knowledge of microscopic forces or fluxes. The method remains effective even under partial observation, providing a practical framework to quantify nonequilibrium behaviour in complex physical and biological systems.

DY 52.8 Thu 17:00 BAR/SCHÖ

Frequency-space trajectory Fisher Information to quantify sensitivity in complex living systems — •Zhiheng Wu[1] and Isabella Graf[1,2] — [1]European Molecular Biology Laboratory, Heidelberg, Germany — [2]Department of Physics and Astronomy, Heidelberg University, Heidelberg, Germany

Living systems sense their environment by stochastically mapping external signals onto internal states. For example, several animals including fruit flies and pit vipers encode small changes in the ambient temperature in terms of changes in the interspike time of neurons. The sensitivity of these measurements can be evaluated by the so-called Fisher information (rate). While living systems constantly adapt to changing environments, calculations of Fisher information have so far mostly focused on static signals and internal states. To evaluate measurement sensitivity in the non-static case, we evaluate the trajectory Fisher information and show that, under common assumptions, it can be expressed as an integral over frequency space involving the power spectral density. This expression provides a tractable way to quantify information in adaptive and complex biological systems and we discuss some interesting applications.

DY 52.9 Thu 17:15 BAR/SCHÖ

Ergodicity shapes inference in biological reactions driven by a latent trajectory — •Ricardo Martinez-Garcia[1], Benjamin Garcia de Figueiredo[2], Justin Calabrese[1], and William Fagan[3] — [1]CASUS-HZDR, Görlitz, Germany. — [2]Princeton University, Princeton NJ, USA. — [3]University of Maryland, College Park MD, USA.

Many natural phenomena, from intracellular reactions to predator-prey encounters, can be described as counts of events triggered at random intervals when an underlying dynamical system enters reactive regions of its phase space. These reactions control biological functions across scales, from cellular processes to ecosystem services and stability. We compute the exact distribution of inter-count times under the only assumption that the latent dynamical system is

Markovian and ergodic, recovering widely used Poisson statistics as a limiting case. These results limit what information about the latent process can be inferred from a local detector, which we explore in two biophysical scenarios. First, in estimating an animal's activity from detector crossings, we show that mean counts may fail to capture movement parameters, encoded in higher-order moments. Second, we show that the variance of inter-reaction times imposes a fundamental limit on how precisely detector measurements can infer the size of an ensemble of trajectories, generalizing the Berg-Purcell limit for chemosensation. Overall, we develop a flexible framework for quantifying inter-event time distributions in reaction-diffusion systems that shows which properties of latent processes are inferable from observed reactions.

DY 52.10 Thu 17:30 BAR/SCHÖ

Information Bottleneck in Gene Regulation — •Marianne Bauer — TU Delft

Biological systems need to process information in order to perform specific functions. In the context of gene regulation, regulatory regions process transcription factor signals in order for cells to differentiate towards correct fates. Previously, we have shown that the information bottleneck (IB) framework provides a useful framework for understanding regulatory binding site regions. Here, I will discuss two recent collaborative advances to provide an improved biological understanding from IB based predictions. First, using two complementary models for clustering transcription factors at binding site sensors, we can study information transfer during early fly embryo development with local transcription factor clustering. We find that weak cooperativity or clustering can allow for maximal information transfer, especially about the relevant variable, and that weak clustering also allows the binding site sensors to achieve optimality consistent with the IB bound. Second, we investigate how optimal activation changes when multiple binding site elements can process information, and find that activation profiles consistent with IB optimality resemble gene expression profiles in the early fly embryo.

DY 52.11 Thu 17:45 BAR/SCHÖ

Binary karyotypes are universally selected for across cancers — •Lucija Tomašić[1], Shane A. Fiorenza[1], Hajime Okada[2], Thomas W. van Ravesteyn[3], Uri Ben-David[2], Geert J.P.L. Kops[3], and Nenad Pavin[1] — [1]Univ. of Zagreb, Zagreb, Croatia — [2]Tel Aviv University, Tel Aviv, Israel — [3]Hubrecht Institute, Utrecht, the Netherlands

Aneuploidy, an abnormal chromosome number, is a defining feature of most cancers, yet its vast diversity has made it difficult to identify universal evolutionary rules. By analyzing over 90,000 patient-derived cancer karyotypes using a new visualization approach and mathematical modeling, we uncover a simple organizing principle. Across cancer types, and even in yeast, aneuploid genomes overwhelmingly assemble into "binary karyotypes" composed of only two chromosome copy numbers. Despite the enormous space of theoretically possible chromosome configurations, these states dominate patient data, comprising more than three-quarters of observed karyotypes. Our model shows that this pattern arises from a modest but consistent fitness advantage of binary karyotypes over more complex configurations. This principle also provides insight into how aneuploid cells withstand stress responses, as binary karyotypes exhibit lower rates of tumor suppressor gene inactivation. Together, our results identify binary karyotypes as a conserved evolutionary class of aneuploidy, governed by global organizational rules that may reveal shared vulnerabilities across cancers.

DY 52.12 Thu 18:00 BAR/SCHÖ

Inertial instability of blood in cross microchannels — •Joséphine Van Hulle and Christian Wagner — Experimental Physics, Saarland University, Germany

A localized reduction of vessel diameter (stenosis) increases the local blood flow speed and can trigger downstream recirculation which promotes conditions for the vessel blockage (thrombosis). The role of fluid elasticity in these flows remains underexplored. We isolate the extensional effects using cross-slot microfluidics, which creates an elongation plane with a well-defined inertial instability. By varying the hematocrit and plasma composition, we show that red blood cell deformability and plasma viscoelasticity lower the critical Reynolds number for the onset of vortex formation. These results highlight that even weak elastic stresses of blood can favor recirculation, a characteristic rarely modeled but necessary for physiologically realistic arterial simulations.

general framework for understanding and modeling irreversibility: relaxator Liouville dynamics — •Martin Janssen and Janos Hajdu — Institut für Theoretische Physik, Universität zu Köln, Zülpicher Str. 77, 50937 Köln, Germany

Irreversibility is explained as an emergent phenomenon brought about by a separation between two characteristic time scales: the time t_s up to which relevant degrees of freedom of a system are tracked is extremely much shorter than the spectral resolution time t_e necessary to resolve the spectrum of all degrees of freedom involved. A relaxator that breaks reversibility condenses in the Liouville operator of the relevant degrees of freedom. The irrelevant degrees of freedom act as an environment. The relaxator Liouville equation is a most general equation of motion in a many body quantum system and contains memory effects and initial correlations of all degrees of freedom, generalizing the well known semi-group dynamics. Stationary states turn out to be generically unique and independent of the initial conditions and exceptions are due to degeneracies. Equilibrium states lie in the relaxator's kernel yielding a stationary Pauli master equation and a non negative entropy production rate is identified. Kinetic equations for one-particle densities are constructed as special cases and Kubo's linear response theory is generalized to relaxator Liouville dynamics. In weak coupling between system and environment the relaxator can be factorized in environmental correlations and bilinear system operators.

DY 53.2 Thu 15:15 HÜL/S186

Ground-State Exploration Driven by Thermal and Quantum Fluctuations — •Yoshiaki Horiike[1] and Yuki Kawaguchi[1,2] — [1]Department of Applied Physics, Nagoya University, Nagoya, Japan — [2]Research Center for Crystalline Materials Engineering, Nagoya University, Nagoya, Japan

Simulated annealing provides a heuristic solution to combinatorial optimization problems. The cost function of a problem is mapped onto the energy function of a physical many-body system, and, by using thermal or quantum fluctuations, the system explores the state space to find the ground state, which may correspond to the optimal solution of the problem. Studies have highlighted both the similarities and differences between thermal and quantum fluctuations. Nevertheless, fundamental understanding of thermal and quantum annealing remains incomplete, making it unclear how quantum annealing outperforms thermal annealing. Here, we investigate the many-body dynamics of thermal and quantum annealing by examining all possible interaction networks of $\pm J$ Ising spin systems up to seven spins. Our comprehensive investigation reveals that differences between thermal and quantum annealing become prominent for particular interaction networks, indicating that the structure of the energy landscape distinguishes the two dynamics. We identify the microscopic origin of these differences through probability fluxes in state space, finding that the two dynamics are broadly similar but that quantum tunnelling produces qualitative differences. (arXiv:2511.16457)

DY 53.3 Thu 15:30 HÜL/S186

Symmetry re-breaking in an effective theory of quantum coarsening — •Federico Balducci[1], Anushya Chandran[2], and Roderich Moessner[1] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden — [2]Boston University, Boston, MA

We present a simple theory accounting for two central observations in a recent experiment on quantum coarsening and collective dynamics on a programmable quantum simulator [T. Manovitz et al., Nature 638, 86 (2025)]: an apparent speeding up of the coarsening process as the phase transition is approached; and persistent oscillations of the order parameter after quenches within the ordered phase. Our theory, based on the Hamiltonian structure of the equations of motion in the classical limit of the quantum model, finds a speeding up already deep within the ordered phase, with subsequent slowing down as the domain wall tension vanishes upon approaching the critical line. Further, the oscillations are captured within a mean-field treatment of the order parameter field. For quenches within the ordered phase, small spatially-varying fluctuations in the initial mean-field lead to a remarkable long-time effect, wherein the system dynamically destroys its long-range order and has to coarsen to re-establish it. We term this phenomenon symmetry re-breaking, as the resulting late-time magnetization can have a sign opposite to the initial magnetization.

DY 53.4 Thu 15:45 HÜL/S186

Pairing-induced phase transition in the non-reciprocal Kitaev chain — •Pietro Brighi and Andreas Nunnenkamp — Faculty of physics, University of Vienna, Boltzmanngasse 5, 1090, Vienna, Austria

Investigating the robustness of non-reciprocity in the presence of competing interactions is central to understanding non-reciprocal quantum matter. In this

work, we use reservoir engineering to induce non-reciprocal hopping and pairing in the fermionic Kitaev chain, and reveal the emergence of a pairing-induced phase transition. The two phases appear in the spectrum of the non-Hermitian Kitaev Hamiltonian describing the dynamics of correlations, separated by an exceptional point. In the non-reciprocal phase, dynamics are characterized by directionality and slow relaxation, and the steady state supports non-reciprocal density and spatial correlations. At strong pairing, we uncover an unexpected density wave phase, featuring short relaxation times, a modulation in particle occupation and strikingly different correlation spreading depending on pairing non-reciprocity. Our work highlights the non-trivial breakdown of non-reciprocity due to superconducting pairing and invites experimental investigation of non-reciprocal fermionic systems.

DY 53.5 Thu 16:00 HÜL/S186

Harnessing spin qubit decoherence to probe strongly interacting quantum systems — Marcin Płodzień[1], •Sambunath Das[2], Maciej Lewenstein[1,3], Christina Psaroudaki[4], and Katarzyna Roszak[2] — [1]Institut de Ciencies Fotoniques, The Barcelona Institute of Science and Technology, 08860 Castelldefels (Barcelona), Spain — [2]Institute of Physics of the Czech Academy of Sciences, Na Slovance 1999/2, 182 00 Prague, Czech Republic — [3]Passeig Lluis Companys 23, 08010 Barcelona, Spain — [4]Laboratoire de Physique de l' École Normale Supérieure, Université PSL, CNRS, Sorbonne Université, Université de Paris, 75005 Paris, France

Using a mobile qubit as a probe to study the properties of a larger quantum system is a novel technique that leverages the quantum nature of the probe, the system under study, and the interaction between them [1-3]. By analyzing qubit decoherence, one accesses to properties that are difficult to measure classically. We apply this method to the anisotropic Heisenberg XXZ spin-1/2 chain, an archetypal example of strongly correlated system, and show that qubit dynamics encode key system parameters, including quantum phase transitions and perturbation propagation velocity [4]. This demonstrates the effectiveness of small quantum probes for exploring large quantum systems.

DY 53.6 Thu 16:15 HÜL/S186

Enhancing efficiency of local-information time evolution — •Moksh Bhateja[1], Jonas Rigo[2], and Markus Schmitt[2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Universität Regensburg, Regensburg, Germany — [3]PGI-8: Forschungszentrum Jülich, Jülich, Germany

The time evolution of an initially unentangled system under the von Neumann equation generally leads to rapid entanglement growth. This poses challenges for numerical tractability. The Information Lattice framework addresses this by systematically discarding accumulated non-local information (i.e., entanglement) to maintain computational feasibility. Within the local-information time evolution (LITE) approach, we propose Rényi-2 entropy as a measure of information, eliminating the need for matrix decomposition. When combined with additional approximations, this approach significantly enhances the efficiency and scalability of simulations in terms of both system size and duration of time evolution. We demonstrate the accuracy of this method by computing high-quality diffusion coefficients and local observables for a large non-integrable system.

Fluctuating hydrodynamics of non-equilibrium interacting many-body systems — •Felipe Pereira-Alves and Aljaž Godec — Mathematical Physics and Stochastic Dynamics, Institute of Physics, University of Freiburg (GER)

Extending fluctuating hydrodynamics to non-equilibrium systems remains a significant theoretical challenge. In this work we investigate, on the level of distribution-valued fluctuating hydrodynamics, general short-range interacting systems as well as the long-range interacting Dyson process evolving from deterministic non-equilibrium initial conditions. We characterize the probability measure of the distribution-valued fluctuation field during the relaxation to equilibrium and illustrate the results on the example of discretely (in space) observed fluctuation field and compare the results to particle-resolved simulations.

DY 54.2 Thu 15:15 ZEU/0114

Non-ergodicity and breakdown of hydrodynamics in a one-dimensional cold gas — Taras Holovatch[1,2], Yuri Kozitsky[3], Krzysztof Pilorz[3], and •Yurij Holovatch[1,2,4,5] — [1]Yukhnovskii Institute for Condensed Matter Physics of the NAS of Ukraine, Lviv, Ukraine — [2]L4 Collaboration and Doctoral College for the Statistical Physics of Complex Systems, Lviv-Leipzig-Lorraine-Coventry, Europe — [3]Institute of Informatics and Mathematics, Maria Curie-Skłodowska University, Lublin, Poland — [4]Centre for Fluid and Complex Systems, Coventry University, Coventry, UK — [5]Complexity Science Hub, Vienna, Austria

We study dynamics of a 1D chain of elastically interacting particles with masses alternating between two different values, M,m,M,m,.. . Its dynamics is initiated by giving unit velocity in the positive direction to the particle located at the origin. For random particle positions, the resulting long-time behavior was found (S. Chakraborti et al., SciPost Phys. 2022, 13, 074) to posses rather remarkable features: (i) a shock front develops in the bulk of the gas and is governed by Euler hydrodynamics, (ii) the recoiled particles in the splatter move ballistically. In our study we have found (T. Holovatch et al., Phys. Rev. E 2025, 112, L052101) that for equidistant particle positions there exist mass ratios M/m for which (i) the splatter is absent; (ii) the number of simultaneously moving particles is at most three; (iii) the blast front moves in the ballistic way. We support our explicit calculations by MD simulations.

DY 54.3 Thu 15:30 ZEU/0114

Geometry-induced timescales in viscoelastic fluids — •Rupayan Saha[1], Niloyendu Roy[2], Debankur Das[1], Clemens Bechinger[2], and Matthias Krüger[1] — [1]Institute for Theoretical Physics, Georg-August-Universität Göttingen, Göttingen 37073, Germany — [2]Fachbereich Physik, Universität Konstanz, Konstanz 78457, Germany

Recoil experiments provide a powerful window into the non-Markovian properties of complex fluids, revealing memory effects that are usually obscured in conventional rheological measurements. While translational recoil of colloidal probes in viscoelastic media has been successfully modelled with **few distinct timescales**, orientational recoil exhibits an **unbounded** relaxation spectrum, manifested in the divergence of the recoil amplitude with increasing shear-time (t_{sh}) or system size (L). To resolve its physical origin, we design a **first-principles theoretical framework** rooted in the *geometric constraints of torsional flow*. Our model, based on concentric spherical shells, demonstrates that the orthogonality between angular momentum propagation and torsional stress storage generates **a radial scaling law for relaxation modes**. The theory thus establishes **geometry**—not material-complexity—as the primary candidate for engineering complex memory in soft matter. We finally elucidate why such *long relaxation times* have not been previously discovered through conventional rheology.

DY 54.4 Thu 15:45 ZEU/0114

Ion and Water Density Profiles in Nano-Confinement — •Haoyuan Quan, Maximilian Becker, Hanne Antila, and Roland Netz — Freie Universität Berlin, Berlin, Germany

Confined salt solutions are important in biology and in technical applications, such as environmentally friendly energy conversion, yet even basic trends of how ion and water densities change in confinement remain unclear. Using molecular dynamics simulations of graphene slits in equilibrium with bulk aqueous salt solutions, we determine concentration profiles of a variety of alkali-halide ion pairs as a function of slit width and bulk concentration. Using ion and water depletion lengths, which clearly reflect ion-specific effects, we construct a robust and thermodynamically consistent theory to describe water and ion concentrations in confined systems for varying slit widths and bulk salt concentrations.

DY 54.5 Thu 16:00 ZEU/0114

The electron transfer process at the electrode/electrolyte solution interface: A stochastic model and its Monte Carlo implementation — •Diego Veloza-Diaz[1], Friederike Schmid[1], Robinson Cortes-Huerto[2], Pietro Ballone[2], and Nancy C. Forero-Martinez[1] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz, Germany — [2]Max Planck Institute for Polymer Research, Germany

A kinetic model of the electron transfer at the electrode/electrolyte interface is developed, implemented in a Monte Carlo framework, and applied to simulate this process in idealised systems consisting of the primitive model of electrolyte limited by an impenetrable conducting surface. A charged, spherical interface surrounding an equally spherical sample of electrolyte is introduced to model a single-electrode system, providing a computational analogue to the conceptual half-cell picture widely used in electrochemistry. The electron transfer itself is described as a simple surface-hopping process underlying a first-order reaction corresponding to one of the coupled M/M+ and X*/X half-reactions. Then, electron transfer at the interface is combined with the self-diffusion of ions in the electrolyte, which supply reagents and disperse products, allowing the system to settle into a stationary non-equilibrium state. Simulations of the primitive model of an electrolyte in contact with a charged, impenetrable surface show that, after

a brief transient, the system sustains a steady current through the half-cell. Since the simulated interface is very idealised, strategies to overcome the limitations of the present model are outlined and briefly discussed.

DY 54.6 Thu 16:15 ZEU/0114

Fermion as a non-local particle-hole excitation — •Girish Setlur — Department of Physics, Indian Institute of Technology Guwahati

We show that the fermion, in the context of a system that comprises many such entities, which, by virtue of the Pauli exclusion principle, possesses a Fermi surface at zero temperature, may itself be thought of as a collection of non-local particle-hole excitations across this Fermi surface. This result is purely kinematical and completely general, not restricted to any specific dimension, and is applicable to both continuum and lattice systems. There is also no implication that it is applicable only to low-energy phenomena close to the Fermi surface. We are able to derive the full single-particle dynamical Green function of this fermion at finite temperature by viewing it as a collection of these non-local particle-hole excitations. The Green function of the fermion then manifests itself as a solution to a first-order differential equation in a parameter that controls the number of particle-hole pairs across the Fermi surface, and this equation itself reveals variable coefficients that may be identified with a Bose-Einstein distribution, implying that there is a sense in which the non-local particle-hole excitations have bosonic qualities while not being exact bosons at the level of operators. We also recall the definition of the non-local particle-hole operator that may be used to diagonalize the kinetic energy of free fermions of the sort mentioned above. Number-conserving products of creation and annihilation operators of fermions are expressible as a (rather complicated) combination of these non-local particle-hole operators.

Emergence of generic first-passage time distributions for large Markovian networks — •Julian B. Voits[1] and Ulrich S. Schwarz[1,2] — [1]Institute for Theoretical Physics, University of Heidelberg, Germany — [2]BioQuant-Center for Quantitative Biology, University of Heidelberg, Germany

In many situations of practical interest, for example for decision-making in biological systems, it is sufficient to characterize a stochastic process by the time at which a final, absorbing state is reached (first-passage time). A prominent example is kinetic proofreading, where cells achieve remarkably accurate decisions through non-equilibrium reaction cycles. Earlier work studying corresponding models observed that as the system size grows, the first-passage time distributions converged to one of two universal forms on the time scale of its mean: either quasi-deterministic (delta-like) or quasi-memoryless (exponential). Building on the graph-theoretical interpretation of first-passage processes, here we provide a unifying explanation for these universal limits based on the distribution of the eigenvalues of the generator matrix. Then, we derive general conditions under which the distribution converges to either the deterministic or exponential limit. We demonstrate the theory by applying it to a generic birth-death process and conclude by discussing illustrative cases where the simple limiting behavior does not hold, which contradicts the naive expectation that a forward bias is sufficient to lead to a deterministic outcome.

DY 54.8 Thu 17:00 ZEU/0114

Derivation of a multi-dimensional non-equilibrium generalized Langevin equation — •Benjamin Hery — Department of Physics, Freie Universität Berlin, 14195 Berlin, Germany

The Mori-Zwanzig formalism is a powerful theoretical framework for deriving generalized Langevin equations (GLEs) for observables of interest using evolution and projection operators. Using a multi-dimensional Mori projection operator, we derive a non-equilibrium Mori GLE for a multi-dimensional observable of interest $\vec{A}$ that consists in a Markovian force, a running integral over time of a non-Markovian friction force, and a orthogonal force that is often interpreted as a random force. We study the structure of the derived GLE in three limiting cases: when the components of $\vec{A}$ are uncorrelated, when the system is at equilibrium, and when both conditions happen at the same time. In particular, we highlight the presence of a contribution to the Markovian force that takes the form of an instantaneous friction force which only vanishes when the components of $\vec{A}$ are uncorrelated.

DY 54.9 Thu 17:15 ZEU/0114

Predicting Friction Modifications under Harmonic Confinement via Perturbative Mori Projections — •Felix Riesterer and Roland Netz — Department of Physics, Freie Universität Berlin, Germany

Previous studies have shown that external potentials can alter friction, yet a comprehensive theoretical explanation for this effect is still lacking. This issue is particularly relevant for enhanced sampling techniques, such as umbrella sampling, where applied biases can distort dynamical observables.

We present a theoretical framework based on perturbative projections within the Mori Generalized Langevin Equation (GLE). The approach provides an explicit first-order prediction of the friction correction due to an external potential using only unbiased simulations. Furthermore, it clarifies the conditions under which such corrections arise.

To validate the theory, we perform molecular dynamics simulations of a Lennard-Jones fluid (argon) confined in a harmonic potential of varying strength. The theoretical predictions capture the friction enhancement to first order in the potential stiffness. These results demonstrate how harmonic umbrella sampling can modify friction, highlighting the potential impact on the interpretation of dynamical quantities obtained from biased simulations.

DY 54.10 Thu 17:30 ZEU/0114

Perturbative projection of many-body systems with applications in enhanced sampling of biomolecules — •Joan Salas-Llabrés — Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany

Using a modification of the well-known Mori-Zwanzig projection operator formalism, a Generalized Langevin Equation (GLE) is derived for a general observable of interest that only depends on the phase space positions, from a many-body Hamiltonian in the presence of a constant linear external potential. In particular, the friction memory kernel is analytically computed, and via an operator perturbative expansion, it is expanded in terms of the external potential up to first order in the potential strength. We name this approach "perturbative projection", and it allows to see the effects that this bias can have on the effective dynamics of a reaction coordinate, in particular on its friction. To test the obtained analytical expression and thus compare to some order of approximation the change in friction with direct results, we choose the conformational dynamics of alanine nonapeptide in water, obtained via molecular dynamics simulations. The results show agreement over a range of bias strengths. This provides new insight into the effects of an external bias on the dynamics of a system of interest, pointing to its fundamental nature in the level of its Hamiltonian, and which in particular has important consequences for the analysis of results coming from enhanced sampling techniques.

DY 55: Focus Session: Emergent Transport in Active Systems (joint session DY/BP)

Collective motion and directed transport are hallmark phenomena of active matter, arising from the interplay of self-propulsion, interactions, and nonequilibrium fluctuations. Even in the absence of global biases, assemblies of active particles can exhibit spontaneous currents, self-organized chemotaxis, and rectified transport due to broken symmetries or nonlinear feedbacks. Directed transport often emerges in inhomogeneous environments, where variations in particle activity or interaction strength can bias motion and organization. Activity gradients represent a particularly relevant example, providing a tunable mechanism to steer collective motion and pattern formation. These processes link microscopic activity to macroscopic material behavior and transport. This focus session aims to bring together theorists and experimentalists working on the fundamental mechanisms and control of emergent transport in active systems.

Out-of-equlibrium synthetic cells: the future of active matter — •Laura Alvarez — Univ. Bordeaux, CNRS, CRPP, UMR 5031

Colloidal active swimmers are broadly used as model systems to design microswimmers, yet their rigid and solid architecture limits their adaptability and functionality. A promising alternative is using bioinspired soft compartments

for the design of cell-mimetic functional architectures while avoiding the complexity of living cells.

Here, I will showcase our latest results on driving giant unilamellar vesicles (GUVs) out of equilibrium via controlled external actuation to mimic and study life-like processes. We fabricate phase-separated Janus lipid vesicles, harnessing membrane fluidity to obtain reconfigurable motion. Under external electric fields, these asymmetric compartments self-propel and display transient run-and-tumble-like dynamics arising from the coupling between mobile membrane domains and the field. By tuning lipid composition and using temperature as an external trigger, we modulate membrane fluidity and phase separation, enabling in situ control over the frequency of tumble events. Beyond motility, we exploit electric fields to induce controlled shape transformations and vesicle division events, showing that the same actuating scheme can access higher-order cell-like functions. In parallel, we use light to drive strong, localized membrane fluctuations, providing a route to study active, non-thermal shape dynamics in soft compartments. These results highlight synthetic cell membranes as versatile platforms in which different functions can be triggered using simple external fields.

DY 55.2 Thu 15:30 ZEU/0160

Biohybrid active matter: active cargo transport by motile cells — Jan Albrecht[1], Lara S. Dautzenberg[1], Manfred Opper[2], Carsten Beta[1], and •Robert Grossmann[1] — [1]University of Potsdam, Potsdam, Germany — [2]Technical University Berlin, Berlin, Germany

We describe the transport of polystyrene beads whose motion is actively driven by cells via direct mechanical contact. We will first discuss the stochastic dynamics of a single cell-cargo pair, focusing on the existence of an optimal cargo size that enhances the diffusion of the load-carrying cells, and estimate the active forces exerted by cells to move colloids. Furthermore, we present the collective transport of these micron-sized particles on a monolayer of motile cells. The colloids' mean-square displacement shows a crossover from superdiffusive to normal-diffusive dynamics. The particle displacement distribution is, however, distinctly non-Gaussian even at macroscopic timescales exceeding the measurement time. We attribute the non-Gaussian statistics to heterogeneity and non-stationarity of the dynamics, and particularly apply a likelihood-based inference framework to estimate the heterogeneity of the bead dynamics from their discretely sampled trajectories. We showcase how this approach can deal with information-scarce situations and provides natural uncertainty bounds for heterogeneity estimates. Similar transport properties are expected for many composite active matter systems. These results thus provide the basis for the future design of cellular microcarriers and for more advanced transport tasks in complex, disordered environments, e.g. tissues.

Chemotactic like behavior in by active Brownian particles: from single particles to to polymers — •Hidde Vuijk — University of Augsburg, Universitätsstraße 1, 86159, Augsburg, Germanz

Active Brownian particles can be used as simplified models for microscopic, motile organisms. This research investigates the behavior of such self-propelled objects in spatial gradients of activity, where their self-propulsion speed varies with position. A single active particle tends to accumulate in low-activity regions. When activity is assumed to be proportional to fuel, this corresponds to antichemotactic like behavior. We demonstrate how this behavior can be reversed by structuring particles into simple complexes. For example, by connecting active particles to passive cargo or linking them into chains, we predict a crossover from accumulation in low-activity regions to accumulation in high-activity regions, that is chemotaxic like behavior. These active dimers and polymers can autonomously move up an activity gradient, accumulating where the fuel concentration is highest. This emergent gradient-sensing arises from the physical interactions, offering a novel mechanism for the design of active matter and providing insight into how primitive life forms without complex information processing might have located nutrients.

DY 55.4 Thu 16:15 ZEU/0160

Fluctuation-induced transition in transport of active colloidal cells — •Shashank Ravichandir[1,2], Jens-Uwe Sommer[1,2], and Abhinav Sharma[1,3] — [1]Leibniz Institute of Polymer Research, Dresden, Germany — [2]Technical University Dresden, Dresden, Germany — [3]University of Augsburg, Augsburg, Germany

The transport of active-passive assemblies and their self-localization behavior have been studied in some detail in recent years [1,2]. The "chemotactic" property these exhibit has been attributed to the separation of time scales, i.e between the persistence time of the active particle and the characteristic time scale associated with the interaction between the particles (ex - harmonic springs). We consider a gas of active particles enclosed in a circular vesicle and observe that the transport behavior of the vesicle depends on the density of the enclosed gas or the number of active particles. This is a new mechanism for achieving desired transport of active colloidal cells as no new timescales are introduced by changing the number of active particles. This transition in transport behavior of these vesicles seems to be driven by fluctuations. The proposed model is also experimentally reproducible, contrary to the active-passive assemblies that have been studied so far.

From non-reciprocal torques towards shape-flexible and res-ponsive prototypic worms — •Holger Stark and Jeanine Shea — Institute of Physics and Astronomy, Theoretical Physics, Techni-sche Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Non-reciprocal interactions as seen in active matter allow the formation of novel collective states that are only observable in the non-equilibrium. They may serve as prototypes for mimicking what is observed in the real world or for guiding robotic applications.

We start from non-reciprocal orientational interactions, where an active Brownian particle turns away from its neighbors [1]. By varying range and strength of the torque, we discover novel states such as travelling bands or dynamic flocking. Reversing the sign, makes the orientational interaction cohesive. We combine it with aligning torques and again for varying range and torque strength observe multiple, rotary, and persistent worms as well as an aster state [2]. In particular, the persistent worm represents a prototype for a flock of active constituents, either natural or robotic, which shows a remarkable flexibility and integrity when performing shape changes. This becomes obvious when hunting a prey, which leaders inside the worm sense via some chemotactic mechanism. In contrast to the macroscopic world, here without inertia, moving on a straight line seems the best strategy to escape. We also observe that the worm stays intact, even when squeezing through a narrow, long pore.

DY 55.6 Thu 17:15 ZEU/0160

Directed motion of active collectives in activity gradients — •Hossein Vahid[1], Jens-Uwe Sommer[1,2], and Abhinav Sharma[1,3] — [1]Leibniz-Institut für Polymerforschung Dresden, 01069 Dresden, Germany — [2]Technische Universität Dresden, 01069 Dresden, Germany — [3]Institute of Physics, University of Augsburg, Universitätsstraße 1, 86159 Augsburg, Germany

Directed motion appears across all scales of active matter, from biomolecular condensates inside cells to large assemblies of migrating filaments. By simulating active particles and polymers, we identified the mechanisms that enable activity gradients to steer these collectives and control their assembly [1,2]. In cohesive mixtures, droplets climb activity gradients, fragment when the activity becomes too intense, and reassemble in low activity regions. This creates a robust cycle of positioning without needing any biochemical feedback. Similarly, in assemblies of active polar polymers, spatial gradients in activity, combined with temporally stochastic propulsion, generate net body forces on dimers, asters, and multiarm structures. This biases their motion toward high-activity regions and stabilizes long-lived entangled clusters even at low concentrations.

Activity hallmarks in kinetic theory: Exceptional Points, Disorder Regularization, Non-Reciprocal Orientation-Displacement Coupling — •Horst-Holger Boltz and Thomas Ihle — University Greifswald, Institute for Physics, Greifswald

The dynamics of active systems are not subject to the same constraints as that of passive classical systems. This is particularly true for self-propelled particles with alignment interactions that have orientation-displacement coupling, i.e. the alignment is dependent on the relative position of the interacting particles to each other. We present recent work within first-principle kinetic theory that highlights key hallmarks of these more generalized dynamics. In particular, we discuss the effect of a cascade of exceptional points in the relevant dynamical operators under finite noise and also how to generally include noise in collision-based kinetic theory beyond mean-field. This allows us to provide analytical insights into the numerically established scaling relations (Kürsten, 2025) underlying the critical exponents in flocking transitions. Also, we are going to explain how to derive a systematic mesoscopic description for aligning self-propelled particles with orientation-displacement coupling and will present results showing a flocking transition in a system of a single species with purely anti-aligning torques and without any forces, simplifying an earlier reported flocking by turning-away mechanism (Das et al, 2024).

DY 55.8 Thu 17:45 ZEU/0160

Rouse Polymers in Time-dependent Nonequilibrium Baths — •Bhavesh Valecha[1] and Abhinav Sharma[1,2] — [1]Mathematisch-Naturwissenschaftlich-Technische Fakultät, Institut für Physik, Universität Augsbur, Augsburg, Germany — [2]Leibniz-Institut für Polymerforschung Dresden, Institut Theory der Polymere, Dresden, Germany

Directed transport is a characteristic feature of numerous biological systems in response to nutrient and chemical gradients. These signals are often time-dependent owing to the high complexity of interactions in these systems. In this study, we focus on the steady-state behavior of polymeric systems responding to such time varying signals. We model them as ideal Rouse chains submerged in a time-dependent and inhomogeneous nonequilibrium bath, which is described by a spatially and temporally varying self-propulsion wave field experienced by the monomer units. Through a coarse-graining analysis, we show that these chains display rich emergent response to the temporal stimuli as a function of their length and topology. In particular, for slow moving waves, short chains composed of up to 3 monomers drift against self-propulsion wave, whereas, longer chains drift in the direction of the wave. In contrast, for fast moving waves, all chains drift along the wave regardless of their length. Moreover, we find that the star topology displays the highest drift for both slow and fast moving waves. We confirm these analytical predictions with robust numerical simulations, showing that response of polymeric systems to temporal stimuli can be controlled by the topology or the length of the polymer.

Swimming in complex environments — •Christina Kurzthaler — Max Planck Institute for the Physics of Complex Systems

Microorganisms are omnipresent in the ocean, the human body, and our soils and therefore play an important role for various geological, biological, and medical processes. To optimize their survival and perform biological functions many microorganisms convert chemical energy into directed motion. In this talk, I will illustrate the underlying physical concepts and show concrete examples of our research, focusing on the interactions of microorganisms with their complex habitats. I will first discuss the motion of sperm in complex fluids and address their emergent dynamics in the presence of a hyperactivation agonist, modifying the sperm beating pattern. Second, I will focus on the first-passage-time statistics of active agents moving towards a target boundary. Our results highlight how swim gait impacts spreading and search efficiency in active systems with potential consequences for sperm motion in the reproductive tract and the accumulation of microbial communities.

DY 57.2 Fri 10:00 BAR/SCHÖ

Motor shot noise explains active fluctuations in a single cilium — •Maximilian Kotz[1], Veikko F. Geyer[2], and Benjamin M. Friedrich[1] — [1]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany — [2]B CUBE, TU Dresden, Dresden, Germany

Molecular motors drive seemingly regular motion, making living matter move - yet also cause non-equilibrium fluctuations that can serve as a probe of internal motor dynamics. Here, we use motile cilia as a model system to investigate how small-number fluctuations shape collective dynamics. Motile cilia exhibit regular bending waves; this motion is driven by the self-coordinated activity of thousands of molecular motors inside the cilia's cytoskeletal core. By developing, to the best of our knowledge, the first stochastic model of cilia beating, we show that the finite number of motors leads to active fluctuations on the mesoscale, sufficient to explain frequency jitter in beating cilia observed in experimental data. We rigorously compare observables of this model, including the quality factor of the oscillation, to experimental data in which motors have been partially extracted from cilia. This is a strong test of this stochastic model. The model also reproduces other phenomena of experimental data, like correlation lengths of intra-cilium synchronization and noise-induced phase slips. We propose that active fluctuations are important new observables, which can guide theoretical models of motor dynamics in beating cilia and other motor systems.

DY 57.3 Fri 10:15 BAR/SCHÖ

Theory of Forces Between Crosslinked Filaments — •Cedrik Barutel and Sebastian Fürthauer — Institute of Applied Physics TU Wien Austria

The cytoskeleton drives essential cellular processes like cell division and chromosome segregation. It consists of filaments that are crosslinked by proteins, many of which are molecular scale motors that consume ATP to do work. The forces that crosslinking proteins generate between cytoskeletal filaments are the key drivers of active cellular mechanics. We derive a generic theory to describe such crosslinking forces.

We construct a theory to describe and predict the forces generated collectively by crosslinking proteins between biofilaments using symmetries, conservation laws, and out-of equilibrium thermodynamic principles. Our approach identifies the full set of phenomenological coefficients governing entropic, active, and frictional crosslinking forces, which allows a quantitative comparison between the effects of different crosslinker mixtures between two filaments. We demonstrate the power and validity of this framework by quantitatively explaining a set of different experimental setups, which combine the effects of passive and active crosslinks

DY 57.4 Fri 10:30 BAR/SCHÖ

Modeling Cooperative Remodeling and Energy Landscapes in the Bacterial Flagellar Motor — •Nils-Ole Walliser — Laboratoire Charles Coulomb, University of Montpellier, Montpellier, France

Bacteria use the flagellar motor to adapt their motility to changing mechanical conditions. This rotary motor tunes its torque by recruiting and releasing torque-generating stator units. I will present statistical-physics-based models that use single-motor measurements to infer interaction potentials and energy landscapes in the bacterial flagellar motor. First, using single-motor bead assays that resolve stepwise changes in rotation speed and thus stator occupancy, we model stator recruitment as a finite-size lattice gas and infer stator-stator cooperativity from occupancy fluctuations. This reveals moderate attractive interactions and shows that the motor operates in a regime that balances responsiveness to load changes with noise in stator number. Second, I will discuss experiments where the motor load is actively perturbed, uncovering a strong asymmetry in the relaxation to the steady state when starting from higher versus lower stator occupancy. A two-state catch-bond model quantitatively explains this stoichiometry-dependent asymmetry and captures the mechanosensitive nature of stator anchoring to the cell wall. Finally, I will show how high-temporal-resolution rotation traces can be used to reconstruct, in a model-independent way, the tilted periodic energy landscape of the rotor/LP ring within a Smoluchowski framework, yielding barrier heights, torque and internal friction.

DY 57.5 Fri 10:45 BAR/SCHÖ

Anisotropic (sub)diffusion of organelles in living cells — •Aranyak Sarkar, Pooja Yadav, and Matthias Weiss — Experimental Physics I, University of Bayreuth, Universitätsstraße 30, 95447 Bayreuth

Eukaryotic cells are neatly organized into distinct, membrane-enclosed compartments ('organelles') with specific duties. A prominent example are peroxisomes, which feature vesicle-like shapes with radii $0.1 - 1\ \mu$m that are dispersed across the cytoplasm. Using time-lapse fluorescence microscopy, we have tracked the motion of individual peroxisomes over extended periods. Analysis of the experimental data revealed two distinct modes of motion: a prevailing (sub)diffusive motion and a quite rare super-diffusive characteristics that is associated with motor-driven transport along microtubules. Focussing on the seemingly unremarkable subset of (sub)diffusive trajectories, we have found a significant anisotropy in the motion that persisted even when microtubules were disrupted. In particular, diffusive steps along the cells' long axis were seen to be favored over steps in the perpendicular direction, indicating an anisotropic materials characteristic of the cytoplasm. Using a simple model, we were able to capture and explain the observed features of the anisotropic diffusion of organelles.

DY 57.6 Fri 11:15 BAR/SCHÖ

Understanding Influenza A Virus particles detaching from reconstructed cell surfaces — •Thomas Kolbe[1,2], Pierre Gaspard[1], and Bortolo Matteo Mognetti[1,2] — [1]CENOLI, Université Libre de Bruxelles (ULB) — [2]IB2 - Interuniversity Institute of Bioinformatics in Brussels

Influenza infection is a multistage process that involves the trafficking of viral particles across the cell membrane. Before endocytosis, virions target the membrane by binding hemagglutinin ligands to sialic acid residues on cell receptors. After budding, neuraminidase cleaves these residues, enabling virions to detach from the infected cell surface.

We examine detachment dynamics through simulations and theoretical analysis. We explain experimental findings showing that the time required for virions to detach can decrease as the single-trajectory average number of bonds increases - a counterintuitive result specific to neuraminidase activity. Furthermore, we demonstrate that the detachment time is not governed by a Poisson distribution but depends on multiple factors, including ligand-receptor reaction rates, virion size, and receptor diffusion constant. These results clarify how biochemical parameters regulate the residence time of virions at the cell surface.

DY 57.7 Fri 11:30 BAR/SCHÖ

Band pattern formation of erythrocytes in density gradients is due to competing aggregation and net buoyancy — •Felix Maurer[1], Camila Romero[1], Nikolas Lerch[1], Thomas John[1], Lars Kaestner[1,2], Christian Wagner[1,3], and Alexis Darras[1,4] — [1]Experimental Physics, Saarland University, Saarbruecken, Germany — [2]Department of Theoretical Medicine and Biosciences, Saarland University, Homburg, Germany — [3]Physics and Materials Science Research Unit, University of Luxembourg, Luxembourg — [4]School of Physics, University of Bristol, Bristol, United Kingdom

Centrifugation of biological matter in density gradient solutions is a standard method for separating cell types or components. It is also used to separate RBCs by age, as they lose water and become denser over their lifespan. When the density gradient is prepared with Percoll, discrete bands of RBCs are systematically observed, despite the continuous density distribution of RBCs. We developed a continuity equation incorporating cell aggregation to describe the macroscopic evolution of RBC volume fraction in a density gradient, considering a continuous RBC density distribution. Numerical solutions demonstrate that the competition between net buoyancy and aggregation is sufficient to create band patterns. Our model reproduces the temporal evolution observed in experiments, but also predicts several types of bifurcation-like behaviors for the steady-state patterns in constant gradients, depending on RBC volume fraction and aggregation energy.

DY 57.8 Fri 11:45 BAR/SCHÖ

Adaptive self-organization in excitable biological collectives — •Bianca Ariani[1,3], Yunus Sevinchan[2,3], and Pawel Romanczuk[2,3] — [1]Bernstein Center for Computational Neuroscience, Berlin — [2]Science of Intelligence, TU Berlin — [3]Institute for Theoretical Biology, HU Berlin

Biological collectives often display complex, context-dependent behavior, such as coordinated responses to predators, despite individuals following simple local rules. This class of phenomena is broadly understood as self-organization.

We examine a system showing rich spatio-temporal dynamics: Sulphur Mollies, Mexican freshwater fish whose group behavior resembles a stochastic excitable medium. To probe the mechanisms behind their collective activity, we study a bio-inspired agent-based model in which individuals estimate the shoal's mesoscale activity from the cues they perceive as they move. Each agent adjusts its sensitivity to cues through a simple homeostatic plasticity rule, allowing the group to regulate its collective state. This formulation links individual adaptation to population-level patterns.

Our results show that local adaptive regulation reproduces key qualitative features of the biological system. More generally, they illustrate how distributed plasticity mechanisms can support robust self-organization in complex biological collectives.

DY 57.9 Fri 12:00 BAR/SCHÖ

Visual-based Collective Shepherding in Swarm Robotic System — •Yating Zheng[1,2] and Pawel Romanczuk[1,2] — [1]Department of Biology, Humboldt Universität zu Berlin, Berlin, Germany — [2]Research Cluster of Excellence 'Science of Intelligence', Berlin, Germany

Collective shepherding presents a rich example of two interacting multi-agent systems coupled through non-reciprocal interactions. While most existing models assume that shepherd agents have global knowledge of the flock-an unrealistic premise for physical or biological systems-we introduce a vision-based, locally interacting model that captures the essential physics of shepherd-flock coordination. The model produces robust, self-organized behavior among shepherds without explicit communication, and we analyze how key control parameters, such as flock size and the number of shepherds, shape the resulting dynamics.

The framework also performs effectively in more challenging regimes, including the manipulation of non-cohesive agents and passive (non-self-propelled) agents, demonstrating its broad dynamical applicability. We further validate the model on a mixed-reality swarm-robotic platform, where physical robots successfully shepherd a virtual flock.

Overall, these results provide a minimal yet powerful physics-based description of multi-agent herding using only local visual information, offering insight into non-reciprocal collective behavior and enabling scalable real-world implementations in swarm robotics.

DY 57.10 Fri 12:15 BAR/SCHÖ

Polymer theory shows DNA motors extrude loops in the monomeric mode — Kirill Polovnikov[1,2] and •Dmitry Starkov[2] — [1]Institute for Physics and Astronomy, University of Potsdam, Potsdam-Golm, Germany — [2]Moscow, Russia

Cohesin-dependent loop extrusion is a key active mechanism of DNA organization, yet it remains unclear whether chromatin loops in living cells are generated primarily by individual cohesin motors or by higher-order structures. To fill this major gap, we build an analytical polymer-physics model that extracts a missing parameter - *the linear density of loops* - directly from Hi-C data. We focus on short genomic distances, where contact statistics simplify, resulting in a perturbative expression for the contact probability of a looped chain under a finite contact-detection radius. Our theory recapitulates a characteristic dip in the *logarithmic derivative* of the contact-probability that is *broadly observed in experiments*. By fitting this minimal model to a diverse range of mammalian Hi-C datasets, we infer approximately six loops per megabase. Independent imaging and mass spectrometry measurements of cohesin density are consistent with our inferred loop density, supporting the monomeric mode of DNA motors extrusion.

DY 57.11 Fri 12:30 BAR/SCHÖ

Universal loop statistics from active extrusion — •Anastasia Chervinskaya[1] and Kirill Polovnikov[1,2] — [1]Moscow, Russia — [2]Institute for Physics and Astronomy, University of Potsdam, Potsdam-Golm, Germany

Cohesin-dependent loop extrusion is a key active mechanism of genome organization, yet quantitative links between extrusion kinetics and measurable loop statistics remain incomplete. We develop an analytical model that predicts the mean loop scale, full loop-length distributions, state composition, and arm-arm correlations for one-sided versus two-sided extrusion. The theory maps the master equations onto diffusion on a state graph yielding state-resolved loop-length PDFs.

We show that one-sided extrusion yields a universal exponential loop-length distribution, whereas two-sided extrusion generates a sum of exponentials that approaches a gamma-like form at high barrier density. The model also predicts a strictly positive lower bound of 1/4 on arm-arm correlations.

Parameterized with independent measurements for HeLa G1 (cohesin residence and spacing; barrier densities and lifetimes), our model quantitatively accounts for the observed loop size. Also, it reproduces the experimentally measured distribution of CTCF-CTCF loop lengths under the assumption of two-sided extrusion, providing additional evidence that cohesin extrusion in living cells is predominantly bidirectional. Our results provide a compact route to infer biophysical parameters of active extrusion from experimental data.

Invited Talk DY 58.1 Fri 9:30 GÖR/0226

What can we learn from neural quantum states? — Brandon Barton[10], Juan Carrasquilla[10], Anna Dawid[9], Antoine Georges[3,6,7,8], Megan Schuyler Moss[1,2], Alev Orfi[3,4], Christopher Roth[3], Dries Sels[3,4], Anirvan Sengupta[3,5], and •Agnes Valenti[3] — [1]Perimeter Institute for Theoretical Physics, Waterloo — [2]University of Waterloo, Waterloo — [3]Flatiron Institute, New York — [4]New York University, New York — [5]Rutgers University, New Jersey — [6]Collège de France, Paris — [7]École Polytechnique, Paris — [8]Université de Genève, Genève — [9]Universiteit Leiden, The Netherlands — [10]ETH Zürich, Switzerland

Neural quantum states (NQS) provide flexible parameterizations of quantum many-body wave-functions that serve as powerful tools for the ground-state search. At the same time, NQS offer something that standard machine-learning tasks and datasets fundamentally lack: a known underlying Hamiltonian and

quantum-physics tools that allow direct examination of the encoded wavefunction. This additional structure makes NQS an interesting platform for probing the behavior of classical neural networks themselves. I will first show how pruning and scaling-law phenomena change when the learning task is the quantum wavefunction itself, and link effects depend on the underlying Hamiltonian. I will then discuss generalization and double descent through the lens of quantum observables, by analyzing how NQS fail at the interpolation threshold. Finally, I will discuss how these results relate back to practical consequences for training and architecture search in the context of the ground state search for quantum many-body systems.

DY 58.2 Fri 10:00 GÖR/0226

The NN/QFT correspondence — •Ro Jefferson — Utrecht University

Exciting progress has recently been made in the study of neural networks by applying ideas and techniques from theoretical physics. In this talk, I will discuss a precise relation between quantum field theory and deep neural networks, the NN/QFT correspondence. In particular, I will go beyond the level of analogy by explicitly constructing the QFT corresponding to a class of networks encompassing both vanilla feedforward and recurrent architectures. The resulting theory closely resembles the well-studied O(N) vector model, in which the variance of the weight initializations plays the role of the 't Hooft coupling. In this framework, the Gaussian process approximation used in machine learning corresponds to a free field theory, and finite-width effects can be computed perturbatively in the ratio of depth to width, T/N. These provide corrections to the correlation length that controls the depth to which information can propagate through the network, and thereby sets the scale at which such networks are trainable by gradient descent. If time permits, I will discuss more recent work incorporating layerwise permutation symmetry. This analysis provides a non-perturbative description of networks at initialization, and opens several interesting avenues to the study of criticality in these models.

DY 58.3 Fri 10:15 GÖR/0226

Online Learning Dynamics and Neural Scaling Laws for a Perceptron Classification Problem — •Yoon Thelge, Marcel Kuhn, and Bernd Rosenow — Institute for Theoretical Physics, University of Leipzig, 04103 Leipzig, Germany

Understanding neural scaling laws and emergence of power law generalisations remains a central challenge in learning dynamics. A natural setting for analysing this behaviour is the online-learning dynamics of a perceptron trained in a teacher*student scenario, where in the thermodynamic limit, the generalisation error exhibits characteristic power-law decay. In realistic classification problems, the teacher is a discrete classifier, while standard gradient-based training requires the student to have continuous outputs. Thus, in practically relevant settings the student is necessarily mismatched to the discrete teacher, a regime that is less well understood. We study this regime for a perceptron with a sign-activation teacher and an error-function student. We derive coupled differential equations for the evolution of the relevant order parameters and verify them via numerical integration and SGD simulations. For fixed learning rates, the generalisation error converges to zero as a power-law with respect to the number of training examples with an exponent of -1/3. The onset of this asymptotic regime shifts with the learning rate, and the generalisation at the onset scales with exponent -1/2, motivating the use of learning-rate schedules to enhance the effective asymptotic decay.

DY 58.4 Fri 10:30 GÖR/0226

Power-Law Correlations in Language: Criticality vs. Hierarchical Generative Structure — •Marcel Kühn[1,2], Max Staats[1,2], and Bernd Rosenow[2] — [1]ScaDS.AI Dresden/Leipzig, Germany — [2]Institute for Theoretical Physics, University of Leipzig, 04103 Leipzig, Germany

Natural language shows power-laws beyond Zipf: the mutual information between words as a function of separation — a two-point correlation — decays approximately as a power-law, a constraint for predictive language models. In autoregressive architectures like transformers, the softmax temperature of the output controls how sharply next-word probabilities concentrate, acting as a thermodynamic knob that might tune correlations. Since phase transitions are a well-known mechanism that generate such scale-free correlations, we ask whether the observed power-law mutual information requires tuning to a critical softmax temperature. Analyzing a Markov (bigram) model, we show that, in a large-system limit, power-law mutual information emerges only at a fine-tuned critical temperature, below correlations decay exponentially. Motivated by the fact that faithful language models must go beyond bigrams and that hierarchical generative processes introducing long range interactions are more representative, we analyze an autoregressive model that perfectly emulates a specific probabilistic context-free grammar. We demonstrate that simple versions of this model preserve power-law mutual information without temperature fine-tuning, and we discuss the generality of this result for variants of the model in which deviations from the grammatical rules may occur.

DY 58.5 Fri 10:45 GÖR/0226

Dynamics of neural scaling laws in random feature regression — •Jakob Kramp[1,2], Javed Lindner[1,2], and Moritz Helias[1,2] — [1]Institute for Advanced Simulation (IAS-6), Computational and Systems Neuroscience, Jülich Research Centre, Jülich, Germany — [2]Department of Physics, RWTH Aachen University, Aachen, Germany

Training large neural networks reveals signs of universality that hold across architectures. This holds also for overparameterized networks which converge to effective descriptions in terms of Gaussian process regression. Those simplified models, already show one ingredient of universality in form of neural scaling laws. An important ingredient are power-law distributed principal component spectra of the training data.

Past work has therefore studied the dynamics of deterministic gradient flow in linear regression with and without consideration of power-law distributed spectra. Previously, dynamics of gradient flow with power law data in a type of linear random feature model were able to mimic effects of feature learning. Our work differs from the former by presenting an approach that holds for Bayesian inference on Gaussian processes obtained by stochastic Langevin training as well as for deterministic gradient flow with or without regularization by weight decay. We obtain interpretability from an effective mean-field theory that requires fewer order parameters than previous works.

Invited Talk DY 58.6 Fri 11:15 GÖR/0226

Creativity in generative AI — •matthieu wyart — JHU & EPFL

Is AI creative? Generative AI such as chatGPT or diffusion models can create new texts or images from a finite training set of examples. I will argue that AI can achieve this magical by learning how compose observed low-level elements into a new whole. I will discuss the type of correlations the model can exploit to do so, how many data are needed for that, and how it relates to a hierarchical construction of latent variables. The analysis is based on the introduction of synthetic languages, and comparison with experiments performed on modern AI architectures trained on real text and images.

DY 58.7 Fri 11:45 GÖR/0226

Understanding Generative Models via Interactions — •Claudia Merger[1,2,3], Alexandre Rene[2,4], Kirsten Fischer[2,3], Peter Bouss[2,3], Sandra Nestler[2,3], David Dahmen[2], Carsten Honerkamp[3], Moritz Helias[2,3], and Sebastian Goldt[1] — [1]SISSA, Trieste, Italy — [2]Jülich Research Centre, Jülich, Germany — [3]RWTH Aachen University, Aachen, Germany — [4]University of Ottawa, Ottawa, Canada

Generative models have become remarkably powerful at reproducing complex data distributions. They can infer the characteristic statistics of a system from comparatively small datasets and even generate new, realistic samples. Yet, our understanding of what these models learn remains limited: which statistics do they capture, and how accurately? To address the first question, we translate the statistics learned by generative models into a central concept of statistical physics: interactions between degrees of freedom that describe how pairs, triplets, and higher-order groups coact to produce the observed statistics of a system. Using invertible neural networks, we extract these interactions directly from trained models, providing a microscopic description of their learned data structure. To assess how accurately these interactions are learned, we use an analytic theory of diffusion models that predicts the precision with which pairwise interactions can be inferred from finite datasets, quantifying how generalization depends on sample size, data hierarchy, and regularization. Together, these results provide a framework grounded in statistical physics to interpret and predict the behavior of modern generative models.

DY 58.8 Fri 12:00 GÖR/0226

From Kernels to Features: A Multi-Scale Adaptive Theory of Feature Learning — •Javed Lindner[1,2], Noa Rubin[5], Kirsten Fischer[1,6], David Dahmen[1], Inbar Seroussi[4], Zohar Ringel[5], Michael Krämer[3], and Moritz Helias[1,2] — [1]Institute for Advanced Simulation (IAS-6), Computational and Systems Neuroscience, Jülich Research Centre, Jülich, Germany — [2]Department of Physics, RWTH Aachen University, Aachen, Germany — [3]Institute for Theoretical Particle Physics and Cosmology, RWTH Aachen University, Aachen, Germany — [4]Department of Applied Mathematics, School of Mathematical Sciences, Tel-Aviv University, Tel-Aviv, Israel — [5]he Racah Institute of Physics, The Hebrew University of Jerusalem, Jerusalem, Israel — [6]RWTH Aachen University, Aachen, Germany

Feature learning in neural networks is crucial for their expressive power and inductive biases, moti- vating various theoretical approaches. Some ap- proaches describe network behavior after train- ing through a change in kernel scale from initial- ization, resulting in a generalization power com- parable to a Gaussian process. Conversely, in other approaches training results in the adapta- tion of the kernel to the data, involving directional changes to the kernel. The relationship and re- spective strengths of these two views have so far remained unresolved. This work presents a theo- retical framework of multi-scale adaptive

feature learning bridging these two views. Using methods from statistical mechanics, we derive analytical expressions for network output statistics which are valid across scaling regimes and in the continuum between them.

DY 58.9 Fri 12:15 GÖR/0226

Statistical physics of deep learning: Optimal learning of a multi-layer perceptron near interpolation — Jean Barbier[1], Francesco Camilli[1], Minh-Toan Nguyen[1], Mauro Pastore[1], and •Rudy Skerk[2] — [1]The Abdus Salam International Centre for Theoretical Physics, Strada Costiera 11, 34151 Trieste, Italy — [2]International School for Advanced Studies, Via Bonomea 265, 34136 Trieste, Italy

We address a long-standing question in statistical physics by analysing the supervised learning of a multi-layer perceptron, beyond narrow models and kernel methods. Crucially, (i) the width scales with input dimension, making the model more prone to feature learning than ultra-wide networks and more expressive than narrow ones; and (ii) we work in the interpolation regime where trainable parameters and data are comparable, forcing task-specific adaptation. In a matched teacher-student setting we establish the fundamental limits for learning random deep-network targets and identify the sufficient statistics that an optimally trained network acquires as data increases. A rich phenomenology appears with multiple learning transitions: with enough data optimal performance arises via model "specialisation", yet practical algorithms can be trapped in theory-predicted suboptimal solutions. Specialisation occurs inhomogeneously across layers, propagating from shallow towards deep ones, but also across neurons in each layer. The Bayesian-optimal analysis thus clarifies how depth, nonlinearity and finite (proportional) width shape feature learning, with implications beyond this idealised setting.

DY 58.10 Fri 12:30 GÖR/0226

Phase Transitions as Rank Transitions: Connecting Data Complexity and Cascades of Phase Transitions in analytically tractable Neural Network Models — •Björn Ladewig, Ibrahim Talha Ersoy, and Karoline Wiesner — Institute of Physics and Astronomy, University of Potsdam, Germany

Tuning the L2-regularization strength in neural networks can result in a cascade of (zero-temperature) phase transitions between regimes of increasing accuracy. This phenomenology was previously numerically observed and linked to a basin structure of the error landscape formed by the underlying data [1]. At the level of analytically tractable models, we (i) establish the existence of cascades of transitions for those models, (ii) give meaning to the transitions in terms of the ordered onset of "learned eigendirections" of the underlying data distribution; and (iii) link the phase transitions and corresponding accuracy regimes to saddle points of the error landscape.

Time reversal invariance breaking in quantum chaotic scattering — •Ahmed Aldabag, Nils Gluth, and Thomas Guhr — Universität Duisburg Essen

A. Aldabag, N. Gluth and T. Guhr, Universität Duisburg-Essen

Scattering theory is a key tool for the investigation of quantum systems. Often, the systems are stochastic or in a broad sense chaotic. Using Random Matrix Theory, our group recently derived the distributions of off-diagonal scattering matrix elements and cross sections with the Supersymmetry Method. We did that for the three Dyson classes which are distinguished by the presence or absence of time-reversal invariance in the system. In some important physics situations, time-reversal invariance is weakly broken. We succeeded in analytically calculating the corresponding effects on the universal behavior of the mentioned distributions. Our results provide new tools to analyze time-reversal invariance breaking in data from scattering experiments.

DY 59.2 Fri 9:45 HÜL/S186

Normalization of resonance states in chaotic scattering systems — •Florian Lorenz, Jan Möseritz-Schmidt, and Roland Ketzmerick — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

The normalization of resonance states in scattering systems poses a challenge due to their divergent asymptotic behavior. As a consequence, they cannot be normalized by the usual norm, but instead, by the overlap between left and right resonance states. For dielectric cavities, we demonstrate that this left-right overlap can be computed efficiently using a boundary integral, avoiding divergent integrands. This result provides a practical numerical tool for resonance state normalization. For example, this allows for exact time evolution of wave packets based on resonance states.

DY 59.3 Fri 10:00 HÜL/S186

How exceptional points conduct mode dynamics in optical microcavities — Tom Simon Rodemund[1], Chang-Hwan Yi[2], Jung-Wan Ryu[2], Síle Nic Chormaic[3], and •Martina Hentschel[1] — [1]Institut für Physik, TU Chemnitz, Germany — [2]PCS, IBS, Daejeon, Korea — [3]OIST, Okinawa, Japan

Optical microcavities confine light through total internal reflection, making them inherently open, non-Hermitian systems. Their resonances have a real and an imaginary part, both of which depend on external parameters such as the resonator geometry or the refractive index. When scanning the parameter space, resonances can coincide and when they do so in their real and imaginary part, they form an exceptional point. We illustrate their occurrence and consequences in mesoscopic optics in two examples. First, we consider two coupled two-dimensional microcavities over coupling distances of several resonance wavelengths. Their mode dynamics is determined by a chain of exceptional points that exhibit a periodicity of approximately the wavelength [1]. The second example is a three-dimensional truncated cone. We investigate the interaction between the two mode polarizations, TE and TM, and find that the mode character changes smoothly, with TE and TM coinciding at exceptional points [2]. We confirm this behavior in phase space by generalizing the concept of Husimi functions to three dimensions. [1] C.-H. Yi, J.-W. Ryu, T.S. Rodemund, and M. Hentschel, Phys. Rev. A 112, L031501 (2025). [2] T.S. Rodemund, S. Li, S. Nic Chormaic, and M. Hentschel, Phys. Rev. A 112, 033528 (2025).

DY 59.4 Fri 10:15 HÜL/S186

Describing the spectral behavior around higher-order exceptional points with "periodic orbits" — •Daniel Grom[1], Julius Kullig[1], Malte Röntgen[2], and Jan Wiersig[1] — [1]Institut für Physik, Otto-von-Guericke-Universität Magdeburg, 39016 Magdeburg, Germany — [2]Laboratoire d'Acoustique de l'Université du Mans, 72085 Le Mans, France

Coupled optical microrings can deliver a simple and robust scheme to generate higher-order exceptional points (EPs), where multiple eigen-values and -modes coalesce. A feature of an EP of order n, is the high sensitivity of the eigenvalues to small perturbations. Two types of perturbations can be classified. The generic behavior, where the eigenvalue response is proportional to the nth root and the non-generic type with a different eigenvalue response.

We present a graph theoretical perspective on the spectral characterization of perturbed higher-order EPs. It turns out that specific "periodic orbits" within the graph picture of the non-chaotic system govern the eigenvalue behavior.

DY 59.5 Fri 10:30 HÜL/S186

Dynamic origin of quantum chaos signatures in the zeros of the Riemann zeta function by means of periodic orbit theory — •Andreas Hötzinger, Sebastian Hörhold, Juan Diego Urbina, and Klaus Richter — Institut für Theoretische Physik, Universität Regensburg, Germany

In the 90's, Berry and Keating [1] provided a qualitative, semiclassical analogy to the counting function of the nontrivial Riemann zeros, i.e. the zeros of the famous zeta function (ZF) $\zeta(s)$. Similar to Gutzwiller's trace formula they obtain a result in which the primes play the role of periodic orbits and argue that the so-called Riemann dynamics, underlying the primes, should be chaotic. It is speculated that this system is the classical limit of a Hermitian quantum Hamiltonian which has eigenvalues coinciding with the nontrivial zeros of $\zeta(1/2+it_n)$.

Recently, a promising candidate for such a Hamiltonian has been proposed [2], which has the potential to advance research toward a proof of the Riemann hypothesis. Based on these results, we use a related and simpler, yet non-Hermitian Hamiltonian and consider its semiclassical regime by employing methods from periodic orbit theory.

In this talk, we present our progress in the study of the classical limit of this operator and its dynamics in a complexified phase space. Through this, we hope to unveil a deeper relation between quantum chaos signatures of number theory encoded in the ZF with classical phase space structures.

Invited Talk DY 59.7 Fri 11:15 HÜL/S186

Anyon dynamics in driven topologically ordered quantum systems — •Francesco Petiziol — Technische Universität Berlin, Institut für Physik und Astronomie, Hardenbergstr. 36, 10623 Berlin

Quantum systems with topological order exhibit long-range entanglement and host quasiparticle excitations with unconventional quantum statistics – anyons. These features make them of great interest from both fundamental and quantum-technological perspectives. Recent progress in realizing topological order in quantum simulators highlights the importance and the challenge of understanding the behaviour of such systems under non-equilibrium conditions. Focusing on Kitaev's toric code, I will discuss how external driving, either coherent or incoherent, can impact and alter anyon properties. Examples include the emergence of more complex anyon classes from simpler ones, the dynamics of entanglement under driven anyon proliferation, and opportunities for controlled anyon transport.

DY 59.8 Fri 11:45 HÜL/S186

Floquet engineering in lattice systems with a parametrically modulated parabolic potential — •Usman Ali[1], Martin Holthaus[1], and Torsten Meier[2] — [1]Institut für Physik, Carl von Ossietzky Universität, D-26111 Oldenburg, Germany — [2]Department of Physics, Paderborn University, Warburger Strasse 100, D-33098 Paderborn, Germany

We present a route to Floquet engineering in lattice systems that exploits a parabolic potential to generate tunable slowly varying on-site energies. When a selected level spacing in the spectrum of the combined parabolic lattice is brought into near resonance with an external periodic drive, nonlinear resonances emerge in the classical phase space and reorganize quantum eigenstates into families of near-resonant Floquet states. Using a Mathieu-resonance approximation together with numerical Floquet calculations, we construct these states and demonstrate how resonant trap eigenstates transmute into resonance-induced effective ground states [1]. The long-time population and transport dynamics are strongly sensitive to the initial phase of the drive, providing a phase-dependent control knob for engineered tunneling and coherence. We identify parameter regimes accessible to present-day cold-atom experiments and argue that selectively populating these Floquet ground states provides a clean testbed for driven many-body and Floquet-band phenomena, enabling novel lattice dynamics inaccessible in solid-state materials [2]. References: [1] U. Ali, M. Holthaus, and T. Meier, New J. Phys. 26, 123016 (2024) [2] U. Ali, M. Holthaus, and T. Meier, Phys. Rev. Research 5, 043152 (2023)

DY 59.9 Fri 12:00 HÜL/S186

Transport through two Floquet-engineered Impurities in a One-Dimensional System: Coherent Control of Fano Resonances, BICs and Localization — •Vincenzo Bruno[1,2], Ameneh Sheikhan[1], Roberta Citro[2,3], and Corinna Kollath[1] — [1]Physikalisches Institut, Universität Bonn, Nussallee 12, 53115 Bonn, Germany — [2]Dipartimento di Fisica "E.R. Caianiello", Università degli Studi di Salerno and INFN, Via Giovanni Paolo II, 132, I-84084 Fisciano (Sa), Italy — [3]CNR/SPIN, Fisciano (Sa), 84098, Italy

Floquet engineering has attracted considerable attention due to its ability to coherently control quantum states, finding successful applications across a wide range of fields such as quantum materials, ultracold atoms, and cavity systems. We investigate particle transport through a one-dimensional system containing two periodically driven impurities. Such a configuration is highly relevant for experimental realizations ranging from ballistic semiconductor wires and electron optics to ultracold atoms, and exhibits remarkably rich transmission properties. A central feature of this system is the emergence of Fano resonances-phenomena arising from the quantum interference between a continuum scattering path and discrete quasi-bound states. We demonstrate how drive parameters can be tuned to dynamically control these resonances. Furthermore, we reveal the existence of Bound States in the Continuum (BICs) and explore the interplay between Fano interference and cavity modes. This interplay leads to a localization mechanism where the system can be switched from a fully localized state to a regime of perfect transparency.

DY 59.10 Fri 12:15 HÜL/S186

Ruelle-Pollicott signatures of unitary quantum systems — •Scott Daniel Linz, Jiaozi Wang, Merlin Füllgraf, and Jochen Gemmer — Department of Mathematics/Computer Science/Physics, University of Osnabrück, D-49076 Osnabrück, Germany

Phenomenological observations demonstrate that unitary quantum systems thermalize and equilibrate. While many concepts have been introduced to describe the equilibrium of a quantum system, the route to this state remains an area of ongoing research. A proposed step towards a general description of this behaviour is that correlation functions of chaotic quantum systems can be described by a superposition of relatively few damped oscillations, where each is weighted and assigned a complex frequency. These frequencies will be called Ruelle-Pollicott signatures after the well-understood Ruelle-Pollicott resonances that govern the decay of correlations in classical chaotic systems featuring dissipation. Following this framework, a deterministic fitting method is applied to the correlation functions of numerical simulations of closed unitary quantum systems. This examination will focus on how the number of frequencies needed to reproduce correlation functions relates to other signatures of quantum chaos.

DY 59.11 Fri 12:30 HÜL/S186

Refinements of the Eigenstate Thermalization Hypothesis — •Elisa Vallini[1], Laura Foini[2], and Silvia Pappalardi[1] — [1]University of Cologne, Köln, Germany — [2]Université Paris-Saclay, France

Understanding how isolated quantum many-body systems reach thermal equilibrium is a central question in nonequilibrium physics. The Eigenstate Thermalization Hypothesis (ETH) provides a powerful framework by linking thermalization to the statistical properties of matrix elements of physical observables in the energy eigenbasis.

In this talk, I will present our recent work, in which we revisit and clarify in detail the ideas that have led to the formulation of full ETH, a generalization of the ETH ansatz that captures multi-point correlation functions. Specifically, using tools from free probability, we explore the implications of local rotational invariance, a property that emerges from the statistical invariance of observables under random basis transformations induced by small perturbations of the Hamiltonian.

This approach allows us to analytically characterize subleading corrections to matrix-element correlations, thereby refining the ETH ansatz. Finally, I will show numerical results from non-integrable Floquet systems that support our analytical predictions.

DY 60: Critical Phenomena and Phase Transitions

Time: Friday 9:30–12:00 Location: ZEU/0114

DY 60.1 Fri 9:30 ZEU/0114

Noise-driven transitions and dynamic restoration in a two-state model under stochastic fields — •Raul Toral[1], Sara Oliver-Bonafoux[1], and Amitabha Chakrabarti[2] — [1]IFISC, Institute for Cross-disciplinary Physics and Complex Systems, UIB-CSIC, Palma de Mallorca, Spain — [2]Physics Department, Kansas State University, Manhattan, Kansas, USA

We study a two-state system influenced by both thermal fluctuations and stochastic external fields to explore how randomness affects non-equilibrium transitions and barrier-crossing dynamics. Using the Ising model in a heat bath as a minimal double-well prototype, we introduce spatially uniform, time-dependent random fields and analyze their impact on phase behavior.

The stochastic driving transforms the usual symmetry-breaking transition of the Ising model into a noise-induced transition between soft-paramagnetic and soft-ferromagnetic phases, where magnetization exhibits broad distributions and dynamical symmetry restoration between ferromagnetic states. For small field amplitudes, the transition coincides with the critical point of the undriven system, while at lower temperatures a genuine ferromagnetic phase emerges, marked by spontaneous state selection and diverging switching times.

These results reveal how stochastic forcing modifies phase behavior in bistable systems, providing new insights into noise-driven symmetry breaking and restoration.

DY 60.2 Fri 9:45 ZEU/0114

The frustrated Ising model on the honeycomb lattice: Metastability and universality — •Denis Gessert[1,2,3], Martin Weigel[3], and Wolfhard Janke[2] — [1]Centre for Fluid and Complex Systems, Coventry University, Coventry, CV1 5FB, United Kingdom — [2]nstitut für Theoretische Physik, Universität Leipzig, IPF 231101, 04081 Leipzig, Germany — [3]nstitut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany

We study the Ising model with competing ferromagnetic nearest- and antiferromagnetic next-nearest-neighbor interactions of strengths $J_1 > 0$ and $J_2 < 0$, respectively, on the honeycomb lattice. For $J_2 > -J_1/4$ it has a ferromagnetic ground state, and previous work has shown that at least for $J_2 \gtrsim -0.2J_1$ the transition is in the Ising universality class. For even lower J_2 some indicators pointing towards a first-order transition were reported. By utilizing population annealing Monte Carlo simulations together with a rejection-free and adaptive update, we can equilibrate systems with J_2 as low as $-0.23J_1$. By means of a finite-size scaling analysis we show that the system undergoes a second-order phase tran-

sition within the Ising universality class at least down to $J_2 = -0.23J_1$ and, most likely, for all $J_2 > -J_1/4$. As we show here, there exist very long-lived metastable states in this system explaining the first-order like behavior seen in only partially equilibrated systems.

DY 60.3 Fri 10:00 ZEU/0114

Hardness of the "swap" spin glass ensemble — •Alexander K. Hartmann[1], Leticia Cugliandolo[2], and Marco Tarzia[2] — [1]University of Oldenburg, Germany — [2]Sorbonne University, Paris, France

The "swap" ensemble [1] consist of spin glasses with quenched interaction constants J_{ij}, where the spins $s_i = \sigma_i\tau_i$ with $\sigma_i = \pm 1$ and $\tau_i \in [1 - /\Delta/2, 1 + \Delta/2]$ exhibit varying lengths τ_i. The value $\Delta = 0$ corresponds to the standard Ising case. Inspired by "swap moves" used for simulating structural classes [2], it was observed [1] that when including swaps $\tau_i \leftrightarrow \tau_j$ within Monte Carlo simulations at finite temperature with annealing $T \to 0$, ground states are easier to find. The actual "swap" ensemble samples consist of the bonds $\mathscr{J}_{ij} = J_{ij}\tau_i\tau_j$ obtained at the end of the annealing, respectively. Here, we study for two-dimensional spin glasses, by applying exact ground-state algorithms [3], the probability p_0 that true ground states have been found in the annealing. This allows us to define the hardness of the bond samples. In particular we consider the results as a function of the total number t_{MC} of annealing steps and length variation Δ. Furthermore, by applying domain-wall energy calculations [3], we investigate for various values of Δ and slow annealing ($p_0 \to 1$) whether the $\{\mathscr{J}_{ij}\}$ samples actually behave like spin glasses or rather like ferromagnets.

Experimental study of dynamic phase transitions in nearly isotropic ferromagnetic films — Juan Marcos Marin Ramirez, Luciano Bravo, and •Andreas Berger — CIC nanoGUNE BRTA, E-20018 Donostia-San Sebastián, Spain

Non-equilibrium phase transitions occur across a wide range of physical systems. A relevant example is the dynamic phase transition (DPT) in ferromagnets, where the time-averaged magnetization Q, the dynamic order parameter, changes sharply under an oscillating field as its amplitude H_0 or period P vary. Hereby, it has also been observed that Q is dependent on the presence of an additional bias field H_b, which turns out to be the conjugate field of Q. Studies of the DPT have yielded important insights into dynamically ordered systems, their phase-space behaviour, and transient properties [1], yet this work has focused almost exclusively on Ising-type systems, restricting our understanding to a single material class [2]. Here, we experimentally investigate the DPT in polycrystalline Co films with very weak anisotropy. Dynamic magnetic states are monitored via real-time magneto-optical Kerr effect measurements across the relevant dynamic phase space. We find that the qualitative features of the dynamic phase diagram closely follow those of uniaxial Ising-type films. However, the metamagnetic anomalies of the paramagnetic dynamic state, ubiquitous in Ising-type films, appear to be significantly weaker in our nearly isotropic films.

Quadrupoling in ferroic materials — •Finja Tietjen and Richard Matthias Geilhufe — Chalmers University of Technology, Gothenburg, Sweden

Quadrupolar ordering has been investigated and characterized experimentally in different materials in recent years, but the theoretical approaches have only focused on special cases so far. We follow a new approach where we describe the quadrupoling as a composite order, arising from the fluctuations of a parent phase. This is in contrast to the conventional approach, where different phases are regarded as competing. We derive a mesoscopic field theory that includes thermal fluctuations. That enables us to find the anisotropy-dependent transition temperature and the free energy of the quadrupolar phase. We identify the phase transition into the quadrupolar phase as first-order and show that it is linked to a tetragonal distortion of the lattice of the material. With this framework, we correctly predict experimental measurements of the distortion in Ba2MgReO6 upon entering its quadrupole phase [1].

Out-of-equilibrium intertwining of Landau and time-crystalline orders via collective excitations — •Andras Szabo[1] and Rama Chitra[2] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]ETH Zurich, Switzerland

The intertwining of multiple order parameters is a widespread phenomenon in equilibrium condensed matter systems, yet its exploration is often hindered by the complexity of real materials. Here, we present a controlled study of intertwined orders in a minimal and versatile driven-dissipative quantum-engineered platform. We consider a Bose-Einstein condensate at the intersection of two optical cavities, realizing two competing copies of a Z2 symmetry-breaking superradiant phase transition characterized by density wave orders. Using periodic drives that exploit dynamical symmetry reduction, we show that collective excitations can be harnessed to stabilize a variety of novel intertwined orders. Going beyond the conventional phenomenology involving Landau orders, we show the emergence of a larger class of out-of-equilibrium intertwined phases, including intertwining of purely time-crystalline orders, as well as between Landau and time crystal orders. These results should be observable in state of the art experimental setups

Nucleation in the Vicinity of the Spinodal — •Sune Kühne and Marcus Müller — Universität Göttingen Institut für Theoretische Physik Friedrich-Hund-Platz 1 37077 Göttingen

Nucleation plays a central role in initiating phase separation across diverse soft-matter systems, from synthetic polymer blends to biomolecular condensates. Near the spinodal, Cahn-Hilliard nucleation theory (CHNT) predicts that the free-energy barrier vanishes while the size and material excess of the critical nucleus diverge. Forming a large cluster significantly delays nucleation even in the absence of a free-energy barrier in analogy to approaching the spinodal from the unstable region. Yet experiments consistently report a finite rate of phase separation even while crossing the spinodal, challenging the classical CHNT scenario. In this work, we investigate the onset of phase separation in the near-spinodal regime and reveal how thermal fluctuations qualitatively modify the nucleation pathway. Using Monte Carlo simulations, we show that fluctuations can locally and transiently push the system beyond the spinodal threshold, enabling the formation of nuclei on a finite length scale well below the system size. This mechanism produces finite nucleation times and naturally explains the experimentally observed smooth crossover from nucleation-dominated to spinodal-like dynamics. By analyzing the free-energy landscape as well as the structure and dynamics of the density fluctuations that eventually become critical, we identify the key physical principles governing phase selection in metastable mixtures.

DY 60.8 Fri 11:30 ZEU/0114

Self-Assembly as a Topological Entropic Transition: Geometry, Connectivity and the Emergence of Molecular Order — •Vicente Domínguez Arca — Biosystem and Bioprocesses Engineering, IIM-CSIC, Spain — Physical and Biophysical Chemistry, Bielefeld University, Germany

Self-assembly in soft-matter systems is traditionally explained through intermolecular forces acting at short metric ranges. Here we propose a radically different view: aggregation emerges from a topological-entropic transition in the geometry of accessible microstates. Using a connectivity-based model of amphiphilic micellization, we show that aggregation reduces the degeneracy of solvent configurations, collapsing a manifold of equivalent states into a confined thermodynamic paraboloid.

This reorganization generates effective forces without invoking pairwise attractions, as entropic gradients arise from the curvature of the configuration manifold itself. The hydrophobic effect thus appears not as a fundamental interaction, but as a solvent-mediated constraint that selects ordered states by maximizing accessible degrees of freedom. This framework explains micellization as a connectivity threshold and rationalizes enthalpy-entropy compensation as a geometric projection of the same curvature tensor. Self-assembly therefore emerges as a topological transition driven by entropy, revealing order as a consequence of state-space geometry rather than microscopic forces.

DY 60.9 Fri 11:45 ZEU/0114

On the adequate and stochastic structure of space in nature and phase transitions in the early universe — •Hans-Otto Carmesin — Universität Bremen, Fachbereich 1, Pf 330440, 28334 Bremen — Studienseminar Stade, Bahnhofstr. 5, 21682 Stade — Gymn. Athenaeum, Harsefelder Str. 40, 21680 Stade

The problem to find an adequate coordinate system (ACS) has been proclaimed by the International Astronomical Union (IAU), and that problem has been solved here. This has far reaching consequences about the structure of space and time: The universal zero of the kinematic time difference δt_{kin} is derived. It corresponds to zero kinetic energy and to the minimum of relativistic energy at a given rest mass. Based on that finding, indivisible volume portions in nature are derived, and homogeneous space is identified as a stochastic average of these indivisible volume portions. With it, gravity and the quantum postulates have been derived. As a consequence, at high density, there occur dimensional phase transitions of space. In the very early universe, there occurred such high densities, and, as a consequence, the corresponding phase transitions took place. This explains the era of 'cosmic inflation', which turns out to be an era of cosmic unfolding.

Time: Friday 9:30–11:15 Location: ZEU/0118

DY 61.1 Fri 9:30 ZEU/0118

Quantifying non-Markovianity via entropy production in rotational Brownian motion — •Felix Hartmann[1], Finja Tietjen[2], Matthias Geilhufe[2], and Janet Anders[1,3] — [1]University of Potsdam, Institute of Physics and Astronomy, Karl-Liebknecht-Str. 24-25, 14476 Potsdam, Germany — [2]Department of Physics, Chalmers University of Technology, 412 96 Göteborg, Sweden — [3]Department of Physics and Astronomy, University of Exeter, Stocker Road, Exeter EX4 4QL, UK

Magnetization dynamics is commonly modeled by the stochastic Landau-Lifshitz-Gilbert (LLG) equation, which describes the rotational Brownian motion of a magnetization vector on a spherical surface, and successfully explains and predicts magnetization experiments. On ultrashort timescales (~ a few picoseconds) an extension of the LLG by an inertial term has been theoretically predicted and experimentally measured. More generally ultrafast magnetization experiments are modeled by an open-system LLG equation, which includes a memory kernel and colored noise. It has previously been reported that if classical entropy production rates become negative, the underlying dynamical evolution is non-Markovian. In this talk we employ this to detect and measure non-Markovianity in the evolution of the magnetization dynamics. We analytically show that the inertial LLG and open-system LLG equation may have temporarily negative entropy production rates. We highlight our findings by numerical calculations of the entropy production rates for the three different LLG equations under different initial conditions and field orientations.

DY 61.2 Fri 9:45 ZEU/0118

Resolving hidden barriers and states form time series of projected observables — •Francesco Malcangi and Aljaz Godec — Mathematical Physics and Stochastic Dynamics, Institute of Physics, University of Freiburg

Single molecule experiments, such as FRET, plasmon ruler, and optical tweezers, probe a low- (often one-) dimensional projection of a higher dimensional dynamics. Unless the hidden degrees of freedom relax faster then the observed ones or they are uncoupled, projection induces memory and hides features of the full dynamics, like the presence of hidden states or energy barriers. In this study we show that the higher-order statistics of appropriately chosen functionals of projected paths can reveal some hidden features directly from the time series. In particular, they can unravel and resolve hidden barriers or states.

DY 61.3 Fri 10:00 ZEU/0118

Intensity countoscope: Quantifying dynamics from intensity correlations in real space — •Sophie Hermann and Sophie Marbach — PHENIX, Sorbonne Université/CNRS, Paris, France

Quantifying the dynamics of particle suspensions is of widespread interest in soft matter, including crystalline aggregates and bacterial colonisation. Here, we develop a new technique to learn about these dynamics directly from microscopy images. The intensity countoscope is based on the analysis of intensity correlations in virtual observation boxes of images. Through colloidal experiments, simulations, and theory, we demonstrate how this method determines equilibrium motion properties, such as self-diffusion coefficients and particle drift. By varying the size of the observation boxes, we can probe dynamics across length scales, disentangling contributions of the particle shape and the point spread function (PSF) from those of the particle motion. The intensity countoscope complements the broad range of existing techniques on interpreting images, such as particle tracking, sitting right in between dynamical differential microscopy (DDM), and particle number fluctuations (Countoscope). One strength is its applicability to situations where particle tracking is difficult, e.g. at high densities, with fast dynamics or with poor image resolution. Additionally, the entire analysis is performed in real space, which makes the technique computationally cheap as it does not require Fourier transformations. This also enables to find more intuitively physical meaning behind the obtained signals. This simplicity opens up broad perspectives on the study of collective phenomena and of interparticle interactions.

DY 61.4 Fri 10:15 ZEU/0118

Leveraging Interactions for Efficient Swarm-Based Brownian Computing — •Alessandro Pignedoli, Atreya Majumdar, and Karin Everschor-Sitte — University of Duisburg-Essen, CENIDE Center for Nanointegration Duisburg-Essen

Brownian particles naturally explore a system's configuration space through thermal fluctuations, requiring no external energy input. This intrinsic property makes them an energy-efficient basis for addressing optimisation problems [1]. Inspired by swarm intelligence [2], we show that short-range interactions between Brownian quasiparticles induce dynamic clustering around the global minimum of a complex temperature landscape [3,4]. By varying the interaction strength and particle density, we identify a broad range of physical conditions in which collective behaviour enhances optimization accuracy. Our results highlight that the emergent collective dynamics of interacting Brownian particles provide a scalable, energy-efficient framework for unconventional computing.

Current reversals in periodically driven many-particle colloidal ratchet — •Seemant Mishra[1], David Vorac[2], Artem Ryabov[2], and Philipp Maass[1] — [1]Universität Osnabrück, Institut für Physik, Germany — [2]Charles University, Faculty of Mathematics and Physics, Czech Republic

We study a many-particle colloidal ratchet and demonstrate the occurrence of current reversals under a symmetric, time-periodic driving force. An overcrowding of particles in the potential wells of the ratchet causes the current to be mediated by propagating solitary waves [1,2]. The current reversals arise from distinct modes of these waves. By a mapping onto a quasiparticle dynamics [3] and applying a unit-displacement law [4], we develop an analytic theory for the particle currents as function of the driving parameters and explain the occurrence of the current reversals. We further examine the role of hydrodynamic interactions in the system.

Advection-diffusion processes of Brownian particles in a long corrugated channel: mean first passage time approach — •Xiaohan Huang, Paolo Malgaretti, and Jens Harting — Helmholtz Institute Erlangen-Nürnberg for Renewable Energy, Cauerstr. 1, 91058 Erlangen, Germany

Transport of particles in porous media in micro- and mesoscopic scales is of interest in many applications, such as the catalytic transport and nanoparticles separations. In such scenarios, the time that a particle takes to reach a target for the first time, namely the mean first passage time (MFPT), represents a standard indicator. We model the advection-diffusion of a finite size particle in a diluted suspension through a corrugated channel of N varying cross sections elements. Under the fast transverse equilibrium and the slow longitudinal transport, we encode the geometric effect to an effective entropic potential via the Fick-Jacobs approximation [1]. Together with the lubrication approximation, the 2D equation is reduced to 1D, allowing us to solve the moments of MFPT. The resulting data collapse onto a master curve, enabling us to identify the relevant dimensionless numbers: the MFPT without advection and the particle-sensitive effective advection v. v is the average velocity of a particle in a single element, accounting for advection, geometry and particle-wall interactions. Thus, 1^{st} and 2^{nd} moment of MFPT are expressed as $f(Pe)$, $Pe = \frac{vNL}{D}$ [2]. The model predicts the particle transport in a long channel, enabling fast parameter studies in porous media design.[1] P. Malgaretti et al. Entropy 2023. [2] X.Huang et al. in preparation.

DY 61.7 Fri 11:00 ZEU/0118

Anomalies in first-passage times and survival profiles of the critical Lorentz gas — •Giorgia Marcelli and Felix Höfling — Institute of Mathematics, Freie Universität Berlin

We investigate the non-equilibrium transport in the three-dimensional Lorentz gas, which is a paradigm of tracer motion in crowded environments and heterogeneous porous media [1]. The model exhibits critical slowing down and the emergence of anomalous diffusion as the porosity approaches the percolation threshold, where the void space loses connectivity [2,3]. Based on large-scale molecular dynamics simulations for transport across a finite sample, we discuss the statistics of first-passage times (FPT) covering a wide dynamic window [4]. Upon decreasing the porosity, the tail of the FPT density $p(\tau)$ broadens beyond the diffusive law, $p(\tau) \sim \tau^{-3/2}$, and attains a critical power law.

The picture is complemented by a discussion of the spatially resolved survival probability $\rho(x, t)$, which, at low obstacle densities, varies almost linearly in the distance x to the finish line, as expected for normal diffusion, but develops a broad interior plateau near the threshold.

The hazard rate, quantifying the likelihood of an arrival to occur at the next moment, becomes strongly time dependent, signalling a non-Poissonian statis-

tics. We test the consistency of our results against the well-known subdiffusive scaling of the equilibrium transport.

DY 62: Active Matter VI (joint session DY/BP)

Time: Friday 9:30–12:15 Location: ZEU/0160

Invited Talk DY 62.1 Fri 9:30 ZEU/0160

Morphogenesis, transport, and computation in micro-scale swarms — •Akira Kakugo — Division of Physics and Astronomy, Graduate School of Science, Kyoto University, Kyoto, Japan

Collective behavior at the microscale offers a powerful route to creating adaptive and functional materials. In this talk, I present a series of studies in which microtubule/kinesin active matter is treated as an ensemble of active agents, and swarming is engineered through DNA-mediated interactions. By introducing programmable dipole-dipole like binding via designed DNA motifs, we establish tunable microscale swarms with controllable cohesion. First, I describe how external mechanical stimuli trigger diverse modes of morphogenesis within these swarms, leading to the emergence of ordered structures and pattern transformations. Next, I introduce a DNA-programmable transport system in which a swarm of millions of active agents cooperatively captures, carries, and releases microscale cargo, enabling light-controlled, spatiotemporally precise transport. Finally, I demonstrate how such active swarms can function as a physical reservoir, where their high-dimensional, nonlinear dynamics are directly harnessed for computation within an active-matter ensemble.

DY 62.2 Fri 10:00 ZEU/0160

Learning effective hydro-phoretic interactions in active matter — •Palash Bera, Aritra K. Mukhopadhyay, and Benno Liebchen — Technische Universität Darmstadt, Darmstadt, Germany.

In the quest to understand collective behaviors in active matter systems, the complexity of hydrodynamic and phoretic interactions remains a fundamental challenge. Despite the substantial progress in identifying effective models, existing approaches often rely on minimalistic approximations, neglecting many-body interactions and the near-field contributions to the full interaction dynamics. We propose a machine learning-based framework to systematically learn hydrophoretic interactions among active colloids from first principles. By combining high-fidelity simulations with symmetry-preserving descriptors and neural network architectures, our approach captures the effective representations of both near- and far-field interactions. This framework bridges the gap between microscopic continuum models and coarse-grained active matter simulations, enabling scalable many-particle modeling without explicitly resolving the fluid flow or concentration fields. Built on two-body interactions, the coarse-grained model captures clustering phenomena consistent with those observed experimentally in active matter systems. We envision that the principles and tools developed here will have broad applicability across a wide range of active and nonequilibrium systems, including driven colloids, active gels, and field-responsive materials, providing a robust framework for modeling emergent behaviors in living and life-like systems.

DY 62.3 Fri 10:15 ZEU/0160

Interactions between Janus particles in optical tweezers — •Arnaud Compagnie[1], Abhimanyu Nowbagh[2], Ivo Buttinoni[2], and Hartmut Löwen[1] — [1]Institute for Theoretical Physics II, Heinrich Heine University Düsseldorf, Düsseldorf, Germany — [2]Institute for Experimental Physics of Condensed Matter, Heinrich Heine University Düsseldorf, Düsseldorf, Germany

Janus particles, by using their asymmetric properties to self-propel due to phoretic effects, are the most prominent artificial active colloids at the microscale. Their ability to extract energy from their surroundings and to self-assemble are used to perform specific tasks. However, due to the vast amount of types of Janus particles and the complex systems they evolve in, the way they interact with their environment remains poorly understood. Optical tweezers can be used to trap them and control their behaviour. By studying how a trapped Janus particle affects the movements of another one in a separate trap, we aim to identify the main physical phenomena - optics, hydrodynamic fluxes, and phoretic fields - that influence the interactions between them. We establish and simulate physical models in order to derive the characteristic dynamical properties of the Janus particles thanks to the comparison with experimental data.

DY 62.4 Fri 10:30 ZEU/0160

Programmable Hydrodynamic Reconfiguration of Active Particles — •Lisa Rohde, Gordei Anchutkin, and Frank Cichos — Molecular Nanophotonics Group, Peter-Debye-Institute for Soft Matter Physics, University Leipzig, Leipzig, Germany

Self-propelled microparticles generate hydrodynamic flow fields that govern their interactions with boundaries and neighbouring particles. The long-range behavior of the flow patterns classifies them as either pushers, pullers or neutral swimmers - each exhibiting fundamentally different collective behaviours. In nature, some microorganisms can adaptively switch between swimming modes in response to their environment. However, in synthetic matter, the hydrodynamic signature is fixed during fabrication constraining our ability to study how switching between modes might enable new emergent behavior. Here, we demonstrate a novel approach for real-time switching of the hydrodynamic character of the microswimmer. By illuminating the particle with a structured light field, we create tailored temperature gradients that drive controllable slip flows on the particle*s surface. This effectively allows control over the swimmer*s flow field and enables mode switching by dynamically changing the illumination pattern on demand. The ability to alter the propulsion characteristics established a versatile platform for experimentally investigating swimming efficiency, adaptivity, and collective behavior.

DY 62.5 Fri 10:45 ZEU/0160

From Passive to Active: Active Particles in Coatings Formulation and Film Formation — •Jan Cammann[1], Karnika Singh[1], Luka Burduli[1,2], Edgar Espinosa Rodriguez[3], Franck D'Agosto[3], Muriel Lansalot[3], and Ignacio Martin-Fabiani[1] — [1]Loughborough University — [2]Constructor University Bremen — [3]Universite Claude Bernard Lyon

Coatings are widely used in protective and functional applications but are fundamentally limited by the passive nature of their formulation ingredients. This leads to a critical lack of control over the spatial distribution of ingredients and prevents the optimization of key functional properties. Addressing this challenge, we propose a paradigm shift towards active coatings formulation. We introduce active Janus particles in coatings formulations and demonstrate how they overcome sedimentation and chemical gradients to accumulate at both the top and bottom coating interfaces. To achieve this programmable microstructure, we balance the timescales of active particle fuel depletion and evaporation induced assembly. We find that Janus particles at the top coating surface have an orientational bias, with the sub-equatorial orientation being the most common. This work lays the foundation for future studies developing functional coatings with programmable microstructures and dual functionalities enabled by orientation-biased active particles.

DY 62.6 Fri 11:15 ZEU/0160

Critical Dynamics of Active, Isotropic Systems — •Emir Sezik and Gunnar Pruessner — Imperial College London

A central result of field theory and renormalisation group (RG) is the concept of universality classes. Systems with different microscopic properties display the same physics near a continuous phase transition as they share the same symmetries. In equilibrium critical dynamics, where systems relax to a thermal steady state, Hohenberg and Halperin have provided the authoritative catalogue, which however, does not immediately extend to critical active matter systems. As they display exciting and new phases by their breaking of detailed balance, we have every reason to attempt to identify the relevant terms and to catalogue these non-equilibrium, critical systems. Motivated by this, in this work, we study an active version of Model A by including the relevant terms that are allowed by symmetry in the coarse-grained description. We show that this universality class encompasses diverse systems including spins with vision-cone interactions and Malthusian flocks. Finally, using field-theoretic RG, we perform a 1-loop calculation, approaching the critical point from the disordered regime, and elucidate the effects of activity on the Wilson-Fisher fixed point.

DY 62.7 Fri 11:30 ZEU/0160

Conservation laws and slow dynamics determine the universality class of interfaces in active matter — •Raphael Maire[1], Andrea Plati[1], Leonardo Galliano[2,3], Frank Smallenburg[1], Ludovic Berthier[2], and Giuseppe Foffi[1] — [1]Université Paris-Saclay, Laboratoire de Physique des Solides, 91405 Orsay, France — [2]Gulliver, ESPCI Paris, PSL Research University, 75005 Paris, France — [3]Dipartimento di Fisica, Università di Trieste, Strada Costiera 11, 34151, Trieste, Italy

While equilibrium interfaces display universal large-scale statistics, interfaces in phase-separated active and driven systems are predicted to belong to distinct non-equilibrium universality classes. Yet, such behavior has proven difficult to

observe, with most systems exhibiting equilibrium-like fluctuations despite their strongly non-equilibrium microscopic dynamics.

We introduce an active hard-disk model that is far from equilibrium but lacks self-propulsion. Contrary to self-propelled models, it displays clear non-equilibrium interfacial scaling and allows the first observation of the $|\boldsymbol{q}|$KPZ and wet-$|\boldsymbol{q}|$KPZ universality classes while revealing a new, previously overlooked universality class arising in systems with slow crystalline or glassy dynamics. We also show that hyperuniformity in the bulk suppresses accordingly the fluctuations of the interface. These distinct classes are selected by conservation laws and slow hydrodynamic modes.

Our model can be experimentally realized in vibrated granular systems and offers a new route to study far from equilibrium interfaces.

DY 62.8 Fri 11:45 ZEU/0160

Spontaneous emergence of solitary waves in active flow networks — Rodrigo García[1], •Gonçalo Antunes[2,3], Jens Harting[2,4], Holger Stark[3], Chantal Valeriani[1], Martin Brandenbourger[5], Juan Mazo[1], Paolo Malgaretti[2], and Miguel Ruiz-García[1] — [1]Universidad Complutense de Madrid, Madrid, Spain — [2]Helmholtz-Institut Erlangen-Nürnberg für Erneuerbare Energien (IET-2), Erlangen, Germany — [3]Technische Universität Berlin, Berlin, Germany — [4]Friedrich-Alexander-Universität Erlangen-Nürnberg, Nürnberg, Germany — [5]Aix Marseille Université, Marseille, France

Flow networks like animal/plant vasculature and power distribution grids can encode, transmit, and transform information embodied in the spatial and temporal distribution of their flows. To study these emergent dynamics, we focus on a minimal yet physically grounded system which supports information transmission. The system is composed of a one-dimensional network of active units that pump fluid via phoresis and elastic units that store volume. We coarse-grain the elastohydrodynamics to an active flow network model. We show that the pressure field can develop solitary waves, resulting in the spontaneous creation and transmission of localized packets of information stored in the physical properties of the flow. We show how the shape and speed of these waves depend on the physical parameters. When the elastic units are coupled to their neighbors, a critical size emerges, below which the solitary waves have a finite lifetime.

DY 62.9 Fri 12:00 ZEU/0160

Instabilities and turbulence in extensile swimmer suspensions — •Purnima Jain[1], Navdeep Rana[3], Roberto Benzi[4,5], and Prasad Perlekar[2] — [1]Leibniz-Institut für Polymerforschung Dresden, Germany — [2]Tata Institute of Fundamental Research, Hyderabad, India — [3]Max Planck Institute for Dynamics and Self-Organization (MPIDS), Göttingen, Germany — [4]Hangzhou International Innovation Institute, Beihang University, Hangzhou, China — [5]Department of Physics and INFN, Tor Vergata University of Rome, Via della Ricerca Scientifica 1, Rome, Italy

Swimmers moving in the same direction form an ordered state of living matter. However, this ordered state is not always stable to ambient disturbances. This may lead to chaotic flows characterized by the presence of topological defects, a phenomenon known as active turbulence. The ordered state of microswimmers can be destroyed by an instability created by their swimming stresses. For slightly larger swimmers, where viscous and inertial forces are comparable, an instability due to the fluctuations in the concentration of swimmers destroys the order [1].

In this talk, I will discuss about the instabilities and turbulence in weakly inertial suspensions of extensile swimmers, where the defect turbulent state transitions to the concentration-wave turbulent state. These findings reveal new ways in which living matter may get organized in nature.

[1] P. Jain et. al., Phys. Rev. Lett. 133, 158302 (2024). [2] P. Jain et. al., Phys. Rev. Fluids 10, 114602 (2025).

DY 63: Nonlinear Stochastic Systems

Time: Friday 11:30–12:45 Location: ZEU/0118

DY 63.1 Fri 11:30 ZEU/0118

Stochastic Dynamics of Noisy Oscillators under Eigenfunction Transformation — •Georg Podhaisky[1,2], Alberto Pérez-Cervera[3], and Benjamin Lindner[1,2] — [1]Bernstein Center for Computational Neuroscience, Berlin, Germany — [2]Humboldt University, Berlin, Germany — [3]Universitat d'Alacant, Alicante, Spain

Stochastic oscillations are observed for a wide range of systems in biology and physics. Although their dynamics may vary drastically, a simple approach for a unified description exists. As recently demonstrated by Pérez-Cervera et al. (PNAS 120, 2023), the first non-trivial eigenfunction $Q_1^*(\mathbf{x})$ of the Kolmogorov backward operator, which is obtained from the adjoint Fokker-Planck equation, can be used as a particularly useful transformation rule: This eigenfunction maps the trajectories of a given stochastic oscillator to a complex-valued domain. In this domain the autocorrelation statistics as well as the system's linear response are characterized by simple and qualitatively universal functions, regardless of the original dynamics. Here we study the stochastic dynamics in the $Q_1^*(\mathbf{x})$ domain, specifically, a number of two-dimensional systems including the Stuart-Landau oscillator and the harmonic oscillation with damping and thermal noise.

DY 63.2 Fri 11:45 ZEU/0118

Impact of heavy-tailed synaptic strength distributions on self-sustained activity in networks of spiking neurons — •Ralf Tönjes — Humboldt Universität, Berlin, Deutschland

We analyze states of stationary activity in randomly coupled quadratic integrate-and-fire neurons using stochastic mean-field theory. Specifically, we consider the two cases of Gaussian random coupling and Cauchy random coupling, which are representative of systems with light- or with heavy-tailed synaptic strength distributions. For both, Gaussian and Cauchy coupling, bistability between a low activity and a high activity state of self-sustained firing is possible in excitable neurons. In the system with Cauchy coupling we find analytically a directed percolation threshold, i.e., above a critical value of the synaptic strength, activity percolates through the whole network starting from a few spiking units only. The existence of the directed percolation threshold is in agreement with previous numerical results in the literature for integrate-and-fire neurons with heavy-tailed synaptic strength distribution. However, we have found that the transition can be continuous or discontinuous, depending on the excitatory-inhibitory imbalance in the network. Networks with Gaussian coupling and networks with Cauchy coupling and additional additive noise lack the percolation transition in the thermodynamic limit.

DY 63.3 Fri 12:00 ZEU/0118

Stochastic thermodynamics of bifurcations in all-to-all interacting systems — •Ankita Gupta[1] and Aljaž Godec[1,2] — [1]Mathematical Physics and Stochastic Dynamics, Institute of Physics, University of Freiburg, 79104 Freiburg im Breisgau, Germany — [2]Mathematical bioPhysics Group, Max Planck Institute for Multidisciplinary Sciences, Am Fassberg 11, 37077 Göttingen, Germany

All-to-all interacting systems provide a fundamental framework for understanding cooperative behavior and synchronization. Here, we examine the stochastic thermodynamics of such systems in continuous space as they are driven across bifurcation. Our analysis centers on the total entropy production rate (tEPR), which quantifies the thermodynamic cost of maintaining or transitioning between different dynamical phases. Focusing on the microscopically reversible Desai-Zwanzig model and irreversible Bonilla-Casado-Morillo models, we investigate how the tEPR depends on microscopic parameters-including interaction strength, temperature, and external driving. Leveraging recent advances on the Onsager-Machlup functional for McKean-Vlasov stochastic differential equations, we study path measures and characterize dynamical fluctuations near criticality. Through a combination of phase-plane methods and numerical simulations, we reveal the structure and nature of the bifurcations across a range of parameter regimes.

DY 63.4 Fri 12:15 ZEU/0118

Estimation of typical time scales in a Langevin-type model for wind turbine power conversion — •Martin Wagner and Joachim Peinke — Carl von Ossietzky Universität Oldenburg, School of Mathematics and Science, Institute of Physics, ForWind - Center for Wind Energy Research, Küpkersweg 70, 26129 Oldenburg, Germany

In the recent years, a data-driven and computationally efficient Langevin approach has been successfully used to detect physically reasonable fixed points in the short-term power conversion dynamics of wind turbines [1]. In our contribution, we aim to use this model to describe the multi-body interaction and possible synergy effects of the power production of many turbines in a wind farm. Additionally to the fixed points, this requires the extraction of the typical inertial time scales of the power conversion from the stochastic model. We find that this is difficult, since the model does not fulfil the Markov property due to a projection that induces a memory kernel to the stochastic differential equation according to the Mori-Zwanzig formalism [2]. Nevertheless, we show that upper boundary estimates for the typical inertial time scales of a wind turbine can be extracted from the stochastic model. In the future, this is a first step towards the stochastic modelling of many turbines, e.g. to model a grid-supportive power production of a whole wind farm.

Universal Kardar-Parisi-Zhang scaling in non-equilibrium magnon condensates — •Alexander Wowchik and Achim Rosch — Institute for Theoretical Physics, University of Cologne, Zülpicher Str. 77, 50937 Köln, Germany

Extensive studies in the past decade have unveiled how driven-dissipative condensates in one and two dimensions can form a unique non-equilibrium phase of matter characterized by a Kardar-Parisi-Zhang (KPZ) equation for the emergent Goldstone modes. We investigate whether the condensation of magnons, as demonstrated in Yttrium Iron Garnet (YIG) films when driven with microwave radiation, is a suitable candidate to study such phenomena. Via micromagnetic simulations of a corresponding system, we show that, after strong initial pumping, the dynamical autocorrelation function of the magnon field exhibits the universal scaling exponent predicted by the KPZ equation.

DY 64: Closing Talk (joint session CPP/BP/DY)

Time: Friday 13:15–14:00 Location: HSZ/0002

Invited Talk DY 64.1 Fri 13:15 HSZ/0002

Biomolecular Condensates: Challenges for Polymer Physics — •Jens-Uwe Sommer — Leibniz-Insitut für Polymerforschung Dresden, Bereich Theorie der Polymere,Hohe Straße 6, 01069 Dresden, Germany — TU Dresden, Insitut für Theoretische Physik, Zellescher Weg 17, D-01069 Dresden, Germany

Biomolecular condensates (BMCs) constitute an emerging paradigm in the understanding of biological functions. They shift the focus from individual biochemical processes toward the collective behavior of biopolymers, in which phase-separation mechanisms and intrinsically disordered proteins lacking canonical enzymatic roles play central and often decisive functions. Consequently, universal principles of complex (bio)polymer solutions gain relevance, and several classical questions in the physics of living matter can now be revisited from this polymer-physics perspective. In this talk, I will discuss theoretical approaches and concepts that are based on universal principles, with a particular emphasis on current challenges in the field.

Overview of Invited Talks and Sessions

(Lecture halls BEY/0138 and BEY/0E40; Poster P4)

Invited Talks

FM 4.1	Mon	15:00–15:30	BEY/0138	**(Anti)Ferroelectric HfZrO2: from non volatile memory to energy storage applications** — •Bertrand Vilquin, Gregoire Magagnin, Jordan Bouaziz, Martine Le Berre, Sara Gonzalez, Ingrid Canero Infante, Brice Gautier, Kevin Alhada-Lahbabi, Damien Deleruyelle
FM 6.1	Tue	9:30–10:00	BEY/0138	**Robust Data Generation, Heuristics and Machine Learning for Materials Design** — •Janine George
FM 9.1	Tue	14:00–14:30	BEY/0138	**Thin film combinatorial studies of functional magnetic materials** — •Nora Dempsey
FM 12.1	Wed	9:30–10:00	BEY/0138	**Shedding Light on Polar Topological Textures** — •Salia Cherifi-Hertel
FM 17.1	Thu	9:30–10:00	BEY/0138	**Piled higher, probed deeper: X-ray insights into ferroelectric devices** — •Martina Müller
FM 18.1	Thu	10:15–10:45	BEY/0138	**Stabilizing antiferroelectricity in PbZrO3 thin films using epitaxial tensile strain** — •Vincent Garcia
FM 18.2	Thu	10:45–11:15	BEY/0138	**Strain effects in free-standing membranes of antiferroelectric Lead Zirconate** — •Umair Saeed, Huazhang Zhang, David Pesquera, Philippe Ghosez, Nini Pryds, Jose Santiso, Felip Sandiumenge, Gustau Catalan
FM 22.1	Fri	9:30–10:00	BEY/0138	**Topological thermoelectrics for solid state cooling** — •Yu Pan, Claudia Felser
FM 23.1	Fri	9:30–10:00	BEY/0E40	**Mapping topological textures in compensated magnets with X-rays** — •Claire Donnelly

Invited Talks of the joint Symposium SKM Dissertation Prize 2026 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	HSZ/0002	**Stochastic-Calculus Approach to Non-equilibrium Statistical Physics** — •Cai Dieball
SYSD 1.2	Mon	10:00–10:30	HSZ/0002	**Nonuniform magnetic spin textures for sensing, storage and computing applications** — •Sabri Koraltan
SYSD 1.3	Mon	10:30–11:00	HSZ/0002	**Anomalous Quantum Oscillations beyond Onsager's Fermi Surface Paradigm** — •Valentin Leeb
SYSD 1.4	Mon	11:00–11:30	HSZ/0002	**Coherent Control Schemes for Semiconductor Quantum Systems** — •Eva Schöll
SYSD 1.5	Mon	11:30–12:00	HSZ/0002	**On stochastic thermodynamics under incomplete information: Thermodynamic inference from Markovian events** — •Jann van der Meer

Invited Talks of the joint Symposium Beyond Transistors: Material-Based Edge Computing Paradigms (SYBT)

See SYBT for the full program of the symposium.

SYBT 1.1	Wed	9:30–10:00	HSZ/AUDI	**Finding Neuromorphic Advantage with Magnetism** — •Johan Mentink
SYBT 1.2	Wed	10:00–10:30	HSZ/AUDI	**Accelerating Neural Networks Computation with Ferroelectric Oxides** — •Laura Bégon-Lours, Nikhil Garg, Alexandre Baigol, Anwesha Panda, Nathan Savoia, Alexander Flasby
SYBT 1.3	Wed	10:30–11:00	HSZ/AUDI	**a photonic approach to probabilistic computing** — •Wolfram Pernice
SYBT 1.4	Wed	11:15–11:45	HSZ/AUDI	**Tackling Reliability and Scalability in Neuromorphic Computing via Noise-aware Learning** — •Eleni Vasilaki
SYBT 1.5	Wed	11:45–12:15	HSZ/AUDI	**Bayesian nanodevices for trustworthy artificial intelligence** — •Damien Querlioz

Sessions

FM 1.1–1.5	Sun	16:00–18:15	HSZ/0002	**Hands-on Tutorial: HyperSpy – Multidimensional data analysis using Python (joint session FM/TUT)**
FM 2.1–2.7	Mon	9:30–11:30	BEY/0138	**Energy Materials**
FM 3.1–3.6	Mon	9:30–12:00	POT/0151	**Focus Session: Novel mechanisms of ferroic switching (joint session MA/FM)**

Members' Assembly of the Functional Materials Division

Thursday 18:00–18:45 BEY/0138

Sessions

– Invited Talks, Topical Talks, Tutorials, Contributed Talks, and Posters –

FM 1: Hands-on Tutorial: HyperSpy – Multidimensional data analysis using Python (joint session FM/TUT)

HyperSpy is a community-developed, open-source library providing a framework to facilitate interactive analyses of multidimensional datasets – in particular spectrum images – in an easy and reproducible fashion. It facilitates the application of analytical procedures operating on individual spectra/images to a multi-dimensional dataset and gives easy access to tools that exploit the multi-dimensionality of the dataset. Born out of the electron microscopy scientific community and building on the extensive scientific Python environment, HyperSpy provides tools to efficiently explore, manipulate, and visualize complex datasets of arbitrary dimensionality, including those larger than a system's memory. The HyperSpy ecosystem includes Python packages that provide dedicated routines for many electron microscopy-based measurement techniques, but also for luminescence spectroscopy and other fields. Through the library RosettaSciIO, the reading and writing of a large range of file formats is supported.

Please bring your laptop. There will be limited power outlets in the room, so come with a fully charged battery.

Materials will be made available from 01.03.2026 via a dedicated GitHub repository. Participants are encouraged to download them ahead of time, set-up Python on their computer following the instructions and run the jupyter notebooks presented during the tutorials on their laptops:

https://github.com/LumiSpy/DPG2026-Tutorial

Organized by Jonas Lähnemann (PDI Berlin), Benedikt Haas (HU Berlin), Aidan Campbell (PDI Berlin), Hannah C. Nerl (HU Berlin) and Magnus Nord (NTNU Trondheim).

Time: Sunday 16:00–18:15 Location: HSZ/0002

FM 1.1 Sun 16:00 HSZ/0002

Introduction to HyperSpy — •Jonas Lähnemann[1], Aidan F. Campbell[1], Hannah C. Nerl[2], Magnus Nord[3], and Benedikt Haas[2] — [1]Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany — [2]Department of Physics, Humboldt Universität, Berlin, Germany — [3]Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway

The session begins with a brief introduction to HyperSpy that with its 2.0 release has grown to an ecosystem of Python packages that provide dedicated routines for electron microscopy-based measurement techniques such as EELS, EDX, 4DSTEM, holography, tomography and CL, but also for luminescence spectroscopy. In general, it can be useful for any measurement, where a signal is mapped over multiple dimensions (position, time, angle, ...).

Tutorial FM 1.2 Sun 16:15 HSZ/0002

Hands-On Session 1: General usage HyperSpy/RosettaSciIO — •Jonas Lähnemann — Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany

In the initial tutorial, we will show how to easily read in data from a variety of formats and introduce the basic data structure of HyperSpy. General data operations, artefact removal and plotting functionalities as a basis of reproducible data analysis workflows will be covered as well.

Tutorial FM 1.3 Sun 16:45 HSZ/0002

lumiSpy for luminescence spectroscopy — •Aidan Campbell — Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany

This session will focus on tools ideal for analysing data recorded with cathodoluminescence, photoluminescence or related spectroscopy techniques. We will demonstrate convenience functions for rapid spectroscopy data analysis, model fitting, and visualisation. Luminescence spectroscopy may also lead to more complicated data sets with spectral, spatial and time dimensions for which we showcase interactive tools for navigating and understanding this data.

Tutorial FM 1.4 Sun 17:15 HSZ/0002

Hyperspy for Electron Energy-loss Spectroscopy — •Hannah Nerl — Humboldt Universität zu Berlin, Berlin, Germany

This hands-on session demonstrates a complete electron energy-loss spectroscopy (EELS) analysis workflow using HyperSpy and its exSpy extension. Participants will work through practical examples covering essential preprocessing steps including spectral alignment and drift correction, followed by quantitative analysis techniques such as model-based peak fitting and automated peak tracking across multidimensional datasets. The tutorial emphasizes reproducible analysis pipelines, showcasing how to leverage principal component analysis (PCA) for noise reduction in low-signal regimes. All examples use real EELS datasets and focus on practical workflows applicable to both core-loss and low-loss spectroscopy of 2D materials and nanostructures. Participants will gain hands-on experience with Jupyter notebooks that can be directly adapted to their own research data.

Tutorial FM 1.5 Sun 17:45 HSZ/0002

Using pyXem for magnetic and structural analysis of 4D-STEM data — •Magnus Nord — Norwegian University of Science and Technology, Trondheim, Norway

pyXem is an extension of HyperSpy with a focus on data processing of 4D-STEM data: from crystallographic analysis using Scanning Precession Electron Microscopy (SPED), to magnetic imaging with Scanning Transmission Electron Microscopy - Differential Phase Contrast (STEM-DPC). In this tutorial, we will show how one can study the crystal structure and domain structure in a nanostructured magnetic material.

FM 2: Energy Materials

Chair: Anna Grünebohm (Ruhr Universität Bochum, DE)

Time: Monday 9:30–11:30 Location: BEY/0138

FM 2.1 Mon 9:30 BEY/0138

Fundementals of elctrochemical hydrogen charging of MAX phases and their storage potential — •Rebeca Miyar, Adam C. Miles, Manoj Prabhakar, Lilian Vogl, Gerhard Dehm, Yug Joshi, Barak Ratzker, and Maria Jazmin Duarte — Max Planck institute for Sustainable Materials, Düsseldorf, Germany

Hydrogen storage remains a central challenge in the transition to renewable energy systems, as current technologies face limitations in scalability, safety, and efficiency. MAX phases, a class of nanolaminated carbides and nitrides composed of an early transition metal, an A-group element, and carbon or nitrogen, are perspective candidates for solid-state hydrogen storage due to their layered structure, which provides potential interstitial trapping sites. Although many theoretical studies discuss their hydrogen trapping behaviour, experimental evidence remains limited and previous work has focused only on gas-phase hydrogenation. Here, we present the first systematic study of electrochemical hydrogen charging and desorption in Ti2AlC and Ti3AlC2, which differ in their metal/ceramic

layer ratio. Hydrogen trapping and release were analysed using thermal desorption spectroscopy, Kelvin probe measurements, and electrochemical methods. Two dominant trap types were identified in both materials, with their relative contributions reflecting the layer ratio. These results provide new insight into hydrogen permeation and trapping in MAX phases.

FM 2.2 Mon 9:45 BEY/0138

Multilayer Na intercalation in bilayer graphene — •Mahdi Ghorbani-Asl and Arkady V. Krasheninnikov — Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01314 Dresden, Germany.

The intercalation of atomic and molecular species into layered materials has emerged as a powerful route for creating novel encapsulated two-dimensional systems with tunable physical properties. Among these, alkali-metal intercalation in graphitic carbon has been widely explored for energy-storage applications. However, sodium (Na) intercalation into bulk graphite is predicted to be energetically unfavorable, making it particularly challenging to realize experimentally. In this work, we combine first-principles calculations with scanning transmission electron microscopy (STEM) to investigate Na intercalation into bilayer graphene. Using DFT simulations, we analyze the energetics and atomic structures of Na intercalants in single-layer and multilayer configurations, and evaluate how charge transfer between graphene and the Na atoms affects their stability. Our simulations reveal that the lowest-energy structure is an fcc trilayer with an A-B-C stacking sequence, whose projected atomic arrangement is fully consistent with the STEM observations. These findings provide new insight into Na intercalation mechanisms and may support the development of future sodium-ion battery technologies.

FM 2.3 Mon 10:00 BEY/0138

The Role of Lone Pairs in Fast Oxide Ion Conduction in $Bi_{0.8}Pr_{0.2}O_{1.5}$ — •Marcin Kryński — Warsaw University of Technology

Elucidating the microscopic processes that enable rapid oxide-ion transport is key to advancing solid electrolyte design. In this study, we integrate total neutron scattering with reverse Monte Carlo modelling and ab initio molecular dynamics to dissect the structural and electronic mechanisms underlying a pronounced conductivity increase observed across the order/disorder phase transition. Our results reveal that this transition is driven not by changes in the cation framework, but by a collective reorganization of oxide ions and local coordination environments. Specifically, oxide ions shift from the edges of fluorite-like blocks into the van der Waals gap, where they gain access to extended, predominantly two-dimensional diffusion pathways. Concurrently, BiO_4 units undergo a subtle yet systematic reorientation linked to the stereochemical activity of Bi^{3+} lone pairs. Although the local coordination of Bi remains largely preserved, the orientation of these lone pairs evolves in tandem with the redistribution of oxide ions, suggesting a dynamic coupling reminiscent of a paddle-wheel-type mechanism. This interplay between lone-pair-driven asymmetry and anion mobility provides a unified mechanistic picture of how structural flexibility and electronic degrees of freedom cooperate to enhance high-temperature oxide-ion transport. The insights gained here establish general principles for designing fast-ion conductors in systems where active lone pairs play an essential role.

Coffee break

FM 2.4 Mon 10:30 BEY/0138

Metal Poisoning of Nafion Proton Exchange Membrane — •Souvik Mitra[1], Jialiang Liu[1], Kristina Fröhlich[1], Simone Köcher[1,2], Christoph Scheurer[2,1], and Rüdiger-A. Eichel[1] — [1]IET-1, Forschungszentrum Jülich GmbH, 52425 Jülich, DE — [2]Fritz-Haber-Institute der MPG, 14195 Berlin, DE

Metal-ion contamination of Nafion proton-exchange membranes (PEMs) remains a persistent durability and performance issue in PEM fuel cells. Metal cations originating from insufficiently deionized feed water, coolant leaks, or corrosion of metallic cell components can exchange with protons at the sulfonate groups (SO_3^-) of Nafion, thereby reducing proton conductivity and overall cell performance.

In this work, we combine atomistic molecular dynamics simulations with in-plane conductivity measurements to build a consistent picture of how a broad series of mono-, di-, and trivalent cations affect transport in Nafion under comparable conditions. For monovalent ions (Li^+, Na^+, and K^+), our study reveals a reversal of the familiar mobility trend of these cations in the presence of Nafion membrane compared to bulk water, reflecting the competition between ion hydration and specific binding to the SO_3^- groups of Nafion. Our study also shows that, as cation charge increases from +1 to +2 to +3, their mobility drops significantly, correlating with longer residence times at sulfonate sites and increasingly multidentate SO_3^- coordination.

Our study highlights the strengths of simulations in elucidating the atomistic origin of diffusivity trends, but also their challenges in making reasonable physical approximations.

FM 2.5 Mon 10:45 BEY/0138

Synchrotron X-ray Characterization of Irradiated Ag/PVA Polymer Electrolyte — Mohamed Salah Soliman Asser and •Mohamed Salah Soliman Asser — Polymer Chemistry Department, National Center for Radiation Research and Technology, Egyptian Atomic Energy Authority, Cairo, Egypt.

Polymer electrolyte membrane thin films were developed and characterized for potential use in electroconductive applications. Polymer composites of polyvinyl alcohol (PVA), sulfuric acid, ethanol, and silver nitrate were prepared using both casting and dip-coating techniques. For the dip-coating method, glass slides were first cleaned by immersion in acetone, rinsed with isopropanol, and dried. The prepared polymer composite solutions were then dip-coated onto the glass substrates. The coated slides were irradiated at three doses: 62 J/cm2 (low), 251 J/cm2 (medium), and 502 J/cm2 (high) using the DXRL beamline. High-resolution X-ray diffraction (HR-XRD) analyses were performed at the Elettra Synchrotron Laboratory, Trieste, Italy, using the MCX beamline at a glancing angle of 1°. The X-rays had an energy of 12 keV (λ = 1.033 Å). Diffraction patterns were recorded in the 2θ range of 1*80° with a step size of 0.01° and an exposure time of 1 s per step for the Ag*PVA samples.

FM 2.6 Mon 11:00 BEY/0138

Tailoring Electrochemical Functionality of Transition-Metal Glycerolates for Next-Generation Energy Storage Devices — •Ali Hyder[1,2], Irlan S Lima[2], Zahid ullah Khan[2], Ayaz Ali Memon[1], and Lucio Angnes[2] — [1]National Centre of Excellence in Analytical Chemistry, University of Sindh, Jamshoro 76080, Pakistan — [2]Departament de Química Fundamental, Institute de Química, University of São Paulo, Av. Prof. Lineu Prestes, 748 * 05508-000, São Paulo, SP, Brazil

Abstract Metal glycerolates are emerging as promising precursors and active materials for electrochemical energy-storage systems due to their tunable coordination chemistry, oxygen-rich structures, and flexible architectures. In this study, transition-metal glycerolates (Mn, Co, Ni, Cu, Fe) were synthesized via a controlled solvothermal method to explore how formation and nanoscale morphology influence electrochemical performance. Structural analyses show that the resulting M*O*C networks form layered or clustered architectures that enhance ion diffusion and electron transport. Used as electrode materials either directly mild thermal treatment the glycerolates exhibit strong pseudo capacitance, improved redox kinetics, and good stability. Metal glycerolytes deliver the highest capacitance due to synergistic redox activity and accessible surfaces. Overall, the results demonstrate the potential of metal glycerolates as low-cost, versatile candidates for advance hybrid energy-storage devices.

FM 2.7 Mon 11:15 BEY/0138

Thermoelectric properties of In-doped Bi2Te3 crystalline bulk alloys — •Alaa Adam[1] and E. Ibrahim[2] — [1]Sohag University — [2]Sohag university

Influence of indium doping on the structure, morphology and thermoelectric properties of bulk Bi2Te3 is investigated in the current work. Bi2Te3 and Bi2-xInxTe3 crystalline bulk samples have been fabricated using a simple mono-temperature melting method. Analyses employing X-ray diffraction (XRD) and scanning electron microscopy (SEM) techniques proved the existence of the concerned phases. In addition, morphology and internal structure have been examined via the scanning electron microscopes and the energy dispersive X-ray (EDX) spectroscopy. Thermoelectric properties were determined in a temperature range between 300*700 K. The electrical conductivity (σ) against the temperature showed metallic-like behavior. Carrier concentration has increased with in-doping. The Seebeck coefficients (S) of the synthesized alloys proved the domination of n-type conduction due to consistently negative S values. The largest Seebeck coefficient was recorded at 203.5 *V/ K which was observed at 700 K for the pristine Bi2Te3 sample. The highest power factor was found at PF = 5.46 mWm-1K-2, obtained for Bi2Te3 at room temperature. Thermal conductivity was measured and studied against temperature elevation. It was found that the thermal conductivity of the In-doped Bi1.98In0.02Te3 alloys are significantly reduced compared with that of the pure Bi2Te3 material.

FM 3: Focus Session: Novel mechanisms of ferroic switching (joint session MA/FM)

This focus session highlights recent advances in ferroic switching across ferroelectric, multiferroic, ferroaxial and magnetic systems. Topics include topologically protected order-parameter dynamics, ultrafast non-thermal switching, and complex domain-wall phenomena revealed by atomistic modeling, ultrafast optics and advanced imaging. Contributions span machine-learning-based simulations of domain kinetics, optical control of ferroaxial and structural orders, multiferroic multi-cell memory concepts, and theoretically predicted unidirectional domain-wall motion with time-crystal behavior. Together, these works uncover new switching pathways and robust functional mechanisms, offering promising routes toward energy-efficient memory and quantum devices.

Organizer: Andrei Pimenov, andrei.pimenov@tuwien.ac.ac

Time: Monday 9:30–12:00 Location: POT/0151

See MA 4 for details of this session.

FM 4: Focus Session: (Anti)ferroic states – Non-conventional states I

chair: Nives Strkalj (University of Zagreb, HR)

This focus session explores recent advances in understanding and control of (anti)ferroic states. Emphasis will be placed on theoretical modelling, advanced characterization techniques, and the engineering of emergent properties for use in nano-electronic devices. The session aims to bridge fundamental research with emerging device-relevant functionalities, bringing together experimental, and theoretical perspectives on ferroic materials.

Time: Monday 15:00–17:45 Location: BEY/0138

Invited Talk FM 4.1 Mon 15:00 BEY/0138

(Anti)Ferroelectric HfZrO2: from non volatile memory to energy storage applications — •Bertrand Vilquin[1], Gregoire Magagnin[2], Jordan Bouaziz[3], Martine Le Berre[1], Sara Gonzalez[2], Ingrid Canero Infante[2], Brice Gautier[1], Kevin Alhada-Lahbabi[1], and Damien Deleruyelle[1] — [1]INSA Lyon, Ecole Centrale de Lyon, CNRS, Universite Claude Bernard Lyon 1, CPE Lyon, INL, UMR5270, 69621 Villeurbanne, France — [2]CNRS, INSA Lyon, Ecole Centrale de Lyon, Universite Claude Bernard Lyon 1, CPE Lyon, INL, UMR5270, 69621 Villeurbanne, France — [3]Ecole Centrale de Lyon, INSA Lyon, CNRS, Universite Claude Bernard Lyon 1, CPE Lyon, INL, UMR5270, 69621 Villeurbanne, France

Fluorite-structured HfZrO2 and ZrO2 thin films are promising for both non-volatile memory and energy storage applications. Antiferroelectric (AFE) capacitors were fabricated by PE-ALD and annealed using BEOL-compatible thermal budgets. All devices exhibit AFE double hysteresis loops, with polarization strongly dependent on film thickness and annealing temperature. Phase-field modeling reveals thickness-driven phase transitions enabling low-voltage, high-polarization operation. These characteristics are relevant for future AFE FET. Energy storage performances of linear dielectric (LD), ferroelectric (FE), and AFE films are compared. While FE films show high energy density but large losses, LDs offer high efficiency with low storage density. AFE ZrO2 provides an optimal balance, reaching up to 84 J/cm3 with 75% efficiency. These results position HfZrO2 as a multifunctional platform bridging memory and energy storage technologies.

FM 4.2 Mon 15:30 BEY/0138

From metal to oxide: Oxygen vacancy evolution in HfO_2 controlled by PLD — •Berk Yildirim[1], Oliver Rehm[1], Philipp Gebauer[1], Marc Neumann[1], Andrei Gloskovskii[3], Christoph Schlueter[3], Lutz Baumgarten[2], Ron Tenne[4], and Martina Müller[1] — [1]FB Physik, U Konstanz — [2]FZ Jülich — [3]DESY, Hamburg — [4]Technion, Haifa, Israel

Hafnium dioxide (HfO_2) has emerged as a ferroelectric material for non-volatile memory applications. The ferroelectric phase is linked to the presence and amount of oxygen vacancies (OVs), but their direct experimental observation is challenging. In this work, a combination of in situ soft X-ray and ex situ hard X-ray photoelectron spectroscopy is used to trace the evolution of OVs. To systematically control the oxidation and OV concentration in HfO_2, 120 nm films are grown from stoichiometric targets by pulsed laser deposition (PLD) without oxygen supply, but varying the $SrTiO_3$ (001) substrate temperature T. With increasing T, the amount of metallic Hf is systematically reduced, while the oxide fraction increases. The evolution of Hf 4f spectral features is evaluated as the indirect signature of the T-dependent OV concentration through the Hf^{3+}/Hf^{4+} spectral weight. In addition, photoluminescence measurements confirm the presence and T-dependent variation of OVs. In situ RHEED, ex situ AFM and XRD validate T-driven changes in morphology and structure, linking Hf oxidation state, vacancy concentration and film properties. These results demonstrate that T-controlled oxidation enables a systematic control of OVs and helps clarify how defects influence the formation of ferroelectric HfO_2.

FM 4.3 Mon 15:45 BEY/0138

Influence of Different Transition-Metal defect Dipoles on Polarization Rotation in $BaTiO_3$ — •Aldo Raeliarijaona[1], Ronald E. Cohen[2], and Anna Grünebohm[1] — [1]Ruhr-Universität, Bochum,Germany — [2]Carnegie Institution for Science, Washington D.C., U.S.A

Ferroelectric materials are an important class of materials for various technological applications such as non-volatile random-access memory mainly due to spontaneous electric polarization. Key ferroelectric property is the switching mechanism induced by an electric field. However, defect dipoles in ferroelectrics can act like a bias field or restoring forces to rotation of the polarization after an electric field has been applied and then removed. Using first-principles molecular dynamics, we compare polarization rotation induced by defect dipoles, in which divalent transition metal dopants on the perovskite B-site couple with neighboring oxygen vacancies, in the archetypical ferroelectric BaTiO3. We compare the effects of Cu^{2+}, Mn^{2+}, and Fe^{2+} dopants. We find that copper is much more efficient at enhancing electromechanical coupling or restoring polarization direction, over manganese or iron. We relate this effect of chemistry to the shape and bonding of the transition metal cations.

Reentrant relaxor behaviours in Ba(Ti0.85Zr0.15)O3-Bi(Zn2/3Nb1/3)O3 — •Vladimir Shvartsman[1], Eva Kröll[1], Boriana Mihailova[2], Vadzim Haronin[3], Juras Banys[3], and Doru Lupascu[1] — [1]University Duisburg-Essen, Essen, Germany — [2]University of Hamburg, Hamburg, Germany — [3]Vilnius University, Vilnius, Lithuania

Upon decreasing temperature, thermodynamic systems usually transform from a disordered high symmetry phase to a more ordered phase with lower symmetry. However, in some cases an unusual phase sequence is observed, where after this *normal* transition, an ordered system reenters a disordered phase. We observed the reentrant behavior in the relaxor ferroelectrics (1-x)Ba(Ti0.85Zr0.15)O3-xBi(Zn2/3Nb1/3)O3 (x = 0 - 0.15) by analysis of temperature dependences of the dielectric permittivity. Namely, a frequency-independent maximum associated with the ferroelectric phase transition is followed by a frequency-dependent anomaly at lower temperatures, which is typical of relaxors. Raman spectroscopy revealed a competition between polar and antiferrodistortive modes. Softening of the polar mode related to correlated B-cation displacements leads to the ferroelectric phase transition. On the other hand, correlated antiferrodistortive rotations of the oxygen octahedra give rise to nanometer size clusters of antipolary shifted A-site cations distributed within the polar matrix. Slowing down the dynamics of these clusters leads to the low-temperature dielectric anomaly and reentrant relaxor behavior.

Time-domain thermoreflectance for monitoring thermal conductivity switching in ferroelectric thin film — •Wasim Akram[1], Stefan Dilhaire[2], Thomas Maroutian[3], and Guillaume F. Nataf[1] — [1]GREMAN UMR7347, CNRS, Université de Tours, France — [2]CNRS-LOMA/UMR5798, Université de Bordeaux, France — [3]C2N, CNRS, Université Paris-Saclay, France

Ferroelectric materials that exhibit thermal conductivity switching under external stimuli could serve as promising candidates for thermal conductivity

switches [1,2]. To integrate these switches into miniaturized devices, nanoscale ferroelectric films are essential. In this work, we aim to study ferroelectric thin films and propose to manipulate their thermal conductivity by applying an electric field. To monitor the thermal conductivity, we employ time-domain thermoreflectance (TDTR). In TDTR, the sample surface is periodically heated with a far-infrared pump laser through a metallic transducer, and the resulting thermoreflectance response is probed using a delayed probe laser. The probe reflectivity change is directly related to the temperature evolution at the sample surface. The analysis relies on multilayer heat-transfer models that incorporate the substrate, film, and transducer. However, modelling is sensitive to several experimental constraints, including non-uniform interface properties and interfacial thermal resistance. Here, we address these challenges by optimizing both data-acquisition and sample-preparation methods. We use a home-made software based on Thermal Quadrupole model to fit the signal received by the photodetector [3]. Additionally, we propose to apply an electric field to ferroelectric films to modulate their domain structures, with the goal of achieving multiple fold switching of thermal conductivity. This approach could pave the way toward a device-compatible ferroelectric thermal conductivity switch. [1] Ihlefeld et al. Nano Letters 15 (3), 1791-1795 (2015). [2] Nataf et al. Nature Reviews Materials 9, 530 (2024). [3] Dilhaire et al. J. Appl. Phys. 110, 114314 (2011).

FM 4.6 Mon 16:45 BEY/0138

Correlated domain and crystallographic orientation mapping in uniaxial ferroelectric polycrystals by interferometric vector piezoresponse force microscopy — •Ruben Dragland[1], Jan Schultheiss[1], Ivan Ushakov[1], Roger Proksch[2], and Dennis Meier[1,3,4] — [1]NTNU Norwegian University of Science and Technology, Trondheim, Norway — [2]Asylum Research an Oxford Instruments Company, Santa Barbara, USA — [3]University of Duisburg-Essen, Duisburg, Germany — [4]Research Alliance Ruhr, Bochum, Germany

Advances in scanning probe microscopy techniques are expanding the possibilities for nanoscale characterization of functional materials, giving new opportunities for correlated studies of their local properties. Here, we apply a recent extension of piezoresponse force microscopy (PFM) for simultaneous mapping of polarization domains and local crystallographic orientation in a uniaxial ferroelectric. By shifting the laser beam position on the cantilever, direction-dependent piezoresponse signals are acquired analogous to classical vector PFM, but without the need to rotate the sample. Using polycrystals of the uniaxial ferroelectric $ErMnO_3$ as a model system, we demonstrate that the reconstructed piezoresponse vectors correlate one-to-one with the crystallographic orientations of the micrometer-sized grains, carrying grain-orientation and domain-related information. We establish a versatile platform for rapid, multimodal characterization of polycrystalline uniaxial ferroelectrics, enabling automated, high-throughput reconstruction of polarization, and grain orientations with nanoscale precision.

FM 4.7 Mon 17:00 BEY/0138

Optical control of ferroelectric polarization in epitaxial lead titanate thin films — •Valentine Gillioz, Manfred Fiebig, and Morgan Trassin — ETH Zurich, Switzerland

In this work, we use light as an active tool for remotely and dynamically controlling ferroelectricity in epitaxial $PbTiO_3$-based thin films and heterostructures. The exposure to above-bandgap ultraviolet (UV) light enables the manipulation of charge-screening dynamics via the accumulation of photo-induced charge carriers at the bottom electrode/ferroelectric Schottky interface. A transient light-induced enhancement (or suppression) of spontaneous polarization is observed using second-harmonic generation (SHG) in films with a pristine upward (or downward)-oriented polarization. Here, we explore the impact of $PbTiO_3$ growth conditions on the photoresponse of the films in more depth. Importantly, we show a robust and improved cyclability of the optical modulation of the ferroelectric polarization in films grown at low oxygen partial pressure ($\sim 10^{-2}$mbar) pointing to the role of oxygen vacancies in the light-induced polarization change. In addition, we combine our ability to monitor the polarization dynamics during the thin-film growth process using in-situ SHG with the UV light exposure to balance the depolarizing-field contribution and the light-induced polarizing effect in our heterostructures. We report a strong on/off ratio in the optical manipulation of ferroelectric polarization between a fully depolarized state in dark conditions and a polarized state under UV light exposure. Our work, hence, constitutes a critical step towards all-optical control of ferroelectricity in functional thin films.

FM 4.8 Mon 17:15 BEY/0138

Ferroelectricity in organic - inorganic TMCM-BCl3 (B=Mn, Fe, Zn) materials — •Mwanaidi Mauwa Namisi and Anna Grünebohm — Interdisciplinary Centre for Advanced Materials Simulation (ICAMS), Ruhr-University Bochum, Germany

Ferroelectric materials have switchable polarization in external electric field and play a central role in sensors, memory devices and dielectrics. Although oxide ceramics have been the main focus, they have limited chemical flexibility [1]. In contrast, hybrid organic-inorganic perovskites combine multiple degrees of freedom of both inorganic and organic frameworks enhancing structural versatility [2]. Their phase transition mechanisms and origin of ferroelectricity however remain underrepresented in literature. Here, we investigate the class of TMCM-BCl3 (B=Mn, Fe, Zn) hybrids using DFT methods and discuss these open questions. Furthermore, by B site compositional tuning, we explore the structure-property relations and how the choice of transition metal affects polarization, electronic properties and magnetism.

Tuning the Properties of the Organic Supramolecular Ferroelectric BTA by Dipole Engineering — •Sophia Klubertz[1], Florian Behrendt[2], Johannes Brendel[2], and Martijn Kemerink[1] — [1]IMSEAM, Heidelberg University, Germany — [2]Bayreuth University, Germany

Benzene-1,3,5-tricarboxamide (BTA) has become the paramount example of an organic supramolecular ferroelectric. To widen the property space of these compounds, and to gain insight into the underlying structure-property relations, this work examines the impact of a stepwise replacement of BTA's three amide groups by urea groups, as well as of the anchoring point of the dipolar group. We investigate BTA-C6/2 analogues, where one (BUDA), two (BDUA), or three (BTU) amide groups are substituted by urea groups. The compounds were newly synthesized in their C-centered and N-centered versions, regarding the amide connectivity. True ferroelectric behavior was experimentally demonstrated for C- and N-centered BUDA and BDUA through temperature- and time-dependent electrical switching measurements. By investigating remnant polarization values and double structures in the switching currents, we can draw conclusions about the switching behavior of urea groups in comparison to amide groups of either connectivity. Moreover, we find orders-of-magnitude differences in key properties like retention time, which we rationalize through molecular dynamics simulations. Overall, the results show how chemical structure translates into (ferroelectric) properties.

FM 5: Focus Session: Holistic structural and safety assessment of battery materials and cells

chairs: Carlos Ziebert (Karlsruhe Institute of Technology, DE), Philipp Finster (KIT, DE)

The focus session is dedicated to the characterization of microstructure, electrochemical, thermal and safety properties of Lithium-ion and Post-Lithium cells and their individual active and passive materials. This is required to obtain quantitative and reliable data, which are necessary to improve the current understanding in order to design and develop better and safer materials and cells. Potential topics include, but are not limited to electrochemical characterization techniques , thermal characterization techniques, safety testing, development of safer materials and cell designs, thermodynamic modelling of materials, modelling of thermal runaway and propagation.

Hot-pressing enhances mechanical strength of PEO solid polymer electrolyte for all-solid-state sodium metal batteries — •Lanqing Zhao[1,2], Huaping Zhao[1], Feng Liang[2], and Yong Lei[1] — [1]Institut für Physik & IMN MacroNano* (ZIK), Technische Universität Ilmenau, 98693, Ilmenau, Germany — [2]Faculty of Metallurgical and Energy Engineering, Kunming University of Science and Technology, 650093, Kunming, China

A PEO-based composite polymer electrolyte (CPE) was successfully prepared using an emerging solvent-free hot-pressing method, with Na3Zr2Si2PO12 (NZSP) and NaClO4 incorporated to improve ionic conductivity. Benefiting

from its good mechanical strength and interfacial contact with the electrodes, the Na||Na3V2(PO4)3@C all-solid-state sodium metal battery (ASSSMB) delivers a high-capacity retention of 97.1% after 100 cycles at 0.5 C and 60 °C. Furthermore, the ASSSMB with an electrolyte thickness of approximately 20 μm also demonstrates excellent cycling stability. This study provides a promising strategy for designing stable polymer-ceramic composite electrolytes through hot-pressing to realize high-energy-density sodium metal batteries.

FM 5.2 Mon 15:15 BEY/0E40

Suppressing Li movement in solid-state electrolyte via Cryo EM Workflows: LLZO case study — •yuqi liu[1], yuwei zhang[1], Jazmin Durate[1], Yug Joshi[1], and Baptiste Gault[2] — [1]Max Planck Institute for Sustainable Materials, 40237 Düsseldorf, Germany — [2]Univ Rouen Normandie, CNRS, INSA Rouen Normandie, Groupe de Physique des Matériaux, UMR 6634, F-76000 Rouen, France

Focused Ion Beam-Scanning Electron Microscopy (FIB-SEM) is widely used to examine solid-state battery materials and prepare site-specific samples for advanced techniques such as Electron Backscatter Diffraction (EBSD), Transmission Electron Microscopy (TEM), and Atom Probe Tomography (APT). However, the electron beam can induce irreversible damage particularly in lithium-containing systems by driving lithium displacement and expulsion, thereby compromising data reliability.

In this work, we investigate how cryogenic conditions mitigate beam-induced damage in LLZO, with an emphasis on lithium expulsion under varying beam parameters. We demonstrate that lithium mobility is significantly suppressed at cryogenic temperatures, leading to a marked reduction in beam-driven lithium redistribution. Based on a comprehensive set of cryogenically prepared EBSD and APT datasets, we show that cryo-enabled workflows are essential for obtaining structurally and chemically artefact-free characterization of LLZO and, more broadly, for reliable analysis of solid-state battery materials.

FM 5.3 Mon 15:30 BEY/0E40

Synthesizing the Solid-State Electrolyte LLZO via the Mixed-Oxide Route: The Li loss - Reality or Fiction? — •Daniel Wagner, Torsten E.M. Staab, and Dominik Boras — LCTM/IFB, Julius-Maximilians Universität Würzburg, D-97070 Würzburg, Röntgenring 11

The solid-state electrolyte LLZO is discussed for applications in all solid-state batteries. Undoped and Fe-doped LLZO ($Li_7La_3Zr_2O_{12}$) samples have been synthesized via the mixed-oxide route, i.e. grinding of the educt's powders followed by calcination at 950°C for 6h and a second grinding before pressing into pellets and finally sintering them at 1200°C. The excess Li content and the restrictiveness for atmospheric gas exchange during the synthesis has been varied through usage of lidded crucibles. The samples were characterized by thermogravimetric analysis (TG), mass spectroscopy of its decomposition gas (TG/MS), X-Ray-diffraction (XRD) in reflection geometry and scanning electron microscopy (SEM).The formed phases (cubic and tetragonal) were identified by XRD. The phase fraction showed a clear influence of a varying lithium-excess and/or usage of a restricted gas exchange capability. Lattice defects were investigated by the method of positron annihilation lifetime spectroscopy (PALS). PALS showed clear differences after calcination and at different stages of sintering for both undoped and Fe-doped samples. One option may be increasingly filled Li-lattice sites after the calcination step or a formation of amorphous Li containing phases. No traces of Li were found in the decomposition gases.

Microstructure of Metal Anodes used in Solid-State Batteries and Strategies for Its Control — •Till Fuchs — Center for Materials Research & Institute of Experimental Physics I, Justus-Liebig-University Giessen

The microstructure of materials fundamentally dictates their mechanical, electrochemical, and transport properties. Electron backscatter diffraction (EBSD) enables direct microscopic visualization of these microstructural features, providing quantitative insight into crystallographic orientation, grain morphology, and defect structures. This technique has become essential for understanding how processing pathways and operational conditions shape functional materials.

In a series of recent studies on lithium metal, we demonstrated how its microstructure can be visualized and conceptualized in detail, how it evolves depending on electrochemical cycling and charging conditions, and how it can be deliberately modified or controlled through the use of engineered interlayers. These findings highlight the interplay between microstructure and performance, and show how EBSD-guided analysis can inform strategies for guiding the growth morphology of alkali metal anodes during operation.

The principles established in lithium metal research are then extended to a broader class of energy materials, including nickel-rich layered oxides (NCM) and solid electrolytes. These systems exhibit their own characteristic microstructural challenges, from anisotropic degradation to cracking and dendrite formation in solid electrolytes.

FM 5.5 Mon 16:00 BEY/0E40

Decoding Complex Solid Electrolyte Architectures by an NMR Simulation Approach — •Javier Valenzuela Reina[1], Vera Barysch[2,3], Simone Köcher[2,1], Josef Granwehr[2,3], and Christoph Scheurer[1,2] — [1]Fritz-Haber-Institute der MPG, Berlin — [2]IET-1, Forschungszentrum Jülich — [3]RWTH Aachen

Advancing next-generation lithium batteries requires a detailed understanding of hybrid electrolytes and the complex organic-ceramic interfaces they contain. Nuclear magnetic resonance (NMR) spectroscopy provides a non-destructive, highly sensitive probe of interfacial structure and ion transport, which however is challenging to interpret unambiguously.

In this work, we combine different NMR experiments with theoretical modeling and high-throughput density-functional theory (DFT) simulations to investigate the structural chemistry of Al-doped lithium lanthanum zirconium oxide (LLZO), a leading hybrid electrolyte candidate. By integrating ^{27}Al, ^{7}Li, and ^{1}H NMR measurements with first-principles calculations and simulated NMR parameters, we resolve key features of the Al-doping mechanism and elucidate both bulk and surface environments within the material.

Our results illustrate how a tightly coupled experimental-computational strategy can reveal interfacial behavior that is otherwise difficult to access, and highlight its promise for guiding the design and optimization of hybrid electrolytes with complex interfaces.

The Inclusive Investigation of Defect Thermodynamics for Cl-Ion Battery Materials using Grand Canonical Diagrams — •Johannes Döhn[1] and Axel Gross[1,2] — [1]Institute of Theoretical Chemistry, Ulm University, Germany — [2]Helmholtz Institute Ulm, Germany

In our contribution we use the example of chloride perovskites to discuss the crucial role of defect thermodynamics for electrode and solid electrolyte materials in Cl-ion batteries. In this regard, the energetic relation between the pristine compound, the formation of defects and the conversion into other materials under varying electrochemical conditions is of great importance, though still underexplored.

Here, we suggest an analysis based on grand canonical approaches which is frequently applied using the concepts of ab initio thermodynamics or the computational hydrogen electrode. Grand canonical diagrams contain in a compact form information on the relative stability of the pristine and defective materials as well as potential decomposition products at varying potentials and loadings. Thus they can help to predict whether topotactic or conversion reactions are to be expected during chlorination/dechlorination. Furthermore, relevant properties as the open circuit voltage or the electrochemical stability window can be read off directly from the diagrams.

We demonstrate that this inclusive investigation of all relevant thermodynamic properties presented here enables a comprehensive and intuitive access to the eludication of materials properties which can hardly be gained otherwise.

FM 5.7 Mon 16:45 BEY/0E40

Polaron Calculations at Scale via a DFT-Based Landau-Pekar Model — •Daria Ustimchuk, Karsten Reuter, and Christian Carbogno — Fritz-Haber-Institut der MPG, Berlin

Polarons are of ubiquitous importance in material science, be it for charge retention in energy materials or as charge reservoirs in heterogeneous catalysis. While perturbation theory allows for an accurate and efficient assessment of isolated polarons in perfect crystals [1], addressing higher concentrations in complex, disordered compounds typically requires costly hybrid density-functional theory calculations in many, extended supercells. To facilitate such investigations, we here present several strategies to accelerate the required calculations. In line with Landau-Pekar schemes, we model the mechanisms underlying polaron formation at different levels of theory, e.g., using the harmonic approximation or machine-learning potentials for describing lattice distortions and Madelung or Born effective charges for electrostatic screening effects. We discuss the pros & cons of these techniques by carefully benchmarking their accuracy and reliability for polaron formation in MgO and $BiVO_4$. Furthermore, we apply them to lithium titanium oxide (LTO), a prototypical anode material hosting elevated polaron concentrations. We demonstrate how the proposed approaches allow to semi-quantitatively predict the relevant energetics and geometric distortions, and thereby substantially accelerate the exploration of the humongous phase space associated with polaron formation in disordered energy materials.

Grain-Boundary-Driven Activity Enabled by Grain Size Engineering in Iron-Air Batteries — •Adam Cohen Miles[1], Yujun Zhao[1], Yan Ma[1,2], Dierk Raabe[1], and Yug Joshi[1] — [1]Max Planck Institute for Sustainable Materials, Max Planck Str. 1, 40237 Düsseldorf — [2]Department of Materials Science & Engineering, Delft University of Technology, Mekelweg 2, Delft 2628 CD, the Netherlands

Iron-air batteries are gaining renewed attention as cost-effective candidates for long-duration energy storage. While research to date has focused on improving anode performance through surface area enhancement or chemical additives, the role of iron microstructure in dictating electrochemical behavior remains unexplored. Here, we systematically isolate and examine the effect of grain size on the electrochemical activity of high-purity iron anodes by eliminating confounding factors such as porosity, dopants, and additives. The results reveal a strong inverse correlation between grain size and electrochemical performance, with ultrafine-grained anodes exhibiting substantially higher current densities and diffusive contributions than coarser grained counterparts. This enhancement is attributed to the increased grain boundary density, which promotes charge transfer and mitigates surface passivation. These findings represent the first direct demonstration of grain-size-controlled electrochemical activity in iron-air systems and establish microstructural engineering as a powerful design lever for performance optimization.

FM 5.9 Mon 17:15 BEY/0E40

Bismuth telluride (Bi2Te3) incorporated on 3D-printed carbon electrode for rechargeable aqueous ammonium-ion battery — •Sunny Nandi[1] and Martin Pumera[2] — [1]NTC, University of West Bohemia in Pilsen, Pilsen, Czech Republic — [2]NTC, University of West Bohemia in Pilsen, Pilsen, Czech Republic

Lithium-ion batteries are leading the battery market but there are ever growing concerns over the sustainability of Li-based batteries due to paucity and escalating cost of Li-resources. Therefore, it become increasingly important to develop a low cost and easily processable novel energy storage technologies in the future. Hence, ammonium-ion battery based on aqueous electrolyte hold great potential owing to their low cost, high safety and excellent electrochemical characteristics. In an effort to develop such NH4+ ion based rechargeable electrochemical cells. Herein, for the first time, we report here the working of a rechargeable aqueous ammonium (NH4+) ion battery by integrating a topological insulator, bismuth telluride (Bi2Te3), onto a 3D printed nanocarbon electrode as anode and copper hexacyanoferrate (CuHCF) as the cathode. Taking advantage of the 3D porous framework and the non-metallic nature of NH4+ ions, the ammonium-ion cell delivers a high energy density of 134.8 Wh kg*1 and a power density of 1800 W kg-1 in 1 M (NH4)2SO4, outperforming previously reported studies. Furthermore, ex-situ characetrization clearly explain the plausible storage mechanism of NH4+ insertion. We show immense promise of the system by recycling and reusing the used 3D printed nanocarbon electrode for next-generation energy storage systems.

FM 5.10 Mon 17:30 BEY/0E40

Investigation of Degradation Mechanisms in High-Nickel NMC Cathodes for Lithium-Ion Batteries — •Yosra Dammak — Max Planck Institute for Sustainable Materials, Düsseldorf, Germany

High-nickel layered oxides like NMC955 are attractive cathode materials for lithium-ion batteries. However, their long-term use is often hindered by structural and mechanical degradation during cycling.

This study examined the influence of electrode microstructure and cycling parameters on the performance and degradation of NMC955 cathodes, comparing two average grain sizes: NMC-1.0 (1 micrometer) and NMC-0.5 (0.5 micrometer). The finer-grained NMC-0.5 consistently outperformed NMC-1.0, showing higher specific capacity, better capacity retention, and superior rate capability. Post-mortem analysis indicated that NMC-1.0 suffered from extensive intergranular cracking, while NMC-0.5 particles mostly remained intact. Microstructural analysis (SEM and EBSD) revealed that the coarser NMC-1.0 accumulated higher, heterogeneously distributed strain, especially at the grain boundaries, which promoted fracture. Conversely, the finer NMC-0.5 accommodated strain through more distributed deformation, facilitated by faster grain boundary diffusion. Both grain sizes maintained their layered structure as confirmed by XRD.

In summary, the enhanced electrochemical and microstructural stability of the finer-grained NMC-0.5 is attributed to its ability to manage strain more effectively, contrasting with the strain-induced cracking observed in the coarser NMC-1.0.

FM 5.11 Mon 17:45 BEY/0E40

Sodium Contamination Impact on Performance of Lithium-Ion Battery Cells — •Slaheddine Jabri[1], Krum Banov[2], Anita Röstek[3], Wibke Dempwolf[4], Olaf Rienitz[3], Petr Novák[2], Markus Etzkorn[1], and Uta Schlickum[1] — [1]Institute of Applied Physics Mendelsohnstraße 2, 38106 Braunschweig, Germany — [2]Institute of Energy and Process Systems Engineering, Langer Kamp 19b, 38106 Braunschweig, Germany — [3]Physikalisch-Technische Bundesanstalt (PTB), Bundesallee 100, 38116 Braunschweig, Germany. — [4]Institut für Technische Chemie, Hagenring 30, 38106 Braunschweig, Germany

Sodium impurities can enter battery materials through several contamination sources, particularly when NaCl or NaOH are used in the recycling processes. Residual sodium is difficult to eliminate completely, and due to its high solubility, it easily dissolves into the electrolyte, where it may influence the cell performance. In this work, the electrochemical testing of high power NMC881-Graphite cells was studied using LP572 electrolyte containing sodium Na+ impurities with various concentrations. It was found that the discharge capacity decreased drastically and increase of impedance compared to Na+ free electrolyte. The Na+ ion sodium could intercalate between the Graphen layers like Li+ and due to its big ionic radius and higher charge density modify the C-C bonding and lattice parameters. The degradation effects could be found with 3 ppm Na level as impurity in electrolyte.

FM 6: Focus Session: Materials Discovery I – Material informatics

chairs: Anna E. Böhmer (Ruhr Universität Bochum, DE), Suguru Yoshida (Kyoto University, JP)

Discovering new functional materials is crucial to advance today's technologies, ranging from caloric cooling via catalysis to next-generation energy conversion and storage, such as thermoelectric, ferroelectric, and ionic conductor materials. New materials also form the basis for potential applications in quantum information technologies. This session provides a platform to highlight functional materials discoveries and how they come about. Notably, systematic searches with high-throughput synthesis approaches, as well as predictions from materials informatics, have helped to go beyond serendipitous discoveries in recent years. However, intuition guided by general principles remains an important factor. In this session, we particularly welcome contributions that showcase the discovery of new functional materials with original approaches. Diverse material systems - from well-established to emerging and niche classes across condensed-matter and materials physics - will be featured. Bringing together diverse discoveries in a single session will help delineate general principles and inspire future work.

Data-driven Discovery of 2D Non-van der Waals Materials and Design of Their Heterostructures — Anastasiia Nihei[1,2], Tom Barnowsky[1,2], and •Rico Friedrich[1,2] — [1]TU Dresden — [2]Helmholtz-Zentrum Dresden-Rossendorf

Two-dimensional (2D) materials and their heterostructures are a platform to realize advanced electronic and magnetic functionalities at the nanoscale. With traditional 2D systems extracted from weakly van der Waals (vdW) bonded bulk layered compounds, the experimental fabrication of semiconducting non-vdW 2D materials obtained from non-layered crystals [1] came as a surprise.

In our recent data-driven investigations [2], we discover several dozens of new candidates exhibiting appealing electronic, optical, and magnetic properties owing to the (magnetic) cations at their active surfaces. The electronic and magnetic properties of these next generation 2D compounds are also demonstrated to be controllable by a surface chemistry approach employing for instance hydrogen passivation [3]. Eventually, their chemically bonded interfaces in non-vdW heterostructures [4] give rise to qualitatively new properties and potential functionalities including hybrid interface bands, strong magnetic coupling, and characteristic strong moiré property variations upon twisting.

Exfoliation and Cleavage of Crystals from a Universal Potential — •Tom Barnowsky[1,2], Carsten Timm[3], and Rico Friedrich[1,2] — [1]Theoretical Chemistry, TU Dresden — [2]Institute of Ion Beam Physics and Materials Research, HZDR — [3]Institute of Theoretical Physics, TU Dresden

Two-dimensional (2D) materials display unique electronic, optical, and mechanical features that differ from their three-dimensional bulk counterparts. Most known 2D materials are derived from layered crystals but recent experiments reveal that even non-layered compounds can give rise to stable so called non-van der Waals (vdW) 2D sheets [1]. Current models, however, provide limited guidance for such materials: existing descriptors and computational approaches are largely tailored to vdW layered systems [2].

We present a computational framework that predicts crystal cleavage and exfoliable 2D sheets directly from arbitrary bulk structures [3]. At its core is a universal interatomic potential enabling rapid, large-scale screening of diverse materials. Two complementary algorithms detect weakly bonded planes and iteratively isolate connected 2D subunits. Applying this approach, we identify several thousand candidate 2D materials from non-layered bulk crystals, opening a systematic route to explore and design new low-dimensional materials with unprecedented chemical and structural diversity.

Research data management for high-throughput DFT calculations using NOMAD Oasis — •Vikrant Chaudhary[1,2], Fu Li[2], Yue Zhao[2], Joseph F. Rudzinski[1], Nathan Daelman[1], and Hongbin Zhang[2] — [1]Physics Department and CSMB, Humboldt-Universität zu Berlin, Germany — [2]Institute of Materials Science, Technical University of Darmstadt, Darmstadt, Germany

NOMAD Oasis is an open-source, locally installable version of the central NOMAD software [nomad-lab.eu] [1]. Importantly, it allows users to add custom extensions such as data schemas and workflows. In this work, we showcase two representative cases implemented in our local NOMAD Oasis: (I) high-throughput spin Hall conductivity calculations for 4486 2D materials [2], and (II) medium-throughput bulk-photovoltaic effect in 549 experimentally available two-dimensional hybrid perovskites. In both cases, data generation relies on complex computational workflows involving multiple software packages, including VASP, Wannier90, and WannierBerri. We implement a customized parser for Wannier90, and a locally developed parser for WannierBerri, with the resulting data organized based on NOMAD's built-in workflow functionalities. These examples show how NOMAD Oasis can simplify large-scale computational data management with custom parsers, automated workflows, unrestricted storage and uploads, and enhanced privacy. It also ensures compliance with the FAIR principles, making data Findable, Accessible, Interoperable, and Reusable.

Finding interoperable datasets in diverse databases via provenance and similarity analysis — •Martin Kuban, Alvin Noe Ladines, Thea Denell, Lauri Himanen, Joseph F. Rudzinski, Claudia Draxl, and FAIRmat team — Physics Department and CSMB, Humboldt-Universität zu Berlin, Germany

Collecting data from different sources has the potential to significantly increase the amount of available data for data-driven discovery. However, different producers of data use distinct methods and setups, e.g., approximations and parameters used in computational data, to achieve the best data quality for the properties that are studied in a specific project. Bringing these data together requires to understand the impact of the method and setup on the accuracy and precision of the produced data. In order to do so, two key requirements must be fulfilled: First, the provenance and metadata of each data point need to be recorded. This can be achieved by leveraging the NOMAD infrastructure[1, 2], an ecosystem of parsers, schemas, and workflow tools, to extract rich metadata and provenance information. Second, using this information, similarity metrics can be used to identify data that achieve similar precision besides distinct computational setups[3]. We showcase our approach on different examples using data from NOMAD.

Search for thermodynamically stable ambient-pressure superconducting hydrides in GNoME database — Antonio Sanna[1,2], Tiago F. T. Cerqueira[3], Ekin Dogus Cubuk[4], Ion Errea[5,6,7], and •Yue-Wen Fang[6] — [1]Max-Planck-Institut für Mikrostrukturphysik, Weinberg 2, D-06120 Halle, Germany — [2]nstitut für Physik, Martin-Luther-Universität Halle-Wittenberg, D-06099 Halle, Germany — [3]CFisUC, Department of Physics, University of Coimbra, Rua Larga, 3004-516 Coimbra, Portugal — [4]Periodic Labs, San Francisco, CA, USA — [5]Fisika Aplikatua Saila, Gipuzkoako Ingeniaritza Eskola, University of the Basque Country (UPV/EHU), Europa Plaza 1, 20018 Donostia/San Sebastián, Spain — [6]Centro de Física de Materiales (CFM-MPC), CSIC-UPV/EHU, Manuel de Lardizabal Pasealekua 5, 20018 Donostia/San Sebastián, Spain — [7]Donostia International Physics Center (DIPC), Manuel de Lardizabal Pasealekua 4, 20018 Donostia/San Sebastián, Spain

There are very few ambient-pressure hydride superconductors in experiment, and their critical temperatures (T_c) are typically < 10 K. Herein, by combining machine learning techniques with ab initio methods, we have identified 25 cubic thermodynamically stable hydrides with T_c beyond the boiling point of liquid helium (4.2 K) from the GNoME database. These cubic hydrides all crystallize in double-perovskite-like or fluorite-like structures, and most of them demonstrate T_c lower than 10 K. Our study provide more candidates for the study of ambient-pressure superconductivity in the hydrides that can be very likely to be synthesized in experiment despite the low T_c.

FM 6.7 Tue 11:30 BEY/0138

Exploration of high-entropy alloys for key electrochemical reactions: a comparative study for the solid solution systems X-Pd-Pt-Ru (X=Cu, Ir, Ni) — •Jan Lukas Bürgel[1], Rico Zehl[1], Felix Thelen[1], Ridha Zerdoumi[1,2], Olga A. Krysiak[2], Benedikt Kohnen[1], Ellen Suhr[1], Wolfgang Schuhmann[2], and Alfred Ludwig[1] — [1]Chair for Materials Discovery and Interfaces, Institute for Materials, Faculty of Mechanical Engineering, Ruhr University Bochum, Bochum, Germany — [2]Analytical Chemistry - Center for Electrochemical Sciences (CES), Faculty of Chemistry and Biochemistry, Ruhr University Bochum, Bochum, Germany

Developing new electrocatalysts is essential for green energy technologies such as hydrogen production, fuel cells, and environmental remediation. Compositionally complex solid solutions offer vast opportunities for catalyst discovery due to their tunable surface sites, but exploring their large compositional spaces requires optimised strategies. Using a high-throughput approach, the electrocatalytic activity of the three quaternary systems X-Pd-Pt-Ru (X = Cu, Ir, Ni) was screened for four reactions in alkaline media: oxygen evolution, oxygen reduction, hydrogen evolution, and nitrate reduction reaction. Thin-film materials libraries were synthesised and characterised to identify composition-activity relationships, while also considering relevant information on crystal structure and surface morphology. The resulting multidimensional dataset reveals clear trends, similarities, and distinct activity maxima, demonstrating the effectiveness of this approach for navigating complex multinary systems.

FM 6.8 Tue 11:45 BEY/0138

Phase formation and stability of transition-metal solid solutions containing volatile elements — Martin Kostka[1], Luqman Mustafa[1], Jill Fortmann[2], Aurelija Mockute[2], Alan Savan[2], Susanne Kunzmann[3], Anna Grünebohm[3], Alfred Ludwig[2], Andreas Kreyssig[1], and •Anna E. Böhmer[1] — [1]Experimental physics IV, Ruhr University Bochum, 44801 Bochum, Germany — [2]Materials Discovery and Interfaces, Institute for Materials, Ruhr University Bochum, 44801 Bochum, Germany — [3]Interdisciplinary Centre for Advanced Materials Simulation (ICAMS), Ruhr University Bochum, 44801 Bochum, Germany

In the combinatorial synthesis of thin films, multiple elements are simultaneously deposited to achieve well-defined composition gradients and create a materials library. However, including volatile elements directly into the combina-

torial synthesis is a challenge. Here, we use instead a two-step synthesis process combining combinatorial cosputtering with a separate ex-situ reaction step with the volatile elements Se and Sb. In particular, we investigate the phase formation and stability of the (Fe,Ni)Sb_2 and (Fe,Cr)Sb_2 solid solutions in the orthorhombic marcasite structure. Further, we study the (Fe,Co)Se_2 solid solution, which is on the brink of transformation from orthorhombic marcasite to cubic pyrite structure. Our preparation route with a separate low-temperature synthesis step permits detailed studies of solid solutions and phase diagrams at well-defined temperatures.

FM 6.9 Tue 12:00 BEY/0138

AI for Complex Catalytic Systems: C2 Catalysis — •Haobo Li — Nanyang Technological University, Singapore

AI-driven big data set analysis offers opportunities for theoretical research on systems that combine complex catalyst materials with intricate catalytic reactions. In this study, we explore high-entropy alloys (HEAs) as potential electrocatalysts for the electrochemical semihydrogenation of acetylene. HEAs provide a variety of surface active sites due to the diverse combination of constituent elements, while the presence of bidentate dicarbon species further complicates surface interactions. By integrating density functional theory computations, geometric optimizer development, and graph neural network-based machine learning predictions, we efficiently compile a comprehensive database of 52,900 adsorption properties for AgAuCuNiPd HEA surfaces. Lasso regression and t-SNE projection reveal the distinct influences of the five metal components on adsorption and reaction properties. Using Cu as a reference, logistic regression assesses the potential for other components to surpass Cu in terms of catalytic activity and selectivity toward ethylene. Our findings suggest that, while HEAs can enhance the reaction, the ternary AgAuCu alloy achieves optimal results, indicating that high entropy is not essential. This research methodology can be extended to other complex catalytic systems, providing valuable insights into catalytic mechanisms and facilitating experimental endeavors.

FM 6.10 Tue 12:15 BEY/0138

Compositional and Structural Impact on the Hydrogen Evolution Reaction Activity across Noble-Metal-Based Compositionally Complex Solid Solutions Thin Film Libraries — •Natalia Pukhareva[1], Moonjoo Kim[2], Felix Thelen[1], Geovane Arruda de Oliveria[2], Rico Zehl[1], Wolfgang Schuhmann[2], and Alfred Ludwig[1] — [1]Materials Discovery & Interfaces, Ruhr University Bochum — [2]Analytical Chemistry - Center for Electrochemical Sciences (CES), Ruhr University Bochum

Compositionally complex solid solutions (CCSS) stabilize multielement alloys and allow tuning of surface chemistry for the hydrogen evolution reaction (HER). Three quinary libraries (Ir-Pd-Pt-Rh-Ru, Ag-Au-Pd-Pt-Ru, Ag-Au-Cu-Pd-Pt) were prepared by sputtering and mapped across 342 positions each. Energy-dispersive X-ray spectroscopy (EDX) confirmed smooth composition gradients, and X-ray diffraction (XRD) showed fcc solid solutions with minor hcp fractions in Rh-Ru-rich regions and no detectable phase effect on HER. X-ray photoelectron spectroscopy (XPS) with Gaussian-process regression revealed composition-dependent surface segregation and distinct surface compositions. HER activity, measured by scanning electrochemical cell microscopy (SECCM), followed Ir-Pd-Pt-Rh-Ru > Ag-Au-Pd-Pt-Ru > Ag-Au-Cu-Pd-Pt. In the Ag-containing libraries Pd-rich compositions outperformed Pt-rich ones, and in Ag-Au-Cu-Pd-Pt Ag-rich regions exceeded Cu-rich regions despite Cu's higher intrinsic activity, consistent with segregation limiting surface Pt and Pd and indicating that HER in these CCSS is dominated by multielement interactions.

FM 6.11 Tue 12:30 BEY/0138

Soft Degradable Magnetic Microcarriers for Encapsulation and Guided Transport of Drugs and 3D Spheroids — •Lulu Song, Xinne Zhao, Xuan Peng, Željko Janićijević, Lin Guo, Denys Makarov, and Larysa Baraban — Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Soft microrobots hold strong promise for next-generation biomedical applications, including targeted drug delivery, tissue engineering, and minimally invasive therapies. However, their translation remains limited by challenges in scalable fabrication, controlled biodegradation, and insufficient co-encapsulation and transport of diverse cargos. Here, we present degradable hydrogel microcarriers fabricated via droplet-based microfluidics and UV photopolymerization, enabling scalable production with tunable properties. These microcarriers can co-encapsulate therapeutic molecules, superparamagnetic particles, and living cell spheroids, supporting multifunctional delivery strategies. Their motion is precisely actuated under externally applied gradient magnetic fields, allowing guided navigation in microchannels for targeted delivery. Importantly, the microcarriers exhibit programmable degradation under physiological conditions, providing temporary mechanical integrity, controlled release, and safe post-treatment clearance, with complete degradation at 37 °C within several days. Overall, this platform offers a robust and biocompatible soft microrobotic system for targeted therapies, micro-tissue transport, and diagnostic monitoring, representing a promising step toward clinical translation.

FM 7: Crystal Defects and Real Structure Physics in Diamond and Functional Materials I

FM 7.1 Tue 9:30 BEY/0E40

Fluorescence lifetime measurements of NV- and NV0 color center ensembles at room temperature and 4K in HPHT, CVD and nanodiamond samples — •Kai Kühnlenz, Kevin Lauer, Phillip Kellner, Mario Bähr, Andreas T. Winzer, and Thomas Ortlepp — CiS Forschungsinstitut für Mikrosensorik GmbH, Konrad-Zuse-Str. 14, 99099 Erfurt, Deutschland

Nitrogen vacancy (NV) centers in diamond are key solid-state quantum emitters whose photophysical properties depend on their charge state and the surrounding diamond lattice. We analyze diamond samples made of chemical vapor deposition- (CVD), high-pressure-high-temperature- (HPHT) or nanodiamond material by exciting them with a 513nm green laser and detecting the fluorescence light via time resolved photoluminescence (TRPL). This work presents measurements of the fluorescence lifetime of NV-ensembles. Hereby a monochromator is employed to detect 20nm wide spectral bands centered at the NV- phonon sideband (710nm) and the zero-phonon-lines of NV- and NV0 (638nm and 575nm) to differentiate between the charge states. Measurements are performed at both room temperature (293K) and 4K. The influence of varying excitation laser power and of the selected spectral detection window is investigated and compared with established reference values. The measurement approach allows a systematic comparison of NV-diamond materials and provides a baseline for quantitative lifetime-based characterization of NV ensembles.

FM 7.2 Tue 9:45 BEY/0E40

Diamond windows for microwave application: numerical analyses and characterization by microscope and Raman measurements — •Gaetano Aiello, Andreas Meier, Theo Scherer, Sabine Schreck, and Dirk Strauss — Karlsruhe Institute of Technology, Institute for Applied Materials, 76021 Karlsruhe, Germany

Electron cyclotron heating and current drive systems in nuclear fusion devices feature optical quality polycrystalline diamond windows for the transmission of microwave beams of 1 to 2 MW power. The windows consist of diamond disks of 1 to 2 mm thickness integrated into a metallic housing. Numerical analyses verify the performance of such windows with respect to temperature and stress limits. In this work, examples of analyses are provided with reference to a Brewster-angle window design featuring a first-of-its-kind manufactured diamond disk with 180 mm diameter. For the first time, instead of a single constant value, the entire map of the loss tangent measured over the disk has been given as input to the analysis. In addition, examples of microscope and Raman investigations of the disks are shown with reference to dark microfeatures and residual stresses generated by the chemical vapour deposition process.

FM 7.3 Tue 10:00 BEY/0E40

Investigation of irradiation effects in artificial diamond — •Theo Andreas Scherer and Francesco Mazzocchi — Karlsruhe Institute of Technology KIT-IAM-AWP 76344 Eggenstein-Leopoldshafen

Diamond is used as window material for high power microwave transmission to heat plasmas and to perform diagnostics in nuclear fusion devices like ITER, Wendelstein 7X or ASDEX-UG. In such environments neutron and gamma radiation has a quite important influence on dielectric and thermal properties of diamond. Spectroscopic investigations, like RAMAN, cathode luminescence or EPR can detect all the defects produced by irradiation. Swift heavy ion and neutron irradiation was us to study defect chemistry and physics in diamond (single crystalline and polycrystalline diamond samples). Newest results of this investigation are presented.

FM 7.4 Tue 10:15 BEY/0E40

EC Heating systems for present and future fusion experiments and power plants — •Peter Späh — KIT, Institute for Applied Materials, Karlsruhe, Germany

CVD diamond windows are an essential component in Electron Cyclotron (EC) plasma heating and stabilisation systems for nuclear fusion reactors. Beside the characterisation and qualification of CVD diamond disks and the design and

analysis of CVD diamond window assemblies, the Institute for Applied Materials (IAM) at Karlsruhe Institute of Technology (KIT) also contributes to concept findings, layout, design and integration of EC heating systems for several fusion experiments and power plant studies.

Experimental fusion devices and future fusion power plants with magnetic confinement require powerful heating systems for plasma core heating, plasma disruption mitigation, breakdown of gas, plasma ramp-up and -down, impurity control and to counteract thermal instabilities. Electron Cyclotron Resonance Heating (ECRH) is one of these heating systems. Microwave beams in the frequency range of 80 to 240 GHz are generated by gyrotrons and subsequently transmitted via waveguides and an antenna into the plasma chamber, where they interact with the electrons.

This talk gives an overview on the design status of the EC heating antennas for the EU DEMO fusion power plant and for the Volumetric Neutron Source (VNS) which is a conceptual study of a beam-driven Tokamak, serving as test-bed for full-sized breeding blanket modules.

coffee break

FM 7.5 Tue 10:45 BEY/0E40

Application of Raman and Photoluminescence Spectroscopy to MgO-C Refractories — •Julia Richter[1], Felix Drechsler[1], Till Stadtmüller[2], Cameliu Himcinschi[1], Christos Aneziris[2], and Jens Kortus[1] — [1]Technische Universität Bergakademie Freiberg - Institut für Theoretische Physik, Leipziger Straße 23, 09599 Freiberg, Germany — [2]Technische Universität Bergakademie Freiberg - Institut für Keramik, Feuerfest und Verbundwerkstoffe, Agricolastraße 17, 09599 Freiberg, Germany

By applying Raman and photoluminescence (PL) spectroscopy in the visible and near-infrared range to MgO, magnesia-carbon (MgO-C) refractory bricks - partially produced from recycled magnesia - are examined in hardened and coked state, and compared with nominally pure MgO powder as a reference. Two sharp, high-intensity PL signals (699 nm and 871 nm), each accompanied by symmetrical sidebands, are investigated by varying the excitation wavelength (532, 633, and 785 nm). The 699 nm PL feature observed for both brick and reference arises from Cr^{3+} impurities within the MgO lattices, whereas the 871 nm signal, associated with V^{2+}, appears only in the brick-derived MgO. To elucidate the origin of the symmetrical sidebands, temperature-dependent spectroscopic measurements from 100 to 295 K are performed, monitoring the intensity ratio of the higher-energy (anti-Stokes) and lower-energy (Stokes) sidebands. The results confirm phonon participation in both the MgO:Cr^{3+} and MgO:V^{2+} emission processes. Together, these findings connect fundamental defect physics with practical considerations in refractory material science.

FM 7.6 Tue 11:00 BEY/0E40

Creation of Color Centers in Magnesium Fluoride Single Crystals by Irradiation with MeV Heavy Ions — •Ayman El-Said — Physics Department and Interdisciplinary Research Center for Advanced Materials, King Fahd University of Petroleum and Minerals, Dhahran 31261, Saudi Arabia

The irradiation of ionic halide single crystals with MeV heavy ions can lead to the creation of various types of color centers [1]. Here, MgF2 single crystals were irradiated with MeV heavy ions of different energies and fluence [2]. UV-Vis spectroscopic measurements demonstrate the existence of F1-, F2-, and F3-centers due to ion irradiation. The type, concentration and creation efficiency of the observed color centers are studied in terms of ion fluence and energy loss. The results are not only of high importance for understanding the creation mechanism of the induced color centers but also for the degradation of optical materials in high-altitude and space environments.

Acknowledgements: Parts of this research were carried out at the Ion Beam Center at the Helmholtz-Zentrum Dresden-Rossendorf e. V., a member of the Helmholtz Association. Ayman S. El-Said acknowledges the support by KFUPM, Saudi Arabia (Project: ISP24236).

FM 7.7 Tue 11:15 BEY/0E40

Oxygen vacancies in vanadium dioxide: A DFT+*V* study — •Oskar Leibnitz[1,2], Peter Mlkvik[1], Nicola A. Spaldin[1], and Claude Ederer[1] — [1]Materials Theory, Department of Materials, ETH Zurich, Switzerland — [2]Present address: Multifunctional Ferroic Materials, Department of Materials, ETH Zurich, Switzerland

We present a density-functional theory study of the effects of oxygen vacancies on the structural and electronic properties of vanadium dioxide (VO_2). Our motivation is the reported suppression of the metal-insulator transition by oxygen vacancies and the lack of a clear consensus on its origin. We use the DFT+*V* method with a static intersite vanadium-vanadium interaction term, *V*, to calculate the properties of the oxygen-deficient metallic rutile and insulating monoclinic M1 phases of VO_2 on the same footing. We find that oxygen vacancies induce local distortions in the M1 phase, but do not destroy the dimerization usually associated with the insulating behavior. In spite of this, we find that the M1 phase becomes metallic as a result of the partial filling of the conduction band due to a rigid-band-like doping effect.

FM 7.8 Tue 11:30 BEY/0E40

Distortion tensor around dislocations in GaN studied by electron backscatter diffraction and cathodoluminescence spectroscopy — •Domenik Spallek, Vladimir Kaganer, Oliver Brandt, Thomas Auzelle, and Jonas Lähnemann — Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany

The effect of elastic distortion in the vicinity of a threading dislocation (TD) in GaN on its luminescence has been shown previously [1]. However, quantifying this distortion and its components remains a challenge. Therefore, we investigate individual TDs by correlated high-resolution electron backscatter diffraction (HR-EBSD) and cathodoluminescence (CL) spectroscopy. The sample is a high-purity, homoepitaxial GaN layer grown by molecular beam epitaxy with a low TD density.

A cross-correlation analysis with the software CrossCourt from BLG Vantage is used to determine the spatially-resolved components of the distortion tensor from the HR-EBSD results [2]. Signatures of the TDs are resolved in the elastic strain and rotation components. Through reference measurements, we explore the resolution limit of this analysis and its dependence on the material and measurement conditions. Hyperspectral CL maps show a reduced intensity as well as a shifted emission wavelength around the TD. With additional modeling of the distortion around a TD, these correlated measurements are related to the Burger's vector of the dislocation, determining its type.

FM 8: Multiferroics and Magnetoelectric Coupling (joint session MA/FM)

Time: Tuesday 9:30–12:30 Location: POT/0112

See MA 17 for details of this session.

FM 9: Focus Session: Materials Discovery II – High throughput searches for functional magnetic materials (joint session FM/MA)

chairs: Jan Schultheiß (Norwegian University of Science and Technology, NO), Hiroki Taniguchi (Nagoya University, JP)

Discovering new functional materials is crucial to advance today's technologies, ranging from caloric cooling via catalysis to next-generation energy conversion and storage, such as thermoelectric, ferroelectric, and ionic conductor materials. New materials also form the basis for potential applications in quantum information technologies. This session provides a platform to highlight functional materials discoveries and how they come about. Notably, systematic searches with high-throughput synthesis approaches, as well as predictions from materials informatics, have helped to go beyond serendipitous discoveries in recent years. However, intuition guided by general principles remains an important factor. In this session, we particularly welcome contributions that showcase the discovery of new functional materials with original approaches. Diverse material systems - from well-established to emerging and niche classes across condensed-matter and materials physics - will be featured. Bringing together diverse discoveries in a single session will help delineate general principles and inspire future work.

Time: Tuesday 14:00–15:30 Location: BEY/0138

Invited Talk FM 9.1 Tue 14:00 BEY/0138

Thin film combinatorial studies of functional magnetic materials — •Nora Dempsey — Institut NEEL, CNRS/UGA, Grenoble, France

Combinatorial studies based on the preparation and characterisation of compositionally graded thin films are being used for the screening and optimization of a range of functional materials [1]. When combined with Machine Learning (ML), such high-throughput film-based studies hold much potential to guide data driven design of new materials [2,3]. In this talk I will outline our work at Institut Néel on high throughput fabrication and characterisation of functional magnetic materials as well as our recent developments concerning data handling and analysis. I will then show examples from on-going studies of the effect of composition and fabrication conditions on both structural and magnetic properties of hard magnetic and magnetocaloric materials. I will finish up by briefly outlining preliminary results from ML-driven data analysis for the accelerated development of functional magnetic materials with reduced dependence on critical elements, carried out in the framework of various collaborations. [1] ML Green et al., J. Appl. Phys. 113 (2013) 231101 [2] A.G. Kusne et al. Sci. Rep. 4 (2014) 6367 [3] A. Ludwig, npj Comput. Mater. 5 (2019) 70

FM 9.2 Tue 14:30 BEY/0138

Potentially magnetic platinum oxides obtained by computationally guided high-pressure synthesis — •Yasuhito Kobayashi[1], Akitoshi Nakano[2], Shunsuke Kitou[3], Tomasz Klimczuk[4], Hidefumi Takahashi[1,5], and Shintaro Ishiwata[1,5] — [1]Division of Materials Physics, The University of Osaka, Japan — [2]Department of Physics, Nagoya University, Japan — [3]Department of Advanced Materials Science, The University of Tokyo, Japan — [4]Advanced Materials Center, Gdansk University of Technology, Poland — [5]Institute for Open and Transdisciplinary Research Initiatives, The University of Osaka, Japan

The exploration of Pt-based oxides has remained significantly limited, primarily due to the high chemical inertness of platinum and the typically nonmagnetic d^6 or d^8 electronic configurations. Here, we report the discovery of a new layered homologous series of Pt-based ternary oxides, $Na(PtO_2)_{2n+1}$ (n = 1, 2), synthesized through a combination of highly oxidizing high-pressure techniques and density functional theory (DFT) calculations. This series features unprecedented layered structural motifs composed of rutile-based PtO_6 octahedra and one-dimensional PtO_4 square-planar chains, distinct from the perovskite-based Ruddlesden-Popper oxides. We discuss the possibility that this layered homologous series represents the first realization of a magnetic Mott insulator within Pt-based oxides, where $NaPt_3O_6$ (n = 1) exhibits localized spin behavior with an effective spin S = 1/2, likely arising from the unusual d^7 electronic configuration of square-planar Pt^{3+} along with one-dimensional antiferromagnetic interactions.

FM 9.3 Tue 14:45 BEY/0138

Magnetism and electrical and thermal transport in the natural $Fe_{1-x}Mn_xWO_4$ (x=0.2) mineral from Potosí, Bolivia — •Skachko Dmytro[1], Bohdan Kundys[2], Volodymyr Levytskyi[1], Esteban Zuñiga-Puelles[1], Andreas Leithe-Jasper[3], and Roman Gumeniuk[1] — [1]Institut für Experimentelle Physik, TU Bergakademie Freiberg, 09596 Freiberg, Germany — [2]Université de Strasbourg, CNRS, Institut de Physique et Chimie des Matériaux de Strasbourg, UMR 7504, Strasbourg F-67000, France — [3]Max-Planck-Institut für Chemische Physik fester Stoffe, 01187 Dresden, Germany

The natural ferberite single crystal of $Fe_{0.8}Mn_{0.2}WO_4$ composition with the monoclinic $NiWO_4$-type structure ($P2/c$) [a = 4.74751(6) Å, b = 5.71335(7) Å, c = 4.96847(5) Å, β = 90.15(1)°] reveals multiple magnetic transitions at T_{N1} = 67(1) K, T_{N2} = 28(3) K, T_{N1}^{cp} = 66(1) K and T_{N2}^{cp} = 8(1) K. The reduced magnetic entropy of ≈ Rln3 observed near T_{N1} indicates the simplified LS-coupling scheme to fail in the description of complex magnetic behavior of the studied ferberite. The temperature dependence of electrical resistivity [$\rho(T)$] shows a semiconducting exponential decay saturating at ≈ 300 K. The activation energy of the decay is found to be ≈310 meV. Temperature dependence of thermal conductivity [$\kappa(T)$] is characterized by a well defined maximum at ≈68 K, which is described by the Debye-Callaway model, pointing to the dominance of phonon scattering on defects and *umklapp* processes. Despite revealing relatively low $\kappa(T)$ and high Seebeck coefficient $Fe_{0.8}Mn_{0.2}WO_4$ is rather poor thermoelectric material because of enhanced $\rho(T)$.

FM 9.4 Tue 15:00 BEY/0138

Ab initio-based phase diagrams for compositionally complex ThMn12-type alloys — •Sourabh Kumar[1], Semih Ener[2], and Tilmann Hickel[1] — [1]Bundesanstalt für Materialforschung und -prüfung, 12489 Berlin — [2]Technische Universität Darmstadt, 64289 Darmstadt

The structural and chemical stability of rare-earth-based transition-metal (such as Nb, Ce, and Sm) alloys is critical in determining the performance of modern hard magnets (HMs), particularly their coercivity and thermal robustness. This study examines the intrinsic phase competition in (Sm/Ce)-(Fe/Co)-Ti systems, focusing on how Ti additions influence the thermodynamic stability of high-temperature HMs. Two compositional pathways were examined: one dominated by Sm/Ce-Fe/Co binary chemistry and the other influenced by (Sm/Ce)-(Fe/Co)-Ti ternary interactions. We employed ab initio calculations to investigate the finite-temperature stability of ordered, disordered, and metastable phases, thereby guiding experiments. Based on the computed energetics, we analyzed how Ti incorporation alters local bonding environments and stabilizes magnetically desirable motifs. Furthermore, we constructed an ab initio phase diagram to reveal the interplay between rare-earth metals and transition metals across a broad temperature range. We have revealed that Ti addition promotes the formation of a more robust Sm-rich phase by strengthening the local Sm-Fe-Ti matrix. This stabilization enhances alloy coercivity and provides insights into the thermodynamic and chemical factors driving phase evolution, enabling the design of better permanent HMs.

FM 9.5 Tue 15:15 BEY/0138

Molecular orbital degeneracy lifting in NbSeI — •Keita Kojima[1], Hayato Takano[1], Youichi Yamakawa[2], Shunsuke Kitou[3], Ryutaro Okuma[1], and Yoshihiko Okamoto[1] — [1]Institute for Solid State Physics, University of Tokyo, Kashiwa 277-8581, Japan — [2]Department of Physics, Nagoya University, Nagoya 464-8602, Japan — [3]Department of Advanced Materials Science, University of Tokyo, Kashiwa 277-8581, Japan

The breathing pyrochlore lattice, composed of alternating small and large tetrahedra, hosts molecular orbitals within the smaller tetrahedra that strongly influences its physical properties. Such molecular-orbital and frustration-driven effects have led to diverse electronic states in related compounds. We investigated NbSeI, a MoSBr-type material with a particularly large breathing distortion whose physical properties remain unexplored despite previous synthesis reports. We synthesized single crystals and conducted x-ray diffraction, physical property measurements, and first-principles calculations. While the calculations predict metallic flat bands originating from Nb 4d orbitals, magnetic and transport measurements reveal a nonmagnetic insulating state below 300 K. NbSeI also undergoes a structural transition at Ts = 106 K. Our structural studies demonstrate local atomic displacements above Ts and a trimer-like molecular transformation below Ts. Our results show that the combination of strong breathing distortion and flat-band*derived electronic structure stabilizes molecular-orbital degrees of freedom, advancing orbital physics beyond single-ion descriptions toward cluster-based electronic phenomena.

Identification of defects in iron molybdate catalysts via first principles calculations — •Young-Joon Song and Roser Valentí — Institut für Theoretische Physik, Goethe-Universität, 60438, Frankfurt am Main, Germany

Iron molybdate ($Fe_2(MoO_4)_3$) is well known as a commercial catalyst for oxidative dehydrogenation. Recently, L. Schumacher et al. reported an experimental reduction in Raman intensity at 782 cm^{-1} during catalytic processes. The authors attribute this decrease to oxygen migration from the bulk to the surface during the reaction, in contrast to the conventional understanding that oxygen atoms are supplied only near the surface. To identify the types of defects responsible for the observed reduction in Raman intensity, we performed DFT electronic and phononic structure calculations for $Fe_2(MoO_4)_3$. Our findings reveal that optical phonon modes involving oxygen dominate the spectrum at around 790 cm^{-1}, with a small contribution from Mo, corresponding to asymmetric MoO_4 stretching modes. In the Raman calculations, a major peak appears at 789.68 cm^{-1} with a small shoulder-like feature and a minor peak at 972.05 cm^{-1}, consistent with the experimental observations. By selectively freezing specific phonon modes, we introduced an effective method to incorporate defect effects into Raman calculations without explicitly creating oxygen vacancies. Using this approach, we found that oxygen vacancies play a dominant role in the reduction of Raman intensity. Finally, we discuss the relaxed structure containing explicit oxygen vacancies. This research was supported by the German Research Foundation for funding through CRC 1487.

Exsolution of metal nanoparticles by control of point defects — •Andreas Rosnes[1], Bo Jiang[2], Holger von Wenckstern[1], Øystein Prytz[1], and Jonathan Polfus[2] — [1]Department of Physics, Centre for Materials Science and Nanotechnology, University of Oslo, PO Box 1048 Blindern, NO NO-0316 Oslo, Norway — [2]Department of Chemistry, Centre for Materials Science and Nanotechnology, University of Oslo, PO Box 1033 Blindern, NO-0315 Oslo, Norway

Exsolution involves redox precipitation of metal nanoparticles from metal oxides, resulting in materials that exhibit excellent electrocatalytic properties and hold great promise for novel types of nanoscale heterostructures. However, a coherent understanding of the phenomenon is lacking. Here, exsolution is described by three point defect equations involving the reduction of the host oxide, reduction and exsolution of the transition metal, and annihilation of host unit cells. Guided by their predictions, significantly enhanced exsolution in terms of molar amount, rate, and nucleation density is shown by acceptor substitution to the system $La_{0.2}Ca_{0.7}Ti_{0.95}Cu_{0.05}O_{3-\delta}$ through atomic scale imaging and in situ X-ray diffraction and spectroscopy. It is demonstrated that the oxygen stoichiometry of the parent oxide increases upon exsolution despite oxygen loss in the reducing environment. Furthermore, strain in both the host oxide and the exsolved metal can constitute an additional thermodynamic barrier for exsolution beyond the availability of the required point defects.

Machine-Learning Potentials Reveal Defect Segregation at Grain Boundaries in Lithium Solid Electrolytes — •Waldemar Kaiser[1], Hyunwon Chu[2], Jennifer L.M. Rupp[1,2], and David A. Egger[1] — [1]TUM School of Natural Sciences, Technical University of Munich — [2]Department of Materials Science and Engineering, Massachusetts Institute of Technology

Grain boundaries (GB) play a central role in ionic and electronic transport in polycrystalline solid electrolytes [1, 2], yet their local defect chemistry remains difficult to resolve. Their structural complexity and chemical heterogeneity introduce a wide distribution of possible defect configurations that are computationally demanding to characterize with first-principles methods. As a result, the origins of variations of ionic and electronic transport often remain unclear.

Here, machine-learning potentials (MLPs) are applied to representative Σ5 and Σ3 GB structures to investigate ionic defects in lithium lanthanum zirconate (LLZO). The MLPs enable the systematic and efficient mapping of lithium- and oxygen-vacancy formation energies, revealing reductions of up to 1 eV within GB cores relative to bulk sites. Structural analysis further identifies locally Zr-deficient coordination environments as preferred incorporation sites for lithium vacancies, and experiments show that Ta-doping fills these bottlenecks and enhances the material's stability.

2 - Dimensional hybrid perovskite as a promising semiconductor for large area electronics — •Tomasz Marszalek, Shuanglong Wang, Zhitian Ling, Denis Andrienko, Hai Wang, Paul W.M. Blom, and Wojciech Pisula — Max Planck Institute for Polymer Research, Mainz, Germany

Two-dimensional (2D) perovskites with bulky spacer cations are promising candidates for field-effect transistors due to the suppressed ion movement caused by large size insulating ligands. However, the relationship between the chemical nature of organic cations and film morphology, crystallinity, molecular organisation and charge carrier transport in 2D layered perovskites is not yet fully understood, which significantly limits the development of 2D perovskite FETs.

This report presents a distinct odd-even effect in 2D Sn-based perovskite semiconductors for the first time, incorporating monovalent phenylalkylammonium-based organic cations with alkyl side chains of different lengths containing either an odd or an even number of carbon atoms. An odd-even oscillation of charge carrier transport was revealed using optically pumped terahertz spectroscopy and transistor devices. By combining density functional theory calculations with simulated grazing-incidence wide-angle X-ray scattering, we demonstrate that organic ligands featuring odd carbon atoms exhibit a disordered crystal lattice and tilted inorganic octahedra. This results in a larger effective mass and inferior charge mobilities compared to perovskites with an even number of carbon atoms in the organic cations. (J. Am. Chem. Soc. 2024, 146, 19128, Mater. Horiz., 2024,11, 1177)

FM 10.5 Tue 15:15 BEY/0E40

On the origin of the strange metal Hall effect in BaFe2(As1-xPx)2 — •Augusto Ghiotto[1], Darian Hall[1], Yuanqi Lyu[1], Kohtaro Yamakawa[1], John Singleton[2], and James Analytis[1] — [1]University of California, Berkeley, USA — [2]National High Magnetic Field Laboratory's Pulsed Field Facility at Los Alamos, USA

BaFe2(As1-xPx)2 is an unconventional superconductor in which the antiferromagnetic, nematic and structural order is suppressed by isovalent P substitution, leading to a quantum critical point at x = 0.31. It has been shown that the Hall effect of the overdoped series contains an anomalous contribution arising from the correlations within the strange metal, whose behavior emanates from a quantum critical point and, in the zero-temperature limit, decays together with the superconducting critical temperature. Here, we present new data on the underdoped series taken at pulsed high magnetic fields. To achieve a large signal to noise ratio and an accurate measurement of the Hall coefficient, we microstructured the crystals into well-defined Hall bars. In this talk, we will draw parallels between the Hall effect in the ordered state and in the strange metal.

Structural and Optical Characterization of FeGaInS* Layered Crystals — •Zeynab Addayeva and Mustafa Muradov — Baku State University, Baku , Azerbaijan

FeGaInS4 layered crystals were synthesized using the Bridgman technique, and their crystal structure was investigated via powder X-ray diffraction (XRD). FeGaInS4 is a quaternary complex metal chalcogenide that belongs to the class of layered, quartz-like A-B-C-X4 type compounds. The material crystallizes in the rhombohedral system and adopts the R3m (No. 160) space group, according to the International Union of Crystallography (IUCr) classification. The refined lattice parameters (a = b = 5.406 Å, c = 10.708 Å) confirm the presence of a highly symmetric and anisotropic layered crystal structure. Within the structure, Fe, Ga, and In atoms occupy different coordination environments and form tetrahedral bonds with sulfur (S) anions, resulting in a complex three-dimensional network. These bonding interactions directly influence the material's electronic structure and related functional properties, including electrical conductivity, op-

tical absorption, dielectric response, and thermal stability. Due to its anisotropic layered architecture, FeGaInS4 exhibits natural cleavage along specific crystallographic directions. This property renders it suitable for exfoliation into few-layer or monolayer nanosheets, making it a promising candidate for the fabrication of two-dimensional (2D) materials and high-performance composite systems. The optical band gap of FeGaInS4 is approximately 1.46 eV.

An Atom Probe Tomography Study of the Bond Breaking Behavior of Transition Metal Chalogenides — •Sophia Schreinemacher[1], Jan Köttgen[1], Elias Hildebrnad[1], Felix Hoff[1], Christian Stenz[1], Vicky Hasse[3], Yuan Yu[1], and Matthias Wuttig[1,2] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany — [3]Max Planck Institute for Chemical Physics of Solids 01187 Dresden, Germany

Chemical bonds are a vital subject in materials science, as they are one of the central factors that define the properties of a material. Transition metal chalcogenides are a group of materials characterized by the bonding between the chalcogenide p-orbitals and the metal d-orbitals, which exhibit unique electronic, optical, and magnetic properties. The main bonding indicator in this study is the probability of multiple events (PME) obtained during atom probe tomography (APT) acquisition.

The results show a medium PME (40-60%), highlighting the unique bond-breaking behavior that transition metal chalcogenides display during APT evaporation. In a plot of the PME against the electrical conductivity, the studied materials cluster at the border between the metavalent and covalent materials. These findings expose a clear connection between transition metal chalcogenides, their d- and p-orbital interaction, and their bonding characteristics, thereby broadening our understanding of metavalent materials.

FM 11.3 Tue 18:00 P4

Epitaxial Growth and Optimization of LiNbO3 Thin Films on LiTaO3 and Al2O3 by Pulsed Laser Deposition Using Machine Learning — •Hyeyeon Cho, Milena Petkovic, Steffen Ganshow, and Jutta Schwarzkopf — Leibniz-Institut für Kristallzüchtung, Max-Born-Straße 2, 12489 Berlin, Germany

Lithium niobate (LiNbO3) thin films are widely used in electro-optical and electro-acoustic devices due to their excellent ferroelectric, piezoelectric, and nonlinear optical properties, offering broader bandwidths at higher frequencies and reduced operational voltages compared to bulk materials. The development of high-quality, phase-pure, and smooth LiNbO3 films is essential for achieving superior device performance. Pulsed Laser Deposition (PLD) offers precise control over growth parameters, enabling the fabrication of epitaxial LiNbO3 layers with tunable structural properties. In our work, we investigated the epitaxial growth of LiNbO3 thin films on LiTaO3 and Al2O3 substrates using PLD. The influence of various PLD growth conditions and substrate materials was systematically investigated with regard to phase formation and structural ordering by x-ray diffraction and surface roughness by atomic force microscopy. Furthermore, a four-step machine learning workflow, including Artificial Neural Network (ANN) and Random Forest (RF) models, was employed to analyze the nonlinear relationships between PLD parameters and structural film properties. This combined experimental and computational approach accelerates development and provides deeper insight into LiNbO3 thin film growth for advanced photonic and optoelectronic applications.

Ferroelectricity in spin-liquid candidate $TbInO_3$ — •Andrea Tobiassen[1], Elvia Chavez[1], Jiali He[1], Dennis Meier[1,2], and Jan Schultheiss[1] — [1]NTNU Norwegian University of Science and Technology, Trondheim, Norway — [2]University of Duisburg-Essen, Duisburg, Germany

Hexagonal rare-earth oxides exhibit a variety of intriguing physical phenomena, ranging from rich magnetism to improper ferroelectricity. Among them, $TbInO_3$ has recently been proposed as a spin-liquid candidate, where magnetic frustration suppresses long-range magnetic order at low temperatures. The ferroelectric properties of $TbInO_3$ remain largely unexplored.

In this work, we synthesize $TbInO_3$ polycrystals via a solid-state route. Phase purity is confirmed by X-ray diffraction (XRD), while Scanning Electron Microscopy (SEM) and Piezoresponse Force Microscopy (PFM) reveal a pronounced domain contrast, evidencing a topological ferroelectric domain structure typical for hexagonal oxides. High-temperature XRD indicates a Curie temperature (T_C) of approximately 1630 K, corresponding to the polar $P6_3cm$ to non-polar $P6_3/mmc$ phase transition. Understanding the ferroelectricity in $TbInO_3$ provides a foundation for engineering its domain structure and exploring potential magnetoelectric coupling effects.

Localized High-Concentration High-Entropy Electrolytes for Superior Lithium Metal Anodes via Solvation Cluster Regulation — •Haixuan Luo and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany

The practical deployment of high-energy-density lithium metal batteries (LMBs) is severely hindered by the thermodynamic instability of the lithium metal anode, which precipitates dendritic growth and poor Coulombic efficiency. Although localized high-concentration electrolytes (LHCEs) have emerged as a promising solution, optimizing their cluster configurations to maximize interfacial durability remains a challenge. Herein, we propose a groundbreaking localized high-concentration high-entropy electrolyte (LHCHEE) strategy that leverages the high-entropy effect to tailor solvation structures at the molecular level. Our systematic investigation reveals that the introduced configurational entropy promotes the formation of uniform, anion-rich solvation clusters while suppressing solvent decomposition. This unique solvation environment facilitates the construction of a robust, inorganic-dominated solid electrolyte interphase (SEI) on the lithium metal. Consequently, the LHCHEE enables exceptional stability, while Li||Cu cells demonstrate significantly improved Coulombic efficiency. Furthermore, full cells paired with high-voltage cathodes exhibit remarkable capacity retention. This work not only demonstrates the superiority of LHCHEEs but also establishes entropy engineering as a critical dimension for designing advanced electrolyte systems.

FM 11.6 Tue 18:00 P4

Ferroelectric switching at edge dislocations in $BaTiO_3$ modelled at the atomic scale — •Himal Wijekoon[1,2], Pierre Hirel[3], and Anna Grünebohm[1,2] — [1]Interdisciplinary Centre for Advanced Materials Simulation (ICAMS) and Center for Interface-Dominated High Performance Materials (ZGH), Ruhr-University Bochum, Universitätsstr 150, 44801 Bochum, Germany — [2]Faculty of Physics and Astronomy, Ruhr-University Bochum, Universitätsstr 150, 44801 Bochum, Germany — [3]Univ. Lille, CNRS, INRAE, Centrale Lille, UMR 8207 - UMET - Unité Matériaux et Transformations, F-59000 Lille, France

Domain nucleation and switching largely govern the functional properties of ferroelectric perovskites. Consequently, one can utilize defects to tailor domain switching and thereby tune the functional properties of these materials. While previous studies have mainly focused on switching in pristine pervoskite materials, the influence of defects, particularly dislocations, on domain nucleation and switching remains insufficiently understood. Using molecular static simulations, we show that ⟨100⟩ edge dislocations cores in barium titanate can serve as domain nucleation sites. By applying an external electric field in three different orientations relative to the Burgers vector and dislocation line, we show how domain nucleation and subsequent growth occurs in dislocations-induced strain variations. Our simulations reveal that the coupling between electric field and polarization is strongest when the field is applied parallel to the Burgers vector.

Topology and Bonding: A bonding-based approach to topological insulators via Atom Probe Tomography — •Elias Hildebrand[1], Jan Köttgen[2], Yuan Yu[1], and Matthias Wuttig[1,2] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany

Ever since the discovery of the quantum Hall effect, interest in topological phases of matter has steadily increased. Initially attributed to spin-orbit coupling, the underlying guiding principle causing these topological phases of matter has been a topic of ongoing discussion.

Here, we want to propose a bonding-based approach to explain nontrivial topological states. The experimental foundation for this connection is established through Atom Probe Tomography (APT). While APT is primarily employed for microstructural analysis, it has recently been proposed as a tool capable of identifying different bonding mechanisms.

Within this method, most topologically nontrivial materials also exhibit distinct bond-breaking behaviour corresponding to their characteristic bonding mechanisms. Here, different materials are investigated regarding their topological nature and behaviour in the APT.

Consequently, APT can be established as an experimental method for identifying topological phases of matter and as an empirical argument highlighting the significance of bonding in understanding the fundamental principles governing topological materials.

Strain-driven phonon instabilities in BaSnO3 — •Benyao Sun and Anna Grünebohm — Interdisciplinary Centre for Advanced Materials Simulation (ICAMS), Ruhr-Universität Bochum, Germany

The perovskite BaSnO3(BSO) has attracted extensive research interest due to its favorable properties, including non-toxicity, high thermal stability, and distinctive electronic characteristics. However, bulk BSO is generally non-ferroelectric, limiting its applications. Fortunately, strain engineering can induce ferroelectricity by tuning the perovskite structure. For example, strain-induced tetragonality leads to a large dipole moment and, consequently, to a high polarization in strained ferroelectrics [1]. BSO exhibits ferroelectric polarization under applied epitaxial strain [2]. Strain-induced ferroelectricity in BSO has been studied, but phonon-spectrum analyses under sustained strain remain limited. In our work, we carry out a systematic study of the phonon instabilities of BSO under compressive strain. We calculate the critical compressive strain at which soft modes

appear in the phonon dispersion of BSO, analyze the contributions of the polar mode and the antiferrodistortive mode to the ferroelectricity as well as the couplings between different soft modes, and also discuss the effect of an external electric field on these soft modes.

Virtual Characterization Lab: A Python Toolkit for Material Characterization from Molecular Dynamics — •Vahid Jamebozorgi[1,2] and Christian Schröder[1,2] — [1]HSBI, Bielefeld, Germany — [2]Bielefeld University, Bielefeld, Germany

Material discovery using traditional experimental methods is a slow and costly process, often limited by the sampling process, characterization condition constraints, and the requirement for expensive equipment. While computational tools have transformed materials research by accelerating the investigation of material properties, a significant gap remains in connecting high-fidelity simulations with established experimental characterization techniques. We present the Virtual Characterization Lab (VCL), a unified, open-source Python toolkit designed to bridge this gap. The VCL streamlines the entire workflow from molecular dynamics simulations, enabling researchers to generate and analyze key characterization data, such as X-ray Diffraction (XRD), Selected Area Electron Diffraction (SAED), and Vibrational Density of States (VDOS), all within a single, intuitive environment. By integrating every step from initial structure preparation to final data visualization, the VCL accelerates materials discovery by making virtual characterization more efficient, accessible, and directly comparable to experimental results.

Structural Factors Governing Stability and Electronic Transport in Future Neuromorphic Memristor Technologies — •Wiktoria Szopa[1,2,3], Marcin Krynski[1], Attila Cangi[2,3], and Piotr Wisniewski[4] — [1]Faculty of Physics, Warsaw University of Technology, 00-662 Warsaw, Poland — [2]Center for Advanced Systems Understanding, 02826 Görlitz, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [4]Centre for Advanced Materials and Technologies CEZAMAT, Warsaw University of Technology, 02-822 Warsaw, Poland

With the rapid rise of artificial intelligence, the demand for technologies that enable its development and application is high, as AI is now widely used across science, industry, and everyday life. Neuromorphic materials may offer a promising solution to the increasingly complex hardware requirements posed by next-generation, high-throughput AI.

Silicon-oxide-based memristors may operate as adjustable weights within hardware neural networks, enabling more efficient, neuromorphic computation. The electronic component contains two electrodes separated by a thin amorphous silicon oxide layer, within which charge transport occurs through filamentary silicon chains that form conductive pathways.

In this project, we investigate how the local atomic structure influences electronic transport. To this end, we generated hundreds of memristor models and identified their most stable configurations, with high structural robustness and defined conduction pathways by using a combination of DFT calculations and machine learning modeling.

Computational modelling of phonon, elastic, and electronic properties of layered quantum crystalline materials — •Zoya Eremenko[1], Yuri Savin[2], and Vladimir M. Fomin[1] — [1]IFW Dresden, Germany — [2]O.Ya. Usikov Institute for Radiophysics and Electronics, National Academy of Sciences of Ukraine, Kharkiv, Ukraine

We present a comparative computational study of the phonon, elastic, and electronic properties of several crystalline quantum materials $NbSe_2$, FeSe, MoS_2, and BSCCO using density functional theory (DFT) and COMSOL Multiphysics. For each material, we analyze the primitive-cell geometry, symmetry, the resulting vibrational and mechanical responses extracted from both the first-principles calculations and the available experimental references. Layered transition-metal dichalcogenides $NbSe_2$, and MoS_2, show significantly anisotropic elastic responses, consistent with their quasi-2D bonding. MoS_2 shows elastic constants aligned with experimental values. Properties of the tetragonal iron-based chalcogenide FeSe are modelled using its primitive cell and the electronic band structure. By leveraging elastic constants obtained from the available experimental and theoretical studies, the BSCCO phonon frequencies are calculated with COMSOL Multiphysics. The close agreement between our simulated phonon frequencies and the experimental data for BSCCO validates our multi-scale approach, providing a solid foundation for future studies of the electron-phonon interactions and structural effects in complex quantum materials. We thank Dr. Golam Haider for providing us with the experimental data for verification of the simulated Raman frequencies.

Efficient Discovery of Intermediate-Temperature Proton Conductors via Ion Exchange Strategy with Machine Learning Potential — •Yun An, Karsten Reuter, and Christoph Scheurer — Fritz Haber Institute of the Max Planck Society, 14195 Berlin, Germany

Proton-conducting solid-oxide fuel cells (H-SOFCs) are promising for direct ammonia-fed SOFC applications, as they eliminate NO_x emissions compared to conventional oxide-ion-conducting solid-oxide fuel cells. However, current proton-conducting electrolytes operate at high temperatures and suffer from leakage currents. Known suitable materials remain rare, calling for systematic investigations into novel proton conductor classes. We present a framework that combines machine-learning techniques with high-throughput computation to screen and design efficient proton conductors at intermediate temperatures. Through an ion-exchange strategy applied to known alkaline-ion conductor classes, we identify a database of potential proton-conducting materials. Machine learning molecular dynamics simulations are employed to assess stability and diffusion barriers, enabling the selection of top-performing candidates. The screened proton conductors contain cations that span from monovalent to pentavalent, including Rb^+, Ba^{2+}, Ca^{2+}, B^{3+}, Zr^{4+}, and Nb^{5+}, and predominantly feature SO_4^{2-} and PO_4^{3-} polyanion groups. Proton transport in these materials follows the Grotthuss mechanism. The strength of hydrogen bonds increases after ion-exchange engineering, thereby enhancing proton transfer.

Dual Strategy Engineering of Zn4Sb3: Indium Doping and ZnO Coating for High zT — •Abhishek Pandey[1], Amin Bahrami[2], and Kornelius Nielsch[3] — [1]Leibniz Institute for Solid State and Materials Research, Helmholtzstraße 20, Dresden 01069, Germany — [2]Leibniz Institute for Solid State and Materials Research, Helmholtzstraße 20, Dresden 01069, Germany — [3]Leibniz Institute for Solid State and Materials Research, Helmholtzstraße 20, Dresden 01069, Germany

Zn4Sb3 is one of the promising thermoelectric materials due to its very low thermal conductivity and favorable electronic properties for high TE performance. However, its practical application to TE device is limited by structural instability and Zinc-ion migration, which lead to the formation of zinc whiskers and degradation of TE performance. In this work, a dual-strategy approach has been adopted to enhance and stabilize Zn4Sb3, (1) Indium doping, and (2) ZnO surface coating of powder. Indium substitution within the Zn4Sb3 lattice is shown to increase the figure of merit (zT). In parallel the bulk modification, ZnO coating on Zn4Sb3 particles acts as a diffusion barrier that mitigates zinc migration and whisker formation, which improves the structural robustness during prolonged thermal cycling.

FM 11.15 Tue 18:00 P4

Towards Quantification of Convergent Beam Electron Diffraction Patterns — •Jimmy Steinweh[1], Daniel Wolf[1], and Axel Lubk[1,2] — [1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [2]Institute of Solid State and Materials Physics, TU Dresden, Germany

Convergent beam electron diffraction (CBED) is a transmission electron microscopy (TEM) method, that utilizes a convergent electron beam to investigate the symmetry of crystalline samples at the nanoscale. A method for quantifying discrete rotational and mirror symmetries in CBED patterns is presented, involving a quantification algorithm for both simulated and experimental CBED patterns. This approach is used to investigate the influence of probe shifts, beam tilts, and thermal lattice vibrations on the symmetry of simulated CBED patterns of silicon to identify crystal structure related asymmetries. It is found that for a semi-convergence angle of $\alpha = 1.7$ mrad, the asymmetry introduced by probe shifts is barely detectable in simulations, whereas beam tilt effects are significant at beam tilt angles as low as 0.1 mrad. Consequently, precise alignment

of the beam in zone axis is crucial. We find furthermore that consideration of lattice vibrations within the frozen lattice approximation also slightly breaks the symmetry and discuss the origin of this effect. These results aim to establish a foundation for further development of CBED as a quantitative tool for probing crystal symmetries at the nanoscale.

FM 11.16 Tue 18:00 P4

Correlated Imaging of Thermal Conductivity and Ferroelectric Domains in $PbTiO_3$ Using Scanning Probe Microscopy — •Ciara Ward, Lindsey Lynch, and Raymond McQuaid — Queen's University Belfast, Belfast, UK

Perovskite ferroelectrics are an attractive platform for realising thermal conductivity switching through voltage configuration of domain microstructure. Reported mechanisms involve thermal conductivity modulation through structural re-orientation (anisotropy) [1,2] or phonon scattering by domain wall defects [3-5], both of which can be controlled through sample geometry and applied fields. Heat flow measurements and thermoreflectance investigations have quantitatively benchmarked thermal switching ratios but, in some cases, a lack of direct thermal mapping introduces ambiguity as to the relative role played by the two mechanisms. We are using Scanning Thermal Microscopy to explicitly map the local thermal conductance in samples of archetypal ferroelectric $PbTiO_3$ to clarify the underlying mechanisms that enable modulation of thermal transport. In tandem, we are using domain engineering and electric-field poling techniques to demonstrate the maximum achievable contrast in thermal conductance in this system.

Impurity-Driven Vacancy Evolution in Irradiated Tungsten Revealed by Positron Annihilation Spectroscopy and Multiscale Modeling — •Zhiwei Hu[1,2], Qigui Yang[3], Jintong Wu[4], François Jomard[5], Thomas Jourdan[6], and Marie-France Barthe[2] — [1]HZDR, Dresden, Germany — [2]CEMHTI-CNRS, Orléans, France — [3]KTH, Stockholm, Sweden — [4]University of Helsinki, Finland — [5]GEMAC; Versailles; France — [6]CEA,Gif-sur-Yvette, France

Thermonuclear fusion demands plasma-facing materials that withstand extreme heat and irradiation. Tungsten, selected for ITER, develops microstructural evolution. Predicting defects behavior is therefore crucial. Using Positron Annihilation Spectroscopy, TEM, atomistic modeling, and DFT, irradiation-induced defects were examined. A new PAS data-inversion method using quadratic programming and two-component DFT was created. This method reconstructs full vacancy-cluster distributions from PAS data. Results show small vacancy clusters dominate after high-temperature irradiation. These clusters remain invisible to TEM yet strongly affect microstructure. Room-temperature electron irradiation showed reduced pure vacancy fractions. Unexpected positron traps were observed. SIMS and DFT identified these traps as oxygen-vacancy complexes. Cluster-dynamics simulations confirmed oxygen interacts with Frenkel pairs. Such interactions significantly modify defect evolution. Comparative irradiations of varying-purity tungsten were performed, PAS and TEM together revealed impurity effects.

Phase Transitions and Ferroic Properties in Organic*Inorganic Hybrid Halide TMCM-Mn*-*Fe*Cl* Crystals — •Chithra Kandappanthodi, Boris Slautin, Sobhan M Fathabad, Daniil Lewin, Doru Lupascu, and Vladimir Shvartsman — University of Duisburg-Essen

Organic*inorganic hybrid halides have garnered significant attention in materials science due to their eco-friendly, cost-effective synthesis, and outstanding optoelectronic properties. We report the properties of Fe-substituted trimethyl chloromethyl ammonium manganese trichloride TMCM-Mn1-xFexCl3 single crystals. The samples were obtained via the solvent evaporation seed assisted crystal growth method. Temperature-dependent X-ray diffraction and differential scanning calorimetry measurements confirm a sequence of structural phase transitions: from a monoclinic P121 phase at 302 K to monoclinic Cc, and subsequently to a hexagonal P6*/mmc phase at 408K for the pure TMCM-MnCl3 sample. Dielectric permittivity measurements indicate the improper ferroelectric transition at 408 K. Piezoresponse force microscopy further identifies well-defined ferroelastic domains at room temperature, which vanish upon heating above 304 K, as also observed using polarized light microscopy. Fe-substituted TMCM*Mn***Fe*Cl* samples exhibit a new intermediate phase transition near 328 K. UV*vis absorption spectra also demonstrate that increasing Fe content tunes the electronic bandgap. This comprehensive characterizations highlights TMCM-MnCl3, and TMCM-Mn1-xFexCl3 as a promising candidate for multifunctional applications.

Polymorph Stability and Mo Substitution in WO_3 — •Hiran Kankanamge[1], Susanne Susanne[2,1,3], and Anna Grünebohm[1] — [1]Scale-bridging simulations of functional composites, Interdisciplinary Centre For Advanced Materials Simulation (ICAMS), Ruhr-University Bochum, Universitätsstr. 150, 44801 Bochum, Germany — [2]Applied Quantum Materials, Institute for Energy and Materials Processes (EMPI), Faculty of Engineering, University of Duisburg*Essen, Forsthausweg 2, 47057 Duisburg, Germany — [3]Research Center Future Energy Materials and Systems (RC FEMS), University of Duisburg*Essen, Forsthausweg 2, 47057 Duisburg, Germany

Mixed molybdenum-tungsten oxides offer tunable electrochromic and catalytic properties [1]. Pure WO_3 exhibits several polymorphs separated by only a few meV·atom^{-1} [2], leaving the structural trends in $Mo_xW_{1-x}O_3$ insufficiently resolved. As a baseline for substitution, we use first-principles calculations to reassess the stability of the main WO_3 polymorphs and recover the characteristic low-energy grouping of the β, γ, and ε phases.

Building on these optimized structures, the focus of this work is to introduce molybdenum across all phases and trace how composition modifies the energy landscape, octahedral tilting, and relative phase preferences. The resulting trends are compared with experimental observations on mixed Mo-W oxides [1] to evaluate their consistency and refine the microscopic picture of phase competition within the Mo-W-O system.

FM 11.20 Tue 18:00 P4

Mechanistic Origin of Charge Separation and Enhanced Photocatalytic Activity in D-π-A-Functionalized UiO-66-NH_2 MOFs — •Anastasiia Kultaeva[1], Timur Biktagirov[2], Volodymyr Vasylkovskyi[1], Andreas Sperlich[1], Eugenio Otal[3], Wolf Gero Schmidt[2], and Vladimir Dyakonov[1] — [1]Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany — [2]Physics Department, Paderborn University, D-33098 Paderborn, Germany — [3]Institute for Aqua Regeneration, Shinshu University, Nagano 380-8553, Japan

Donor-π-acceptor (D-π-A) functionalization of MOF linkers offers a promising route to enhance visible-light photocatalysis, yet the underlying photophysical mechanisms remain insufficiently resolved. Here we investigate UiO-66-NH_2 modified via diazo coupling with anisole, diphenylamine (DPA), and N,N-dimethylaniline (NNDMA) dyes. Optical measurements and first-principles calculations show that all donor groups introduce new occupied states near the valence-band edge, enabling dye-to-framework charge transfer and red-shifted absorption. EPR and transient photoluminescence reveal that anisole uniquely promotes efficient intersystem crossing to a long-lived triplet charge-transfer state, whereas bulkier donors such as DPA and NNDMA can also generate defect-associated traps that enhance recombination. These results clarify how donor structure dictates electronic-state formation, triplet pathways, and defect behavior, providing mechanistic guidelines for tailoring charge dynamics and photocatalytic activity in D-π-A-modified MOFs.

FM 11.21 Tue 18:00 P4

Isovalent exchange of Al, Mg and Zr in strontium hexagallate ($SrGa_{12}O_{19}$) — •Finn Bietz[1], Christian Rhode[2], and Simone Sanna[1,3] — [1]Institut für Theoretische Physik, Justus-Liebig-Universität Gießen, Gießen 35392, Germany — [2]Leibniz Institut für Kristallzüchtung, Max Born Straße 2, 12489 Berlin — [3]Center for Materials Research (ZfM), Justus Liebig University Gießen, Gießen 35392, Germany

Strontium hexagallate ($SrGa_{12}O_{19}$) can be used as a substrate for the growth of barium hexaferrite ($BaFe_{12}O_{19}$), a ferrimagnetic and a quantum paraelectric material. The lattice parameters of $SrGa_{12}O_{19}$ can be adjusted by substitution of Ga by Al or Mg and Zr, respectively, for the lattice-matched growth and strain engineering of ($BaFe_{12}O_{19}$) thin films. Unfortunately, a microscopic picture of the doping mechanisms, as well as of their effect on the lattice parameters, is still missing. In this contribution, we report on first-principles calculations performed to determine the lattice site of Al, Mg and Zr atoms in the $SrGa_{12}O_{19}$ structure, and support corresponding experiments performed at the IKZ in Berlin. Thereby the defect formation energies of Al, Mg and Zr atoms incorporated in the dilute limit at different lattice sites were calculated within density functional theory (DFT). The atomistic models reveal that Mg populates the so called $Ga^{(3)}$ position, Al prefers the $Ga^{(1)}$ site, but also populates the $Ga^{(4)}$ and $Ga^{(5)}$ sites, and that the Zr is incorporated at the $Ga^{(4)}$ site. A substitution at the Sr site is energetically unfavorable for all dopants, instead. The calculated formation energies are in good agreement with the experimental results.

Ferroelectric domain shapes in LiNbO3 and LiTaO3 from a revised Ising model — •Jonas Paul[1], Leonard Verhoff[2], and Simone Sanna[1] — [1]Justus-Liebig-Universität Giessen, Giessen, Germany — [2]Technische Universität Wien, Wien, Austria

Lithium niobate (LN) and lithium tantalate (LT) are both ferroelectric materials whose domains can be influenced by external electric fields. While both crystal-

lize within the same symmetry group (R3c), congruent LN and LT form different domain shapes as experimentally observed [1]. DFT calculations could explain the domain shapes of LN and LT via calculations of the domain wall energy [2], however, knowledge about build-up of domain shapes in mixed lithium niobate-tantalate (LNT) mixed crystals is still lacking.

In this contribution, we demonstrate that the domain build-up in LNT can be modeled with a modified Ising model and performed Monte Carlo and Greedy calculations to simulate the domain growth. We show that an additional interaction term in the Ising model determines the characteristic domain shape. Furthermore, we employ Greedy simulations for different parameters, obtaining a phase diagram for the domain shape transition. In consequence, we predict domain shapes for LN, LT, and LNT mixed crystals.

Reversible nanoscale patterning of WTe_2 with a scanning tunneling microscope — •Kevin Hauser[1,2], Danyang Liu[1], Berk Zengin[1], Jens Oppliger[1], Samuel Mañas-Valero[4], Catherine Witteveen[5], Fabian O. von Rohr[5], Jennifer E. Hoffman[2,3], and Fabian D. Natterer[1] — [1]Department of Physics, University of Zurich, Switzerland — [2]Department of Physics, Harvard University, Cambridge MA, USA — [3]School of Engineering & Applied Sciences, Harvard University, Cambridge MA, USA — [4]Instituto de Ciencia Molecular, Universitat de València, Spain — [5]Department of Quantum Matter Physics, University of Geneva, Switzerland

Manipulating the lattice structure of quantum materials that host ferroelectric or Weyl semimetal phases provides a route to control these states on nanometer length scales. Prior experiments on the type-II Weyl semimetal candidate WTe_2 have demonstrated ferroelectric switching on micrometer length scales and transient control of the predicted topological phase via ultrafast excitations. However, both approaches lack the ability to induce persistent, localized distortions on the nanometer scale. In this contribution, we use current pulses applied by a scanning tunneling microscope (STM) to write, move, and erase nanoscale lattice distortions on WTe_2. The resulting lattice distortions consist of picometer-scale in-plane and out-of-plane atomic displacements, accompanied by changes in the local density of states. The in-plane shifts are on the same order of magnitude as expected for ferroelectric switching. These results demonstrate local, reversible control of the lattice structure of WTe_2 on nanometer length scales.

FM 11.24 Tue 18:00 P4

Phase and microstructure evolution of SnO_x:Ta thin films as a function of the oxygen partial pressure during deposition — Cecilia Bauden[1], Lukas Prager[1], Frans Munnik[1], Fabian Ganss[1], Harish Parala[2], Anjana Devi[2], Carlos Romero-Muniz[3], Ramon Escobar-Galindo[3], and •Matthias Krause[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]IFW Dresden, Dresden, Germany — [3]Universidad de Sevilla, Sevilla, Spain

Recent research on SnO_2-based TCOs has focused on Ta-doped SnO_2 (TTO), since it surpasses In_2O_3:Sn and ZnO:Al in thermal stability under vacuum and in air [1, 2]. This work presents a Raman spectroscopy and XRD study on the phase and microstructure evolution of SnO_x:Ta thin films as a function of the oxygen partial pressure during thin film deposition by reactive DC magnetron sputtering. At low O_2 flow rates a phase structure comprising metallic β-Sn, SnO and Sn_3O_4 without incorporated Ta is found. Higher O_2 flow rates yield the formation of the rutile structure of SnO_2:Ta, where Ta replaces Sn as Ta_{Sn} and transfers free charge carriers into the Sn 5s* conduction band [3]. A resistivity minimum of 1.3 x 10^{-3} Ω cm, a maximum mobility 16 $cm^2\ (Vs)^{-1}$, and a distinct reflectivity edge in the NIR were found for the films with the best transport properties.

FM 11.25 Tue 18:00 P4

Controlled synthesis of the magnetic topological insulator $MnSb_2Te_4$ with variable Curie temperature — •Laura Zeni Cunha[1], Laura T. Corredor[2,3], Anja U.B. Wolter[4], and Anna Isaeva[1,2,3] — [1]University of Amsterdam, The Netherlands — [2]TU Dortmund University, Germany — [3]Research Center Future Energy Materials and Systems, Germany — [4]Leibniz IFW Dresden, Germany

Magnetic topological materials $(MnX_2Te_4)(X_2Te_3)_n$ are promising candidates for spintronic and energy-efficient technologies.[1] $MnSb_2Te_4$ features tunable Mn content that enables optimization of the magnetic ground state and ordering temperature[2-4] - key requirements for potential applications. However, synthetic control over Mn stoichiometry remains to be fully harnessed. This work presents a controlled, rapid, and reproducible synthesis route to phase-pure $MnSb_2Te_4$ by using an optimized tellurium precursor. I investigate by powder XRD, EDX/SEM, and DC magnetization studies how varied synthetic parameters impact its structural and magnetic properties. I observe an increased stability range of ferrimagnetic $MnSb_2Te_4$ compared with Ref. [2], and demonstrate a clear correlation between synthesis conditions and the Tc, spanning more than 10 K across the samples. This insight into synthesis-structure-property relationship advance our goal of a topological ferromagnet with higher Tc, moving toward the quantum anomalous Hall effect at practical temperatures.

Simulation-based optimization of gain characteristics for 3D-nanoprinted microchannel plates — •Kamila Murat, Kristian Deneke, Robert Zierold, Stefanie Haugg, and Robert H. Blick — Universität Hamburg, Hamburg, Germany

Microchannel plates (MCPs) are essential components for signal amplification. However, accurately modeling the complex electron multiplication processes represents one of the most demanding challenges.

Direct laser writing (DLW) techniques enable enhanced design freedom that extends beyond conventional glass-drawn MCPs, allowing the fabrication of structures with diverse materials and complex geometries. Since experimentally iterating such printed structures is both time-consuming and costly, numerical methods become crucial for development.

However, existing theoretical descriptions of electron multiplication remain incomplete and probabilistic, which presents a significant challenge for accurate simulations. To address this, we employ a finite-element-based simulation framework in COMSOL Multiphysics to model the electrostatic fields and electron transport in a 480 μm-long, 12 μm-diameter MCP channel biased at 1000 V. Within this configuration we investigate how geometry, bias voltage, and incidence energy influence electron trajectories and the total gain. To model the underlying electron avalanche mechanism driven by secondary electron emission (SEE), different theoretical models are evaluated to analyze the material-dependent SEE parameters. The resulting workflow establishes a scalable basis for extensions of the model.

FM 11.27 Tue 18:00 P4

Polarons in $LiNb_{1-x}Ta_xO_3$ solid solutions on both sides of the Curie temperature — •Christa Fink-Bauer and Simone Sanna — Institute for Theoretical Physics, Justus-Liebig-University, Heinrich-Buff-Ring 16, 35392 Giessen, Germany

Polaronic defects in LN, LT and their solid solutions $LiNb_{1-x}Ta_xO_3$ are important to understand their (electrical) conductivity. We do not only model these defects in the low-temperature ferroelectric phase, which is of great interest due to its spontaneous polarization leading to special properties as piezoelectricity, photoelasticity or nonlinear optical response, but also model the high-temprature paraelectric phase, which is stable above the Curie temperature and is of relevance for high-temperature applications. We calculate defect levels in the electronic band gap to extract activation energies for electronic transport. In addition, we calculate formation energies in pure LN and LT and their solid solutions, all from first principles using density-functional theory as implemented in VASP [1, 2]. [1] G. Kresse, J. Furthmüller, Computational Materials Science 6, 15 (1996). [2] G. Kresse, J. Furthmüller, Phys. Rev. B 54, 11169 (1996).

FM 11.28 Tue 18:00 P4

Local nanoscale probing of electron spins using NV centers in diamond — •Sergei Trofimov[1], Christos Thessalonikios[1], Victor Deinhart[2,3], Alexander Spyrantis[2], Lucas Tsunaki[1], Kseniia Volkova[1], Katja Höflich[2], and Boris Naydenov[1] — [1]Berlin Joint EPR Laboratory and Department Spins in Energy Conversion and Quantum Information Science (ASPIN), Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [2]Leibniz-Institut für Höchstfrequenztechnik, Ferdinand-Braun-Institut (FBH), Berlin, Germany — [3]Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy, Berlin, Germany

Substitutional nitrogen atoms in a diamond crystal (P1 centers) are crucial for creation of nitrogen-vacancy (NV) centers. However, P1's electron spin generates paramagnetic noise that degrades the NV's performance by shortening its coherence time. Bulk characterization methods of nitrogen concentration based on optical absorption or electron paramagnetic resonance often overlook local variations in the nitrogen content. In this work, we use a helium ion microscope to fabricate nanoscale NV center ensembles at predefined sites with a nano-scale resolution in a diamond crystal containing low concentrations of nitrogen. We then utilize these NV-based probes to measure the local P1 concentration on the level of 230 ppb using the double electron-electron resonance (DEER) technique. Moreover, by comparing the DEER spectra with numerical simulations, we determined the concentration of other unknown paramagnetic defects created during the ion implantation to be up to 15 ppb depending on the implantation dose.

FM 11.29 Tue 18:00 P4

Plug-and-play modification of a scanning electron microscope with a secondary electron yield detector — •Kristian Deneke[1], Stefanie Haugg[1], Isabel González Díaz-Palacio[2], Marc Wenskat[1,3], Wolfgang Hillert[2], Bent Andersen[1], Robert Zierold[1], and Robert Blick[1,3] — [1]Center for Hybrid Nanostructures, University of Hamburg, Germany — [2]Institute of Experimental Physics, University of Hamburg, Germany — [3]Deutsches Elektron-Synchrotron (DESY), Hamburg, Germany

Secondary electrons are already detected and used to achieve image contrast in a scanning electron microscope (SEM). However, measuring the secondary electron yield (SEY) requires a detector configuration that goes beyond the standard features of an SEM. The SEY is an important figure of merit for many different applications and research fields such as electron multipliers, vacuum cavities, and spacecrafts. Therefore, we present a plug-and-play configuration that allows an existing SEM to be modified with an SEY detector. This detector unit enables SEY measurements of conductive and insulating thin films in a pulsed operation mode. Furthermore, planar thin films can be examined not only at normal incidence, but also at an angle of inclination of the primary electrons, allowing for angular-dependent SEY characterization. Finally, the integration of our detector unit within an SEM enables the recording of a 2D SEY map, visualizing structural variations of patterned substrates. This detector setup could increase accessibility of SEY measurements and pave the way to improvements of applications and new measurement techniques.

FM 11.30 Tue 18:00 P4

A high-temperature optical spectroscopy study of congruent $LiTaO_3$ — •Ludmila Eisner[1], Angélique Hoffmann[2], Ani Manucharyan[2], Sebastian Inckemann[2], Yuriy Suhak[1], Steffen Ganschow[2], Holger Fritze[1], and Klaus.-D. Becker[3] — [1]Clausthal University of Technology, Germany — [2]Leibniz-Institut für Kristallzüchtung, Germany — [3]Technische Universität Braunschweig, Germany

Spectroscopic studies of congruent lithium tantalate (cLT) were performed to analyze the optical absorption edge under different thermal treatments in air and to relate its changes to band gap variations with temperature. At room temperature, the material exhibits an absorption edge near 4.45 eV. Thermal measurements, extending up to 900°C, show a systematic shift of about 0.138 eV toward lower photon energies per 100 K with increasing temperature. The treatments at reducing conditions (Ar/5% H_2) were found to induce significant changes in the spectra after cooling down to room temperature. These spectra show the formation of extended absorption tails down to photon energies of about 2.5 eV. This may suggest enhanced occupation or reconfiguration of intrinsic defect states, including polaronic states, vacancies, and antisite-related centers. These spectral changes largely evade observation under high-temperature in-situ conditions due to the redshift of the absorption edge. Comparison of spectra recorded after thermal cycling shows partial reversibility of these defect-related features. The present results provide a picture of how temperature and reduction-induced defect chemistry impact the optical response of cLT.

FM 11.31 Tue 18:00 P4

Analysing the laser-driven tetragonal-to-cubic phase-transition in ferroelectric $BaTiO_3$ using EXAFS spectroscopy as a local probe — •Janosch Tasto[1], Rajdwip Bhar[1], Simon Rauls[1], Marco Reinhard[2], Dimosthenis Sokaras[2], Uwe Bovensiepen[1], and Heiko Wende[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen — [2]SLAC National Accelerator Laboratory, Stanford University

This work aims to establish time-resolved Extended X-ray Absorption Fine Structure (tr-EXAFS) spectroscopy as a methodology for solids where the structural information of the EXAFS is combined with a pump-probe setup to study local dynamic lattice processes in the time domain.

As a proof of concept, we analyze the structural cubic-to-tetragonal phase-transition in the ferroelectric perovskite $BaTiO_3$. The coexistence of displacive and order-disorder phenomena accompanying this transition is a topic of debate in the literature on this extensively studied material.Difference-EXAFS scans at the Ti K-edge and the Ba L_3-edge between the pumped and unpumped state provide a direct way to investigate changes in lattice-structure and thermal-induced disorder in the vicinity of the absorbing atom. We correlate our spectroscopic findings with *ab initio* multiple-scattering calculations using the FEFF10 code to quantify structural dynamics.

We thank the Deutsche Forschungsgemeinschaft (in the framework of the Collaborative Research Center 1242) for financial support.

Correlation between grain size and dielectric properties in medium entropy titanate-based perovskite oxides — Amirhosein Paryab, •Doru Lupascu, and Vladimir Shvartsman — Institut für Materialwissenschaft Universität Duisburg-Essen Essen, Germany

High-entropy perovskite oxides have attracted significant attention as promising materials for energy storage applications. The configurational entropy is modulated by substituting different elements at a specific ionic site. If it is in the range of 0.7R-1.6R or above 1.6R, the oxides are called medium-entropy or high-entropy, respectively. We report a study of the influence of the synthesis method on the structure, dielectric, and ferroelectric properties of medium entropy titanate-based perovskite oxides (Ba0.34Sr0.33Ca0.33)TiO3 and (Ba0.25Sr0.25Ca0.25Pb0.25)TiO3. Compared to the solid state method, the sol-gel derived materials have a smaller grain size and higher lattice strain. This results in a more diffuse phase transition and a significant shift in the Curie temperature by 60 and 10 K in (Ba0.34Sr0.33Ca0.33)TiO3 and (Ba0.25Sr0.25Ca0.25Pb0.25)TiO3, respectively. Furthermore, fine grained samples were found to exhibit broader polarization hysteresis loops that could be ascribed to higher barriers to dipole switching and the pinning effect. The interplay of configuration entropy, microstructure, and functional behavior is analyzed.

FM 11.33 Tue 18:00 P4

Characterization and Fabrication of Silicon Wave Guides for the Study of Quantum Material Properties — •Sierra Randall Heinrich[1,2], Sebastian Zafra Koch[1,2], Florian Spickmann[1,2], Murat Sivis[1,2], Claus Ropers[1,2], and Hannes Böckmann[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]University of Göttingen, 4th Physical Institute, Göttingen, Germany

Placing quantum materials into optical cavities promises active control of material properties and functionality. Low-dimensional systems are particularly susceptible and exhibit electronic phases that can be switched by an external stimulus. However, the required extreme light-matter coupling is hampered by intrinsic cavity losses and poor overlap with optical modes. Here, we work towards the integration of a prototypic Peierls insulator at the surface of a silicon waveguide resonator. This project focuses on the creation of the resonator. A resonator couples the light into the sample by always totally internally reflecting it, thus generating the evanescent fields used in light matter coupling. To couple the light into the wafer, the angle of reflection has to be controllable. Here, we used diffraction gratings etched onto the surface with varying periods to achieve this. Next, we used Fabry-Pérot interference to maximize the effect of the evanescent fields. As a result, the resonance conditions of a 25 micrometer thick wafer were observed and accurately predicted for the first four resonance peaks. The two aspects of this project will be combined in future, with etched diffraction gratings on a thin wafer.

FM 11.34 Tue 18:00 P4

Understanding the formation of metal-semiconductor contacts in ferroelectric p-type oxides — •Ailu Sackey[1], Ruben Dragland[1], Egil Tokle[1], Zewu Yan[2,3], Edith Bourret[2], Jan Schultheiss[1], Mario Hentschel[4], and Dennis Meier[1,5] — [1]NTNU, Trondheim, Norway — [2]Lawrence Berkeley National Laboratory, Berkeley, CA, USA — [3]ETH Zurich, Zürich, Switzerland — [4]University of Stuttgart, Stuttgart, Germany — [5]University of Duisburg-Essen, Duisburg, Germany

Ferroelectric semiconductors exhibit highly tunable electronic responses, opening new pathways for nanoelectronics beyond Si-based approaches. Of particular interest are functional properties that arise at internal interfaces in ferroelectrics, such as domain walls or phase boundaries, which, when leveraged, can serve as ultra-small active elements or as extended 3D networks, requiring a thorough understanding of the contacts used for current injection and sensing.

Here we investigate metal-semiconductor contacts formed by deposited electrodes on the surface of the model p-type ferroelectric $ErMnO_3$. By cation doping and O_2 annealing, we methodically modify the charge carrier distribution and monitor the related changes. We find that donor doping promotes ohmic contact formation, whereas annealing in O_2-rich atmospheres leads to Schottky-like barriers. The results align with expected Fermi-level shifts and band-bending phenomena described by traditional semiconductor physics. Our findings offer fundamental guidance for controlling the contact formation in hexagonal manganites and related p-type ferroelectric semiconductors.

Energy Profile and Hopping Barriers for Small Electron Polarons at Ferroelectric Domain Walls in Bismuth Ferrite from First Principles — •Sabine Körbel — Friedrich Schiller University Jena, Germany

Evidence from first-principles calculations indicates that excess electrons in $BiFeO_3$ form small polarons with energy levels deep inside the electronic band gap. Hence, n-type electronic transport could occur by polaron hopping rather than by band-like transport. Here, using first-principles calculations, small electron polaron hopping in $BiFeO_3$ is investigated. Both bulk $BiFeO_3$ and a typical ferroelectric domain wall, the neutral 71° domain wall, are considered to account for experimental observations of electrical conductivity at domain walls in otherwise insulating ferroelectrics. The object of this study is to shed light on electron conduction in $BiFeO_3$ and the influence of pristine neutral ferroelectric domain walls. The computed energy barriers for small electron polaron hopping are near 0.2 eV, similar to other perovskite oxides, both in the bulk and within the neutral 71° domain wall. Trapping energies of small electron polarons at the three prevalent domain walls, the 71°, the 109°, and the 180° wall, are determined. The domain walls are two-dimensional traps for small electron polarons, with a trap

depth of about twice the thermal energy at room temperature. Based on these findings, the n-type mobility and the diffusion constant in $BiFeO_3$ are estimated, and experimental conductivity data for $BiFeO_3$ are discussed.

Smart DNA lithography as a tool for nanoelectronics — •Raufar Shameem[1], Charlotte Kielar[1], Christoph Hadlich[2], Borja Rodriguez-Barea[1], Ralf Seidel[2], and Artur Erbe[1] — [1]Institute of Ion Beam Physics and Materials Research, HZDR, Dresden, Germany — [2]Peter Debye Institute for Soft Matter Physics, University of Leipzig, Leipzig, Germany

Precise nanoscale patterning enables geometry-dependent functions across electrical, optical, and magnetic systems. DNA-templated hybrid lithography employs programmable molecular templates to define complex nanoscale shapes. Here, we use long DNA origami structures in a workflow integrating self-assembly, selective bottom-up oxide growth, and conventional top-down processing. The origami patterns form durable stencil masks on sapphire, guiding etching and metal deposition to create nanowire geometries beyond optical lithography. To generate these masks, DNA origami is assembled on sacrificial silicon, followed by controlled SiOx growth via chemical vapor deposition. Removing the DNA exposes nanowire-like and cavity-like oxide features that accurately reproduce the origami geometry and serve as robust patterning masks. AFM, SEM, and FIB cross sections verify shape transfer, growth behavior, and patterning resolution. This approach extends DNA-assisted lithography toward clean, versatile metal architectures for geometry-sensitive applications. It also improves integration with existing fabrication by providing stable masks, reliable shape transfer, and added flexibility in designing nanoscale features.

Theory-Guided Discovery of Ion-Exchanged Poly(heptazine Imide) Photocatalysts Using First-Principles Many-Body Perturbation Theory — •Zahra Hajiahmadi and Thomas D. Kühne — CASUS - Center for Advanced Systems Understanding, Helmholtz-Zentrum Dresden-Rossendorf e.V. (HZDR), Untermarkt 20, D-02826 Görlitz, Germany

Poly(heptazine imides) (PHI) show strong promise in photocatalysis, but limited control over electronic properties continues to constrain their full potential. We modulated PHI's photocatalytic activity to overcome this limitation by incorporating mono-, di-, and trivalent metal cations into its framework. To elucidate the underlying mechanisms, we employed calculations based on many-body perturbation theory, a highly accurate approach for electronic structure calculations that provides improved accuracy in quasiparticle energy predictions compared to conventional density functional theory, particularly for band gaps and excitonic properties. Our analysis identifies several metal-doped PHI systems with electronic structures well suited for hydrogen and oxygen evolution, CO_2 reduction, and H_2O_2 production. Guided by these theoretical insights, we synthesized a subset of *M*-PHI materials (where *M* is either K, Na, Li, Ca, Mg, or Zn) predicted to enhance photocatalytic reactivity.

Soft X-ray Spectroscopy at the HESEB Beamline, SESAME — •Ahlam Farhan — SESAME, Allan, Jordan

The ID11-L Helmholtz-SESAME Soft X-ray Beamline (HESEB) represents a significant step forward in soft X-ray research infrastructure in the Middle East. Operating in the 70-2000 eV energy range, HESEB provides photon fluxes between 10-3404 Giga photons/s, with an energy resolution exceeding $E/\Delta E >$ 8000. The beamline delivers a focused spot size of 500*250μm and offers tunable circular polarisation, enabling precise investigations of the electronic and magnetic properties of a wide range of materials.

The X-ray absorption spectroscopy (XAS) end station is equipped with a motorised manipulator, magnetic sample holders, and a differential pumping system, allowing measurements under ambient conditions or in a helium atmosphere. This flexibility supports the study of vacuum-sensitive materials, including valuable cultural heritage samples.

Recent XAS and XMCD measurements demonstrate HESEB's excellent stability, high resolution, and precise polarisation control, establishing it as a versatile platform for soft X-ray spectroscopy and magnetic materials research at SESAME.

FM 12: German-French Focus Session: Materials Research in Polar Oxides – From Domain Engineering to Photonic and Electronic Devices I

chair: Simone Sanna (Justus-Liebig-Universität Gießen, DE)

The focus session is dedicated to bridge the gap between materials research in polar oxides and research fields that apply those materials, such as nonlinear and quantum optics, electronics or sensoring, spanning experimental studies and first-principles simulations.

Shedding Light on Polar Topological Textures — •Salia Cherifi-Hertel — CNRS and University of Strasbourg, IPCMS

The study of topological polarization textures in ferroelectric materials represents a rapidly evolving frontier in ferroic research, with implications for solitonic information technologies and emergent phenomena in correlated oxides. Complex configurations, such as non-Ising and chiral domain walls, bubble domains, (anti)vortices, and polar (anti)skyrmions, highlight the diversity of polarization states in low-dimensional systems, where symmetry breaking, strain, and electrostatic boundary conditions produce novel functionalities. While piezoresponse force and transmission electron microscopies remain central to nanoscale characterization, optical methods are emerging as powerful, noninvasive alternatives. Second-harmonic generation (SHG) microscopy, in particular, provides intrinsic sensitivity to symmetry and polarization orientation, enabling three-dimensional mapping of polar architectures. This presentation will outline recent advances in SHG polarimetry combined with machine-learning-assisted analysis, enabling rapid, quantitative reconstruction of 3D polarization textures. This integrated approach offers a robust framework for probing polar topologies and uncovering the intricate coupling between structure, symmetry, and functionality in ferroic materials.

Origin and Evolution of Domain-Wall Conductivity in LiNbO3 — •Iuliia Kiseleva[1], Boris Koppitz[1], Matthias Roeper[1], Elke Beyreuther[1], Samuel Seddon[1], and Lukas Eng[1,2] — [1]Institute of Applied Physics, Technische Universität Dresden, Nöthnitzer Straße 61, Dresden, 01187, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden

Ferroelectric domain walls, which effectively serve as two-dimensional interfaces, exhibit functionalities markedly distinct from those of the bulk, such as enhanced conductivity and strong coupling to external fields, making them promising for nanoelectronic applications. Among various systems, lithium niobate (LiNbO3) stands out due to its high Curie temperature, chemical stability, and thoroughly characterized bulk properties. Yet the microscopic origins and dynamic evolution of domain-wall conductivity remain insufficiently understood, largely due to limited in-situ, time-resolved characterization. Here, we combine in-situ second-harmonic-generation (SHG) microscopy with electrical transport measurements and complementary chemical analysis to investigate domain-wall behavior under controlled electric and mechanical loading. This multimodal approach enables real-time visualization of domain restructuring, correlation of conductivity changes with wall inclination, and the dynamics of defects. The results aim to advance the understanding of functional domain-wall states and the mechanism of electrical transport in ferroelectric 2D systems.

FM 12.3 Wed 10:15 BEY/0138

Persistent photoconductivity in reduced lithium niobate bidomain crystals — •Philipp Fahler-Muenzer, Marios Hadjimichael, Ana Sanchez-Fuentes, Richard Beanland, Eoin Moynihan, and Marin Alexe — University of Warwick, Coventry, United Kingdom

The uniaxial ferroelectric lithium niobate ($LiNbO_3$) can exhibit significantly enhanced domain wall (DW) conductivity, rendering it an interesting system for DW-based nanoelectronics. Specifically, head-to-head (h2h) DWs exhibit conductivities several orders of magnitude higher than that of the surrounding bulk. We create h2h DWs with a near-90° inclination angle by using the diffusion annealing technique, followed by chemical treatment to change the functional properties. The characterization of the structure and morphology is conducted by piezoresponse force microscopy and transmission electron microscopy. To characterize electronic transport, we use resistivity measurements under varying temperatures in dark or under UV light illumination, complemented by conductive atomic force microscopy. Our findings indicate only transient conductivity at the DWs, but substantial differences in photoconductivity between monodomain and bidomain crystals, with persistent photoconductivity in crystals with DWs. Furthermore, we report a drastic drop in domain wall photoconductivity upon heating above 80°C, which can be explained by the emptying of charge carrier traps in the DW as the system gains higher thermal energy.

FM 12.4 Wed 10:30 BEY/0138

Photocurrent-based recognition in time-series tasks using reservoir computing — •Yan-Meng Chong[1], Atreya Majumdar[2], Ingvild Hansen[1], Karin Everschor-Sitte[2], and Dennis Meier[1,2,3] — [1]Department of Materials Science and Engineering, Norwegian University of Science and Technology (NTNU), Trondheim, Norway — [2]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [3]Research Center Future Energy Materials and Systems, Research Alliance Ruhr, Bochum, Germany.

In reservoir computing, input data are mapped into higher dimensional space, translating non-linear problems into linearly solvable ones. In general, any physical system that possesses non-linearity, complexity, short-term memory, and reproducibility can serve as reservoir. Here, we investigate the ferroelectric semiconductor $ErMnO_3$ as a potential candidate material for reservoir computing. We show that the system displays pronounced non-linear changes in photocurrent under varying light intensity. The response can be tuned by changing the metal-semiconductor contacts (Schottky- or Ohmic-like behavior) used for readout, determining the timescale on which the photocurrent vanishes after illumination. This relaxation behavior in the OFF state gives fading memory. We perform training on variations in the output (photocurrent), which allows for recognition in time-series tasks. Interestingly, ferroelectric domain walls can also be used as reservoirs with characteristic photocurrent signals, giving new opportunities to down-scale or enhance the complexity of physical reservoirs.

Properties of Charged Interfaces in Uniaxial Ferroelectrics — •Conor McCluskey, Kristina Holsgrove, Andrew Rogers, James Dalzell, Ronan Lynch, Raymond McQuaid, Tchavdar Todorov, and Marty Gregg — Queen's University Belfast, United Kingdom

When the polarisations of neighbouring ferroelectric domains abut, a bound charge develops at the interface. Often, these charged domain walls show enhanced electrical conductivity, which is typically taken as a sign that the polar divergence is fully screened by the mobile transport carriers. Transport measurements, however, suggest the carrier densities associated with domain wall conductivity lie well below that expected for a fully screened ferroelectric bound charge. In fact, some charged domain walls lack enhanced conductivity entirely. In these cases, polar rotation occurs to fully avoid the development of bound charge, leading to topological patterns in the polarisation field. Here, we discuss the interfaces formed between thermally bonded lithium niobate single crystals generated with intentional head-to-head character. We show that the interfaces formed uniquely host both of these properties: enhanced conductivity, and a striking array of polarisation vortices. Furthermore, since this interface is formed by thermal bonding of two crystalline structures, there is freedom to introduce relative lattice twists between the two parent crystals, which is unavailable at regular domain walls within a single parent crystal. We will discuss the interplay of strain and electrostatics at these unique interfaces in the context of their emergent functionality.

FM 12.6 Wed 11:15 BEY/0138

Polar Discontinuities, Emergent Conductivity, and Critical Twist-Angle-Dependent Behaviour at Wafer-Bonded Ferroelectric Interfaces — Andrew Rodgers[1], Kristina Holsgrove[1], Conor McClusky[1], Samuel Seddon[2], Marty Gregg[1], and •Lukas M. Eng[2,3] — [1]Centre for Quantum Materials and Technologies, School of Mathematics and Physics, Queen's University Belfast, UK — [2]Institut für Angewandte Physik (IAP)- Nöthnitzer Str. 61, 01187 Dresden — [3]ct.qmat: Dresden-Würzburg Cluster of Excellence*EXC 2147, TU Dresden, Germany

Probing novel properties, arising from twisted interfaces, has traditionally relied on the stacking of exfoliated 2D materials and the spontaneous formation of van der Waals (vdW) bonds. So far, investigations involving intimate covalent or ionic bonds have not been a focus. Yet, we show here that an established technique, involving thermocompressional wafer bonding, works well for creating twisted non-vdW interfaces. We have successfully bonded z-cut lithium niobate single crystals to create ferroelectric oxide interfaces with strong polar discontinuities and have mapped the associated emergent interfacial conductivity. In some instances, a dramatic change in microstructure occurs, involving local dipolar switching. A twist-induced collapse in the capability of the system to effectively screen interfacial bound charge is implied. Importantly, this only occurs around specific moiré twist angles with sparse coincident lattices and associated short-range aperiodicity. In quasicrystals, aperiodicity is known to induce pseudo-bandgaps and we suspect a similar phenomenon here.

FM 12.7 Wed 11:30 BEY/0138

Machine learned potential for ferroelectric heterostructure BaTiO3/SrTiO3 — •Lan-Tien Hsu[1], Jonathan Schmidt[2], Aaron Iten[2], Nicola Spaldin[2], and Anna Grünebohm[1] — [1]Interdisciplinary Centre for Advanced Materials Simulation (ICAMS), Faculty of Physics and Astronomy, and Center for Interface-Dominated High Performance Materials (ZGH), Ruhr-University Bochum, Germany — [2]Department of Materials, ETH Zürich, Zürich, CH-8093, Switzerland

Ferroelectric heterostructures offer a platform to realize topological patterns with functionalities relevant to future electronic devices.[1] While short-range machine-learned interatomic potentials can capture ferroelectric instabilities in pure materials, long-range dipole interactions remain essential for heterostructures, where depolarizing field plays a role.[2] We address this challenge by combining MACE message-passing networks with a latent Ewald-summation scheme[3] capable of learning long-range interactions and inferring Born effective charges without explicit training on response properties. The model predicts transition temperature and spontaneous polarization of $BaTiO_3$ in close agreement with experiments. It further captures the multidomain formed in heterostructures, consistent with coarse-grained effective-Hamiltonian results, and generalizes well to untrained configurations, including those containing oxygen vacancies.

From Stacking Faults to Field-Stabilized Polarity: Connecting RP Phases and the MFP Phase in $SrTiO_3$ — •Christian Ludt[1,2], Hartmut Stöcker[1,2], Matthias Zschornak[1,2,3], and Dirk C. Meyer[1,2] — [1]TU Bergakademie Freiberg, 09599 Freiberg, Germany — [2]Zentrum für Effiziente Hochtemperatur-Stoffwandlung, 09599 Freiberg, Germany — [3]Hochschule für Technik und Wirtschaft Dresden, 01069 Dresden, Germany

Polar functionalities in perovskites often arise from a subtle interplay between lattice distortions, defect chemistry, and stacking faults. In this work, particular attention is given to the migration-induced field-stabilized polar (MFP) phase in $SrTiO_3$, a recently identified polar state that arises from field-driven oxygen mobility and picometer-scale cation displacements. To provide a structural framework for understanding and enhancing this phenomenon, the electronic properties of Ruddlesden-Popper-type (RP) stacking faults in $SrO(SrTiO_3)_n$ are analyzed using density functional theory. These faults introduce symmetry breaking, modified lattice environments and characteristic changes in the electronic structure that closely resemble the local conditions required to form the MFP phase. By combining insights from RP-layered configurations with the field- and defect-driven mechanisms underlying MFP formation, a unified perspective emerges in which stacking faults act as natural templates that support, amplify, or localize MFP-like polar distortions. This connection highlights new pathways for engineering polar responses and optoelectronic functionalities in complex perovskite oxides.

FM 12.9 Wed 12:15 BEY/0138

Integration of imprint-free and low coercivity ferroelectric $BaTiO_3$ thin films on silicon — Jingtian Zhao[1,2], Majid Ahmadi[1,2], Beatriz Noheda[1,2], and •Martin F. Sarott[1,2] — [1]Zernike Institute for Advanced Materials, University of Groningen, The Netherlands — [2]Groningen Cognitive Systems and Materials Center (CogniGron), University of Groningen, The Netherlands

Highly-crystalline ferroelectric oxides integrated on Si hold great promise for energy-efficient memory and logic technologies. Exploiting epitaxial strain engineering in these materials is, however, severely hampered on Si, where the large structural mismatch often results in an inferior interfacial quality and causes a degradation of the ferroelectric switching characteristics. In this work, we present the growth of single-crystalline $BaTiO_3$ thin films on Si, exhibiting imprint-free switching, low coercivity, high remanent polarization, and no fatigue for over 10^{10} switching cycles. We accomplish this via the insertion of a $SrSn_{1-x}Ti_xO_3$ layer on $SrTiO_3$-buffered Si. This layer serves as a pseudo substrate that alleviates the *thermal strain* that the Si substrates imposes on the $BaTiO_3$ layer, while simultaneously providing moderate compressive strain that stabilizes a pure out-of-plane polarization. Thus, our work paves the way toward the fabrication of Si-compatible, low-power-consuming ferroelectric devices for non-volatile memory applications.

Polarity and polarons in WO_3 through epitaxial shear strain — •Ewout van der Veer[1], Martin Sarott[1,2], Jack Eckstein[3,5], Stijn Feringa[1], Dennis van der Veen[1], Johanna van Gent González[1], Majid Ahmadi[1,2], Horatio Cox[1,2], Ellen Kiens[4], Gertjan Koster[4], Bart Kooi[1,2], Michael Carpenter[3], Ekhard Salje[3], and Beatriz Noheda[1,2] — [1]ZIAM, Uni. of Groningen, Netherlands (E. vd V. now: Fac. of Phys., UDE, Duisburg, Germany and RC FEMS, Bochum, Germany) — [2]CogniGron, Uni. of Groningen, Netherlands — [3]Dept. of Earth Sci., Uni. of Cambridge, UK — [4]MESA+ Inst., Uni. of Twente, Netherlands — [5]Center for Nano. Mater. Sci., ORNL, USA

Tungsten oxides have been investigated for gas sensing, catalytic and electrochromic capabilities. Epitaxial thin films of WO_3 on (110)-oriented $YAlO_3$

even exhibit piezoelectricity and conductivity at monoclinic twin walls due to local strain gradients. We grew epitaxial films of WO_3 on (001)$YAlO_3$ by pulsed laser deposition and reveal a previously unreported polar phase by imposing epitaxial shear strain, stabilizing a triclinic structure up to large film thicknesses and elevated temperatures. The films have periodic in-plane domains with needle bifurcations and enhanced conductivity at domain walls. STEM shows that these walls exhibit a reduction of a structural distortion, evidence for recently predicted anti-distortive polarons. Our films are structurally and functionally different from known bulk phases and previous epitaxial films due to subtle epitaxial interactions. They are candidates for oxide electronics, neuromorphic computing and catalysis.

FM 12.11 Wed 12:45 BEY/0138

Inducing Strain Gradients in Transition Metal Oxides using Ferroelastic Domain Patterns — •Freya Watson[1], Aditya Singh[1], Katarzyna Sopinska[1], Daniel Chaney[2], Marin Alexe[1], and Marios Hadjimichael[1] — [1]University of Warwick, Coventry, United Kingdom — [2]ESRF, avenue des Martyrs, 38043 Grenoble Cedex 9, France

Strain engineering is a powerful tool for accessing new and versatile properties of materials. The use of ferroelectric domain patterns instead of conventional substrates further allows for the modification of the properties of these materials using electric fields. $PbTiO_3$ is a ferroelectric and ferroelastic perovskite which forms a periodic in-plane and out-of-plane domain structure when deposited on (110)-$DyScO_3$ substrates, caused by lattice mismatch. In this work, we explore inducing strain gradients in metallic perovskite thin films grown on this $PbTiO_3$ domain structure. Using this approach we are able to effectively couple strain between heterostructure interfaces and produce large anisotropy in electronic transport and material properties, which are found to be tuneable by altering $PbTiO_3$ layer thickness, and thus domain period. The effects of this strain engineering are demonstrated by scanning probe techniques, microscopy imaging and 4-probe resistivity measurements.

Probing ferroelastic domain properties of lanthanum aluminate via spontaneous Raman scattering — •Robin Buschbeck[1], Susanne C. Kehr[1], Lukas M. Eng[1,2], and Samuel D. Seddon[1] — [1]TU Dresden, Institute of Applied Physics, Nöthnitzer Strasse 61, 01187 Dresden, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence EXC 2147, TU Dresden, 01062 Dresden, Germany

Lanthanum aluminate ($LaAlO_3$, LAO) is a rhombohedrally distorted oxide perovskite, exhibiting ferroelastic twinning at room temperature. Frequently employed as a thin film substrate [1], it is often overlooked [2] for being optically uniaxial and thus birefringent. The effect of the ferroelastic twins sees an in-plane rotation of this optical axis, with regions of opposing optical axes coexisting (delineated by twin walls).

Here, we present a detailed experimental analysis of LAO(100) using spontaneous Raman scattering (SR). SR is a widely employed technique for obtaining spectral information from a broad range of materials [3]. Using SR, we demonstrate several spatially resolved non-trivial, three-dimensional intrinsic properties of LAO. Special attention is given to the different LAO(100) domains and their behaviour under various SR measurement conditions, including polarization-dependent and spatially resolved in-plane or depth-dependent measurements.

Strain Driven Ferroelastic Switching and Barkhausen Type Behavior in $LaAlO_3$ — •Vladyslav Kovtunovych, Matthias Roeper, Lukas M. Eng, and Samuel D. Seddon — Institut für Angewandte Physik (IAP)- Nöthnitzer Str. 61, 01187 Dresden

Lanthanum aluminate ($LaAlO_3$; LAO) is an oxide perovskite widely used in nano-electronics, and frequently employed as a thin-film substrate therein due to its convienient lattice match to many multiferroic and/or ferroelectric materials. Although oftentimes overlooked, LAO is an improper ferroelastic, posessing crystallographic domains delineated by twin walls, responding to the global application to strain akin to ferromagnetic or ferroelectric materials to magnetic or electric fields respectively. This study focuses on twin wall motion, which was induced and recorded using a commercial Razorbill strain cell with a high-resolution capacitive sensor. Measurements of $LaAlO_3$ under increasing uniaxial compression, revealed the expected jerky domain wall motion indicative of Barkhausen noise, the stochastic stepped reordering of local ordering parameters common among all ferroic materials. This scale invariant physics acts as a power law governing all length scales, from avalanches on mountains down to the nanoscale. Complementary XRD measurements of the expected Bragg peak splitting are correlated with polarised light microscopy imaging all as a function of lattice strain, to observe this effect in a whole new light.

FM 14.3 Wed 15:30 BEY/0138

Single crystal growth of stoichiometric lithium tantalate — •Sebastian Inckemann, Roberts Blukis, Angélique Hoffmann, Matthias Bickermann, and Steffen Ganschow — Leibniz-Institut für Kristallzüchtung, Max-Born-Straße 2, 12489 Berlin, Germany

A material isomorphous to the intensively investigated lithium niobate (LiNbO3, LN) that has the same inherent non-stoichiometry is lithium tantalate (LiTaO3, LT). Despite similar characteristics to LN, the properties of LT are significantly less studied, even though there are notable differences that favor the use of LT in certain applications. Of special interest is the investigation of stoichiometric LT (sLT) compared to congruent LT (cLT), as the lithium deficiency in cLT causes a high concentration of defects (Kim et al., 2001). Literature describes multiple methods to achieve stoichiometric LN single crystals, exemplary via the double crucible method. However, the growth method reporting a crystal composition closest to the stoichiometric ratio is the growth via the flux method (Polgár et al., 2002). Due to the similarities between LN and LT an analogous approach is the most promising, with the use of K_2O as a solvent showing the best results in the case of LN (Polgár et al., 1997). To ensure an efficient single crystal growth in this system, knowledge about the Li_2O-K_2O-Ta_2O_5 phase diagram is vital (Mühlberg et al., 2008). As there is no literature regarding this phase diagram, this presentation will present our current progress by combining DTA, PXRD and SEM measurements. Furthermore, results regarding the single crystal sLT growth attempts will be presented.

FM 14.4 Wed 15:45 BEY/0138

Poling and acoustic characterization of near-stoichiometric $Li(Nb,Ta)O_3$ crystals — •Éva Tichy-Rács[1], Stepan Hurskyy[1], Steffen Ganschow[2], Fatima El Azzouzi[1], Holger Fritze[1], and Yuri Suhak[1] — [1]Clausthal University of Technology, Goslar, Germany — [2]Leibniz Institut für Kristallzüchtung, Berlin, Germany

$Li(Nb,Ta)O_3$ solid solutions bridge the high Curie temperature of $LiNbO_3$ and the thermal stability of $LiTaO_3$, while maintaining a strong piezoelectric performance, making them attractive for high-temperature sensing and actuation. The

intrinsic properties of $LiNbO_3$, $LiTaO_3$ and, consequently, their $Li(Nb,Ta)O_3$ solid solutions are well known to be highly sensitive to lithium stoichiometry. In the present work the acoustic properties of near-stoichiometric $LiNb_{1-x}Ta_xO_3$ (x=0; 0.45; 1) single crystals are investigated as a function of temperature and time by resonant piezoelectric spectroscopy. The near-stoichiometric compositions were obtained by the vapor transport equilibration (VTE). Subsequently, the samples were electrically poled to ensure a single-domain state. The study shows that acoustic losses in nsLT remain in the range of 10^{-4}–10^{-3} up to 620 °C, i.e., within the ferroelectric phase, and increase monotonically with temperature, though only weakly, with an activation energy of about 0.05 eV. In contrast, nsLN and nsLNT45 exhibit a pronounced loss increase above 600 °C, attributed to the conductivity-related relaxation mechanism. Under constant operation at 600 °C for 350 h, all samples demonstrate excellent long-term stability, with resonance frequency deviations not exceeding ± 100 ppm of the initial value.

Nanoscale Phonon Dynamics Studied In-Situ by Laser Stimulated Vibrational Electron Energy-Gain Spectroscopy — •Mairi McCauley[1,2], Joel Martis[3], Ondrej Krivanek[3], Ben Plotkin-Swing[3], Tolga Wagner[1,2], Hüseyin Çelik[1,4], Grigory Kornilov[1], Katrina Coogan[1,2], Meng Zhao[1,2], Andreas Mittelberger[3], Matthias Meffert[5], Luca Piazza[5], Tracy Lovejoy[3], Guillaume Radtke[6], Christoph Koch[1,2], and Benedikt Haas[1,2] — [1]Department of Physics, Humboldt-Universität zu Berlin, Berlin, Germany — [2]Center for the Science of Materials Berlin, Humboldt-Universität zu Berlin, Berlin, Germany — [3]Bruker AXS LLC, Kirkland, WA, USA — [4]Institute for Physics and Astronomy, Technische Universität Berlin, Berlin, Germany — [5]DECTRIS AG, Baden-Daettwil, Switzerland — [6]Sorbonne Université, CNRS UMR 7590, MNHN, IMPMC, Paris, France

Advances in instrumentation allow to directly probe phonon dispersions at the nanoscale using electron energy gain and loss spectroscopy (EEGS/EELS) within a scanning transmission electron microscope (STEM). By integrating a laser injection system, we enable the investigation of stimulated phonons at the spatial resolution determined by the electron beam. A synchronised laser-detector configuration enables nanosecond-scale time-resolved measurements. The thermal conductivity of amorphous carbon and silicon nitride was investigated by local time-resolved temperature measurements and is compared to numerical simulations. Ongoing work applies the system to study phonon transport through defects and interfaces at atomic resolution.

FM 15.2 Wed 15:15 BEY/0E40

Photoluminescence Spectroscopy of Platinum (II) and Palladium (II) Dimers in Organic Molecular Single Crystals Under Pressure — Paul Steeger[1], Tobias Theiss[2], Dominik Schwab[3], Ivan Maisuls[2], •Vedhanth Senthiappan Vellaiappan Uthayasurian[1], Robert Schmidt[1], Ilya Kupenko[4], Carmen Sanchez Valle[4], Steffen Michaelis de Vasconcellos[1], Nikos L. Doltsinis[3], Cristian A. Strassert[2], and Rudolf Bratschitsch[1] — [1]Institute of Physics, University of Münster — [2]Institut für Anorganische und Analytische Chemie, University of Münster — [3]Institute of Solid State Theory, University of Münster — [4]Institute of Mineralogy, University of Münster

Cyclometalated transition-metal complexes are promising for applications ranging from bioimaging to light-emitting diodes. We investigate two tailored biscyclometalated Pd(II) and Pt(II) complexes, which feature ligands that promote head-to-tail dimer formation to enable interactions between their metal centers [1]. We prepare molecular single crystals and apply hydrostatic pressure with a diamond anvil cell in the GPa range [2]. The photoluminescence shows a prominent redshift under pressure. Density functional theory calculations link this effect to a reduced metal-metal distance. Importantly, the observed mechanochromism is reversible, which holds the promise for pressure sensing and optical storage applications. References: [1] T. Theiss et al., J. Am. Chem. Soc. 145, 3937 (2023), [2] P. Steeger et al., Nano Lett. 25, 2628 (2025)

FM 15.3 Wed 15:30 BEY/0E40

A novel Approach to parametrize a ferroelectric Phase-Field Model from atomistic Simulation Data — •Frank Wendler[1], Dilshod Durdiev[2], Xuejian Wang[1], Hikaru Azuma[3], Takahiro Tsuzuki[3], Tomohiro Ogawa[3], Ryo Kobayashi[3], Masayuki Uraganase[4], Shuji Ogata[3], and Michael Zaiser[1] — [1]Institute of Materials Simulation, FAU Erlangen-Nürnberg, Dr.-Mack-Str. 77, 90762 Fürth, Germany — [2]Division Mechanics of Functional Materials, TU Darmstadt, Germany — [3]Physical Science and Engineering Department, Nagoya Institute of Technology, Japan — [4]RIKEN Center for Biosystems Dynamics Research, Japan

Based on molecular dynamics simulations using a core-shell potential for polarization switching in ferroelectric BaTiO3 (BTO) with and without vacancy defects, a parametrization framework for phase-field simulations is established. Crucial material properties such as elastic and piezoelectric tensor components, kinetic coefficients, as well as domain wall characteristics are extracted from the MD results to adjust the anisotropic gradient energy. The 6th order Landau polynomial coefficients are derived from statistical analysis of polarization switching data, including the activation parameters for BTO that govern domain nucleation. The proposed energy landscape favours polarization switching in two subsequent 90° steps over 180° switching, which was observed experimentally and in recent MD simulations. The method is important for phase-field simulations of domain nucleation and domain wall motion in presence of point defects carrying mono- or dipolar electric fields as well as elastic strain fields.

Piled higher, probed deeper: X-ray insights into ferroelectric devices — •Martina Müller — Fachbereich Physik, Universität Konstanz

In ferroelectrics, the nothing is mighty: The key to shaping the ferroelectric functionalities of oxide/nitride materials and devices lies in the tunability of their oxygen/nitrogen sublattice, particularly their defect structure. While dopants and vacancies are a key aspect of emerging ferroelectricity in HfO_2 and AlScN, their detection is much more subtle than that of atomic properties. This is because the experimental observation of e.g. oxygen vacancies means the detection of something absent. This requires access to indirect signatures, which often are of very low intensity and located within a device structure - a combination of experimental conditions that are challenging to meet in practice.

This talk presents recent advances in the expertise required to detect defects and dopants related ferroelectric functionality in HfO_2 and AlScN using synchrotron radiation. Bulk-sensitive hard X-ray photoelectron spectroscopy (HAXPES) enables the non-destructive depth profiling of heterostructures, revealing spectroscopic fingerprints also in subtle core-level signatures. Performing HAXPES 'in operando' is a powerful tool for determining the band alignment and chemical state of interfaces under operating conditions of real-world ferroelectric devices.

FM 18: German-French Focus Session: (Anti)ferroic states – ferroelectrics, ferroelastics and antiferroelectrics II

chair: Elzbieta Gradauskaite (CNRS/Thales, FR)

This focus session explores recent advances in understanding and control of (anti)ferroic states. Emphasis will be placed on theoretical modelling, advanced characterization techniques, and the engineering of emergent properties for use in nano-electronic devices. The session aims to bridge fundamental research with emerging device-relevant functionalities, bringing together experimental, and theoretical perspectives on ferroic materials.

Stabilizing antiferroelectricity in PbZrO3 thin films using epitaxial tensile strain — •Vincent Garcia — Laboratoire Albert Fert, CNRS, Thales, Univ. Paris-Saclay, France

The antiferroelectric nature of lead zirconate, the historical and most studied antiferroelectric material, has recently been challenged. Progress in atomic-level characterization using aberration-corrected scanning transmission electron microscopy (STEM) has revealed the complex nature of polar textures in PbZrO3. In single crystals, ferrielectric phases have been detected, while in PbZrO3 epitaxial films, thickness reduction engenders competition among antiferroelectric, ferrielectric and ferroelectric phases. All studies so far on PbZrO3 films have utilized commercially-available oxide single crystals with large compressive lattice mismatch, causing the films to undergo strain relaxation within a few nanometres. Interestingly, first principles calculations have predicted that tensile strain can stabilize antiferroelectricity down to the nanometre scale. Here we use tensile strain imposed by artificial substrates of LaLuO3 to stabilize a pure antiferroelectric phase in epitaxial ultrathin films of PbZrO3. Sharp double hysteresis loops of polarization vs electric field in these PbZrO3-based capacitors show zero remanent polarization, and atomic scale mapping of polar displacements using STEM reveals the characteristic antipolar pattern of the Pbam phase in film thicknesses down to 9 nanometres. These results highlight the critical role of coherent epitaxial strain in the phase stability of PbZrO3.

Invited Talk FM 18.2 Thu 10:45 BEY/0138

Strain effects in free-standing membranes of antiferroelectric Lead Zirconate — •Umair Saeed[1,2], Huazhang Zhang[3,4], David Pesquera[1], Philippe Ghosez[3], Nini Pryds[5], Jose Santiso[1], Felip Sandiumenge[6], and Gustau Catalan[1,7] — [1]ICN2, Catalonia — [2]UAB, Spain — [3]ULiège, Belgium — [4]WUT, China — [5]DTU, Denmark — [6]ICMAB, Catalonia — [7]ICREA, Catalonia

Antiferroelectrics like PbZrO3 (PZO) exhibit reversible switching between antiferroelectric and ferroelectric phases. However, complex energy landscape of PZO and few lattice matching substrates render strain engineering challenging. In this context, free-standing membranes provide a unique opportunity for strain tuning due to their flexibility.

We studied PZO membrane capacitors under homogeneous in-plane strain applied via bending, observing that the hysteresis decreases under in-plane compression and increases under tension. The results suggest that the changes in the switching behavior originate from the modification of energy barriers between the phases under the influence of strain rather than the energies of the phases. Molecular dynamic simulations show that this response depends on crystallographic directions of strain and electric field.

In wrinkled stand-alone PZO membranes, on the other hand, high strain gradients induce flexoelectric effects, leading to non-canonical antiferroelectric-like ordering under tensile and ferroelectric phases under compressive strain, highlighting strain as a tool to control PZO functionalities.

Strain induced ferroelastic twin-domain dynamics in lanthanum aluminate — •Matthias Roeper[1], Robin Buschbeck[1], Jakob Wetzel[1], Lukas M. Eng[1,2], and Samuel D. Seddon[1] — [1]Institute of Applied Physics, TU Dresden, Nöthnitzer Strasse 61, 01187 Dresden, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence - EXC 2147, TU Dresden, 01062 Dresden, Germany

Over the last decades scientific attention of the oxide perovskite lanthanum aluminate ($LaAlO_3$) has turned (due to the absence of ferroelectric contributions) from originally only an active interfacial substrate material into a model system of ferroelastic twin domain walls. Our new results explore ferroelastic twin-domain dynamics induced by the controlled application of uniaxial strain in single crystalline samples. The domains are spacially resolved by Atomic Force Microscopy and μ-Raman Spectroscopy as a function of applied strain, as well as structural analysis by X-ray diffraction. All experimental investigations are complemented by density functional perturbation theory calculations.

FM 18.4 Thu 11:30 BEY/0138

MD data-driven physics-informed neural network for multi-scale modelling of ferroelectric: parameter identification and field reconstruction — •Xuejian Wang[1], Frank Wendler[1], Hikaru Auzuma[2], and Shuji Ogata[2] — [1]Institute of Materials Simulation, Department of Materials Science and Engineering, Friedrich-Alexander-Universität Erlangen-Nürnberg, Fürth, Germany — [2]Graduate School of Engineering, Nagoya Institute of Technology, Nagoya, Japan

A persistent challenge in multiscale ferroelectric modeling is connecting atomistic information with continuum phase-field descriptions. Here, we develop a PINN framework driven by MD polarization data. The loss function combines supervised fitting of MD-derived polarization fields with physics-based residuals of the steady-state phase-field PDEs. Minimizing the total loss enables the network to reconstruct polarization, strain, stress, and electric field distributions, while simultaneously identifying key phase-field parameters, including characteristic energy and length scales, gradient anisotropy, and Landau coefficients. Using these PINN-identified parameters in COMSOL reproduces ferroelectric domain structures and their electromechanical responses with high fidelity. This approach provides an efficient route to establishing atomistic-to-continuum links and inferring physical properties directly from polarization configurations.

FM 18.5 Thu 11:45 BEY/0138

Evidence of ferroelectricity in epitaxially strained tungsten trioxide thin films — •Nives Strkalj[1,2], Zhuotong Sun[1], Ming Xiao[1], Ziyi Yuan[1], Xuan T. Nguyen[1], Simon M. Fairclough[1], Caterina Ducati[1], Giuliana Di Martino[1], and Judith L. MacManus-Driscoll[1] — [1]University of Cambridge, UK — [2]Institute of Physics, Zagreb, Croatia

Ferroelectric films offer a promising path to faster, more energy-efficient CMOS technologies. Here, we report the deposition of epitaxial tungsten trioxide films at temperatures below 400°C using atmospheric pressure spatial chemical vapour deposition. In these films, epitaxial strain imposed by the substrate promotes the formation of the low-temperature polar phase at room temperatures, evidenced by x-ray diffraction, scanning transmission electron microscopy, piezoresponse force measurements, and Raman spectroscopy. Exploring ferroelectricity in ultrathin tungsten trioxide films could provide a new platform for polarization-controlled electronic and optical applications.

FM 18.6 Thu 12:00 BEY/0138

Investigating metallicity in layered Carpy-Galy ferroelectrics through topotactic transformation. — •Lilia Huynh[1], Marko Kuvezdic[1], Dongxin Zhang[1], Annouk Goossens[1], Luis Moreno[1], Alexandre Gloter[2], Lucia Iglesias[1], Manuel Bibes[1], and Elzbieta Gradauskaite[1] — [1]Laboratoire Albert Fert, Palaiseau, France — [2]Laboratoire de Physique du Solide, Orsay, France

Combining seemingly incompatible properties within a single material can yield unconventional functionalities. For instance, polar metals host inversion-symmetry breaking displacements despite finite metallicity. However, they remain scarce, as conventional ferroelectricity usually relies on orbital rehybridization and gets suppressed by free charge carriers. Here, we report the epitaxial stabilization of the layered Carpy-Galy ferroelectric $Sr_2Nb_2O_7$ ($A_nB_nO_{3n+2}$, $n = 4$), which exhibits a geometric in-plane polarization driven by collective octahedral rotations. These films can be successfully transformed into the metallic perovskite $SrNbO_3$ through a topotactic interfacial reduction mediated by an Al overlayer, which drives oxygen-vacancy migration and electron doping. This redox-engineering route enables fine, continuous and even reversible tuning of oxygen stoichiometry, allowing us to stabilize intermediate $Sr_2Nb_2O_{7-x}$ phases, as confirmed by XRD, XPS, STEM, and transport measurements. In contrast to bottom-up synthesis of polar metals, this top-down strategy provides fine control of metallicity in a geometric ferroelectric host and opens avenues for exploring charge- and spin-transport phenomena in polar metals.

FM 18.7 Thu 12:15 BEY/0138

Dynamical tuning of the depletion region at a single ferroelectric domain wall — •Jiali He[1], Ruben Dragland[1], Jan Schultheiss[1], Zewu Yan[2,3], Edith Bourret[3], and Dennis Meier[4] — [1]NTNU, Norway — [2]ETH Zurich, Switzerland — [3]LBNL, USA — [4]University of Duisburg-Essen, Germany

Ferroelectric domain walls (DWs) are promising building blocks for future nanoelectronics, combining ultra-small feature size with emergent device-relevant behaviors. Most studies so far focused on bulk crystals and thin films, where the measured response reflects convoluted contributions from, e.g., the hidden subsurface wall structures and the networks they form. The intrinsic behavior of individual DWs thus often remains unclear. In my talk, I will present the extraction of a single insulating ferroelectric DW, situated in a 1-μm-thick $ErMnO_3$ lamella, mounted on a conductive back electrode. This configuration enables a well-defined top-bottom current path using an AFM tip as movable top electrode. Consistent with previous measurements on single crystals, we observe that the initially thin insulating wall (~200 nm electronic width) transforms under applied bias into a narrow conductive core surrounded by a broad asymmetric depletion region, leading to a fivefold increase in apparent wall width. Systematic bias variation demonstrates a highly tunable electronic wall width, manifesting as voltage-controlled expansion and contraction of the depletion region. The results corroborate that functional DW properties known from crystals are transferable to nano-structured device-relevant systems, revealing new possibilities for electronic signal control.

FM 18.8 Thu 12:30 BEY/0138

Hybrid antiferroelectric-ferroelectric-ferroelastic domain walls in non-collinear antipolar oxides — •Ivan N. Ushakov[1], Mats Topstad[1], Muhammad Z. Khalid[1], Niyorjyoti Sharma[2], Christoph Grams[3], Ursula Ludacka[1], Jiali He[1], Kasper Hunnestad[1], Mohsen Sadeqi-Moqadam[1], Julia Glaum[1], Sverre M. Selbach[1], Joachim Hemberger[3], Petra Becker[3], Ladislav Bohatý[3], Amit Kumar[2], Jorge Íñiguez-González[4,5], Antonius T.J. van Helvoort[1], and Dennis Meier[1,6] — [1]NTNU, Trondheim — [2]QUB, Belfast — [3]University of Cologne — [4]LIST, Luxembourg — [5]University of Luxembourg — [6]University of Duisburg-Essen

Antiferroelectrics are emerging as advanced functional materials and are fertile ground for unusual electric effects. Here, we demonstrate how antiferroelectricity induces noncollinearity in dipolar order and establish it as an additional degree of freedom, unlocking physical nanoscale properties that are symmetry-forbidden in classical antiferroelectrics. We show that antiferroelectrically driven noncollinear order of electric dipole moments in $K_3[Nb_3O_6|(BO_3)_2]$ leads to a coexistence of antiferroelectric and ferroelectric behaviors. Besides the double-hysteresis loop observed in antiferroelectrics, a pronounced piezoresponse and electrically switchable hybrid domains are observed, forming atomically sharp and micrometer long charged domain walls with inseparably entangled antiferroelectric and ferroelectric properties. Hybrid antiferroelectric-ferroelectric responses are expected in a wide range of noncollinear systems, giving a new dimension to the research on antiferroelectrics and multifunctional oxides in general.

Electron Beam-Induced Currents as a Quantitative Probe for Nanoscale Semiconductor Devices — •Sebastian Schneider[1], Sebastian Beckert[1], René Hammer[2], Markus König[3], Grigore Moldovan[2], Darius Pohl[1], and Bernd Rellinghaus[1] — [1]Dresden Center for Nanoanalysis (DCN), TU Dresden, Dresden, Germany — [2]Point Electronic GmbH, Halle (Saale), Germany — [3]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

Electron beam-induced current (EBIC) mapping in the scanning transmission electron microscope (STEM) enables the direct visualization of charge carrier transport with nanometer resolution. We present a comparative STEM-EBIC study on silicon photodiode lamellae prepared by gallium and xenon focused ion beam milling. The EBIC mapping reveals the p-n junction and allows for the extraction of the effective electron and hole diffusion lengths as a function of local thickness. These values are up to three orders of magnitude smaller than bulk EBIC results, highlighting strong surface recombination and preparation-induced artifacts. Complementary I-V measurements show significant deviations from the expected diode-like behavior, which we attribute to high resistive contacts at the metal-semiconductor interfaces. Our findings emphasize the critical role of sample preparation for quantitative EBIC analysis.

Financial support by the DFG through TRR 404, project no. 528378584, is gratefully acknowledged.

X-ray Stress Tensor Tomography — •Peter Modregger[1,2], Ahmar Khaliq[1,2], and Felix Wittwer[1,2] — [1]Physics Department, University of Siegen — [2]Center for X-ray and Nano science, CXNS, DESY, Hamburg

The possibility for tomographic reconstrution of strain and stress tensor present in poly-crystalline samples has been discussed for nearly two decades. We will demonstrate the successful retrieval of all 6 strain/stress tensor components in martensitic steel samples from experimental data acquired at the ID11 beamline of the ESRF. Compared to established techniques this novel approach for the depth-resolved determination of stress states offers the tantalizing advantages of a simple experimental setup, isotropic gauge volumes and faster scans. In our presentation, we will discuss the possible adverse effects of detector parallax and crystallographic texture. Further, we will provide specific experimental requirements such as the required photon flux or the available scattering angles. With these in mind, we have achieved a strain sensitivity of 10^{-4} and a stress sensitivity of 20 MPa.

Developing a resuable optical fiber-based sensing system for in-situ X-ray radiaiton monitoring — Ali Karatutlu[1,2], Esra Kendir Tekgül[2], Zehra Gizem Mutlay[1], Andriy Budnyk[1], Gianluca Iori[3,4], Philipp Hans[5], Fareeha Hameed[5], and •Bülend Ortaç[1] — [1]Bilkent University, Institute of Materials Science Nanotechnology and National Nanotechnology Research Center (UNAM), Ankara, 06800 Turkey — [2]Sivas University of Science and Technology, Department of Engineering Basic Sciences, Sivas, 58100 Turkey — [3]Swiss Light Source, Paul Scherrer Institute, Villigen, Switzerland — [4]GratXray, Villigen, Switzerland — [5]Synchrotron-light for Experimental Science and Applications in the Middle East (SESAME), Allan, 19252, Jordan

Specialty optical fibers doped with rare-earths such as Yb, and Tm are utilized for various applications from medical to high-power beam delivery for materials processing. Nevertheless, radiation-induced defects can occur due to irradiation, causing a degradation of beam quality. In this study, we utilize this type of degradation, referred to as radiation-induced attenuation, as an X-ray sensing and the conditions in the in-situ recovery of color centers. The experiments were conducted at hard X-ray beamline at BEATS, SESAME, using different monochromatic beams such as 10 keV and 20 keV, suggesting the origin of color centers playing role in the RIA and the sensing and recovery behavior that are related to the optical and morphological effects of the X-ray irradiation.

FM 19.4 Thu 11:00 BEY/0E40

Multiscale characterization of porous carbon fibers — •Markus Löffler[1], Mohsen Sadeghi Bogar[2,3], Paul Bertram[3,4], Jan Wolf[2,3], Darius Pohl[1], Thomas Behnisch[2,3], Iris Kruppke[3,4], Chokri Cherif[3,4], Maik Gude[2,3], and Bernd Rellinghaus[1] — [1]Dresden Center for Nanoanalysis (DCN), cfaed, TUD Dresden University of Technology (TUD), Dresden, Germany — [2]Institute of Lightweight Engineering and Polymer Technology (ILK), TUD, Dresden, Germany — [3]Research Center Carbon Fibers Saxony, TUD, Dresden, Germany — [4]Institute of Textile Machinery and High Performance Material Technology (ITM), TUD, Dresden, Germany

Porous carbon fibers (PCF) are valued for structural energy storage because they combine low density, high thermal and electrical conductivity, low thermal expansion, strong mechanical properties, and a large specific surface area. Key pore features - volume, shape, and connectivity - determine their suitability for use as electrodes in batteries, supercapacitors, and as structural materials. A hierarchical pore structure with sizes from 2 nm to over 50 nm is desirable. These PCFs are made by wet-spinning polyacrylonitrile (PAN) with nanocellulose as a pore-forming additive, followed by electron beam irradiation, stabilization, and carbonization. To understand how processing affects pore development, fibers are analyzed at various stages and scales using submicro-XCT, FIB, SEM, and TEM. All fibers show a low density of large pores, while precursor and irradiated fibers also have a high density of nanoscale pores.

FM 19.5 Thu 11:15 BEY/0E40

Tomographic Electron Holography reveals 3D-Potential Variations from Surface Segregation in p-n doped InGaAs Nanowires — •Kai-Luis Jakob[1], Laura Niermann[1], Tore Niermann[1], Frederik Otto[1], Rahel Specht[1], Daniel Wolf[2], Esmaielpour Hamidreza[3], Gregor Koblmüller[1], and Michael Lehmann[1] — [1]TU Berlin — [2]IFW Dresden — [3]TU München

Mapping the three-dimensional electrostatic potential distribution at the nanoscale is crucial for tuning the electrical properties of semiconductor nanostructures, such as InGaAs nanowires utilized in optoelectronics. Off-axis electron holography enables measurement of the projected electrostatic potential

with nanoscale spatial resolution; however, the 3D information typically remains inaccessible. In this work, we combine electron holography with tomography to reconstruct 3D potentials, thereby investigating subtle effects such as surface segregation, Fermi-level pinning, and damages induced by Focused Ion Beam preparation. Here, we focus on MBE-grown InGaAs nanowires featuring an axial p-n junction. A tilt series of holograms is acquired over a wide tilt range in a FEI Titan 80-300 TEM. Projected electrostatic potentials are reconstructed individually and aligned for tomographic reconstruction. This approach allows us to access the electrostatic potential and resolve both axial and radial changes from the wire core to its surface. We observed a largely constant potential step across the axial p-n junction of 0.5 V, however, near-surface regions exhibited deviations from it. At the surface of the n-doped segment, we found a thin p-type layer, likely attributable to known surface segregation.

Defects in Materials: Limitations of the Trapping Model - the Influence of Corrupt Components in Positron Lifetime Spectra - cured by a New Spectrometer? — Torsten Staab, •Dominik Boras, and Danny Petschke — LCTM / IFB, Department of Chemistry, University of Wuerzburg, Roentgenring 11, D-97070 Wuerzburg, Germany

Positron lifetime spectroscopy is able to extract densities for defects (e.g. vacancies or dislocations) from the measured spectroscopic data by applying the so-called trapping model, which describes the decomposition of lifetime spectra into two or more components (lifetimes and intensities). Since the procedure of fitting several exponential decays folded by a mimicked instrumental resolution function (IRF) is a so-called ill-posed problem, the goodness of the fit relies heavily on the quality of the recorded data. By our digital twin of a positron lifetime spectrometer we could clearly see the strong influence of back scattered and corrupted coincidences on recorded spectra. Unfortunately, even by physically filtering digitised pulses, those events cannot be removed. One way to reduce their effect are changes in the geometry (90° instead of 180°) of the detector set-up leading to heavy losses in efficiency (about 90%). However, this leads to much more realistic bulk positron lifetimes of light materials (Mg, Al, Si) in accordance with calculations, and enables correct decompositions by the trapping model. We present here a new fully digitised spectrometer with an IRF described by one singe Gaussian and a FWHM of 128ps together with 22-Na sources without positronium having a single lifetime component.

Characterising electron vortex beams inside crystalline materials via vorticity — •Christian Bick, Dorothee Hüser, and Tobias Klein — Physikalisch-Technische Bundesanstalt, Braunschweig, Germany

Convergent electron beams with an orbital angular momentum (OAM), also known as electron vortex beams or twisted electrons, have been investigated for multiple applications in material science. Recently, first measurements of vortex electron magnetic circular dichroism (EMCD) in the electron microscope have been reported.

We present a simulation-based study on vortex beam behaviour inside crystalline material utilising vorticity as a local property to characterise the beam. This quantity, which is widely used in fluid mechanics, can be understood as a local measure of OAM . We relate it to commonly used integrated quantities like the total OAM and channelling strength in order to further the understanding of the beams behaviour inside of model crystals and discuss possible measurements.

FM 19.9 Thu 12:30 BEY/0E40

Toward Atomic-scale Imaging of Resistive Switching Mechanisms in Prussian Blue Memristors — •Mohammed Fayis Kalady[1], Johannes Schultz[1], Michael Pohlitz[2], Falk Röder[1], Darius Pohl[3], Daniel Wolf[1], and Axel Lubk[1,4] — [1]Leibniz Institute for Solid State and Materials Research, Dresden, Germany — [2]Faculty of Physical Engineering/Computer Sciences, University of Applied Sciences, Zwickau, Germany — [3]DCN, TU Dresden, Germany — [4]IFMP, TU Dresden, Germany

Prussian blue and its analogues are promising materials for memristive devices based on resistive switching. To obtain a microscopic understanding of the structural and chemical processes responsible for switching, we employed a detailed high-resolution transmission electron microscopy (HRTEM), scanning transmission electron microscopy combined with electron energy loss and energy dispersive x-ray spectrum imaging (STEM-EELS and STEM-EDX) studies on pristine films and on films previously subjected to electrical biasing. The pristine film exhibits a homogeneous distribution of K, Fe, C, N, and O, whereas the electrically biased regions display clear nanoscale modifications, including local changes in elemental distribution and a phase transition from Prussian blue to Prussian white. The electrical measurements on the bulk reveal transitions between low-resistance and high-resistance states, demonstrating bipolar switching behavior across multiple cycles. These results provide the first steps toward in-situ TEM biasing experiments aimed at directly resolving elemental migration pathways and phase evolution under applied voltages.

FM 20: Excursion and Network-Event at Infineon Dresden AG (joint session FM/HL)

We are organizing an Excursion and Network-Event to Infineon Dresden AG.
Only for registered and selected participants.
Please register until latest February 12th here:
https://www.icams.de/news-events/events/registration-infineon/?api=561b8d7cfcb678e9f0938830d78cf979

Time: Thursday 13:30–17:00 Location: Infineon

Only for registered and selected participants.

FM 21: Members Assembly

We will elect our spokespersons, plan the programme for the coming years, and award the poster prize. This is also your opportunity to suggest topics for focus sessions, symposia, and plenary speakers for the next DPG conference!

chairs: Jan Schultheiß (NTNU, NO), Anna Grünebohm (Ruhr University Bochum, DE), FM spokespersons

Time: Thursday 18:00–18:45 Location: BEY/0138

All members of the Functional Materials Division are invited to participate.

FM 22: Focus Session: Materials Discovery III – New materials and functionalities by general principles

chairs: Hiroki Taniguchi (Nagoya University, JP), Akitoshi Nakano (Nagoya University, JP)

Discovering new functional materials is crucial to advance today's technologies, ranging from caloric cooling via catalysis to next-generation energy conversion and storage, such as thermoelectric, ferroelectric, and ionic conductor materials. New materials also form the basis for potential applications in quantum information technologies. This session provides a platform to highlight functional materials discoveries and how they come about. Notably, systematic searches with high-throughput synthesis approaches, as well as predictions from materials informatics, have helped to go beyond serendipitous discoveries in recent years. However, intuition guided by general principles remains an important factor. In this session, we particularly welcome contributions that showcase the discovery of new functional materials with original approaches. Diverse material systems - from well-established to emerging and niche classes across condensed-matter and materials physics - will be featured. Bringing together diverse discoveries in a single session will help delineate general principles and inspire future work.

Time: Friday 9:30–12:45 Location: BEY/0138

Topological thermoelectrics for solid state cooling — •Yu Pan[1] and Claudia Felser[2] — [1]Chongqing University, Chongqing, China — [2]Max Planck Institute for Chemical Physics of Solids

Thermoelectric effects enable the direct conversion between thermal energy and electrical energy, and has broad application potential in areas such as thermoelectric power generation, solid-state cooling, and precise temperature control. Classic thermoelectric materials mainly focus on heavily doped narrow bandgap semiconductor materials, whose thermoelectric performance is limited above room temperature (> 300 K). So far, further enhancement of thermoelectric performance at low temperatures (<300 K) faces significant challenges, severely restricting the application of thermoelectric materials in low-temperature solid-state cooling. In recent years, the surge of topological quantum materials has triggered many novel thermoelectric transport behaviors, especially the significantly enhanced low-temperature thermoelectric performance under magnetic fields, providing new opportunities to greatly improve low-temperature thermoelectric performance. For example, their linear-dispersion energy band structures and ultrahigh mobility significantly enhance the magneto-Seebeck effect and Nernst effect. On the other hand, topological quantum materials with broken symmetry can exhibit an anomalous Nernst thermoelectric potential far higher than that of conventional ferromagnets due to the presence of nonzero Berry curvature, laying a scientific foundation for thermoelectric applications of the anomalous Nernst effect under low or even zero magnetic fields.

FM 22.2 Fri 10:00 BEY/0138

Topological quantum materials for high performance heterogenous catalysis — •Xia Wang and Claudia Felser — Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany

The electronic structure of a catalyst plays a pivotal role in governing its performance1. Topological quantum materials, known for their symmetry-protected electronic states, offer a unique platform to bridge solid-state topology and heterogeneous catalysis. When combined with chirality, topological quantum materials give rise to novel material systems exhibiting distinct chiral phenomena, opening new avenues for the development of next-generation chiral catalysts. Situated at the interface of condensed matter physics and chemistry, the emerging field of topological catalysis exploits the exotic quantum properties of topological quantum materials to not only enhance catalytic activity and selectivity but also to enable fundamental studies of reaction mechanisms. Our recent experimental and theoretical work demonstrates a direct link between spin-orbit coupling and the kinetics of oxygen electrocatalysis, including both the oxygen reduction and evolution reactions. Furthermore, we show that external stimuli such as magnetic fields can effectively tune catalytic performance by modifying the topological features of the electronic structure. Together, these insights establish topological quantum materials as a compelling framework for designing high-performance, field-tunable catalysts, with far-reaching implications for asymmetric synthesis to probing the origins of life.

FM 22.3 Fri 10:15 BEY/0138

Ta2PdSe6: A guide towards high performance thermoelectric semimetals — •Akitoshi Nakano — Nagoya University, Nagoya, Japan

We have recently discovered that a transition-metal chalcogenide Ta2PdSe6 exhibits an extraordinary thermoelectric property despite its semimetal character. Ta2PdSe6 crystallizes in a layered structure, each layer of which consists of quasi-one-dimensional chains formed by prismatic TaSe6 and square-planner PdSe4. The thermoelectric property measured along this direction is highly exotic; an ultra-high conductivity (σ) above 10^6 Ω^-1cm^-1 is compatible with a substantial thermopower (S) of 40 μVK^-1 at 20K. As a result, the power factor (= S^2σ) reaches above 2000 μWcmK^-2, which is top level among bulk thermoelectric materials thus far.

Furthermore, we have found that the thermal conductivity of Ta2PdSe6 is relatively small (~ 100 Wm^-1K^-1) for such a good electrical conductor associated with a serious violation of the Wiedemann-Franz law. As a result, the thermoelectric figure of merit Z (= S^2$\sigma\kappa$^-1) of Ta2PdSe6 at 14 K reaches as high as 3*10^-3 (K^-1), which is comparable to Bi2Te3 at 300 K.

In the presentation, we will discuss the origin of the anomalous transport properties of Ta2PdSe6 from the viewpoint of the carrier dynamics.

FM 22.4 Fri 10:30 BEY/0138

Symmetry-Driven Transitions Between Flat Bands and Dirac Cones in Bilayer Kagome Lattices — •Taylan Gorkan — Bilkent University-UNAM

Flat bands (FBs) and Dirac cones represent two distinctive features of topological electronic systems, yet a unified mechanism enabling transitions between them has remained elusive to date. Here, we demonstrate a symmetry-governed and tunable transition from flat bands to Dirac cones in AB-stacked bilayer kagome lattices. This transition is mediated by the interplay between destructive quantum interference (DQI), C3 rotational symmetry, and spatial inversion symmetry. Strong interlayer coupling enhances DQI and stabilizes compact localized states that produce FBs, while weaker coupling allows C3 and inversion symmetries to dominate, giving rise to robust Dirac nodal points. Using a minimal tight-binding model, we map the continuous evolution of topological states-including type-II and type-III Dirac cones, spin-1 Dirac nodes, and partial flat bands-as a function of interlayer coupling. We further demonstrate this transition mechanism by examining an AB-stacked bilayer derived from the experimentally synthesized Nb3TeCl7 structure. In particular, first-principles calculations on bilayer Nb3TeCl7 reveal that vertical strain/pressure modulates interlayer interactions, enabling the entire FB-Dirac cones transition sequence. These findings establish a realistic novel pathway for gaining further insights into flat-band physics and engineering tunable topological phases in two-dimensional materials.

FM 22.5 Fri 10:45 BEY/0138

Emergent High Conductivity Transport Channel in $Bi_{12}Rh_3Ag_6I_9$ Single-Crystalline Multilayer Heterostructure — •Nicolas Perez[1], Eduardo Carrillo-Aravena[2], Christian Niclaas Saggau[1], Kornelius Nielsch[1], and Michael Ruck[2] — [1]Leibniz Institute for Solid State and Materials Research Dresden, Helmholtzstrasse 20, 01069 Dresden, Germany — [2]Faculty of Chemistry and Food Chemistry, Technische Universität Dresden, 01062 Dresden, Germany

$Bi_{14}Rh_3I_9$-type weak 3D topological insulators (TIs) can be seen as nano-periodic multilayer heterostructures of 2D TIs spaced by topologically trivial insulators. The newest member $Bi_{12}Rh_3Ag_6I_9$ exhibits 2D cationic conductivity in the silver iodide spacer, which allows to electrochemically adjust the Fermi level, and has the widest band gap so far in this family of compounds, 286 meV. It shows strongly increasing diamagnetism at low temperatures in a field perpendicular to the layers. Magnetoresistance measurements in macroscopic crystals reveal confinement and oscillatory behaviour, which coincides with a drastic drop in resistivity both parallel and across the layers. The observation of such an effect in a crystalline multilayer structure is compatible with the theoretically predicted formation of a collective [1+1]-dimensional sheath state involving all lateral crystal faces and probably arising from tunneling between the protected edge states of the numerous closely spaced 2D TI layers. A macroscopic system of some 10^5 coupled spin channels appears promising for applications in spintronics and quantum computation.

FM 22.6 Fri 11:00 BEY/0138

Simulating the Schrödinger equation in anti-Hermitian electrical circuits — •Ivan Scolan[1], Ronny Thomale[2], Jasper Van Wezel[3], Viktor Könye[3], Ali Moghaddam[4], Jeroen Van Den Brink[1], and Joseph Dufouleur[1] — [1]Leibniz Institute for Solid State and Materials Research Dresden — [2]Institute for Theoretical Physics and Astrophysics, University of Würzburg — [3]Institute for Theoretical Physics Amsterdam — [4]Faculty of Engineering and Natural Sciences, Tampere Finland

In recent years, a number of condensed matter lattice models have been realized using classical electric circuits, exploring topological phases hitherto inaccessible experimentally. In these previous works, the Hamiltonian of a system was implemented in a topo-electronic circuit, thus possessing the same spectrum as any equivalent condensed matter system, but the dynamics of the electronic circuit remained distinct from the quantum dynamics given by the Schrödinger equation. Here we propose a new way to realize electronic circuits that are equivalent to solid-state lattices based on anti-hermitian circuits the dynamic of which perfectly follows the Schrödinger dynamics.

Intrinsic symmetries of these circuits allow the experimental measurement of all eigenstates. Using this framework, we apply it to a 1D atomic chain with position-dependent hopping terms and experimentally retrieve the theoretical results presented in Mertens et al. (2022), Morice et al. (2021). Finally, we show how our method can be used to develop novel electronics which can be used for concrete applications and also for solving fundamental physics problems.

Photo-dielectric synaptic plasticity in Zn-substituted $BaAl_2O_4$ — •Hiroki Taniguchi — Department of Physics, Nagoya University, Nagoya 464-8602, Japan

Optical control of material properties is pivotal for advancing the evolution from conventional electronics to next-generation photoelectronics. Although a variety of photo-induced phenomena, including the photovoltaic effect and photoconduction, have been well established as key mechanisms for photoelectronic devices, the optical manipulation of dielectric responses has remained comparatively unexplored.

Here, I demonstrate a photo-dielectric effect in partially Zn-substituted $BaAl_2O_4$, in which the dielectric permittivity increases under below-bandgap photo-irradiation without inducing photoconduction. First-principles calculations indicate that Zn substitution creates a unique defect complex. Upon photo-irradiation, photo-generated electron*hole pairs form a local dipole around this defect complex, producing an additional polarization contribution and consequently enhancing the dielectric permittivity. Furthermore, transient permittivity measurements under sequential pulsed optical excitation reveal synaptic-plasticity-like responses in Zn:$BaAl_2O_4$, highlighting its potential for neuromorphic device applications.

Triclinic distortion in titanite-type oxides CaSnGeO5 and SrSnGeO5 — •Taro Kuwano[1], Hiroko Yokota[1], Manabu Hagiwara[2], Toshiya Uohashi[3], Akitoshi Nakano[3], and Hiroki Taniguchi[3] — [1]4259 Nagatsuta-cho, Midori-ku, Yokohama, Kanagawa, 226-8501 Japan — [2]3-14-1 Hiyoshi, Kohoku-ku, Yokohama, Kanagawa, 223-8522 Japan — [3]Furo-cho, Chikusa-ku, Nagoya, Aichi, 464-8602 Japan

Titanite-family oxides have been emerging as a novel vein of antiferroelectric materials owing to their unique pseudo-one-dimensional structure hosting "antipolar arrangement of polar chains." In this study, we focus on another characteristic feature of the titanite-type structure: ferroelastic phase transition associated with triclinic distortion. We will propose one couple of representatives, SrSnGeO5 and CaSnGeO5, which exhibit the phase transition at about 150 and 600 K, repectively. In comparison with the cases of SrZrGeO5 and CaZrGeO5, the origin of the triclinc distortion will be discussed.

FM 22.9 Fri 12:00 BEY/0138

Interplay between Lattice Dynamics and Free Electrons in Polar Metals: A Chemical-Bonding Perspective — •Hiroto Kikuchi[1], Suguru Yoshida[1], Hiroshi Takatsu[1], Kantaro Murayama[1], Peter Lemmens[2], and Hiroshi Kageyama[1] — [1]Department of Energy and Hydrocarbon Chemistry, Graduate School of Engineering, Kyoto University, Nishikyo-ku, Kyoto 615-8510, Japan — [2]Institute for Condensed Matter Physics, Technische Universitat Braunschweig; Braunschweig 38106, Germany

Polar-nonpolar (P-NP) transitions in metals such as $LiOsO_3$ show that polar order can coexist with metallicity, defining "polar metals" as a new class of quantum materials. However, the microscopic mechanism remains under debate, with competing scenarios invoking electron-phonon coupling and coordination bonding.

We recently found that metallic $LiReO_3$, isostructural with $LiOsO_3$ and adopting the $LiNbO_3$-type structure, undergoes a P-NP structural transition at T_s = 170 K. Unlike the second-order transition in $LiOsO_3$, $LiReO_3$ shows thermal hysteresis and strong lattice softening, indicating enhanced fluctuations between polar and nonpolar phases.

We investigated Raman scattering across T_s, combined with phonon calculations and crystal orbital Hamilton population (COHP) analysis, and reveals strongly redshifted LiO_6-related optical phonons in $LiReO_3$ compared with $LiOsO_3$. These results, supported by computed force constants and bond strengths, provide a unified picture of phonon softening and polar stability in metallic $LiReO_3$.

NaSICON with Mg and Ca as charge carriers — •Katharina Helmbrecht and Axel Gross — Institute of Theoretical Chemistry, Ulm University, 89069 Ulm, Germany

While the Mo_6S_8 chevrel phase is frequently used as cathode material in Mg–ion batteries, theoretical studies on this material are comparatively scarce. Mo_6S_8 as a cathode material for mono– and multivalent–ion batteries is an interesting candidate. Furthermore, magnesium and calcium both show much promise a charge carriers for a suitable battery system of the future.

In this work we study the behavior of mono– and multi–valent charge carriers (Li, Na, K, Mg, Ca, Zn, Al) at the low vacancy limit of intercalation and its influence on stability and kinetics of Mo_6S_8 intercalation compounds to reach fundamental understanding of the material and its properties.

Upon varying the charge carriers in the Chevrel phase at the upper vacancy limit in a previous study [1], their diffusion barriers were observed to scale linearly with the ion size, almost independent of the charge of the considered ions. This indicates a rather unique and geometry dominated diffusion mechanism in the chevrel phase and raises the question whether this trend persists at the lower vacancy limit.

High pressure crystallography: from mineral physics to material sciences — •Leonid Dubrovinsky — BGI, Bayreuth University, Bayreuth, Germany

Modern science and technology rely on the fundamental knowledge of matter that is provided by crystallographic studies. About a decade ago, our group pioneered an approach to the SCXRD data collection and analysis for the products of chemical reactions in laser heated DACs. Since then we have designed and built new instrumentation to enable sophisticated in situ experiments in house and on synchrotron radiation facilities. Our efforts have pushed the range of static pressures achievable in a DAC up to 1 TPa and enabled single-crystal X-ray diffraction experiments at such extreme conditions. Structural studies at simultaneous high pressures of over ~200 GPa and temperatures of several thousand degrees have also become possible. This has led to remarkable findings in solid state physics, mineral physics, and chemistry at extreme conditions.We illustrate application of new methodology for simultaneous high-pressure and high-temperature single crystal diffraction studies using examples of investigations of chemical and phase relations in the halides, nitrides, and carbonates.

FM 23: Focus Session: (Anti)ferroic states – Magnetic and magnetoelectric III (joint session FM/MA)

chair: Morgan Trassin (ETH Zurich, CH)

This focus session explores recent advances in understanding and control of (anti)ferroic states. Emphasis will be placed on theoretical modelling, advanced characterization techniques, and the engineering of emergent properties for use in nano-electronic devices. The session aims to bridge fundamental research with emerging device-relevant functionalities, bringing together experimental, and theoretical perspectives on ferroic materials.

Time: Friday 9:30–11:30 Location: BEY/0E40

Invited Talk FM 23.1 Fri 9:30 BEY/0E40

Mapping topological textures in compensated magnets with X-rays — •Claire Donnelly — Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

Extending spin systems to three dimensions promise significant opportunities for applications, for example providing higher density devices and new functionalities associated with complex topology and greater degrees of freedom. Until now, however, insight into three dimensional spin systems has mainly been limited to ferromagnetic and ferrimagnetic systems through X-ray magnetic tomography [1], where a variety of topological textures [1,2], as well as 3D dynamics [3,4], have been observed. In this talk I will describe our recent work mapping topological textures in compensated systems. I will first describe the development of X-ray linear orientation tomography [5], which we have harnessed to map three-dimensional orientation fields - both crystallographic [5], and antiferromagnetic - at the nanoscale. Second, I will present our recent mapping of topological textures in altermagnets [6], harnessing both X-ray circular and linear magnetic dichroism. These insights into the formation of topological textures in compensated magnets not only paves the way for enhanced understanding of these systems, but also towards the next generation of technological devices.

FM 23.2 Fri 10:00 BEY/0E40

Exploring Magnetoelectric Effects in 1T-$FeCl_2$/bilayer-GaSe Multiferroic Heterostructures — •Fahmida Fakhera[1], Oliver J. Conquest[1], Carla Verdi[1,2], and Catherine Stampfl[1] — [1]School of Physics, The University of Sydney, NSW 2006, Australia — [2]School of Mathematics and Physics, The University of Queensland, QLD 4072, Australia.

Multiferroic materials exhibit multiple ferroic orders simultaneously, including ferromagnetism and ferroelectricity [1]. A recent study [2] on sliding ferroelectricity in bilayer GaSe adds a novel dimension, making it useful as a ferroelectric (FE) sublayer in multiferroic heterostructures. We employ first-principles density functional theory (DFT) to investigate the interlayer and intralayer sliding mechanisms of FE GaSe. Moreover, this study investigates the structural and electronic properties, energy band alignments, magnetic anisotropy, binding energies, electric dipole moments, and interfacial charge transfer of different stackings of 1T-$FeCl_2$/bilayer GaSe. For all stackings, the magnetic anisotropy energies indicate an in-plane easy axis of magnetization in both upward and downward polarization directions. The contact interfaces form Ohmic contacts, enabling sufficient charge transfer between the layers. As the first study on sliding-induced FE and ferromagnetic interfaces, this work offers new insights into the design and understanding of multiferroic materials for the future.

FM 23.3 Fri 10:15 BEY/0E40

Nonlinear phononic slidetronics — •Pooja Rani and Dominik Juraschek — Eindhoven University of Technology, Eindhoven, Netherlands

We investigate ultrafast switching of ferroelectricity in bilayer hexagonal boron nitride using nonlinearly driven phonons. Conventional coherent phonon excitation mechanisms such as infrared absorption, Raman-based techniques, and terahertz sum-frequency excitation produce too small a shear-mode amplitude to overcome the barrier between stacking orders. Using first-principles calculations and phenomenological modeling, we demonstrate instead that strong excitation of high-frequency intralayer phonons dynamically tilts the interlayer potential, enabling efficient and deterministic switching at experimentally accessible pulse strengths. Our results establish nonlinear phononic slidetronics as a powerful method for ultrafast, energy-efficient control of stacking order and related electronic phases in van der Waals materials, with potential for future all-optical ferroelectric memory devices.

Coffee break

FM 23.4 Fri 10:45 BEY/0E40

Resolving the chemical depth profile of ultrathin EuO films by grazing incidence HAXPES measurements — •Katharina Wehrstein[1], Umut Parlak[1], Pia Düring[1], Oliver Rehm[1], Andrei Gloskovskii[2], Christoph Schlueter[2], and Martina Müller[1] — [1]FB Physik, Uni Konstanz — [2]DESY

Magnetic proximity effects enable control of magnetic order in ferromagnetic insulators without altering their intrinsic properties. Europium oxide (EuO) thin films coupled with heavy metals (HM) are promising systems for spintronic applications, in which spin-polarized states are induced, altered or converted via interface coupling. These systems require a sharp interface between the metal and the EuO layer, as well as stoichiometric EuO. As ferromagnetic Eu(II)O is metastable and tends to oxidize to paramagnetic $Eu(III)_2O_3$, investigating the depth-resolved chemical and thus magnetic nature of an EuO layer is mandatory to observe and eventually tune magnetic proximity effects.

Ultrathin EuO films (2-15 nm) were prepared by molecular beam epitaxy on $Pt/SrTiO_3$ and $W/SrTiO_3$ substrates. Grazing incidence hard X-ray photoelectron spectroscopy (GIXPES) enables high X-ray intensity at the sample surface due to reflection of the X-ray beam on the heavy metal layer, leading to the formation of X-ray standing waves. By changing the incidence angle of the X-ray beam, spectra with modulated depth-sensitivity were recorded, revealing variations in the Eu^{3+} content at different depths of the ultrathin EuO layer. This yields a chemical depth profile and thus a magnetic profile that provides insight into the magnetic behavior of the EuO/HM system.

FM 23.5 Fri 11:00 BEY/0E40

Optical manipulation of multiferroic phases in $BiFeO_3$ thin films — •Bixin Yan[1], Lauren J. Riddiford[1,2], Ales Hrabec[1,2], Annika Mechnich[3], Christian L. Degen[3], Manfred Fiebig[1], and Morgan Trassin[1] — [1]Department of Materials, ETH Zurich, Switzerland — [2]PSI Center for Neutron and Muon Sciences, PSI, Switzerland — [3]Department of Physics, ETH Zurich, Switzerland

Employing light as a means of actively tuning material properties unlocks the potential for non-invasive, remote, and macroscopic control over technology-relevant functionalities. In our work, we demonstrate optical control over multiferroic phases in prototypical magnetoelectric $BiFeO_3$ (BFO) thin films, utilizing above-bandgap UV light illumination. Taking advantage of the enhanced response at the strain-driven morphotropic phase boundary, we show that by modifying the electrostatic boundary conditions with photoinduced charge carriers, the rhombohedral-like (R-like) phase of BFO can be selectively suppressed within the tetragonal-like (T-like) phase BFO matrix. Furthermore, the electronic origin of such an optical response permits a pronounced polarization-dependent R-to-T-phase conversion. Finally, using scanning nitrogen-vacancy magnetometry, we correlate optically induced ferroelectric phase conversion with a change from uncompensated magnetic ordering to G-type antiferromagnetic ordering. Our work thus presents a novel approach to writing multiferroic states, which is key to magnetoelectric oxide electronics.

FM 23.6 Fri 11:15 BEY/0E40

Time resolved X-ray diffraction study of polarization reversal in uniaxial ferroelectric $BaMgF_4$ single crystals — •Nathan Leubner[1,4], Sara Polo-Filisan[2], Gaetano Bonetti[2], Hiroki Tanaka[2], Matthias Zschornak[3], Dirk C. Meyer[1], Carsten Richter[2], and Semën Gorfman[4] — [1]Institut für Experimentelle Physik, TU Bergakademie Freiberg — [2]Leibniz-Institut für Kristallzüchtung, Berlin — [3]Fakultät Maschinenbau, HTW Dresden — [4]Department of Materials Science and Engineering, Tel Aviv University, Israel

$BaMgF_4$ (BMF) is a uniaxial ferroelectric material crystallizing in the orthorhombic space group $Cmc2_1$ and being a compelling candidate for frequency conversion in far ultraviolet regime. In this work, we present time-resolved X-ray diffraction (XRD) studies of single-crystalline BMF under applied electric fields, enabling direct observation of atomic-scale structural changes during domain switching. Complementary dielectric measurements provide insights into the kinetics of domain wall motion. The XRD data reveal the electric-field dependence of strain, allowing for the determination of the components of the piezoelectric tensor of BMF. Furthermore, by exploiting the resonant Friedel pair contrast between oppositely polarized domains, we achieve a direct determination of the crystal structure of each domain. This approach eliminates the need for conventional correction factors (e.g., absorption, extinction), offering a robust and accurate alternative to traditional structure refinement methods. Our findings advance the fundamental understanding of ferroelectric switching in BMF.

– Invited, Topical, Contributed Talks, and Posters –

HL 1: Optical Properties I

Time: Monday 9:30–12:45 Location: POT/0006

HL 1.1 Mon 9:30 POT/0006

Critical-Point Analysis of Ta_3N_5 Light Absorbers from Room-Temperature Photo-Modulated Spectroscopy — •Matthias Quintern[1,2], Johannes Dittloff[1,2], Lukas Wolz[1], Gabriel Grötzner[1,2], Johanna Eichhorn[1], and Ian D. Sharp[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Department of Physics, 85748 Garching, Germany — [2]Technical University of Munich, Walter Schottky Institute, 85748 Garching, Germany

Tantalum nitride (Ta_3N_5) thin films are promising photoanode materials for solar water splitting. However, the fundamental nature of the Ta_3N_5 bandgap remains under debate. To overcome the limitations of conventional Tauc-plot analysis, we built a new combined photoreflectance (PR) and phototransmittance (PT) setup. Our measurements indicate a direct fundamental bandgap of 2.1 eV, but also reveal higher-energy critical points. Furthermore, we find that the PR and PT spectra closely match temperature-corrected transient absorption spectra. The overall differences in the transmission spectra are minor, suggesting that the samples share a similar bulk electronic structure. At the same time, the more surface-sensitive PR signals exhibit greater variations and even additional sub-gap features in some samples. By performing measurements using different pump wavelengths and power densities, as well as employing a phase analysis, we assign individual features of PR spectra to a surface layer. This has implications for out-of-plane charge transport properties and interfacial energies, both of which are crucial parameters for photoelectrochemical performance.

HL 1.2 Mon 9:45 POT/0006

OptiMate3B: Three-body-information-based prediction of optical spectra for semiconductors and insulators — •Malte Grunert, Max Grossmann, and Erich Runge — Institute of Physics and Institute of Micro- and Nanotechnologies, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Optical spectra of semiconductors and insulators are essential both for many technologically important applications as well as for the understanding of materials. However, their computation via adequate ab initio techniques remains prohibitively expensive for either large-scale studies or many realistic systems. Recently however, machine learning techniques have emerged as promising alternative. We present OptiMate-3B, a line graph attention network capable of predicting the optical spectra of semiconductors and insulators under both the independent particle approximation and the random phase approximation - i.e. incorporating local-field effects - within milliseconds. OptiMate-3B incorporates three-body information to capture angular information in crystalline materials, further enhancing its predictive accuracy. Having been trained on tens of thousands of high-fidelity first-principles spectra, the model generalizes across a broad chemical and structural space. Its open and user-friendly interface facilitates direct integration into high-throughput materials workflows, providing an efficient surrogate for ab initio optical spectroscopy.

HL 1.3 Mon 10:00 POT/0006

Intensity-dependent excitonic second- and third-harmonic generation enhanced by static electric fields — Ruixin Zuo[1], •Matthias Reichelt[1], Cong Ngo[1], Xiaohong Song[2], Weifeng Yang[2,3], and Torsten Meier[1] — [1]Department of Physics and Center for Optoelectronics and Photonics Paderborn (CeOPP), Paderborn University, Warburger Straße 100, D-33098 Paderborn, Germany — [2]School of Physics and Optoelectronic Engineering, Hainan University, Haikou 570288, China — [3]Center for Theoretical Physics, Hainan University, Haikou 570288, China

The many-body Coulomb interaction plays a decisive role in the ultrafast photoinduced carrier dynamics governing semiconductor high-harmonic generation, see, e.g., [1,2]. Moreover, static electric fields were shown to surprisingly enhance excitonic second- and third-harmonic generation [3]. Here, we study this enhancement for material models corresponding to transition-metal dichalcogenides and study the dependencies on several parameters.

HL 1.4 Mon 10:15 POT/0006

Thin Films of Size-Selected Cu_2ZnSnS_4 and Cu_2NiSnS_4 Nanocrystals: Structural and Optical Properties — •Oleksandra Ivakhno-Tsehelnyk[1], Serhiy Kondratenko[2], Volodymyr Dzhagan[3], and Dietrich R.T. Zahn[1] — [1]Semiconductor Physics & Research Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology. — [2]Taras Shevchenko National University of Kyiv, 01601 Kyiv, Ukraine. — [3]Lashkaryov Institute of Semiconductor Physics, NAS of Ukraine, 03038 Kyiv, Ukraine.

An investigation was conducted into thin films of Cu_2NiSnS_4 (CNTS) and Cu_2ZnSnS_4 (CZTS) nanocrystals (NCs) in the context of their promising use for photovoltaics (PV). Colloidal NC ensembles were obtained by "green" colloidal synthesis and directly subjected to size-selective centrifugation, yielding fractions of different sizes. This approach provides a relatively non-toxic and scalable method of producing light-absorbing NC materials. The thin films were prepared by spin-coating the NC fractions onto various substrates. A range of analytical techniques were employed to investigate their properties, encompassing Raman spectroscopy, atomic force microscopy (AFM), X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS), and spectroscopic ellipsometry. These techniques enabled the investigation of the relationship between the crystal structure, composition, morphology, and optical properties with the size of CZTS and CNTS nanocrystals.

HL 1.5 Mon 10:30 POT/0006

Simulations of the nonlinear optical dynamics of quantum dot ensembles in a microcavity — •Mohit Kumar[1,2], Hendrik Rose[2], and Torsten Meier[1,2] — [1]Department of Physics and Center for Optoelectronics and Photonics Paderborn (CeOPP), Paderborn University, Warburger Strasse 100, D-33098 Paderborn, Germany — [2]Institute for Photonic Quantum Systems (PhoQS), Paderborn University, Warburger Strasse 100, D-33098 Paderborn, Germany

Recently, it has been demonstrated that photon echoes emitted from ensembles of inhomogeneously-broadened quantum dots can be controlled in several ways by suitably designed light pulses [1,2]. The strong coupling of a single two-level system to the mode of a microcavity results in a complex nonlinear optical dynamics [3]. Here, we present numerical simulations of the coherent dynamics of quantum dots ensembles, described as two-level systems, inside a single-mode microcavity. The coupling to the field mode results in a complex dynamics which is studied numerically as function of the relevant system parameters and for different excitation conditions.

HL 1.6 Mon 10:45 POT/0006

Optical Limiting Induced by Excited-State Absorption in Thiophene Oligomers — •Mustapha Driouech, Michele Guerrini, and Caterina Cocchi — Friedrich-Schiller Universität Jena, Institute for Condensed Matter Theory and Optics, 07743 Jena, Germany

Optical limiting (OL) is a nonlinear effect that reduces light transmission at high intensities, providing protection for sensitive optical devices and human eyes. Non-perturbative ab initio methods have proven to be powerful predictive tools for OL [1]. In this work, we investigate the optical absorption spectra of a set of thiophene oligomers under the influence of a broadband, instantaneous electric field [2]. At sufficiently high intensities, absorption peaks that are absent in the linear response emerge below the absorption onset in the linear regime. To elucidate the optical nonlinearities involved, we perform pump-probe simulations and analyze the population dynamics, revealing that these emergent features originate from excited-state absorption in the near-infrared to visible region. Further analysis, taking into account both molecular length and applied laser intensity, demonstrates how these factors influence the nonlinear response. Our results show that this fully ab initio approach can accurately capture and unravel the fundamental processes driving optical nonlinearities in thiophene oligomers.

HL 1.7 Mon 11:15 POT/0006

Polarization-resolved Raman measurements on optically anisotropic crystals — •Susanne Moritz, Lukas Trefflich, Ron Hildebrandt, Marius Grundmann, and Chris Sturm — Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik, Germany

Raman spectroscopy provides a powerful, non-destructive way to probe lattice vibrations, crystal symmetry, and electron-phonon interactions. For years, optically anisotropic materials have been gaining importance in solid-state physics research. These materials are investigated by measuring the Raman intensity in two configurations, namely cross-polarized and parallel polarization. However, due to their low symmetry, this is not sufficient in order to extract the properties of the Raman tensor and extensive polarization-resolved Raman measurements are required for a precise determination, particularly of the Raman tensor [1,2,3]. Here, we present an efficient measurement scheme in order to determine the Raman tensor of optically anisotropic materials with high precision. Special care must be taken regarding the influence of the used polarizing optics, such as half-wave plates, as well as the impact of the non-idealities of all optical elements included in the setup, such as mirrors or beam splitters. For this purpose, we also show a procedure for calibrating these elements.

HL 1.8 Mon 11:30 POT/0006

Quadrupole Transitions in Molecules from Real-Time Time-Dependent Density Function Theory — •Anvar Khujakulov[1], Michele Michele Guerrini[1], Carlo Andrea Rozzi[1], and Caterina Cocchi[2] — [1]Institute for Condensed Matter Theory and Optics, 07743 Jena, Germany — [2]Istituto Nanoscienze - 41125 Modena, Italy

The breakdown of the dipole approximation in tightly focused or short-wavelength laser fields is driven by spatial electric field variations, leading to significant beyond-dipole effects including quadrupole transitions and a nonlinear optical response [1]. We extend the Yabana-Bertsch implementation of real-time time-dependent density functional theory to include quadrupole transitions in the absorption cross-sections and apply the developed approach to atoms and small molecules. Our results reveal absorption peaks appearing above the linear absorption onset, a clear signature of quadrupole transitions. Critically, for molecules with appropriate symmetry, the quadrupole contribution to the absorption cross-section is maximized when a specific molecular axis aligns with the electric field gradient, analogous to the dipole case. By systematically rotating the molecular axis relative to the laser polarization vector, we calculate the orientation-dependent absorption cross-section and differentiate the contributions from dipole and quadrupole transitions. We quantitatively demonstrate that quadrupole transition is not a minor effect but a significant contributor to absorption spectra beyond the dipole approximation.

HL 1.9 Mon 11:45 POT/0006

Phase-matched electron-photon interactions enabled by 3D printed helical waveguides — •Masoud Taleb[1], Mohsen Samadi[2], and Nahid Talebi[1] — [1]Institute of Experimental and Applied Physics, Kiel University, 24098 Kiel, Germany — [2]Department of Electrical and Information Engineering, Kiel University, 24143 Kiel, Germany

We demonstrate a new phase-matching mechanism between free electrons and guided optical modes using 3D-printed helical waveguides. The structure consists of a polymer micro-fiber coated with a thin gold layer, fabricated by two-photon polymerization. When an electron beam propagates parallel to the helix axis, the helical geometry extends the optical path and enables sequential, phase-synchronous coupling to a plasmonic hybrid mode. This interaction unifies elements of Smith-Purcell and Cherenkov emission and yields a strong, highly directional visible-light output. Cathodoluminescence measurements reveal a dominant emission near 2.1-2.2 eV, collimated along the electron trajectory and exhibiting circular polarization dictated by the helix handedness. The observed photon yield (~0.02 photons per electron for an 11-turn helix) exceeds that of planar electron-driven photon sources by more than two orders of magnitude. These results introduce helical micro-waveguides as an efficient platform for directional, polarization-controlled electron-photon interactions.

HL 1.10 Mon 12:00 POT/0006

Quantum-engineered CaAlSiN3 via terbium substitution: coupling spin, optical, and lattice responses in a rare-earth nitride host — •Sikander Azam and Jan Minar — University of West Bohemia New Technologies - Research Centre Univerzitní 8 301 00 Plzeň Czech Republic

Rare-earth nitrides attract interest because they link optical activity, magnetism, and mechanical stability. CaAlSiN3 is a robust wide-gap host, but the microscopic role of terbium substitution is not well established. We study pristine and Tb-doped CaAlSiN3 (8.5 and 17 percent) using spin-polarized density functional theory within GGA+U and spin-orbit coupling in WIEN2k. Tb narrows the bandgap and introduces 4f-derived mid-gap states that enhance visible-range absorption. The densities of states show hybridization between Tb 4f levels and the surrounding network. The optical response shows higher absorption, a larger refractive index, and shifts in dielectric features that follow these electronic changes. Simulated Tb L*-edge X-ray absorption spectra display white-line shifts and peak broadening with increasing Tb content, consistent with the modified unoccupied 4f states. Tb carries a strong local moment, raising the total moment to about 11.8 μB at higher doping. All compositions remain mechanically stable, and bulk and shear moduli increase moderately. The piezoelectric response also strengthens, with d33 and e33 roughly doubling compared to the undoped host. These results show that Tb substitution tunes the electronic, magnetic, optical, and mechanical behaviour of CaAlSiN*, supporting its potential in photonic and spin-related applications.

HL 1.11 Mon 12:15 POT/0006

Accurate computation of Berry connection purely limited by basis set completeness — Martin Thümmler[1], •Alexander Croy[1], Thomas Lettau[2], Ulf Peschel[2,3], and Stefanie Gräfe[1,3,4] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena — [2]Institute of Condensed Matter Theory and Optics, Friedrich Schiller University Jena — [3]Abbe School of Photonics, Friedrich Schiller University Jena — [4]Fraunhofer Institute for Applied Optics and Precision Engeneering Jena

Wannierization provides a reliable framework for interpolating operator matrix elements in the Brillouin zone. This Fourier-type interpolation of the matrix elements of **k**-local operators, e.g., the Hamiltonian, is well understood. However, the Berry connection is computed from the overlap matrices of the cell periodic parts of the Bloch functions with different **k** and hence non-local. So far, all proposed interpolation schemes do not account for the matrix structure of the overlap matrices, but treat the matrix elements as independent when computing the Berry connection. In this work, we propose a consistent interpolation scheme based on the matrix logarithm. Its accuracy is only limited by the basis set incompleteness of the considered bands in the ab-initio calculation. The quality of the new interpolation scheme is demonstrated by an improved agreement between the velocity and momentum operator over the full Brillouin zone. As an application, we demonstrate how this refinement impacts the predicted linear and non-linear optical properties of semiconductors.

HL 1.12 Mon 12:30 POT/0006

Focused Ion Beam (FIB) patterned Microcavities for Topological Lasers — •Lorenz Löffler[1,4], Dominik Horneber[1,4], Jakob Lindenthal[2,4], Johannes Düreth[1,4], Markas Sudzius[2,4], Monika Emmerling[1], Martin Kamp[3], Simon Betzold[1,4], Johannes Benduhn[2,4], Sven Höfling[1,4], Karl Leo[2,4], and Sebastian Klembt[1,4] — [1]University of Würzburg, Physikalisches Institut, Lehrstuhl für Technische Physik — [2]Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP), and Institute of Applied Physics, Technische Universität Dresden — [3]University of Würzburg, Physikalisches Institut and Wilhelm-Conrad-Röntgen-Research Center for Complex Material Systems — [4]Würzburg-Dresden Cluster of Excellence ct.qmat

Topological lasers can be realized by coupling individual photonic resonators in topologically non-trivial lattice geometries. Optical microcavities have been found to be a promising platform for studying topological laser interfaces with long-range coherence. The fabrication of such structures typically involves etching of the microcavity and through the emitter layer. In our work, we create the photonic potential by FIB milling of a glass substrate prior to depositing dielectric Bragg reflectors. This technique allows the potential to be engineered while keeping the emitter layer intact. Here, the emitter is either semiconductor quantum wells or the organic semiconductor Alq_3 doped with DCM dye. By exploring modified lattice geometries that enhance the interface-to-bulk ratio as well as temperature-dependent studies, we aim for the next step towards practical topological lasers.

HL 2: Focus Session: Biocompatible Organic Semiconductors for Artificial Intelligence

This Focus Session deals with electronic components that interface with biological systems and offer diverse possibilities in research and applications, e.g., in healthcare. Carbon-based organic semiconductors are particularly well-suited to this interface: They enable electronic devices with a broad spectrum of electronic and optoelectronic functions that are biocompatible and often even resorbable by the body. Furthermore, they are particularly well-suited for neuromorphic functions that enable local data analysis computing towards artificial and neurohybrid intelligence. Turning this vision into practice requires extensive interdisciplinary research on semiconductor materials, components, and electronic systems. This Focus Session aims to provide an overview of the current state of the art including new organic materials, devices and core applications in bioelectronic interfaces.

Organized by Karl Leo

Time: Monday 9:30–12:45 Location: POT/0051

Invited Talk HL 2.1 Mon 9:30 POT/0051

Intrinsically stretchable polymers and devices for biosensing applications — •Ulrike Kraft — Organic Bioelectronics Research Group, MPI for Polymer Research, Mainz, Germany

Organic electrochemical transistors (OECTs) currently attract vast interest for biosensing applications due to their, intrinsic signal amplification and low operating voltages, enabling sensing in close contact to the human body and in aqueous environments with liquid analytes. Furthermore, the low elastic modulus of polymers can be tailored to match that of soft biological tissues, drawing increasing interest towards soft and stretchable health-monitoring devices.

The first part of the talk will focus on our work on biosensors based on planar OECTs that are functionalized with antibodies for e.g. the detection of the SARS-CoV-2 spike protein or with aptamers for the detection of e.g. cytokines, which are proteins crucial for immune regulation and inflammatory responses.

In the second part, I will summarize our efforts on stretchable electronics including a fast and reliable transfer-printing method for the deposition of conductive polymer films (e.g. PEDOT:PSS) onto stretchable, biodegradable substrates Taking advantage of this method and infusing the substrates with small-molecule plasticizers that also diffuse into the conductive films, improves the electrical performance as well as the mechanical properties. Lastly, this platform is employed for studying the effect of strain on the figures-of-merit of intrinsically stretchable OECTs.

Invited Talk HL 2.2 Mon 10:00 POT/0051

Complexity in Organic Mixed Ionic Electronic Conductors and its Application in Neuromorphic Computing — •Hans Kleemann — Technische Universität Dresden, Dresden, Germany

Complexity is decisive property enabling systems to work at the edge of chaos, which is necessary for resource-efficient computing and the design of intelligent machines. The complex behavior of a system originates from the nonlinear properties of all its components, resulting in a plethora of different signatures such as multi-state stability, stochastic oscillations, etc. These nonlinear properties and their couplings need to be understood and modeled to develop intelligent & energy-efficient computers.

Organic mixed ionic-electronic conductors (OMIECs) based on conjugated polymers open up a fascinating field of research where the ionic-electronic coupling, in combination with correlation effects at high charge carrier densities enables the implementation of various paradigms of neuromorphic computing. In this contribution, I will discuss the various signatures of nonlinearity and complexity that have been observed in OMIECs in recent years and review the current understanding of these effects. Furthermore, I will discuss how phenomena such as hysteresis and bistability can be employed to design fundamental elements of asynchronous computing, such as spiking neurons or C-elements, providing the foundation for the efficient implementation of approaches of stochastic computing in hardware. Finally, I will present a technology platform that allows us to integrate such devices in all-printed, complementary circuits operating above 1kHz.

Invited Talk HL 2.3 Mon 10:30 POT/0051

Organic Neuromorphic Interfaces for Biohybrid Systems: Material and Structural Biomimicry of Synaptic Plasticity — •Francesca Santoro — Forschngszentrum Jülich

Organic neuromorphic interfaces offer a promising route toward biohybrid systems that emulate neural function. We present PEDOT:PSS-based organic electrochemical transistors that exploit mixed ionic*electronic conduction and biocompatibility to reproduce key mechanisms of synaptic plasticity. Through the integration of bio-gels and azopolymer-functionalized conjugated polymers, neural activity is modulated by chemical and optical stimuli, enabling short- and long-term plasticity and interactions with neurotransmitters such as dopamine and glutamate. Beyond planar devices, 2.5D and 3D microfabricated organic semiconductor architectures fabricated by two-photon lithography or electrodeposition mimic neuronal morphology and promote cell adhesion and connectivity. The mechanical compliance of these materials supports stable interfacing with soft tissues, underscoring the role of material and structural biomimicry in next-generation organic biohybrid neuromorphic platforms.

15 min. break

Invited Talk HL 2.4 Mon 11:15 POT/0051

Fully-organic flexible detectors for real-time dose monitoring during radio/proton therapy — •Beatrice Fraboni — Department of Physics and Astronomy , University of Bologna, Italy

The development of detectors for high energy ionizing radiation is a long-lasting research topic not only for fundamental applications but also for medical applications in radio and hadron therapy. Innovative sensors are needed, able to provide, in-situ and in real-time, an accurate recording and mapping of the dose delivered during a treatment plan. Organic small molecules and polymers are promising active layers for advanced dosimetry purposes, as their mechanical features allow the development of devices able to adapt to complex contoured surfaces with outstanding portability (low power operation) and lightweight. They also provide the unique possibility to develop human-tissue-equivalent dosimeters, thanks to their density and composition. The physical process of radiation detection for organic thin- film based detectors will be discussed in two different configurations: 1) the direct one, based on a simple planar device with an organic thin film as active conversion layer, and 2) the indirect one, based on a polysiloxane-based scintillating layer effectively coupled to an organic phototransistor (OPT). A new kinetic model has been developed to describe the organic dosimeter response mechanism under photon/proton irradiation and to provide further insight into the physical processes controlling its response.

I.Fratelli et al Science Advances 11, 7633 (2025) S. Calvi et al., NPJ Flexible Electronics 7,5 (2023)

Invited Talk HL 2.5 Mon 11:45 POT/0051

Organic LEDs and photodetectors for light-based diagnostics and therapy — •Caroline Murawski[1,2], Rabiul Islam[1,2], Siddhartha Saggar[1,2], and Jens P. Weber[1,2] — [1]Institute of Solid-State Electronics, TUD Dresden University of Technology, 01062 Dresden, Germany — [2]Kurt Schwabe Institute for Sensor Technologies, 04736 Waldheim, Germany

Light-based biomedical sensing and therapy enables highly precise, timely and contactless interventions and range from neuronal stimulation via optogenetics over sensing cellular activity by functional fluorescence to monitoring health signals using wearable devices. Organic semiconductors are ideally suited building blocks due to their tunability of material properties, mechanical flexibility and ability for patterning to microscopic shapes. Here, I will present the development of organic LEDs (OLEDs) and photodiodes (OPDs) as light sources and sensors for biomedical applications. The OLEDs are tailored towards high power output and application-specific angular and spectral emission properties. Devices are fabricated on flexible substrates, patterned to sub-mm scale, and applied in optogenetics and fluorescence imaging. Furthermore, I will show flexible OPDs used for photoplethysmography at ambient light conditions and under water.

HL 2.6 Mon 12:15 POT/0051

Reservoir computing with mixed ionic-electronic conductors — •Richard Kantelberg, Hans Kleemann, and Karl Leo — Institut für Angewandte Physik, TU Dresden

Reservoir computing (RC) is a promising paradigm for machine learning that utilizes dynamic systems, termed as reservoirs, to process and analyze complex temporal data. Organic mixed ionic electronic conductors (OMIECs) have emerged as a novel class of materials with intriguing properties, such as their ability to exhibit both electronic and ionic conductivity, as well as their biocompatibility, flexibility, and low power consumption[1]. These features make OMIECs particularly suitable for the development of unconventional computing architectures in the field of bioelectronics[2]. We present recent findings interlinking electronic conductivity, system nonlinearity and reservoir size with the

neuromorphic functionality and RC performance of self-organized and structured OMIEC reservoirs. This study includes novel insights into the differences and similarities of p-type, n-type and ambipolar semiconductors in terms of operation speed and energy consumption. The recent progress in reservoir computing using organic mixed ionic electronic provides valuable knowledge for the targeted development OMIEC reservoirs.

HL 2.7 Mon 12:30 POT/0051

Redundant information in physical reservoir computing — •Andreas Hofacker, Richard Kantelberg, Hans Kleemann, and Karl Leo — Dresden Integrated Center for Applied Physics and Photonic Materials (DC-IAPP), TU Dresden, Dresden, Germany

Maximizing the processing power of a physical reservoir given its physical constraints is crucial for practical applications, but remains an open problem. As a basis for such an optimization, a quantity measuring reservoir capability is needed. To address this need, we propose the use of independent component analysis for assessing information content in reservoir outputs. We present evaluations of organic mixed ionic-electronic conductor based physical and simulated reservoirs and show that task-specific performance is linked to information redundancy in the output channels. By leveraging this insight, sparser reservoir readout can be realised without loss of performance.

HL 3: 2D Materials I – Excitonic properties

HL 3.1 Mon 9:30 POT/0081

Exciton-Electron Complexes in Multilayer Transition-Metal Dichalcogenides — •Florian Hirsch[1], Alexandra Hübler[1], Jonas von Milczewski[2], and Richard Schmidt[1] — [1]Institute for Theoretical Physics, Heidelberg University, Philosophenweg 16, 69120 Heidelberg, Germany — [2]Department of Physics, Harvard University, Cambridge, Massachusetts 02138, USA

Understanding few-body correlations in van der Waals heterostructures is essential for uncovering emergent electronic phases in layered quantum materials. We report recent progress in identifying exciton-electron-electron bound states in multilayer transition-metal dichalcogenides (TMDs). Starting from the two-body problem, we employ complementary theoretical approaches to characterize bound states and systematically extend this framework to the four-body regime. Within an effective-mass model, we solve the resulting few-body Hamiltonians using exact diagonalization, enabling efficient exploration of material and geometric parameters. This allows us to map out regimes in which such exciton-electron complexes become bound. Our results provide a versatile framework for investigating exciton-mediated correlations in complex multilayer TMD structures and related systems, including platforms where exciton-induced electron pairing or superconductivity may emerge.

Intra- and Interlayer Excitons in TMDC bilayers under external influence — •Jan-Hauke Graalmann and Michael Rohlfing — University of Münster, Institute of Solid State Theory, Wilhelm-Klemm-Straße 10, 48149 Münster, Germany

External influences lead to several changes in the optical spectrum of TMDC bilayers obtained by solving the Bethe-Salpeter. We discuss both the effect of applied pressure and that of an electric field [1,2].

To get the deformation induced by applied pressure, we use Hooke's law. In this case, our investigations show an effective shift of the intralayer A exciton whose direction depends on the stress conditions and we observe a similar behavior for the interlayer exciton, while the shift rate is smaller for the latter. Our results for the 2H-MoS_2 bilayer compare very well with available room-temperature measurements for the interlayer exciton.

An electric field applied perpendicular to the 2H-$MoSe_2$ bilayer does not lead to a deformation, but instead to a Stark shift of the excitons. To explain that, we focus on the lifting of the degeneracy in the band structure by breaking the symmetry of the potential.

HL 3.3 Mon 10:00 POT/0081

Optical probing of the gate-tunable electronic band structure of bilayer graphene using a WSe_2 sensor layer — •Jonas Blum[1], David Tebbe[1], Takashi Taniguchi[2], Kenji Watanabe[2], Lutz Waldecker[1], Christoph Stampfer[1,3], and Bernd Beschoten[1] — [1]2nd Institute of Physics and JARA-FIT, RWTH Aachen University, Aachen, Germany — [2]National Institute for Materials Science, Namiki, Tsukuba, Japan — [3]PGI-9, Forschungszentrum Jülich, Jülich, Germany

Rydberg excitons in transition-metal dichalcogenide monolayers are highly sensitive to their dielectric environment. Previous work has shown that reflection-contrast spectroscopy provides a non-invasive optical probe of their binding energies, enabling the detection of subtle variations in the charge-carrier density n in adjacent layers of van der Waals (vdW) heterostructures. Here, we apply this technique to a fully hBN-encapsulated WSe_2/bilayer-graphene (BLG) device with graphite top and bottom gates and compare the optical response with transport measurements. By applying a displacement field D, we open a band gap in BLG. As the Fermi level is tuned from the valence band across the band gap into the conduction band, we capture changes in n through shifts in the 2s exciton binding energy. These measurements further allow us to resolve the layer population of BLG upon sign reversal of D. We also demonstrate optical quantum Hall measurements, enabling extraction of gate lever arms optically. Unlike transport measurements, this optical technique offers highly local, spatially-resolved access to the electronic band structure of BLG.

HL 3.4 Mon 10:15 POT/0081

Anisotropic Excitonic Response in $MoSe_2$-WSe_2 Lateral Heterostructures — •Miguel Morales Cocera[1,2], Franz Fischer[1,2], Carl Emil Mørch Nielsen[1], and Gabriel Bester[1] — [1]University of Hamburg, Institute of Physical Chemistry, 22761 Hamburg, Germany — [2]Max Planck Institute for the Structure and Dynamics of Matter, 22761 Hamburg, Germany

We investigate lateral heterostructures of transition-metal dichalcogenide monolayers, in particular $MoSe_2$-WSe_2. In these systems, the one-dimensional (1D) interface together with the type-II band alignment enables the emergence of 1D exciton physics within a two-dimensional monolayer material, with the "interlayer" excitons retaining near monolayer-level brightness. Motivated by the recent experimental observation of these spatially indirect excitons [1], we calculate the exciton and trion fine structure using ab initio many-body screened configuration interaction [2]. We find that the lowest bright exciton state is non-degenerate due to the loss of symmetry induced by the 1D interface. Moreover, the many-body dipoles of these two excitons lie along different in-plane polarization axes, leading to an anisotropic optical response that may be useful for optoelectronic applications.

HL 3.5 Mon 10:30 POT/0081

Substrate interaction on local exciton/trion ratio in mono- to few-layer WS2 — •Appanna Parvangada[1,2], Dmitrii Sychev[1], and Ilka Hermes[1] — [1]Leibniz Institute of Polymer Research Dresden e.V., Dresden, Germany — [2]Institute of Applied Physics, Dresden University of Technology, Dresden, Germany

Two-dimensional Tungsten Disulfide (WS2) possesses distinctive optoelectronic properties such as high photoluminescence yield, a tunable band gap, large exciton binding, quantum confinement, strong-light matter interaction. The combination with low dimensionality makes them a favorable candidate for a variety of lightweight and flexible optoelectronic devices such as photodetectors, solar cells and LEDs.

However, large-scale industrial implementation of optoelectronic 2D materials is often impeded by their high spatial heterogeneity, caused by nanoscale variations in layer thickness, substrates interactions and local strain. Thus, standard optical characterization methods like Photoluminescence (PL) and Raman spectroscopy, which commonly provide such information, can lack the spatial resolution to resolve these variations. Here, electrical atomic force microscopy (AFM) methods with in-situ illumination at different wavelengths deliver nanoscale information on the impact of layer thickness, changes in substrates interactions and local strain onto the material's optoelectronic response.

In our study, we demonstrate the capability of photo-Kelvin probe force microscopy (pKPFM) to capture local photo-potential in mono- and few-layer WS2 and correlate PL spectroscopy. Furthermore, we investigate the impact of substrates on the local charge carriers.

HL 3.6 Mon 10:45 POT/0081

Signatures of efficient intervalley scattering by acoustic phonons in WSe2 monolayers — •Hendrik Lambers[1], Daniel Groll[2], Daniel Wigger[2], Nihit Saigal[1], Lara Blinov[1], Tilmann Kuhn[2], Alexander W. Holleitner[3], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster — [2]Institute of Solid State Theory, University of Münster — [3]Walter Schottky Institute, Technical University of Munich

When group VI TMDC are thinned down to the monolayer limit, their bandgap transfers from indirect to direct. While their strong exciton dominated light-matter coupling can be easily investigated by optical spectroscopy, exciton-phonon coupling is often inaccessible, even though it is important for exciton thermalization and intervalley scattering. We employ resonant Raman scattering at cryogenic temperatures to study the exciton phonon coupling in WSe_2 monolayers. In resonance with the WSe_2 exciton, we observe rich Raman spectra. Here, we focus on the resonance profiles of the degenerated A_1'/E' mode, that exhibits two asymmetric resonance peaks that cannot be described by a first order Raman scattering process. A higher-order Raman scattering process including simultaneous generation and annihilation of acoustic M-point phonons describes the experimental resonance profile well. Our results indicate a strong electron phonon coupling and efficient intervalley scattering between the nearly degenerate direct and indirect exciton transitions in WSe_2. The findings are relevant to understand unusual bright emission in WSe_2 monolayers despite spin-forbidden lowest interband transition.

HL 3.7 Mon 11:15 POT/0081

Transport of exciton complexes in the presence of Fermi sea of free carriers in monolayer semiconductors — •Minushree Rout[1], Koloman Wagner[1,2], Jonas Ziegler[1,2], Raul Perea-Causin[3], Samuel Brem[4], Ermin Malic[4], and Alexey Chernikov[1] — [1]Institute of Applied Physics, Technische Universität Dresden, Germany — [2]Department of Physics, University of Regensburg, Germany — [3]Department of Physics, Stockholm University, Sweden — [4]Department of Physics, Philipps-Universität Marburg, Germany

Exciton-carrier interactions in doped monolayer semiconductors present an interesting and technologically relevant scenario in solid-state physics. Among the consequences is the formation of trions-three particle system formed when excitons bind with free charge carriers. Here, we aim to explore how trion-phonon and exciton-carrier interactions influence excitonic quasiparticle diffusion using transient microscopy. Theoretical results predict that trions have reduced mobility at low carrier densities due to strong phonon coupling and increased mass. At higher densities, effective trion diffusion should increase significantly due to the Fermi pressure effect. Previous experimental studies revealed that exciton diffusion shows a non-monotonic dependence on carrier density, transitioning from elastic scattering regime to the formation of bound quasiparticle states like trions and fermi-polarons. This work aims to uncover the fundamental mechanisms governing the transport of light-emitting quasiparticles in the presence Fermi-bose mixtures in 2D semiconductors and experimentally test the prediction of the Fermi-pressure effect.

HL 3.8 Mon 11:30 POT/0081

Investigation of dynamics and character of excitons in WSe_2 and $MoSe_2$ multilayers — •Anna Weindl[1], Matthias Brem[1], Jennifer Lehner[1], Kenji Watanabe[2], Takashi Taniguchi[3], and Christian Schüller[1] — [1]Institut für Experimentelle und Angewandte Physik, Universität Regensburg, 93053 Regensburg — [2]Research Center for Functional Materials, National Institute for Materials Science, Tsukuba Ibaraki 305-0044, Japan — [3]International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Tsukuba Ibaraki 305-0044, Japan

We report about our time-resolved Faraday ellipticity (TRFE) experiments on multilayers of the transition metal dichalcogenide WSe_2 and $MoSe_2$. In a continuation of our recent work by Raiber et al. [1], we aim to investigate the nature of the pseudospin oscillations that appear in the TRFE signal when we apply an in-plane magnetic field to our multilayer samples. Now we try to characterize and manipulate these oscillations by playing with different experimental parameters. Varying the angle of the magnetic field, adding an electric field or investigating the layer dependence are examples for our toolbox of parameters to gain further insights into the dynamics of the multilayers. The current results, for example on the resonance behavior of the oscillations and the layer-dependent starting point of the oscillations, will be presented.

HL 3.9 Mon 11:45 POT/0081

In-situ mapping of pressure-induced exciton traps in suspended MoS2 monolayers using Fabry-Perot interference — •Niklas Walter[1,3], Leonard Geilen[1,3], Lukas Schleicher[2,3], Alexander Musta[1,3], Anne Rodriguez[3], Benedict Brouwer[1,3], Eva Weig[2,3], and Alexander Holleitner[1,3] — [1]Walter Schottky Institute, TU Munich, Germany — [2]Chair of Nano and Quantum Sensors, TU Munich, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

We demonstrate the in-situ readout of the spatial profile of suspended MoS2 monolayers hosted on substrates with nanostructured holes. As the profiles are spatially bent, the suspended MoS2 monolayers act as exciton traps with a tunable luminescence intensity and energy. The tunability is realized by controlling the environmental pressure on the monolayers, which allows one to control hundreds of suspended MoS2 monolayers on a single substrate. The in-situ readout is based on Fabry-Perot interferences and a model of the corresponding reflectance contrast maps of the investigated monolayers.

HL 3.10 Mon 12:00 POT/0081

Coherent two-dimensional electronic spectroscopy integrated with confocal microscopy for probing 2D materials — •Trideep Kawde, Pavel Trofimov, Matteo Russo, Anton Trenczek, and Hélène Seiler — Freie Universität Berlin, 14195, Berlin, Germany

Two-dimensional electronic spectroscopy is a powerful tool for probing ultrafast processes in van der Waals materials and heterostructures. As these structures are typically only 10x100 μm in size and highly heterogeneous, the challenge of ultrafast studies on such materials is to balance requirements in spatial and angular resolutions - often requiring highly dispersive microscope objectives - with temporal resolution. We present a coherent 2D electronic spectroscopy setup integrated with a confocal back focal plane imaging setup, featuring high magnification, spatial and angle resolution, while maintaining a time resolution of ~15 femtosecond. We demonstrate this approach on an exfoliated WSe_2 monolayer. The data reveal <100 femtosecond homogeneous linewidth broadening of the A exciton lineshape, indicating rapid exciton-energy fluctuations. These measurements provide insight into dephasing mechanisms such as excitation-induced dephasing, which sets fundamental limits to coherent control and quantum-optical applications.

HL 3.11 Mon 12:15 POT/0081

Acousto-optic characterization of van der Waals systems — •Felix Ehring, Benjamin Mayer, Hubert Krenner, Ursula Wurstbauer, and Emeline Nysten — Institute of Physics, University of Münster, Germany

With wavelengths in the micrometer range at GHz frequencies, surface acoustic waves (SAWs) are a versatile tool for radio frequency control and probing of charge carrier dynamics in novel semiconductor nanostructures. They are generated on a piezoelectric chip and routed over long distances to couple either mechanically or electrically to many solid-state nanosystems [1]. In our experiments, we fabricated hybrid lithium niobate SAW-devices in which different mechanically exfoliated transition metal dichalcogenide (TMDC) 2D materials were transferred. We investigated the influence of SAW-induced dynamic electric and strain fields on the photoluminescence (PL) of various TMDCs and their heterostructures. By combining optical and acoustic measurements, we were able to gain insights on the charge carrier dynamics and their resulting impact on exciton recombination and lifetime [2].

Dark exciton activation in WSe_2 monolayer by tip-enhanced photoluminescence spectroscopy — Adlen Smiri, Fenda Rizky Pratama, and •Takeshi Nakanishi — MathAM-OIL AIST, Sendai, Japan

Dark excitons in 2D transition metal dichalcogenide semiconductors are characterized by long lifetimes, making them highly attractive candidates for quantum computing and optoelectronics.The purpose of this paper is to theoretically address the interactions between local electromagnetic fields and dark excitonic states, and show that the strong out-of-plane near field from a metallic tip enhances radiative recombination of spin-forbidden dark excitons by providing additional in-plane momentum to overcome momentum mismatch [1]. Using ab initio calculations, a Wannier-Mott exciton model, and a numerical solution of the Laplace equation, we model the tip-enhanced near-field and its interaction with excitons via first-order time-dependent perturbation theory. Focusing on WSe_2 monolayers, we demonstrate that the activation of dark excitons is attributed to the strong z-component of the near field induced by the tip. We also analyze substrate screening effects on excitonic properties and lifetimes. Our results offer a theoretical framework for controlled activation of dark excitons toward quantum and nanophotonic applications.

X-ray nanodiffraction studies of lead-halide perovskite supercrystals — Jonas Hiller[1], Robert Thalwitzer[1], Ata Bozkurt[1], Matheus Ferreira[2], Richard Hodak[1], Fabian Strauss[1], Elke Nadler[1], Gerard Hinsley[3], Bihan Wang[3], Kuan Hoon Ngoi[3], Witold Rudzinski[4], Ekaterina Kneschaurek[1], Wojciech Roseker[3], Michael Sprung[3], Dmitry Lapkin[1], Dmitry Baranov[2], Frank Schreiber[1], Ivan Vartanyants[3], Marcus Scheele[1], and •Ivan Zaluzhnyy[1] — [1]University of Tübingen — [2]Lund University — [3]Deutsches Elektronen-Synchrotron DESY — [4]University of Krakow

We synthesize mechanically robust supercrystals built from cubic lead halide perovskite nanocrystals by a two-layer phase diffusion self-assembly with acetonitrile as the antisolvent. This method yields highly faceted thick supercrystals, which are robust enough to be picked up and relocated by microgrippers. We employed X-ray nanodiffraction together with high-resolution scanning electron microscopy and atomic force microscopy to reveal the structure of $CsPbBr_3$, $CsPbBr_2Cl$, and $CsPbCl_3$ supercrystals and explain their unusual mechanical robustness. We show that the removal of organic ligands from perovskite nanocrystals results in a size gradient of the nanocrystals within the supercrystals.

HL 4.2 Mon 10:00 POT/0251

Impact of Antisolvents on Halide Perovskite Nanocrystal Synthesis — •Tim Julius Hashagen, Leo Luber, and Alexander Skyrme Urban — Nanospectroscopy Group, Nano-Institute Munich, Department of Physics, Ludwig-Maximilians-Universität München, Königinstraße 10, 80539 Munich, Germany

Lead halide perovskite nanocrystals (NCs) offer highly tunable optical properties and high photoluminescence efficiencies, making them promising for optoelectronic and photocatalytic applications. Their synthesis, however, is extremely sensitive to the choice of antisolvent, which governs nucleation and growth kinetics and thereby the structural and optical quality of the resulting NCs. [1] In this work, we systematically investigate how structural and chemical variations among antisolvents affect the formation of CsPbBr2 NCs. By tuning precursor compositions and antisolvent identities, we identify clear trends in crystallization behavior and photoluminescence characteristics. These experimental results are combined with a Gaussian Process regression model that encodes antisolvent geometry to predict NC emission wavelengths.[2] The model performs accurately for well-represented antisolvent classes but still faces challenges when extrapolating to sparsely sampled or previously unseen antisolvents. Our combined experimental and data-driven approach highlights the decisive role of antisolvent molecular structure in NC synthesis and demonstrates a pathway toward predictive control over perovskite nanocrystal properties.

Tuning Lead Halide Perovskite Nanocrystal Properties via Controllable Synthesis and Machine-Learning Insights — •Maximilian Dörfler, Leo Luber, and Alexander Urban — Nanospectroscopy Group, Nano-Institute Munich, Department of Physics, Ludwig-Maximilians-Universität München, Königinstraße 10, 80539 Munich, Germany

Halide perovskite nanocrystals (NCs) combine high photoluminescence efficiency with tunable emission, but achieving narrow linewidths requires tightly controlled, highly monodisperse synthesis. In this work, we perform in situ observations of CsPbBr3 NC formation under ambient conditions and systematically evaluate how synthesis parameters shape their optical response. By analyzing the evolving photoluminescence spectra, we assess how reaction time, dilution, and precursor-to-antisolvent ratios jointly influence crystal growth and resultant morphology. The in situ approach allows us to track nanocrystal growth pathways and provides the opportunity for real-time steering of the synthesis. Particular emphasis is placed on understanding the conditions under which the NCs adopt 2D versus 3D morphologies. In future work, we will employ machine-learning tools - specifically Bayesian optimization - to efficiently navigate the sparsely sampled synthesis parameter space. This data-driven strategy aims to identify regions that yield high quantum efficiencies and narrow linewidths, enabling rapid discovery of conditions that favor predominantly monodisperse nanocrystals or nanoplatelets with minimal experimental iteration.

HL 4.4 Mon 10:30 POT/0251

Scalable Perovskite-Silicon Tandem Photovoltaics by Hybrid 2-Step Inkjet Printing — •Theresa Kuechle[1], Raphael Pesch[1,2], Jinzhao Li[1,2], and Ulrich W. Paetzold[1,2] — [1]Light Technology Institute, KIT, Germany — [2]Institute of Microstructure Technology, KIT, Germany

In recent years, the power conversion efficiency (PCE) of perovskite-silicon tandem photovoltaics has improved significantly on a lab scale. For photovoltaics industry, fully scalable processes are required to ensure homogeneous thin-film formation while maintaining conformity to the bottom cell.

Here, we show a hybrid two-step process for the perovskite thin film fabrication whereby inorganic components are evaporated, followed by inkjet printing of organic components. Our approach addresses scalability challenges and highlights the suitability of inkjet printing with a green solvent for the fabrication of large textured tandem solar cells. We show that optimizing the stoichiometry is necessary and can be achieved by fine-tuning the dots per inch in the second step. Through inkjet printing parameter optimization, we achieve wide-band gap single-junction perovskite solar cells with close to 20 % PCE. Additionally, we successfully fabricate large-textured (3 to 5 μm pyramid size) tandem solar cells with an active area of 1 cm^2, achieving a single-JV-scan PCE of 27.4 %. These results underscore the potential of this hybrid fabrication process to overcome upscaling hurdles and advance the development of highly efficient tandem solar cells for industrial applications.

HL 4.5 Mon 10:45 POT/0251

A Materials Perspective on Sequential Inorganic Scaffold Deposition for Hybrid-Processed Perovskite Thin Films — •Ronja Pappenberger[1,2], Julian Petry[1,2], Alexander Welle[3,4], Tonghan Zhao[1], Alexander Diercks[2], Raphael Pesch[1,2], Paul Fassl[1,2], and Ulrich W. Paetzold[1,2] — [1]Institute of Microstructure Technology, KIT, Germany — [2]Light Technology Institute, KIT, Germany — [3]Institute of Functional Interfaces, KIT, Germany — [4]Karlsruhe Nano Micro Facility, KIT, Germany

As perovskite solar cells (PSCs) advance toward industrial-scale production, fabrication processes must combine high-throughput with simple integration. In this regard, the hybrid two-step deposition route has emerged as a promising method, allowing for conformal coatings on micron-scale textures, a critical feature for perovskite/silicon tandem photovoltaics. This work presents a fully sequential route, wherein the inorganic materials CsCl and PbI_2 are deposited separately, simplifying industrial implementation compared to co-deposition. Microstructural analysis shows that sequential deposition promotes vertical PbI_2 growth with a secondary tilted orientation, unlike the horizontal orientation from co-deposition. Elemental distribution reveals high diffusivity for Cs, formamidinium, and I, yielding a homogeneous distribution in the perovskite absorber, while Pb and Cl remain largely scaffold-bound. PSCs with a 1.69 eV bandgap achieve efficiencies of 19.3% (co-deposition) and 18.7% (sequential), highlighting fully sequential hybrid deposition as a promising route toward industrial PSC production.

HL 4.6 Mon 11:15 POT/0251

How stable are mixed-metal chalcohalides? — •Pascal Henkel[1], Jarno Laakso[1], Jingrui Li[2], and Patrick Rinke[1,3] — [1]Department of Applied Physics, Aalto University, Espoo, Finland — [2]Xi'an Jiaotong University, Xi'an, China — [3]Technical University of Munich, Garching, Germany

Perovskite-inspired quaternary mixed-metal chalcohalides (MMCHs, $M(II)_2M(III)Ch_2X_3$) are an emerging materials class for photovoltaics,[1,2] capable of delivering high conversion efficiencies.[3] Yet, their thermodynamic stability remains largely unexplored.

We assess the thermodynamic stability of 54 MMCH compounds by modelling their phase diagrams using DFT, *pymatgen* tools from Materials Project[4] and the Alexandria Materials Database.[5] All studied MMCHs lie above the convex hull, independent of their space group ($Cmcm$, $Cmc2_1$, $P2_1/c$). Accounting for computational uncertainty (mostly from the applied exchange-correlation functional) moves a considerable fraction of MMCHs close to or below the hull. The MMCH decomposition paths follow five reactions, with $4\,M(II)_2M(III)Ch_2X_3 \leftrightarrow 2\,M(III)_2Ch_3 + 6\,M(II)X_2 + 2\,M(II)Ch$ occurring most frequently. Experiments show that compounds close to the convex hull can be synthesized, whereas compounds far from the hull decompose following the predicted reactions. Overall, our results show that MMCHs are synthesizable, but fabrication conditions need further optimisation.

minimizing ionic losses in DMSO-free tin-based perovskite solar cells — •Paria Forozi Sowmeeh[1], Shengnan Zuo[2], Chiara Frasca[2], Biruk Alebachew Seid[1], Sercan Ozen[1], Wentao Liu[2], Mahmoud Hussein Aldamasy[2], Yuan Zhang[3], Fengshuo Zu[2,3], Norbert Koch[2,3], Martin Stolterfoht[4], Antonio Abate[2], Artem Musiienko[2], and Felix Lang[1] — [1]Institute of Physics and Astronomy University of Potsdam, Potsdam-Golm, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [3]Department of Physics, Humboldt University of Berlin, Berlin,

Germany — [4]Electronic Engineering Department, The Chinese University of Hong Kong, Hong Kong SAR, China

The presence of mobile ions and the potential toxicity of Pb-based perovskite solar cells remain two major drawbacks for their commercialization despite their exceptional optoelectronic properties. On the other hand, Sn-based perovskites, which are believed to exhibit smaller ion-induced instabilities, have been revealed as eco-friendly perovskite counterparts, though thorough investigations are still missing. Herein, we investigate the nature of mobile ions, quantify the ionic loss within Sn-based perovskite solar cells and compare with those of Pb-based and mixed PbSn devices. We report minimal ionic losses and over 10-fold lower ion densities in DMSO-free processed Sn samples compared to Pb-based perovskites. The Sn-based devices also exhibit the lowest associated ionic losses with sustained device stability upon illumination. This study paves the way for development of innovative, stable thin film solar cells with suppressed ion migration.

HL 4.8 Mon 11:45 POT/0251

Beyond 1D: How Edge Effects Impact Ion Densities and Stability in Perovskite Solar Cells — •Jarla Thiesbrummel[1,2], Francisco Peña-Camargo[2], Bruno Ehrler[3], Dilara Abdel[4], Patricio Farrell[4], and Felix Lang[1] — [1]University of Potsdam, Potsdam, Germany — [2]Helmholtz-Zentrum zu Berlin, Berlin, Germany — [3]AMOLF, Amsterdam, Germany — [4]Weierstrass Institut, Berlin, Germany

Understanding how mobile ions redistribute within metal halide perovskites is essential for interpreting device stability and quantitative ion-density measurements. While most studies focus on ion transport along the device stack, lateral ion motion and edge effects remain relatively unexplored, despite their strong relevance, especially in small-area, lab-scale photovoltaic devices. In this work, we investigate side collection of ions at device edges and its consequences for both apparent ion densities and long-term material stability, using a combination of 2D drift-diffusion simulations and experiments.

Lightwave Engineering of Excitonic States in an Atomically Thin Semiconductor — •Omer Kneller[1], Niloufar Nilforoushan[1], Matthias Knorr[1], Markus Borsch[2], Fabian Mooshammer[1], Mackillo Kira[2], and Rupert Huber[1] — [1]Department of Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, Michigan 48109, USA

Coherently shaping excitonic states holds great potential for novel optoelectronics and quantum information processing. Yet, their femtosecond-scale coherence time substantially constrains coherent control. Here, intense phase-stable carrier waves of light resonantly drive the excitonic 1s-2p states in monolayer $MoSe_2$ faster than their natural decoherence rate, driving the excitonic system into multiple Rabi oscillations that occur during a single cycle of light. The dynamics are probed by injecting excitons into the 1s state using femtosecond NIR pulses and measuring the induced high-order sideband emission. The signal exhibits surprising spectro-temporal signatures that are reproduced by many-body simulations and a reduced two-level model, exposing the dominant role of the 1s-2p sub-system, even under these extreme driving conditions. An intuitive Floquet analysis links these features to light-induced avoided crossings between higher-order Floquet replicas of the driven two-level system. Our results bridge lightwave electronics in quantum materials, attosecond science, and atomic physics, and establish an exciting new route to shaping many-body quantum correlations at optical clock rates.

HL 8.2 Mon 15:15 POT/0006

Light-Induced Polarization Switching in R-Stacked Bilayer WSe_2 — •Xiangzhou Zhu, Stefono Mocatti, and Matteo Calandra — Department of Physics, University of Trento, Via Sommarive 14, 38123 Povo, Italy

Sliding ferroelectricity in two-dimensional van der Waals materials enables polarization control by relative layer motion, offering a promising platform for novel memory devices. Recent works show that strong laser pulses can reverse the polarization of such systems by driving shear phonons, but the required interlayer sliding and structural distortions limit the achievable switching speed. Here, we demonstrate a purely electronic pathway for light-induced po-

larization reversal in rhombohedrally stacked bilayer transition-metal dichalcogenides (TMDs). With constrained density-functional theory (cDFT), we find that photoexcited carrier densities below 0.2 e per unit cell are sufficient to switch the intrinsic ferroelectric dipole without interlayer sliding in WSe_2. This occurs because photoexcitation induces an imbalanced charge redistribution between the layers, which generates a counter-dipole. Using real-time semiconductor Bloch equation simulations, we shows that the total polarization can reverse by light within a few hundred femtoseconds. Furthermore, time-dependent charge analysis reveals that this ultrafast switching is primarily driven by a localized dipole rearrangement around the tungsten sites. These results establish a new mechanism for electronic control in 2D ferroelectrics, relevant for high-speed volatile memory applications.

Ultrafast excitonic coherent oscillations in monolayer tungsten disulphide — •Jorge Cervantes Villanueva[1], Davide Sangalli[2], Alberto García-Cristóbal[1], and Alejandro Molina-Sánchez[1] — [1]Institut de Ciència dels Materials (ICMUV), Universitat de València, Catedrático José Beltrán 2, 46980 Paterna, Valencia, Spain — [2]Istituto di Struttura della Materia-CNR (ISM-CNR), Area della Ricerca di Roma 1, Monterotondo Scalo, Italy

Understanding coherent excitonic dynamics in two-dimensional semiconductors is crucial for advancing quantum-optical technologies. Monolayer transition metal dichalcogenides (TMDs) provide an ideal platform due to their strong Coulomb interactions and large exciton binding energies. We perform ab initio pump-probe simulations by propagating the time-dependent density matrix under the influence of overlapping pump and probe fields, capturing the generation and detection of coherent excitons on femtosecond timescales. Focusing on monolayer WS2 with a pump tuned between the A and B excitons, we observe ultrafast oscillations arising from coherent coupling among multiple excitonic states, including the intermediate A* resonance. Exploiting the balance between exciton populations, we propose a scheme to control the coherent response, realizing an optical switch with potential applications in quantum information. These results establish ab initio pump-probe modeling as a predictive tool for characterizing and manipulating coherent excitonic states.

HL 8.4 Mon 15:45 POT/0006

Carrier-envelope phase control of ultrafast photocurrents in layered MoS2 — •Johannes Schmuck[1,2], Björn Sinz[1,2], Nina Pettinger[1,2], Sergey Zherebtsov[1,2], and Alexander W. Holleitner[1,2] — [1]Walter Schottky Institute and Physics Department, Technical University of Munich, Garching, Germany — [2]Munich Center of Quantum Science and Technology, Munich, Germany

We demonstrate carrier-envelope-phase (CEP)-controlled photocurrents in mono-, bi-, and tri-layer MoS2 driven by few-cycle laser pulses. The photocurrent in the two-terminal devices scale quadratically with the field amplitude, indicating perturbative carrier dynamics in the weak-field regime distinct from strong-field tunnelling [1]. Our results extend light-field-sensitive current control from bulk dielectrics, semiconductors, and graphene to two-dimensional transition-metal dichalcogenides, highlighting their potential for electric-field sensitive optoelectronics.

HL 8.5 Mon 16:00 POT/0006

Development of an ultrafast scanning electron microscope — •Leon Kross[1], Benjamin Schröder[1], Niklas Wemheuer[1], Leon Brauns[1], Murat Sivis[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]University of Göttingen, 4th Physical Institute, Göttingen, Germany

Ultrafast electron microscopy (UEM) enables the study of structural and electronic dynamics in solid-state materials with nanoscale spatial and femtosecond temporal resolution [1]. While UEM at high (> 30 keV) and low (< 1keV) electron energies is well established, ultrafast experiments in the intermediate energy regime have been less employed thus far, despite their potential to bridge the gap between surface- and bulk-sensitive measurements. Here, we present a new ultrafast scanning electron microscope (USEM), designed to investigate physical phenomena in the energy range from 1 to 30 keV. The modular architecture supports diverse experimental configurations and detection schemes, spanning from standard SEM operation modes - such as secondary- and backscattered-electron imaging - to more advanced techniques including cathodoluminescence or electron diffraction. In this contribution, we show example measurements, highlighting the performance of our USEM and its potential for exploring ultrafast physical phenomena. [1] A. Feist et al. Ultramicroscopy, 176, 63-73 (2017)

HL 8.6 Mon 16:15 POT/0006

Ultrafast X-ray diffraction shows dynamics of phase domains make V2O3 films remember photoexcitation ten thousand times longer — •Oleg Gorobtsov[1,2], Yoav Kalcheim[3,4], Ziming Shao[1], Anatoly Shabalin[3], Nelson Hua[3], Daniel Weinstock[1], Ryan Bouck[1], Mathew Seaberg[5], Diling Zhu[5], Oleg Shpyrko[3], Ivan Schuller[3], and Andrej Singer[1] — [1]Cornell University, USA — [2]University of Tübingen, Germany — [3]University of California San Diego, USA — [4]Technion-Israel Institute of Technology, Israel — [5]SLAC National Accelerator Laboratory, USA

Metal-insulator transitions in vanadium oxides combine electronic and structural phase transformations. Memory effects present during the phase transition in thin V2O3 films make the material a candidate for neuromorphic computing, but what role does the structural phase heterogeneity play in memory? We used an X-ray free-electron laser probe to show that strain feedback on structural phase domain nucleation increases the metal-insulator relaxation time after an optically induced insulator-metal transition from nanoseconds to a hundred microseconds. The dynamic range and precision of the experiment distinguish that the memory follows a stretched exponential law, not a power law. We also provide an experimental basis for the transition incubation times during the first 10 picoseconds after the excitation.

HL 8.7 Mon 16:45 POT/0006

Carrier-envelope phase modulation of ultrafast photocurrents in indium nitride — •Maximilian A. Gruber, Alexandra V. Nemmaier, Johannes Schmuck, Abhilash Ulhe, Gregor Koblmüller, and Alexander W. Holleitner — Walter Schottky Institute and Physics Department, Technical University of Munich, Munich, Germany

Few-cycle laser pulses allow for electronic transport at petahertz frequencies, where the carrier-envelope phase (CEP) controls the direction and strength of the ultrafast photocurrents. While such effects have been studied in graphene, bulk semiconductors and wide-bandgap dielectrics, their realization in group-III nitrides remains largely unexplored. We demonstrate CEPdependent photocurrents in InN devices excited by stabilized 6 fs optical pulses. The response reveals fieldsensitive contributions and strong interface effects close to the contacts of the investigated sample, highlighting the microscopic role of builtin electric fields in device architecture. The results position InN as a promising platform for CEP-controlled ultrafast transport.

HL 8.8 Mon 17:00 POT/0006

Towards studying quasi-particle interactions on the nanoscale — •Philipp Kessler, Matthias Hensen, Victor Lisinetskii, and Tobias Brixner — Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg

Investigating the properties and dynamics of quasi-particles is essential for tailoring material functionality in device fabrication. Nonlinear optical spectroscopy has become a standard tool for probing ultrafast single quasi-particle dynamics. However, the use of high light intensities, intended to improve the signal-to-noise ratio, can also generate multiple quasi-particle excitations, which may interact with each other. As a result, the measured signal consists of overlapping contributions from single- and multi-particle processes, each with distinct dynamics. To address this, our group recently developed the intensity cycling technique, which enables the experimental separation of individual perturbative orders in nonlinear light–matter interaction [1,2]. Here, we report our progress in extending this technique to time-resolved photoemission electron microscopy (PEEM) to study quasi-particle interactions with high spatial resolution. In our PEEM setup [3], we employ a 680 nm pump pulse with variable intensity for excitation and a 340 nm probe pulse for photoemission. This scheme allows us to investigate organic thin films of molecular aggregates, focusing primarily on exciton–exciton annihilation as a probe of exciton diffusion.

HL 8.9 Mon 17:15 POT/0006

Watching polarons form in real time — •Victor Garcia-Herrero and Fabio Caruso — Institute of Theoretical Physics and Astrophysics, Christian-Albrechts University of Kiel, Germany

Polaron formation in pump-probe experiments is a fast, non-equilibrium process arising from the coupled motion of electrons and lattice vibrations, leading to the emergence of a localized quasiparticle. A new first-principles quantum-kinetic approach is introduced to track the real-time dynamics of electrons and the lattice under electron-phonon interactions. We applied this method to the polar insulators MgO and LiF, and determine the characteristic timescales of polaron localization and identify its unique dynamical signatures. The results reveal distinct dynamical signatures of polaron formation and establish clear, practical criteria for its detection in ultrafast pump-probe experiments, providing a direct connection between theory and experiment.

Dynamic control of electron correlations in photodoped charge-transfer insulators — •Thomas C. Rossi[1,2], Nicolas Tancogne-Dejean[3], Malte Oppermann[1,4], Michael Porer[5], Arnaud Magrez[6], Rajesh V. Chopdekar[7], Yayoi Takamura[7], Urs Staub[5], Renske M. van der Veen[2], Angel Rubio[3,8], and Majed Chergui[1,9] — [1]LSU and LACUS, EPFL, Lausanne, Switzerland — [2]PS-ADLU, HZB, Berlin, Germany — [3]MPI for the Structure and Dynamics of Matter, Hamburg, Germany — [4]Department of Chemistry, University of Basel, Switzerland — [5]SLS, PSI, Villigen, Switzerland. — [6]Crystal Growth Facility, EPFL, Lausanne, Switzerland — [7]Department of Materials and Science Engineering, UC Davis, USA — [8]ICC and CCQ, Simons Foundation Flatiron Institute, New York, USA — [9]Elettra-Sincrotrone, Trieste, Italy

Tuning the electronic properties of materials is typically achieved by altering their chemical composition or thermodynamic parameters. An alternative route relies on ultrafast light excitation, which can create transient phases such as light-induced superconductivity and hidden insulator-to-metal transitions. In this talk, I will present evidence of light-driven dynamic screening of electron correlations in a prototypical charge-transfer insulator, nickel oxide (NiO). The excited state, characterized by weakened electron correlations, is metastable for hundreds of picoseconds. The high degree of control achieved over both the energetic and temporal aspects of electronic correlations offers a promising path toward full optical control of the electronic properties of correlated systems and the Mott transition.

HL 8.11 Mon 17:45 POT/0006

Photostriction-Driven Phase Transition in Layered Chiral $NbOX_2$ Crystals: Electrical-Field-Controlled Enantiomer Selectivity — •Jorge Cardenas-Gamboa[1], Martin Gutierrez-Amigo[2], Aritz Leonardo[3], Gregory A. Fiete[4], Juan L. Mañes[3], Jeroen van den Brink[1], Claudia Felser[5], and Maia G. Vergionry[3] — [1]Institute for Theoretical Solid State Physics, IFW Dresden — [2]Department of Applied Physics, Aalto University — [3]Donostia International Physics Center — [4]Northeastern University, Boston — [5]Max Planck Institute for Chemical Physics of Solids

Controlling the handedness of crystal structures is essential for developing next-generation optical, electronic, and information technologies. Yet, achieving reversible and selective control over crystal chirality remains a major challenge. In this work, we demonstrate a two-step pathway for enantiomer selectivity in layered chiral $NbOX_2$ (X = Cl, Br, I) crystals based on photostriction-driven phase transitions. *Ab-initio* simulations reveal that optical excitation is capable of inducing a structural phase transition in $NbOX_2$ from the monoclinic ($C2$) ground state to the higher-symmetry ($C2/m$) structure. In the resulting transient high-symmetry state, an applied electric field breaks the residual inversion-symmetry degeneracy, selectively stabilizing one enantiomeric final state configuration over the other. Our results establish a combined optical-electrical control scheme for chiral materials, enabling reversible and non-contact enantiomer selection with potential applications in ultrafast switching, optoelectronics, and chiral information storage.

HL 8.12 Mon 18:00 POT/0006

Efficient Two-Dimensional Spectroscopy Simulations including Realistic Pulse Shapes, Overlapping, and Time-Ordering Effects — Rémi Gilliot[1,2], •Matteo Russo[1], Alexander Blech[1], Manuel Joffre[2], Christiane Koch[1], and Hélène Seiler[1] — [1]Freie Universität Berlin, Berlin, Germany — [2]Institut Polytechnique de Paris, Palaiseau, France

We present an approach capable of simulating Two-Dimensional Electronic Spectroscopy (2DES) spectra with arbitrary pulse shapes, pulse overlap, and pulse ordering on a standard laptop. Under the assumption of simple dephasing, we show that the 2DES emitted signal - a convolution integral that involves pulses* fields and material response and that is traditionally challenging to evaluate numerically - reduces to a simple product of three independent one-dimensional integrals. This fortunate simplification makes this approach fast and computationally less expensive than others, while still capturing most of the realistic pulse-dependent effects listed above. Finally, we benchmark the effectiveness of this approach on three canonical systems - an anharmonic oscillator, two coupled oscillators, and a dimer model - studying how spectral phase distortions and strongly non-Gaussian pulse shapes, such as those produced by hollow-core fibers, can influence the 2DES emitted signal.

HL 9: Oxide Semiconductors: Growth and Fabrication

Growth of rutile GeO_2 by plasma-assisted suboxide molecular beam epitaxy — Alexander Karg[1], •Satjawoot Phiw-Ondee[1], Manuel Alonso-Orts[1,2], Marco Schowalter[1], Andreas Rosenauer[1,2], Martin Eickhoff[1,2], and Patrick Vogt[3] — [1]Institute of Solid State Physics, University of Bremen, Bremen, Germany — [2]MAPEX Center for Materials and Processes, University of Bremen, Germany — [3]Max Planck Institute for Solid State Research, Stuttgart, Germany

The interest in ultra-wide bandgap (UWBG) semiconductors for high-power electronic applications is rapidly increasing, for which rutile germanium dioxide (r-GeO_2) is a promising material. It possesses excellent properties: a bandgap of 4.6 eV [1], thermal conductivity of 51 W/mK [1], and a breakdown electric field of 7 MV/cm [1] and theoretical bipolar dopability [2].

This work reports on the growth of r-GeO_2 on m-plane Al_2O_3 substrates using plasma-assisted suboxide molecular beam epitaxy, using a SnO_2 buffer, followed by a r-$Ge_xSn_{(1-x)}O_2$ buffer to stabilize the r-GeO_2 phase. The growth of r-GeO_2 on those buffer layers is demonstrated and the responsible nucleation mechanism is investigated in detail. Characterization was performed by atomic force microscopy (AFM) and high resolution X-ray diffraction (HRXRD). Selected r-GeO_2 layers were analyzed by scanning transmission electron microscopy (STEM).

HL 9.2 Mon 15:15 POT/0051

Wafer-scale transfer and integration of tungsten-doped vanadium dioxide films — •Guanyi Li[1,2], He Ma[2], and Peter J. Klar[1] — [1]University of Giessen Institute of Physic, Giessen, 35392, Germany — [2]Beijing University of Technology, Institute of Information Photonics Technology, Beijing 100124, People's Republic of China

The trend in modern optoelectronic devices is towards greater flexibility, wearability, and multifunctionality. This demands more flexible fabrication methods of functional layers. Vanadium dioxide (VO_2), with its metal-insulator transition (MIT) at 68 °C, is of interest for many optoelectronic devices. However, high-quality VO_2 usually needs to be grown at T >450 °C in an oxygen-containing atmosphere implying a low compatibility with many optoelectronic device concepts, e.g., on flexible substrates. Here, we use a layer-by-layer transfer method of wafer-scale tungsten-doped VO_2 films, which enables sequential integration of VO_2 films with different MIT temperatures (down to 40 °C) onto arbitrary substrates. By stacking multiple VO_2 films with different doping levels of W, a quasi-gradient-doped VO_2 architecture can be achieved, effectively broadening the MIT temperature window and reducing the hysteresis of VO_2. Such integrated VO_2 films find a wide scope of applications, e.g., flexible temperature indicator strips, infrared camouflage devices, nonreciprocal ultrafast light modulators, or smart photo actuators. Our work promotes the development of more flexible and tunable optoelectronic devices integrated with VO_2.

HL 9.3 Mon 15:30 POT/0051

Growth and characterization of ultra-wide bandgap oxide semiconductor $LiGa_5O_8$ — •Nazar Masiuta, Sofie Vogt, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group, Leipzig, Germany

Lithium gallium oxide ($LiGa_5O_8$) has been recently grown as an ultra-wide bandgap oxide semiconductor with robust p-type conductivity using mist chemical vapor deposition[1]. This discovery suggests application of the material in high-power electronics by forming p-n junctions with n-type α-Ga_2O_3, β-Ga_2O_3, and isostructural γ-Ga_2O_3. However, establishing the origin of p-type conductivity of lithium gallium oxide remains an experimental challenge[2], while a theoretical prediction argues that neither native nor dopant defects in $LiGa_5O_8$ could be responsible for it[3]. We analyze the influence of pulsed laser deposition growth parameters on the quality of lithium gallium oxide films on different substrates. The structural, optical, and electrical characterization of $LiGa_5O_8$ is performed to determine the type of conductivity and its origin in the fabricated samples.

HL 9.4 Mon 15:45 POT/0051

(N:)CuBi2O4 photocathode thin films for photoelectrochemical water splitting — •Miriam J. Fehrenbach[1,2], Dominic Rapf[1,2], Katarina S. Flashar[1,2], Ian D. Sharp[1,2], and Verena Streibel[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Garching, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Garching, Germany

Photoelectrochemical (PEC) water splitting is a promising pathway to carbon-neutral solar fuels. While metal oxides are well explored as photoanodes, complementary photocathodes remain scarce. Potential candidates are Cu-based oxides, which naturally exhibit p-type conductivity. Among them, copper bismuthate (CuBi*O*) is a promising material [1], combining a visible-light bandgap with high photocurrent onset potentials [2], but suffering from poor charge transport [1]. To address this limitation, we developed a reactive co-sputtering and annealing process to synthesize high-quality, nitrogen-modified CuBi*O* thin films. We systematically examine structural and optical effects of nitrogen incorporation and find a significant improvement in PEC activity. To understand this enhanced performance, we investigate the charge carrier transport properties with (photo)conductivity measurements. [1] J. K. Cooper et al., Chem. Mater., 2021, 33, 3, 934*945. High-throughput combinatorial synthesis of perovskite-type materials for solar applications — •Clemens Petersen, Andreas Rosnes, and Holger von Wenckstern — Centre for Materials Science and Nanotechnology, University of Oslo, Norwa

Recently, combinatorial deposition methods have increasingly gained attention due to the high experimental throughput and resource-wise efficiency they offer in materials discovery. Our combinatorial pulsed laser deposition (c-PLD) approach enables the fabrication of material libraries on a single substrate, spanning wide compositional spaces with precise spatial control. Combined with high-throughput characterization techniques (HTC) such as spatially resolved UV-VIS spectroscopy and X-ray diffraction, the properties of complex materials can be rapidly mapped with high chemical resolution and minimal effort. We demonstrate the potential of c-PLD for accelerating the discovery of perovskite oxides for solar-energy-related applications. Using the $SrTiO_3$*$BaTiO_3$ (STO-BTO) system as an example, we showcase rapid screening of structural and optical properties on small area spatially addressable material libraries (SAML) covering the full composition range. In addition, STO-BTO SAMLs enable systematic strain engineering of functional perovskite materials. The tunable band structures and suitability for catalytic processes such as photoelectrolysis and proton-coupled electron transfer render titanate perovskites promising candidates for solar fuel production. Our results underline the capability of c-PLD and HTC workflows to efficiently identify and optimize oxide perovskites for sustainable energy technologies.

HL 9.6 Mon 16:15 POT/0051

Pulsed laser deposition of rutile GeO_2 thin films — •Hannah Dichelle, Sofie Vogt, Marius Grundmann, and Holger von Wenckstern — Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik, Germany

Rutile germanium-oxide has recently come into focus as an ultrawide bandgap material which is predicted to offer the possibility of ambipolar doping. [1,2] The stabilization of rutile phase GeO_2 is challenging due to the similar formation energies of the amorphous phase and α-Quarz phase.[2] We present GeO_2 thin films fabricated by pulsed laser deposition at heater temperatures >450°C. To facilitate the crystallization in the rutile phase (Sn, Ge)O_2 buffer layers are grown on sapphire and TiO_2 substrates at heater temperatures >600°C. Both ternary $Sn_xGe_{1-x}O_2$ buffer layers and vertically composition graded buffer layers are used to stabilize the rutile phase. The structural properties of rutile phase GeO2 thin films are investigated as a function of the growth temperature and oxygen pressure.

HL 10.1 Mon 15:00 POT/0081

Ballistic electrostatic graphene superlattices using He ion-milled etching masks — •Rebecca Hoffmann[1], Giulia Piccinini[1], Julien Barrier[1], David Barcons Ruiz[1], Hanan Herzig Sheinfux[1], Takashi Taniguchi[2], Kenji Watanabe[3], Adrian Bachtold[1,4], and Frank H.L. Koppens[1,4] — [1]ICFO-Institut de Ciencies Fotoniques, Castelldefels, Spain. — [2]International Center for Materials Nanoarchitectonics, NIMS, Tsukuba, Japan — [3]Research Center for Functional Materials, NIMS, Tsukuba, Japan — [4]ICREA-Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain

An electrostatic superlattice is created by applying a periodic electrostatic potential to a material using patterned gates or dielectrics, leading to tunable band structure reconstruction. This approach enables free design of the superlattice geometry and lattice period. While high mobility has been observed, signatures of ballistic transport (e.g. negative resistance in cross geometry, transverse magnetic focusing) remain to be reported. Here, we present a nanofabrication technique combining Helium ion milling of etching masks with damage-free etching of graphite gates [1]. Using these gates in a graphene heterostructure creates an electrostatic superlattice which preserves graphene's high mobility. We report superlattice features. The high electronic quality is confirmed by transverse magnetic focusing and device-size limited mean free path.

Tomographic flow regime in the 2D Corbino disk geometry — •Grigorii Starkov — Institute for Theoretical Physics and Astrophysics, University of Würzburg, D-97074 Würzburg, Germany

2D materials offer a unique test ground to study electron transport regimes dominated by the electron-electron collisions. This makes them the perfect platform to observe the electron hydrodynamic flows.

Not so long ago, it has been realized that precisely in 2D, the electron collisions constrained due to Pauli blocking result in the appearance of the long lived collective modes with odd angular character. The corresponding novel transport regime has been dubbed "tomographic".

In the recent experiment [2], magnetoresistance in Corbino-shaped graphene devices was used to disentangle different contributions to the electron transport and to determine viscosity. The obtained temperature-dependence thereof has been linked to the tomographic flow. However, the analysis is based on the bulk expressions for the conductivity and does not treat boundary corrections in detail. At the same time, boundary layers have been shown to be anomalously large in the tomographic flow regime [3].

To take into account the boundary effects, I analyze the magnetoresistance in the 2D Corbino disk geometry across different regimes, using the linearized Boltzmann equation.

Pulsed-gate spectroscopy of the electron-hole block- ade in bilayer graphene double quantum dots — •Lars Mester[1,2], Hubert Dulisch[1,2], Katrin Hecker[1,2], Konstantinos Kontogeorgiou[3], Samuel Möller[1,2], Leon Stecher[1], Kenji Watanabe[4], Takashi Taniguchi[5], Fabian Hassler[3], Christian Volk[1,2], and Christoph Stampfer[1,2] — [1]JARA-FIT and 2nd Institute of Physics, RWTH Aachen University, Aachen, Germany — [2]PGI-9, Forschungszentrum Jülich, Jülich, Germany — [3]JARA- Institute for Quantum Information, RWTH Aachen University, Aachen, Germany — [4]Research Center for Functional Materials, Na- tional Institute for Materials Science, Namiki, Japan — [5]International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Namiki, Japan

Pauli blockade is an established read-out mechanism for quantum-dot (QD) spin qubits. Using bilayer graphene (BLG) as a platform offers advantages such as a tunable valley degree of freedom. Recently, a strong spin-valley blockade was demonstrated in an electron-hole BLG double quantum dot (DQD) using time-averaged transport measurements. Here, we employ pulsed-gate spectroscopy by pulsing between the (0e, 0h) and (1e, 1h) charge configurations. Comparison with sim- ulations allows us to identify unconventional higher-order tunneling as the dominant blockade-lifting mechanism, with timescales governed by QD-lead coupling and the number of accessible states. Our results provide direct access to blockade-lifting dynamics in a BLG DQD, offering relavant insights for the development of future BLG-based qubits.

HL 10.4 Mon 15:45 POT/0081

Temperature Dependent Electrical Transport in Thin $SnSe_2$ — •Lars Thole[1], Aarti Lakhara[2], Preeti A. Bhobe[2], and Rolf J. Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany — [2]Department of Physics, Indian Institute of Technology Indore, Khandwa Road, Indore, Simrol, 453552, India

The two-dimensional material $SnSe_2$ shows special temperature dependent behavior [1], which has not been understood to its full capacity as of now.

We fabricated thin samples of $SnSe_2$ and investigated its electrical transport behavior in regards to its temperature dependence [2]. These samples show a metal-insulator transition with a metallic state for higher temperatures. The low-temperature transport regime is dominated by variable-range hopping. Additionally, the influence of defect states in these samples is investigated by looking at the thickness dependence for different samples [3].

HL 10.5 Mon 16:00 POT/0081

Polarization resolved Electron Spin Resonance in two-dimensional electron systems — •Daniiar Khudaiberdiev[1], Alexey Shuvaev[1], Michail Glazov[2], Anton Shchepetilnikov[3], Viacheslav Muravev[3], Christian Reichl[4], Werner Wegscheider[4], and Andrei Pimenov[1] — [1]Institute of Solid State Physics, Technische Universität Wien, 1040 Vienna, Austria — [2]St. Petersburg, Russia — [3]Chernogolovka, Russia — [4]Laboratory for Solid State Physics, ETH Zurich, CH-8093 Zurich, Switzerland

Electron spin resonance (ESR) has long served as a powerful probe of g-factor anisotropy, spin-orbit interactions, hyperfine coupling, and collective many-body spin phenomena in two-dimensional electron systems (2DESs). Most prior studies detect ESR in the photoresistance of Hall bars, where the excitation-field distribution and polarization are distorted, complicating the analysis of the excitation conditions.

In contrast, we report polarization-resolved ESR in sub-THz transmission using a quasi-optical setup and large-area samples that ensure high polarization purity. First we study the 2DES hosted in a 4.5-nm AlAs quantum well with a single isotropic valley. The selection rules indicate that Dresselhaus spin-orbit coupling mediates the electric-dipole-active spin absorption. Further we examine systems with more complex spectra such as wide AlAs wells with an active pseudospin, HgTe and InAs quantum wells with low effective mass and strong spin-orbit coupling enhancing the effects.

HL 10.6 Mon 16:15 POT/0081

First-Principles Investigation of Electronic Transport in 2D GaSe: Backward Diodes, p-i-n FETs, and Double-Gate MOSFETs — •Dogukan Hazar Ozbey and Engin Durgun — UNAM - National Nanotechnology Research Center and Institute of Materials Science and Nanotechnology, Bilkent University, Ankara, Turkey

In this study, we present a comprehensive first-principles investigation of charge transport in monolayer GaSe nanodevices by combining density functional theory with the nonequilibrium Green's function (DFT + NEGF) formalism. Three representative architectures, namely p–n junctions, p–i–n field-effect transistors (FETs), and double-gate MOSFETs, are systematically analyzed. Our calculations reveal that GaSe p–n junctions display an unconventional backward diode response, in which reverse currents within the ±1 V window exceed forward currents owing to tunneling-assisted transport, as evidenced by the projected local density of states. When configured as p–i–n FETs, electrostatic gating allows selective control over tunneling conduction. Moderate gate biases suppress the reverse current, whereas stronger gating reactivates and amplifies it. Finally, double-gate GaSe MOSFETs with channel lengths of approximately 5 nm exhibit competitive figures of merit that meet or surpass the ITRS-2028 high-performance benchmarks, achieving an on/off ratio of 1.2×10^4, intrinsic delay time of 0.24 ps, and power–delay product of only 0.06 fJ·μm^{-1}. Our results highlight GaSe as a single 2D semiconductor capable of integrating backward-diode behavior with high-speed transistor operation.

HL 11: Focus Session: Quantum Emitters in 3D Semiconductors

Quantum emitters in 3D semiconductors play a crucial role in many applications. In this focus session, we focus on the latest developments for their use in quantum technologies. In addition to the well-known NV center in diamond, there are a number of other defect centers in various semiconductor systems that hold great potential for quantum sensing, quantum cryptography, and/or quantum information technology. Today's research focuses on the discovery of new centers, their properties, synthesis, and their microscopic origin. For the latter, ab initio methods are often used, and the material systems span silicon, nitrides, carbides, and other semiconductors with large band gaps.

Time: Monday 15:00–18:15 Location: POT/0251

Invited Talk HL 11.1 Mon 15:00 POT/0251

Quantum Repeater Hardware made from Silicon Carbide — •Jörg Wrachtrup — Center for Applied Quantum Technologies, University of Stuttgart

Distributing entanglement via quantum repeaters is a formidable challenge. Memory-based approaches require quantum emitters that couple strongly to optical fields, and at the same time demand stationary qubits with excellent coherence properties. Colour centres in solids meet these requirements remarkably well and are therefore leading contenders in the field. However, existing solutions are either technically demanding or result in limited network efficiency.

Silicon carbide (SiC) offers several advantages over current approaches. Most notably, SiC is a wafer-scale material with excellent nanophotonic properties and hosts defects with outstanding spin coherence. In this talk, I will highlight recent progress in incorporating colour centres into nanophotonic structures and achieving efficient photon extraction. In addition, the electron spins of these colour centres can be coupled to nuclear spin qubits with exceptional coherence properties. I will discuss this coupling and its use as quantum memories for repeaters.

Invited Talk HL 11.2 Mon 15:30 POT/0251

Diamond based quantum sensing for drug testing — •Romana Schirhagl — University Medical Center Groningen, Groningen, the Netherlands

Free radical generation plays a key role in the mechanisms of action of many different drugs. Additionally, free radical generation offers a powerful biomarker to quantify the drug efficacy. However, free radicals are difficult to measure since they are short lived and reactive. Diamond based quantum sensing offers a possible solution to this problem. We have demonstrated recently that we can predict which drugs might work in clinical samples. Here we can either measure stress responses [1] (as for instance caused by anti-cancer drugs or anti-biotics) or reduction of oxidative stress [2] (as caused by anti-inflammatory drugs, certain inhibitors or anti-oxidants). We tested synovial fluid from rheumatoid arthritis and osteoarthritis patients. We can clearly differentiate the two groups which differ in their responsiveness to Piroxicam. Such ex-vivo measurements can be used for diagnostic purposes, to predict the effectiveness of a drug or to elucidate its mechanism of action. In my talk I will show different examples of how quantum sensing can be used in drug development.

Invited Talk HL 11.3 Mon 16:00 POT/0251

The oxygen-related ST1 centre in diamond: a room temperature coherently controllable electron spin — •Sebastien Pezzagna — Applied Quantum Systems, Universität Leipzig, Leipzig, Germany

The development of quantum information and technologies has rapidly evolved from the beginning of the century. Nowadays, there exists a variety of defects and host crystals which are suitable for applications in quantum computing, sensing or communication, such as the nitrogen-vacancy (NV) centre in diamond. However, the reliable and scalable employment of such a system requires the ability to produce it on demand together with a deep understanding of its optical and spin properties, as well as charge states and close by environment.

In this presentation, we will discuss the so-called ST1 centre in diamond, one of the few defect centres possessing a coherently controllable electron spin at room temperature. We will first show how we could identify the nature of the ST1 centre and how it can then be produced on demand. We will then emphasize the large spin readout contrast and charge state stability which characterise the ST1 centre, and how this compares to the well-known NV centre. Finally, we will highlight the peculiarities of the ST1 centre, supported by optical spectroscopy and by investigations of the hyperfine interactions with surrounding carbon-13 nuclear spins and with the oxygen-17 nuclear spin within the centre itself.

15 min. break

Invited Talk HL 11.4 Mon 16:45 POT/0251

Silicon quantum emitters emitting in the optical telecommunication range for scalable quantum photonic circuits — •Yonder Berencén — Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, 01328 Dresden, Germany

Silicon has recently emerged as a promising host for single-photon emitters operating at telecom wavelengths, offering a pathway toward scalable quantum photonic technologies on a CMOS-compatible platform. In this invited talk, I will provide an overview of the most relevant intrinsic and extrinsic-based quantum emitters in silicon, including the W, G, T, and C centers as well as erbium. I will discuss their optical and spin properties, deterministic creation via broad-beam ion implantation and focused ion beam implantation, and recent progress toward realizing spin-optical interfaces in the optical telecom bands. Particular emphasis will be placed on single-emitter spectroscopy, demonstration of optically detected magnetic resonance (ODMR) in silicon at telecom wavelengths, and the integration opportunities enabled by silicon*s mature photonic and electronic fabrication ecosystem. Finally, I will outline a roadmap toward fully monolithic silicon quantum photonic integrated circuits that combine single emitters with on-chip photonic routing and a groundbreaking approach for silicon-based single-photon detectors at the telecom range.

Invited Talk HL 11.5 Mon 17:15 POT/0251

Advances in materials processing for quantum sensing — •Adam Gali — HUN-REN Wigner Research Centre for Physics, Budapest, Hungary — Budapest University of Technology and Economics, Budapest, Hungary

For more than a decade, our first-principles studies have suggested that neutral divacancy defects in silicon carbide (SiC) could provide such an alternative. These defects can be excited in the infrared and emit in the second biological window, making them intrinsically attractive for biological sensing. The next step is to engineer the SiC surface and introduce shallow divacancy species suitable for nanoscale sensing. Under ambient conditions, however, SiC readily oxidizes and forms a high density of optical and paramagnetic defects at the interface, necessitating new materials-processing strategies. We have shown with first-principles calculations that the ODMR contrast of divacancy centers can be enhanced through strain engineering, a prediction verified experimentally by our collaborators. Additionally, we proposed replacing the native oxide with carbon-chain terminations to prevent oxidation. Our simulations revealed that such surfaces serve as ideal hosts for shallow divacancy quantum sensors capable of detecting external paramagnetic species [1]. This theoretical proposal has since been experimentally demonstrated by our collaborators, paving the way toward non-invasive, room-temperature quantum sensor devices.

HL 11.6 Mon 17:45 POT/0251

Generation of Vacancy-Based Colour Centres in 4H-Silicon Carbide for Quantum Nanophotonics with Optically Active Spins — •Leonard K.S. Zimmermann[1,2], Jonah Heiler[1,2], Samuel C. Eserin[3], Matthias Rupp[1], Ella B. Schneider[3], Jean-Nicolas Audinot[1], Steven K. Clowes[3], Ben N. Murdin[3], Stephan Kucera[1], and Florian Kaiser[1,2] — [1]Luxembourg Institute of Science and Technology (LIST), Esch-sur-Alzette, Luxembourg — [2]University of Luxembourg, Esch-sur-Alzette, Luxembourg — [3]Advanced Technology Institute, University of Surrey, United Kingdom

Silicon carbide (SiC) has emerged as a promising colour centre platform for scalable quantum systems based on nanophotonics and -electronics. Integration into nanophotonic circuits requires sub-micron three-dimensional positioning control of colour centres, achievable via ion implantation to create vacancies followed by thermal annealing. Spin-optical quantum coherence properties vary significantly with implantation parameters. We present initial results from an ongoing implantation-annealing study for generating VSi and VSiVC colour centres in 4H-SiC. Helium and Neon are implanted with varied doses at different energies, and different annealing processes for colour centre formation are investigated. We summarise single-emitter yield and show basic spin coherence measurements for the different processes. Our study highlights parameters necessary for optimal generation conditions of colour centres in 4H-SiC.

HL 11.7 Mon 18:00 POT/0251

Controlled generation of color centers in MBE-grown AlN for quantum photonics applications — •Meysam Saeedi[1], Duc V. Dinh[1], Andrey N. Anisimov[2], Mingyun Yuan[1], Georgy V. Astakhov[2], and Alberto Hernández-Mínguez[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., 10117 Berlin, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, 01328 Dresden, Germany

The large electronic band gap of aluminium nitride (AlN), its compatibility with CMOS technology, and the presence of defect centers acting as quantum light sources in the visible spectral range, make this material attractive for applications in integrated quantum photonics. In this contribution, we demonstrate the controlled generation of optically active defect centers in AlN thin films grown on 4H-SiC by molecular beam epitaxy (MBE). To this end, we compare the photoluminescence (PL) spectra of pristine AlN samples grown under both N-rich and Al-rich conditions with their corresponding PL spectra after H-ion irradiation and annealing. We show that achieving high-purity single-photon emitters in samples grown under N-rich conditions is hindered by a broad background PL, primarily arising from native oxygen-related defect complexes already present in as-grown samples. However, the PL background is reduced by more than one order of magnitude by turning the MBE growth conditions from N-rich to Al-rich regimes. These results outline a clear pathway toward the engineering of integrated, high-purity quantum emitters in epitaxial AlN.

HL 12: Heterostructures, Interfaces and Surfaces: Photonics

Time: Monday 16:45–18:30 Location: POT/0051

HL 12.1 Mon 16:45 POT/0051

Surface patterning for high index contrast AlOx/GaAs distributed Bragg reflectors — •Frederike Jaeschke[1,2], Yurii Kutovyi[1,2], Nils von den Driesch[1,2], Serhii Darahan[3], Christoph Krause[1], Benjamin Bennemann[1], Frank Vewinger[3], and Alexander Pawlis[1,2] — [1]Peter Gruenberg Institute, Forschungszentrum Juelich GmbH, Juelich, Germany — [2]JARA-Fundamentals of Future Information Technology, Juelich-Aachen Research Alliance, Aachen, Germany — [3]Institut für Angewandte Physik, Universitaet Bonn, Bonn, Germany

Enhancing the refractive index contrast between the constituent materials in a distributed Bragg reflector (DBR) leads to stopband broadening and an increase in the attainable reflectivity for a given number of layer pairs, thereby mitigating the impact of growth-induced thickness variations on optical properties. One promising approach involves the post-growth wet-oxidation of AlAs to amorphous AlOx, which substantially increases the index contrast relative to conventional AlAs/GaAs stacks. In this talk, we present optimization of the AlAs/GaAs DBR growth parameters alongside different substrate patterning approaches which facilitate controlled lateral oxidation for micrometer-scale AlOx/GaAs pillar structures. We compare the optical properties of wet-oxidized AlOx/GaAs and as-grown AlAs/GaAs DBRs to explore the potentials and limitations of such pre-structuring concepts for realizing high index contrast DBRs with decreased growth times and improved layer thickness accuracy.

HL 12.2 Mon 17:00 POT/0051

Improving Photoelectrochemical Nitrate Reduction on Copper (I) Oxide Electrodes — •Maximilian Christis[1,2], Jasmin Zitzmann[1,2], Saswati Santra[1,2], and Ian Sharp[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Germany

The photoelectrochemical (PEC) nitrate reduction reaction (NO_3RR) offers a green approach for simultaneous production of ammonia (NH_3) and removal of the wastewater pollutant nitrate (NO_3*) in ambient conditions. Copper (I) oxide (Cu_2O) was recently reported to be active for both electrochemical (EC) and PEC NO_3RR, but its practical application is limited by stability issues. Thus, optimal reaction conditions that balance NH_3 selectivity and catalyst stability remain to be established. In the current investigation, we find that alkaline electrolytes enhance Cu_2O-catalyzed PEC NO_3RR compared to neutral conditions, and higher NH_3 selectivity is achieved at lower applied potentials. However, under illumination and at potentials < 0.3 V vs. RHE, the catalyst rapidly reduces to metallic Cu, favoring EC rather than PEC NO_3RR. To address this challenge, we are exploring possible strategies to reduce in-situ decomposition of Cu_2O photocathodes, aiming to enable their long-term use for solar NH_3 synthesis.

HL 12.3 Mon 17:15 POT/0051

InGaN/GaN nanowire arrays for photoelectrochemical biosensors — •Hannah Nell, Genrietta Steingelb, Rudolfo Hötzel, Ruben Neelissen, Stephan Figge, Tim Grieb, and Martin Eickhoff — Institute of Solid State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359 Bremen, Germany

Group III-nitride materials are known for their stability under physiological conditions, making them promising candidates for use as electrochemical biosensors [1]. In this work, we analyse the simultaneous detection by photoluminescence (PL) and photocurrent measurements of InGaN/GaN nanowire (NW) arrays, enabling sensitive and selective sensing of redox-active biomolecules. However, the performance of the NW photoelectrode is constrained by non-radiative surface recombination of photogenerated carriers at the semiconductor-electrolyte interface, leading to irreversible photooxidation of the NW surface, mainly driven by non-passivated surface states. The deposi-

tion of ultra-thin metal oxide films is a possibility to suppress such effects. The influence of TiO2 as a surface coating on the sensor properties was analysed by photoelectrochemical characterisation, demonstrating how surface modifications can affect the sensor performance in biochemical environments. [1] G. Steinhoff, et al., Appl. Phys. Lett. 83, 177 (2003)

HL 12.4 Mon 17:30 POT/0051

Metal-oxide passivation for high-efficiency photoelectrochemical devices — •Negin Mogharehabed[1], Mohammad Amin Zare Pour[1,2], Christian Höhn[3], Roel van de Krol[3], Thomas Hannappel[2], and Agnieszka Paszuk[1] — [1]BMFTR Junior Research Group PARASOL, Technische Universität Ilmenau, Germany — [2]Fundamentals of Energy Materials, Technische Universität Ilmenau, Germany — [3]Institute for Solar Fuels, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Germany

Thin metal-oxide protection layers are crucial in highly efficient III-V photoelectrochemical (PEC) devices to suppress interfacial recombination and ensure long-term stability. Here, we study TiO_2 layers deposited on AlInP/GaInP(100) photoabsorbers, examining how surface preparation prior to atomic layer deposition and the Ti-precursor chemistry affect the chemical composition and band alignment at the TiO_2/III-V heterointerface, as well as the TiO_2 bulk and surface properties. Before TiO_2 deposition, the native oxide on AlInP(100) was removed by wet-chemical etching. TiO_2 films were grown using either TTIP or $TiCl_4$ with H_2O at various substrate temperatures. X-ray photoelectron spectroscopy was used to characterize the interface and TiO_2 bulk composition. We observe precursor-dependent differences in contaminant species in the TiO_2 bulk, at the surface, and at the TiO_2/III-V heterointerface, while their concentration is strongly influenced by deposition temperature and post-growth annealing. Finally, we correlate precursor choice and initial surface condition with TiO_2 layer stability in aqueous electrolytes under PEC-relevant conditions.

HL 12.5 Mon 17:45 POT/0051

Lab-Based NAP-XPS for Probing Photoelectrochemical Interfaces: The Case of $CuBi_2O_4$ — •Katarina S. Flashar[1,2], Miriam Fehrenbach[1,2], Gaurav Anand[3], Dominic Rapf[1,2], Barbara A. J. Lechner[3], Ian D. Sharp[1,2], and Verena Streibel[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Garching, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Garching, Germany — [3]Chemistry Department, TUM School of Natural Sciences, Technical University of Munich, Garching, Germany

Understanding complex (photo)electrochemical conversion processes at functional interfaces requires in situ and operando characterization. A tool enabling such investigations is near-ambient pressure X-ray photoelectron spectroscopy (NAP-XPS). In this contribution, we discuss the implementation of an open liquid cell for (photo)electrochemical measurements at our recently installed, lab-based NAP-XPS system (SPECS). As a photoelectrochemical case study, we examine sputter-deposited copper bismuthate ($CuBi_2O_4$) thin film photocathodes in contact with water-based electrolytes. We thereby extend previous NAP-XPS studies on light- and gas-dependent changes in surface chemistry of $CuBi_2O_4$ [1] to the solid|liquid interface under illumination. These investigations demonstrate the capability of our lab-based NAP-XPS to probe functional interfaces of energy materials under working conditions, offering an accessible and flexible alternative to synchrotron-based measurements. [1] F. E. Oropeza et al., ACS Appl. Energy Mater. 2019, 2, 6866 - 6874.

HL 12.6 Mon 18:00 POT/0051

Correlative Atomic Force Microscopy to Understanding Local Charge Transport in Photoanodes — •Sven Doll and Johanna Eichhorn — Technical University of Munich, Garching, Germany

Efficient photosystems for solar-to-chemical energy conversion are often based on nanostructured semiconductor architectures. In these material systems, the nanoscale properties frequently dominate the performance at the macroscale. Therefore, local understanding of their charge transfer and transport properties is decisive for optimizing their efficiency and stability.

To this end, we correlate Kelvin probe force microscopy (KPFM) and (photo)conductive atomic force microscopy (AFM) to study the local band bending, charge accumulation, as well as variations in the generated surface photovoltage and (photo)conductivity. However, analyzing nanostructured materials with complex morphologies is not trivial, because effects such as topographic crosstalk can significantly influence the results obtained. To overcome these issues, we leverage 2nd eigenmode and heterodyne KPFM measurements with improved resolution and sensitivity compared to conventional tapping mode KPFM techniques. For $BiVO_4$, one of the most extensively studied metal oxide photoanode materials, we compare different KPFM modes and correlate the results with local conductivity measurements to gain insights into local semiconductor properties at grain boundaries or different crystal facets. Overall, the gained nanoscale insights will put forward the development of rational design strategies to enhance the macroscale durability and efficiency of solar energy conversion systems.

HL 12.7 Mon 18:15 POT/0051

Persistent UV-Induced Work Function Control at Atomic Layer Deposited TiO_2 /Ta_2O_5 Bilayer Interfaces — •Julius Kühne[1,2], Tim Rieth[1,2], Katarina S. Flashar[1,2], Johannes Dittloff[1,2], Lukas Wolz[2], Johanna Eichhorn[2], Verena Streibel[1,2], and Ian D. Sharp[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Am Coulombwall 4, 85748 Garching — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Am Coulombwall 4, 85748 Garching

While atomic layer deposition (ALD) enables precise fabrication of ultrathin metal-oxide films, the mechanisms governing charge-carrier dynamics and band alignment at their interfaces often remain poorly understood. Oxide bilayers grown by ALD offer a versatile platform to characterize and tune defects that dictate interface energetics and charge transfer. Here, we examine the optical tuning of interface energetics in ultrathin ALD TiO_2/Ta_2O_5 bilayer films. A persistent -0.4 eV work-function (WF) shift is observed via contact potential difference (CPD) measurements after 275 nm illumination, with polarity reversal upon bilayer sequence inversion. This response arises from long-lived deep-trap filling, suggesting oxygen-vacancy migration. Capacitance-voltage (C-V) profiling, in-plane transport, and Kelvin probe force microscopy (KPFM) confirm vertical and lateral charge redistribution, while X-ray photoelectron spectroscopy (XPS) probe defect states. The results indicate that WF modulation originates from charge trapping by deep-trap states at the interface, offering insight into defect-driven effects in oxide heterointerfaces.

HL 13: 2D Materials III – Interlayer excitons

Time: Monday 16:45–18:30 Location: POT/0081

HL 13.1 Mon 16:45 POT/0081

Robust Interlayer Exciton Interplay in twisted Van der Waals Heterobilayer and Heterotrilayer on a Broadband Bragg Reflector up to Room Temperature — •Bhabani Sankar Sahoo, Shachi Machchhar, Avijit Barua, Martin Podhorsky, Chirag Chandrakant Palekar, and Stephan Reitzenstein — Technische Universität Berlin, Berlin, Germany

The MoSe2/WSe2/WSe2 Heterotrilayer (HTL) shows higher interlayer exciton (IX) emission intensity compared to the MoSe2/WSe2 heterobilayer (HBL) due to the additional WSe2 monolayer in the HTL, which improves interlayer coupling and provides additional radiative pathways. However, its coupling strength and thermal stability with increasing temperature remain unexplored. Here, we fabricate HTL and HBL using H-type stacking with twist angle of 55 and 50 for the MoSe2/WSe2 and WSe2/WSe2 heterostructures (HS) on the chirped distributed Bragg reflectors (cDBRs) centered at 800 nm. Photoluminescence (PL) emission at 4K shows that HTL exhibits more than 10-fold higher intensity compared to HBL. The temperature-dependent valley polarization reveals the interplay of triplet and singlet IX in the PL emission of the HBL and Indicates the influence of band modulation on the PL emission of the HTL. The temperature-dependent lifetime further provides insights into the different decay processes in both the HS, highlights the variations in optical performance between HTL and HBL HS with temperature. Additionally, through the combined effect of controlled stacking angles and the use of cDBR substrate, we successfully achieve room temperature IX across both regions of HS.

HL 13.2 Mon 17:00 POT/0081

Ring-shaped Interlayer Exciton Ensembles in $MoSe_2/WSe_2$ Heterostructures by Laguerre-Gaussian Excitation — •Mirco Troue[1], Johannes Figueiredo[1], Gabriel Mittermair[1], Jonas Kiemle[1], Hendrik Lambers[2], Ana Senkić[2], Ursula Wurstbauer[2], and Alexander Holleitner[1] — [1]Walter Schottky Institute and Physics Department, TU Munich, Am Coulombwall 4a, 85748 Garching, Germany — [2]Institute of Physics, Münster University, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Transition metal dichalcogenide monolayers exhibit strong light-matter interactions, which promotes them as ideal candidates for novel 2D optoelectronic applications. A vertical stacking into van der Waals heterostacks leads to the formation of long-lived interlayer excitons in adjacent layers. We report on ring-shaped ensembles of interlayer excitons in $MoSe_2/WSe_2$ heterostructures as excited by an optical Laguerre-Gaussian mode. The excitation is achieved with the help of a spatial light modulator. A hyperspectral analysis of the exciton photoluminescence suggests that the excitation scheme generates a non-uniform momentum distribution that favors the accumulation of high-energy excitons in the rings' center. We discuss the mechanisms leading to such a distribution, includ-

ing exciton-exciton interaction, phase-space filling, and incomplete thermalization.

HL 13.3 Mon 17:15 POT/0081

Exciton-Exciton Interactions in Van der Waals Heterobilayers — •Tommy Schulz[1], Alexander Steinhoff[2], and Frank Jahnke[1] — [1]University of Bremen, Bremen, Germany — [2]Carl von Ossietzky University Oldenburg, Oldenburg, Germany

Optically excited van der Waals heterobilayers hosting long-lived interlayer excitons provide a compelling platform for exploring correlated electronic states. In this work, we compute the exciton energy shift as a function of excitation density and temperature. This shift arises from a subtle interplay of various many-body interaction processes, each of which contributes either a blue- or a redshift, corresponding to repulsive or attractive interactions, respectively. By incorporating the fermionic substructure of excitons as well as dynamical screening effects, we show that the commonly assumed dominant repulsive dipole-dipole interaction is almost perfectly compensated. This finding challenges the simple picture of a purely bosonic exciton gas. Moreover, we identify a crossover from attractive to repulsive behavior at elevated exciton densities. Comparing these results - obtained using first-principle band structures and Coulomb matrix elements - with those from a simpler two-band model highlights the importance of a material-realistic description of the electronic states.

HL 13.4 Mon 17:30 POT/0081

Optical Injection and Detection of Long-Lived Interlayer Excitons in van der Waals Heterostructures — •Anna Seiler, Alperen Tügen, Arthur Christianen, Martin Kroner, and Atac Imamoglu — ETH Zurich, Switzerland

Interlayer excitons, electron-hole pairs spatially separated between two layers of 2D materials, have gained attention for their potential to enable the exploration of bosonic quantum phases. A promising strategy to stabilize these excitons is to use transition metal dichalcogenide (TMD) bilayer structures, where the two TMD layers are separated by a few layers of hexagonal boron nitride (hBN), effectively isolating itinerant electrons and holes. While these systems have primarily been studied through transport measurements, challenges such as difficulties in making ohmic contacts to TMD monolayers and the lack of photoluminescence have limited their broader exploration. Here, we demonstrate optical generation of dipolar interlayer excitons in TMD bilayers separated by up to seven hBN layers. We observe that the 2s excitons in the individual layers remain intact in the presence of opposite charges in both layers, suggesting that the oppositely charged carriers are strongly bound, forming stable interlayer excitons. We measure exciton lifetimes up to ten microseconds, underscoring their potential for studying exotic quantum phases such as Bose-Fermi mixtures and excitonic condensates [1]. These phenomena can be accessed through optical spectroscopy, enabling future exploration.

[1] A. Tüğen, A. M. Seiler, et al., Phys. Rev. Lett. DOI: https://doi.org/10.1103/stgs-2s58

HL 13.5 Mon 17:45 POT/0081

Influence of hBN spacer layers on atomic reconstruction in $MoSe_2$/WSe_2 heterostructures probed by electron microscopy — •Johannes Figueiredo[1,2], Kaiyuan Chen[3], Aubrey Penn[4], Mirco Troue[1,2], Sebastian Loy[1,2], Frances M. Ross[3], Julian Klein[3], and Alexander Holleitner[1,2] — [1]Walter Schottky Institute, TU Munich — [2]MCQST — [3]Massachusetts Institute of Technology — [4]MIT.nano

Atomically thin hexagonal boron nitride (hBN) tunnelling barriers in transition metal dichalcogenide (TMD) heterobilayers have recently facilitated the observation of macroscopic interlayer exciton phases interpreted as possible condensation and superfluid phenomena. However, such hBN spacer layers are also expected to modify moiré-driven atomic reconstruction. Here, we resolve local stacking configurations, lattice relaxation patterns and twist-angle variations across encapsulated $MoSe_2$/WSe_2 heterobilayers using a combination of high-angle annular dark-field scanning transmission electron microscopy (HAADF STEM), convergent-beam electron diffraction and four-dimensional STEM. Our analysis shows that the presence and thickness of the hBN spacer layers alter the balance between elastic relaxation and interlayer registry, producing a reconstruction landscape that differs qualitatively from that of directly contacted $MoSe_2$/WSe_2 bilayers. We also discuss how the resulting changes in structural homogeneity tune the moiré potential experienced by interlayer excitons and outline the implications for realizing spatially uniform macroscopic exciton phases in TMD-based quantum devices.

HL 13.6 Mon 18:00 POT/0081

Spin-bright interlayer exciton and trion ground state in Janus transition metal dichalcogenide bilayers from first-principles — •Franz Fischer[1,2], Carl Emil Mørch Nielsen[1], Marta Prada[1], and Gabriel Bester[1] — [1]University of Hamburg, Institute of Physical Chemistry, 22761 Hamburg, Germany — [2]Max Planck Institute for the Structure and Dynamics of Matter, 22761 Hamburg, Germany

We investigate bilayer Janus transition metal dichalcogenides using ab initio many-body screened configuration interaction calculations [1] and find that MoSSe–WSSe and WSSe–WSSe, with Se–S interfaces, exhibit spin-allowed interlayer exciton and trion ground states [2], in contrast to the spin-forbidden ground states of conventional transition metal dichalcogenides bilayers. This distinctive behavior is driven by the intrinsic structural asymmetry and interface-induced polarization, which significantly modify the electronic band structure. Moreover, we demonstrate that external mechanical strain allows to tune the optical properties of these excitons, enabling precise control over their brightness and potential applications in optoelectronic devices.

HL 13.7 Mon 18:15 POT/0081

Interplay of excitonic species in vertical and lateral transition metal dichalcogenide heterostructures — •Sai Shradha[1], Md. Tarik Hossain[2], Nicole Engel[1], Luc Oswald[1], Julian Führer[1], Daria Markina[1], Andrey Turchanin[2], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 6-8, D-64289 Darmstadt, Germany — [2]Institute of Physical Chemistry, Friedrich Schiller University Jena, Lessingstr. 10, D-07743 Jena, Germany

The properties of transition metal dichalcogenides (TMDs) can be extended beyond those offered by individual monolayers by combining different monolayers to create heterostructures. Vertically stacked heterostructures host quasiparticles such as interlayer and Moiré excitons. In lateral heterostructures (LHs), where monolayers of different materials are covalently bonded in the plane of their atoms, unidirectional exciton transport and the formation of charge-transfer excitons can be realized [1]. Chemical vapour deposition (CVD) has been a key fabrication technique for LHs. This work investigates composite CVD-grown $MoSe_2$-WSe_2 heterostructures consisting of both lateral and vertical interfaces, providing a single platform to study exciton dynamics across different interface types. Optical spectroscopy reveals efficient interlayer coupling in such structures, resulting in a uniquely strong interlayer exciton emission. Several spectroscopy techniques, including magneto-optics, are employed to characterize and shed light on exciton dynamics in such systems.

HL 15: Organic Semiconductors: Optics and Photonics

Time: Tuesday 9:30–12:00 Location: POT/0006

HL 15.1 Tue 9:30 POT/0006

Accessing 'Slow' Dynamics in Photocatalysts with PIAS — •Maria Ferree[1], Rebecca Gröninger[2], Tianhao Xue[1], Thomas Bein[1], Bettina Lotsch[2], and Frédéric Laquai[1] — [1]Dept. Physical Chemistry, LMU München, Germany — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany

Quasi-steady-state Photoinduced Absorption Spectroscopy (PIAS) is a highly sensitive tool for probing long-lived excited states and charge carriers in semiconductors. We showcase PIAS capabilities by studying diverse systems, ranging from conjugated polymers and COF-based films to nanoparticle dispersions. PIAS is often overshadowed as researchers default to sophisticated Transient Absorption (TA) Spectroscopy. However, low-frequency modulated excitation

with lock-in signal detection capture extremely weak changes in transmission induced by polarons or triplet states with lifetimes ranging from nanoseconds to seconds - dynamics that remain largely inaccessible by TA, but highly relevant for diffusion-limited processes, e.g. photocatalysis. Frequency-dependent measurements provide insight into lifetimes and concentrations of long-lived species. Whilst Time-resolved Photoluminescence (TRPL) can further reinforce the conclusions obtained from PIAS by extracting exciton recombination kinetics. Our studies of organic semiconductor-based photocatalysts are a reminder that PIAS is a powerful, often more suitable method complementary to ultrafast spectroscopy and other characterisation techniques. It provides unique access to 'slow' excited-state dynamics through relatively straightforward data acquisition and processing.

HL 15.2 Tue 9:45 POT/0006

Subwavelength OLED pixels based on plasmonic electrodes — •Leo Siebigs[1], Cheng Zhang[2], Björn Ewald[1], Luca Steinbrecher[2], Maximilian Rödel[1], Thomas Fleischmann[1], Monika Emmerling[2], Bert Hecht[2], and Jens Pflaum[1] — [1]Experimental Physics 6, University of Würzburg, 97074 Würzburg — [2]Experimental Physics 5, University of Würzburg, 97074 Würzburg

Next-generation display technologies, such as augmented and virtual reality, demand the continued miniaturisation of individual pixels. A novel approach towards achieving the necessary ultra-high resolution involves subwavelength organic light-emitting diode (OLED) pixels based on plasmonic nanoelectrodes. The nanoelectrode acts as an optical antenna, ensuring efficient light-outcoupling to the far-field and control over the emission characteristics by adjusting the antenna geometry. However, upon scaling the pixel dimensions below the wavelength of light, sharp nanoelectrode contours dominate the device operation. As a result (i) filament growth leads to rapid device failure and (ii) spatially imbalanced charge-carrier transport and recombination limits the external quantum efficiency (EQE). We address these challenges by selectively passivating the nanoelectrode edges with an insulating layer and defining the active area via a nanoaperture. As proof-of-concept, efficient and stable hole-injection is shown in hole-only devices based on gold nanoelectrodes. For the first time, we demonstrate light extraction from individually addressable 300 nm x 300 nm plasmonic OLED pixels with a maximum luminance of 3000 cd m^{-2} and 1% EQE. C., Zhang et al., Sci. Adv. 2025, DOI: 10.1126/sciadv.adz8579

HL 15.3 Tue 10:00 POT/0006

Near infrared OLEDs for neuroimplants — •Sabina Hillebrandt[1], Sumit Mohapatra[1], Ahmed Gaber Abdelmagid[2], Konstantinos C. Daskalakis[2], Andreas Mischok[1], and Malte C. Gather[1,3,4] — [1]Humboldt Centre for Nano- and Biophotonics, University of Cologne, Germany — [2]Department of Mechanical and Materials Engineering, University of Turku, Finland — [3]School of Physics and Astronomy, University of St Andrews, United Kingdom — [4]CECAD, University of Cologne, Germany

OLEDs offer spectral tunability, mechanical flexibility, and compatibility with scalable thin-film fabrication, making them strong candidates for biointegrated photonic technologies. Near-infrared (NIR) OLED emission can penetrate deep into tissue and may enable neuromodulation without the need for genetic interventions.

We present the development of high-brightness, top-emitting NIR OLEDs specifically engineered for implantable neurotechnology. Using optimized emitter-host combinations, microcavity tuning, and customized charge-transport layers, these devices exhibit peak emission above 800 nm with no measurable output below 700 nm, thereby reducing off-target excitation and tissue scattering. The devices achieve power densities approaching 0.1 mW/mm^2, levels relevant for neuromodulation, while maintaining both thermal stability and robust operational performance. To further refine spectral purity and directional control, we integrate strong-coupling architectures, yielding polariton OLEDs with angular-stable NIR emission above 800 nm even on flexible, implantable polymer substrates.

HL 15.4 Tue 10:15 POT/0006

Aggregation enhanced singlet emission in a purely organic emitter with thermally activated delayed fluorescence — •Jiacheng Gong, Xin Zhou, Kaiwen Guo, Toulik Maitra, Denis Andrienko, Gert-Jan Wetzelaer, Paul W. M. Blom, and Yungui Li — Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany

Purely organic thermally activated delayed fluorescence (TADF) emitters have gained great attentions in the field of organic light-emitting devices. However, the long-lived triplet exciton contributes to efficiency roll-off and device degradation at high current densities. Great efforts have been made to accelerate reverse intersystem crossing (rISC), while there are less studies on the increase of singlet radiative transition rate (krS). Herein, based on the benchmark TADF emitter CzDBA, it is found that it exhibits a larger krS in neat film, which is ~ 4 times faster than that in toluene with similar dielectric environment. The modelling of excited-state dynamics for electrically excited TADF emitters demonstrates that the increased krS reduces triplet and singlet densities simultaneously, while retaining high charge-to-photon conversion efficiency. Furthermore, time-resolved photoluminescence and steady-state absorption spectroscopic analysis shows that the broadened absorption feature increases the oscillator strength and hence increases krS in terms of Strickler-Berg relation. Gaussian disorder model is further applied to PL excitation spectra, and a larger disorder factor from the film samples implies that the large disorder of energetic landscape may contribute to the enhanced krS.

HL 15.5 Tue 10:30 POT/0006

Spectral diffusion of charge-transfer states in organic donor:acceptor blends due to carrier relaxation — •Giacomo Cotelli[1], Anna Köhler[1], and Reinder Coehoorn[2] — [1]University of Bayreuth, Bayreuth, Germany — [2]Eindhoven University of Technology, Eindhoven, The Netherlands

Blends of small-molecule organic semiconductors may display emission from an intermolecular charge transfer (CT) excited state. An aspect that is not well understood so far is the spectral diffusion of such CT states. We present a comprehensive study of CT state spectral diffusion in two- and three-component blends, using kinetic Monte Carlo simulations. We disentangle the effects of the CT state lifetime, charge carrier energetic disorder and blend composition on the emission spectra. Furthermore, we highlight similarities and differences between the emission of photogenerated CT states in films and electrically generated CT states in OLEDs.

HL 15.6 Tue 10:45 POT/0006

Direct Prediction of Organic Light-emitting Diode Efficiency Roll-off from Photophysical Parameters of Thermally Activated Delayed Fluorescence Emitters — •Kaiwen Guo, Yungui Li, and Paul Blom — Max Planck Institute for Polymer Research, Mainz, Germany

Severe efficiency roll-off significantly limits the practical performance of organic light-emitting diodes (OLEDs) at high luminance, especially for the devices based on thermally activated delayed fluorescence (TADF) emitters. Although numerous TADF emitters have been developed and investigated over last decade, in molecular scale the intrinsic molecular-origin of roll-off still remains unclear. In this work, we establish a direct correlation between device roll-off and intrinsic photophysical properties of TADF emitter, and analytically derive the roll-off as a function of exciton generation rate.

We propose an integrated methodology to extract complete set of photophysical parameters of TADF emitter, including the rates of exciton decays, spin conversion kinetics and bimolecular annihilation coefficients. Notably, we reveal that the roll-off behavior in TADF based OLED is not solely governed by bimolecular annihilation processes, but also influenced by the lifetime of delayed fluorescence. This knowledge enables us to predict the severity of roll-off directly from optical measurements and provides insight for further molecule designing.

15 min. break

HL 15.7 Tue 11:15 POT/0006

OLED-based implants for neurostimulation — •Sumit Mohapatra[1], Falko Fuhrmann[2], Julian F. Butscher[1,3], Sabina Hillebrandt[1,3], Martin Fuhrmann[2], and Malte C. Gather[1,3,4] — [1]Humboldt Centre for Nano- and Biophotonics, Department of Chemistry, University of Cologne, Germany — [2]Neuroimmunology and Imaging Group, DZNE, Bonn, Germany — [3]School of Physics and Astronomy, University of St Andrews, UK — [4]CECAD, University of Cologne, Germany

Light-based neurostimulation allows precise manipulation of neural circuits, yet delivering light to deep tissue remains a challenge. OLEDs combine spectral tunability, mechanical flexibility, and thin-film integration, enabling fabrication of neural probes for localized stimulation.

We advance this approach by integrating OLEDs onto magnetoelectric substrates to create fully wireless neuromodulation platforms, which are 200 μm-thick, contain 300*500 μm^2 OLEDs delivering mean power densities of 0.04 mW/mm^2. Tunable kilohertz-range resonances allow clustered multi-pixel operation, while thin-film encapsulation ensures biocompatibility and protection in a physiological environment. We also introduce a flexible OLED-based neuroprobe by integrating OLEDs onto 15 μm-thick commercial electrophysiology arrays. Using these pre-validated implantable platforms, they are transformed into μOLED arrays with 28 individually addressable μOLEDs (50 μm diameter, 300 μm pitch), achieving power density up to 0.1 mW/mm^2 at 7 V. In vivo optogenetic experiments using μ-OLEDs in mice confirm effective neuronal activation, verified by two-photon calcium imaging.

HL 15.8 Tue 11:30 POT/0006

Exploring Molecular Stability in Organic Solar Cells: A Combined DFT and ML Approach — •Muhammad Waqas and Harald Oberhofer — Chair for Theoretical Physics VII and Bavarian Center for Battery Technologies, University of Bayreuth

The stability of organic solar cells (OSCs) remains a significant challenge in the field. In this work, we present a data-driven approach that integrates density functional theory (DFT) and machine learning (ML) to identify molecular parameters that influence device stability. For this purpose, we compute different

optical and electronic parameters by using DFT and time-dependent DFT and check their influence on the lifetime (T80) of OSCs. The first step is to collect lifetime data from the already published literature for different OSC materials. The second step involves DFT and TD-DFT calculations for the selected molecules, thereby generating a dataset. This dataset serves as a foundation for training the ML models. Based on the DFT-generated data, we train ML models that can help us recognise the most influential parameters that affect the stability of OSCs. Furthermore, based on the insights gained from the ML models, we can explore the chemical space to find other molecules that can be used to prepare more stable devices.

HL 15.9 Tue 11:45 POT/0006

Accurate characterization of next-generation photodiodes — Siddhartha Saggar[1,2], Giedrius Puidokas[2], and •Caroline Murawski[1,2] — [1]Institute of Solid-State Electronics, TUD Dresden University of Technology, 01062 Dresden, Germany — [2]Kurt Schwabe Institute for Sensor Technologies, 04736 Waldheim, Germany

Photodiodes based on organic and emerging semiconductor materials have demonstrated high potential for optical sensing in biomedicine, imaging applications, and light-based data transmission. During the last decade, concerns have arisen regarding the reliable reporting of the device performance, especially under low illumination conditions. This work addresses these concerns and provides a robust framework for measuring and reporting standardized photodetection metrics. We have developed a measurement setup including a highly sensitive electrometer, calibrated optical filters, and light sources with narrowband emission spectra. For operation of the setup, we provide open-source Python scripts and outline protocols suitable for accurate characterization of steady-state photodetecting metrics.

HL 16: Focus Session: Quantum Emitters in 2D Semiconductors

Quantum emitters are fundamental building blocks in the development of scalable quantum communication networks. They provide capabilities for single-photon generation, quantum memory, and entanglement distribution*essential components for quantum key distribution, quantum repeaters, and future quantum internet infrastructure. Two-dimensional (2D) materials have recently emerged as a highly promising platform for quantum photonics. Their atomically thin nature enables strong light-matter interaction, high tunability, and seamless integration with photonic and electronic environments. Moreover, the reduced dielectric screening and strong excitonic effects inherent to 2D materials provide unique opportunities to engineer and control localized excitonic states that act as quantum emitters. This combination of physical richness and technological compatibility places 2D materials at the frontier between fundamental quantum optics and device-level quantum technologies. To advance the field, it is essential to understand both the microscopic theoretical principles and the engineering challenges associated with integrating such systems into communication networks.

Organized by Michael Lorke, Iris Niehues and Tobias Heindel

Time: Tuesday 9:30–12:45 Location: POT/0081

Invited Talk HL 16.1 Tue 9:30 POT/0081

Tailoring the performance of WSe_2 quantum emitters via cavity quantum electrodynamics and coherent driving — •Ivan Solovev — Institute of Physics, Carl von Ossietzky University of Oldenburg, Oldenburg, Germany

The ability to create scalable arrays of bright and easily-fabricated single photon sources has sparked keen interest in Van der Waals materials, rendering them a promising platform for emerging quantum technologies. Here I will provide an overview how their performance can be substantially improved via integration into a tunable microcavity as well as exploiting resonant excitation schemes. The implementation of the monolithic Fabry-Pérot open cavity, operating in a weak coupling regime, enables the observation of phenomena such as Purcell enhancement of radiative decay, strain-induced tuning of the emitter energy and two-photon interference. An impact of phonons on dephasing and resulting indistinguishability will be discussed. Furthermore, the selective excitation in a coherent manner is achieved via resonant driving, leading to the observation of Rabi oscillations.

Invited Talk HL 16.2 Tue 10:00 POT/0081

Deterministic single-photon emitters in 2D materials — •Ursula Wurstbauer — University of Münster, Germany

Single-photon emitters (SPEs) play a pivotal role as building blocks for quantum technologies. In two-dimensional (2D) materials, SPEs can deterministically be generated, externally manipulated and monolithically integrated. The properties of SPEs in atomically thin membranes are strongly dependent on the host materials and differ e.g. between TMDCs and hBN but also on the emitters origin, like defects, strain or moiré-potentials in twisted structures [1,2]. SPEs can be generated on-demand and on-chip with high lateral precision in the prototypical TMDC monolayer MoS2 by defect engineering utilizing focused helium ions [3]. These defect states in TMDCs interact with the electronic bands, whereas some defects in hBN show color center like behavior [1]. Following a general introduction, we focus on generation and characterization of rather monoenergetic SPEs in hBN by Argon ion irradiation [4]. We gratefully acknowledge A. R. Bhuiyan, R. Schmidt, A. Michaelis de Vasconcellos, R. Bratschitsch and Harry Mönig for fruitful collaboration. [1] S. Michaelis de Vasconcellos et al. Physica status solidi b259, 2100566 (2022). [2] M. Brotons-Gisbert, et al. MRS Bulletin 49, 914-931 (2024). [3] J. Klein et al. ACS Photonics, 8, 2, 669-677 (2021). [4] A. R. Bhuiyan et al.

Invited Talk HL 16.3 Tue 10:30 POT/0081

Resolving atomic and electronic structure of point defects in MoS_2 by first-principles calculations and scanning tunneling microscopy — •Hannu-Pekka Komsa — University of Oulu, Oulu, Finland

A unique advantage of 2D materials is that the defects in them are always at or very near to the surface, which can be highly beneficial in quantum emitter and quantum sensing applications. Importantly, this also enables direct characterization and manipulation of the defects with surface-sensitive techniques, such as scanning tunneling microscopy (STM). Since STM probes mainly the electronic structure, defect identification often requires comparison to results from first-principles calculations.

I will present our recent investigations on the electronic structure of a few common point defects in 2D MoS_2, such as S vacancies, Mo and Fe adatoms, and C substitutional on S site, combining first-principles calculations and experimental STM results from University of Cologne and Karlsruhe Institute of Technology. I will first discuss the computational aspects that were found to be important in achieving good agreement with experiments. A careful analysis and comparison of the computational and experimental results then allow us to infer defect identity, charge state, defect-defect interactions, magnetic moment, and dynamic effects such as defect transformations among Jahn-Teller configurations, defect charging, and spin lifetimes. Finally, benefiting from the atomic manipulations inside STM, rational atom-by-atom fabrication of defect structures can be envisioned.

Invited Talk HL 16.4 Tue 11:15 POT/0081

Polarization dynamics of isolated defects in hexagonal boron nitride — Serkan Paçal[1], Çağlar Samaner[1], Furkan Ağlarcı[1], Ömer S. Tapşın[1], and •Serkan Ateş[1,2] — [1]Department of Physics, Izmir Institute of Technology, Izmir, Turkey — [2]Faculty of Engineering and Natural Science, Sabanci University, Istanbul, Turkey

Single-photon sources (SPSs) are indispensable for quantum information technologies like Quantum Key Distribution. The practical success of these applications critically depends on the high purity and long-term stability of the emitted light's polarization state, which serves as the information-carrying quantum bit (qubit). Understanding and controlling polarization dynamics, therefore, presents a universal challenge for establishing reliable solid-state quantum interfaces. We propose using hexagonal Boron Nitride (hBN) defect centers as a

promising new platform for SPSs exhibiting strong, stable single-photon emission at room temperature, making it an ideal model system. In this work, we specifically investigate the polarization properties of hBN defect centers. We analyze the dynamics and temperature dependence of the polarization degree, focusing on the influence of electron-phonon interactions. Our results offer crucial insights that enable the development of targeted strategies to enhance the polarization stability of single-photon emitters, thereby facilitating more robust quantum optical systems.

Invited Talk HL 16.5 Tue 11:45 POT/0081

Defect-driven quantum emission in 2D materials — •Magdalena Grzeszczyk — IFIM, NUS, 117544, Singapore

Carbon-doped hexagonal boron nitride (hBN:C) provides a compelling 2D analogue to classical wide-bandgap hosts such as ruby (Cr:Al2O3), where isolated impurity centers give rise to sharp, stable optical transitions. These point defects have emerged as robust and manipulatable single-photon emitters (SPEs). By combining a broad suite of experimental techniques with advanced theoretical modeling, we introduce a consistent assignment of the observed excitations in hBN:C to the most likely underlying defect complexes. The described defect states residing in close proximity to the surface present an ideal sensors of local fields at the nanoscale. An example of how the local dielectric environment strongly modulates these centers, producing distinct spectral shifts will be discussed. Additionally, these defect states can be electrically excited in hBN-based light-emitting diode structures, providing a route toward integrated quantum emitters in van der Waals devices. Finally, ZnPS3 will be introduced as an emerging new host of SPEs. As a representative member of a broader family of layered MPX3 compounds, such as MnPS3 and FePS3, this emergent host opens new platform for future exploration of SPEs with intrinsic magnetic tunability.

HL 16.6 Tue 12:15 POT/0081

Nanoscale magnetic field sensing with spin defects in hexagonal boron nitride — •Korbinian Felber, Timo Strobl, Paul Konrad, Andreas Sperlich, and Vladimir Dyakonov — Experimental Physics 6, Julius-Maximilians-Universität Würzburg (JMU), 97074 Würzburg, Germany

The development of quantum sensors based on solid-state spin defects is a vibrant research area, yet most host materials are three-dimensional, making it challenging to position the sensing spins in close proximity to a target sample. This limitation was recently overcome in 2020 with the discovery of the negatively charged boron vacancy (V_B^-) in the two-dimensional van der Waals material hexagonal boron nitride (hBN). Exfoliating spin-active hBN flakes provide coherent spin manipulation in an atomically thin host. Using optically detected magnetic resonance (ODMR), these hBN spin defects provide sensitive readout of local magnetic fields, temperature, and strain, making functional hBN layers an ideal platform for exploring fundamental questions in 2D magnetism. In this study, we assemble a vdW heterostructure by stacking active hBN on top of a 2D ferromagnet. By employing spin-relaxometry techniques, we probe nanoscale magnetic fluctuations near the Curie temperature of the exfoliated ferromagnet. Our results highlight the potential of hBN-based quantum sensors for characterizing local magnetic properties in vdW heterostructures, offering substantial benefits for the design of next-generation 2D devices.

HL 16.7 Tue 12:30 POT/0081

Ion-beam induced quantum emitters in hexagonal boron nitride — •Jan Böhmer, Annkathrin Köhler, Hannes Simon, Lucas Böhme, and Carsten Ronning — Friedrich Schiller University, Jena, Germany

Defect centers in solid-state materials are emerging as highly promising candidates for realizing robust quantum light sources. Among these, hexagonal boron nitride (hBN) has attracted significant interest due to its potential for hosting room-temperature single photon emitters (SPEs). We utilize ion-beam irradiation to introduce optically active defect centers into hBN, offering a controlled and tunable method for engineering defect centers. We have investigated intrinsic and extrinsic ion-beam induced defect centers in exfoliated hBN flakes: Micro-photoluminescence spectroscopy (μ-PL) was employed to characterize the spectral properties of the induced emitters, while second-order correlation measurements ($g^{(2)}$) were performed to demonstrate the single-photon emission behavior and determine the quantum nature of the sources. Additionally, in-situ electrical measurements were used to monitor the reaction of the hBN flakes to irradiation in real-time. The results demonstrate that ion-beam irradiation can be successfully utilized for creation of quantum emitters in hBN. This work contributes to the ongoing effort to develop reliable, solid-state single photon emitters for quantum applications.

HL 17: Quantum Dots and Wires: Rings, Wires and Transport

Time: Tuesday 9:30–12:15 Location: POT/0251

HL 17.1 Tue 9:30 POT/0251

Growth of hexagonal Silicon Germanium quantum rings — •Marvin Marco Jansen[1], Mette F. Schouten[1], Denny Lamon[1], Wouter H.J. Peeters[1], Marcel A. Verheijen[1,2], and Erik P.A.M. Bakkers[1] — [1]Department of Applied Physics, Eindhoven University of Technology, Groene Loper 19, 5612AP Eindhoven, The Netherlands — [2]Eurofins Materials Science BV, High Tech Campus 11, 5656 AE Eindhoven, The Netherlands

Developing a silicon-based laser represents a key step toward commercially viable photonic circuits. A promising route is the recently discovered hexagonal silicon germanium (hex-SiGe) grown as shells around gallium arsenide (GaAs) nanowires (NWs), which has demonstrated efficient direct band-gap emission. In addition, type-I band alignment was demonstrated in hex-SiGe/Ge quantum wells (QWs), pushing the system closer to lasing. Theory predicts that combining hexagonal/cubic Ge(Si) QWs could further enhance optical performance. Here, we investigate the growth of hex-SiGe/Ge QWs on GaAs NWs that alternate between wurtzite (WZ) and zinc blende (ZB) crystal phases, forming ring-shaped hexagonal Ge QWs. These quantum rings feature two types of confinement: crystal-phase-induced axial confinement and radially controlled alloy composition. We explore several different WZ/ZB superlattice designs and TEM analysis confirms successful integration of hexagonal/cubic SiGe alloys and SiGe/Ge QW shells on the designed superlattices. Our results establish crystal-phase superlattice NWs as a promising platform realizing hex-Ge quantum rings and marking progress towards a hex-SiGe laser.

HL 17.2 Tue 9:45 POT/0251

A road to parallelisation - spin qubits as single electron pumps — •Dustin Wittbrodt[1], Johannes Christian Bayer[1], Lars Schreiber[2], Janne Lehtinen[3], and Frank Hohls[1] — [1]Physikalisch-Technische Bundesanstalt, Braunschweig, Germany — [2]JARA Institute for Quantum Information, Forschungzentrum Juelich, Germany — [3]SemiQon Technologies Oy, Espoo, Finland

The main workhorse of low current Ampere realization is the Single Electron Pump (SEP), which generates quantized currents based on the quantized transport of single charge carriers. The result are currents in the fA-pA range, measureable with a precision of as low as 0.1 ppm. For further improvement of accuracy and current output, parallelization of pumps is the necessary next step. Semiconductor spin qubit devices offer an interesting solution. In addition to sharing the same central building unit, the quantum dots, spin qubits also offer the possibility of incorporating CMOS logic and taking advantage of a mature, high-yield industry for large scale SEP manufacturing, thus allowing for the implementation of a high number of pumps with minimal control inputs. Various Si and Si-compound spin qubit technology platforms are being tested as SEP candidates, within the EU-funded AQuanTEC project. The focus of the activities includes the characterisation of these spin qubits in DC measurements and then in a series of AC measurements to characterise the pumping behaviour of these devices. We present the results of this effort here, offering a perspective on the potential application of Qubit technology for broader use as quantum metrological instruments.

HL 17.3 Tue 10:00 POT/0251

Using full counting statistics to identify interactions in the electron dynamics in a self assembled quantum dot — •Johann Zöllner, Hendrik Mannel, Daniel Oppers, Axel Lorke, Martin Geller, and Jürgen König — Faculty of Physics and CENIDE, University of Duisburg-Essen

We study interactions and electron dynamics in a self-assembled quantum dot using full counting statistics. Each tunneling event identified with a resonance-fluorescence-based continuous measurement [1]. Full counting statistics provides much more information than just the average current through the system. The details of the probability distribution obtained from full counting statistics depends on whether interactions play a role in electron transport or whether it can be modeled by noninteracting fermions [2,3]. This is reflected in sign changes of the factorial cumulants calculated from the probability distribution. Factorial cumulants are a measure for fluctuations and are particularly suited to characterize discrete distributions. We identify these sign changes predicted by theory in the experimental data. In this way, simply by observing individual tunneling events between the dot and a reservoir, we have gained information about the electron dynamiks like spin relaxation between Zeeman-split energy level and the presence of interactions.

HL 17.4 Tue 10:15 POT/0251

Effective Hamiltonians for Ge/Si core/shell nanowires from higher-order perturbation theory — Sebastian Miles[1], A. Mert Bozkurt[1], •Dániel Varjas[2,3,4], and Michael Wimmer[1] — [1]QuTech and Kavli Institute of Nanoscience, Delft University of Technology — [2]IFW Dresden and Würzburg-Dresden Cluster of Excellence ct.qmat — [3]Max Planck Institute for the Physics of Complex Systems — [4]Budapest University of Technology and Economics

We theoretically explore the electronic structure of holes in cylindrical Germanium/Silicon core/shell nanowires using a perturbation theory approach. The approach yields a set of interpretable and transferable effective low-energy model parameters for the lowest few sub-bands up to fifth order in perturbation theory for various experimentally relevant growth directions. In particular, we are able to resolve higher-order cross terms, e.g., the dependency of the effective mass on the magnetic field. Our study reveals orbital inversions of the lowest sub-bands for low-symmetry growth directions, leading to significant changes of the lower order effective coefficients. We demonstrate a reduction of the direct Rashba spin-orbit interaction due to competing symmetry effects for low-symmetry growth directions. Finally, we find that the effective mass of the confined holes can diverge, yielding quasi flat bands interesting for correlated states. We show how one can tune the effective mass of a single spin band allowing one to tune the effective mass selectively to its divergent points.

HL 17.5 Tue 10:30 POT/0251

Improving optical quality in highly strained GaAs/$In_xAl_{1-x}As$ core/shell nanowires — Xiaoxiao Sun, •Alexej Pashkin, René Hübner, Finn Moebus, Yuxuan Sun, Andreas Worbs, Slawomir Prucnal, Shengqiang Zhou, Stephan Winnerl, Manfred Helm, and Emmanouil Dimakis — Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

III-V semiconductor nanowires are promising for applications in photonics, electronics, and sensing. In lattice-mismatched GaAs/$In_xAl_{1-x}As$ core/shell nanowires, tensile strain in the GaAs core enables substantial bandgap tuning across the near-infrared spectrum. However, $In_xAl_{1-x}As$ shells are typically grown at low temperatures, which compromises their structural quality and induces non-radiative recombination. We present two strategies to mitigate it. The first employs a dual-shell architecture in which an intermediate $Al_yGa_{1-y}As$ shell spatially separates carriers in the GaAs core from the $In_xAl_{1-x}As$ shell [1]. Optimizing the spacer thickness significantly enhances photoluminescence efficiency and extends emission lifetimes. The second strategy focuses on optimizing the shell growth conditions. We show that higher growth temperatures improve the core/shell interface quality, reducing non-radiative recombination and carrier scattering, with optimal performance near 500°C [2]. This allows a simple single-shell structure to approach the performance of the more complex dual-shell design.

HL 17.6 Tue 10:45 POT/0251

Quantum dot as a model system for a Hund's coupled impurity — •Olfa Dani[1], Johannes C. Bayer[1,2], Timo Wagner[1], Gertrud Zwicknagl[3], and Rolf J. Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Hannover, Germany — [2]Physikalisch-Technische Bundesanstalt, Braunschweig, Germany — [3]Institut für Mathematische Physik, Technische Universität Braunschweig, Braunschweig, Germany

In this work, we investigate electron transport through the third shell [1] of a gate-defined GaAs quantum dot, where the exact electron number (N) is determined using a quantum point contact and tuned in a controlled manner by changing the applied gate voltages of the device [2]. For N = 7-11, the addition energy shows a triangular evolution with a maximum at half-filling. This trend is reproduced by model calculations including Hund's rule exchange. In the same filling range, a zero-bias anomaly (ZBA) characteristic of the Kondo effect appears. Its width and amplitude display a similar triangular dependence, reflecting the particle-hole symmetry of the three spin-degenerate orbitals. The pronounced ZBA is attributed to the contribution of both the Kondo resonance and low-energy Hund satellite excitations associated with degenerate orbitals observed in the spectral function [3]. The quantum dot is viewed as a multi-orbital Kondo impurity with Hund's interaction and serves as a model system for a Hund's coupled impurity.

Quantum stochastic resonance in a single-photon emitter — •H. Mannel[1], J. Zöllner[1], E. Kleinherbers[2], M. Zöllner[1], N. Schwarz[1], F. Rimek[1], A. Ludwig[3], A. Lorke[1], J. König[1], and M. Geller[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, 47057 Duisburg, Germany — [2]Department of Physics and Astronomy, University of California, Los Angeles, California 90095, USA — [3]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, 44780 Bochum, Germany

Classical stochastic resonance (SR) describes how noise can enhance the response of a driven bistable system. Recently, it has been extended to the quantum regime, where fluctuations originate from single tunneling events [1]. Building on optical real-time charge detection in self-assembled quantum dots [2], we demonstrate quantum stochastic resonance in a single InAs/GaAs quantum dot, weakly tunnel-coupled to an electron reservoir. Periodic modulation of the gate voltage synchronizes the electron tunneling with the external drive, while resonance fluorescence provides a fully optical, high-resolution readout of the charge state. From the full counting statistics of the tunneling events, we observe a pronounced narrowing of the distribution at the resonance condition, marking the transition from stochastic to increasingly deterministic transport [3].

HL 17.8 Tue 11:30 POT/0251

Spin relaxation dynamics of the excited triplet state in self-assembeld quantum dots — •Carl Nelson Creutzburg[1], Arne Ludwig[2], Andreas D. Wieck[2], Martin Geller[1], and Axel Lorke[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany — [2]Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

The two-electron triplet state in self-assembled quantum dots (QDs) can pair with the singlet ground state to form an electrically addressable spin qubit candidate. Using such qubits for quantum information processing requires long coherence times T_2, ultimately limited by the spin relaxation time T_1. While T_1 has predominantly been probed using optical techniques, we here present an all-electrical approach to access the spin relaxation dynamics.

The QDs are embedded in an inverted high-electron-mobility transistor, allowing controlled electron tunneling between the dots and a coupled two-dimensional electron gas (2DEG), which also serves as a sensitive charge detector. Using time-resolved transconductance spectroscopy [1] with a three-level pulse sequence, we observe the relaxation from the excited triplet to the singlet state as a function of the charging interval. A rate-equation analysis yields the spin relaxation time T_1. This approach provides an independent and complementary route to previous studies [2] and may help refine key assumptions.

HL 17.9 Tue 11:45 POT/0251

CMOS Compatible Short-Channel Junctionless Nanowire Transistors — •Sayantan Ghosh[1,2], Alessandro Puddu[1,2], Slawomir Prucnal[1], Yordan M. Georgiev[1], Ahmad Echresh[1], and Artur Erbe[1,2] — [1]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [2]Technische Universität Dresden, 01069 Dresden, Germany

The demand for miniaturized, high-speed, and energy-efficient electronics is pushing conventional planar transistors to their scaling limits, where short-channel effects and fabrication complexity constrain performance. Junctionless nanowire transistors (JNTs) offer a promising alternative through simplified architecture, strong electrostatic control, and CMOS compatibility. Using uniformly doped channels and eliminating pn-junctions, JNTs reduce process complexity and improve scalability for next-generation nanoelectronics. In this work, short-channel silicon JNTs were fabricated on SOI substrates using a CMOS-compatible top-down method. The devices use 20 nm-wide n-type Si nanowires with channel lengths from 1000 nm to 50 nm. Back-gate operation shows clear ambipolar behaviour, while top-gate operation yields the unipolar response characteristic of true JNTs. The 50 nm device achieves a current on/off ratio > 5 orders of magnitude and a subthreshold swing of around 200 mV/dec, demonstrating strong potential for low-power nanoscale technologies.

HL 17.10 Tue 12:00 POT/0251

Majorana bound states in 1D superconducting nanowires: detection, transport, and braiding — •Suhas Gangadharaiah — Indian Institute of Science Education and Research Bhopal India

Majorana bound states (MBSs) have emerged as promising candidates for robust quantum computation due to their topological protection. However, similar tunneling conductance features for both the MBSs and certain types of Andreev bound states have turned out to be a major obstacle in the verification of the presence of MBSs in semiconductor-superconductor heterostructures. In this talk, we will first discuss our protocol to probe properties specific to the MBSs and use it to distinguish the topological zero-bias peak (ZBP) from a trivial one [1]. We will next consider the dynamical transport of MBSs in the semiconductor-superconductor heterostructure in a realistic scenario involving noisy conditions and their role in inducing diabatic errors. We will discuss the scaling laws that relate these errors to the drive time [2]. Finally, we will discuss our ongoing work on MBS braiding in a trijunction geometry composed of three connected Kitaev chains.

HL 18: Nanomechanical systems (joint session HL/TT)

Time: Tuesday 10:00–12:45 Location: POT/0051

HL 18.1 Tue 10:00 POT/0051

Mechanical characterization of freely-suspended crystalline YIG nanodevices — •Jonny Qiu[1,2], Matthias Grammer[4,5], Sebastian Sailler[6], Sebastian T. B. Goennenwein[6], Michaela Lammel[6], Hans Huebl[3,4,5], and Eva Weig[1,2,3] — [1]TUM School of Computation, Information and Technology, Garching, Germany — [2]Zentrum für Quantum Engineering, Garching, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany — [4]TUM School of Natural Sciences, Garching, Germany — [5]Walther-Meißner-Institut, BAdW, Garching, Germany — [6]University of Konstanz, Department of Physics, Konstanz, Germany

Efficient quantum transduction, the reciprocal conversion of quantum signals from one energy level to another, is an ongoing challenge in quantum network applications. Engelhardt et al. [1] proposed a microwave to optical converter (MWOC) that co-localizes microwave, magnetic and elastic excitations within a suspended optomechanical crystal (OMC) made of crystalline yttrium iron garnet (YIG).

In this talk, we report our progress towards realizing the MWOC and present freely-suspended YIG nanodevices. We fabricated YIG cantilevers and beams using an electron beam lithography process and a subsequent crystallization by annealing approach. Piezo-driven interferometric spectroscopy reveals the mechanical response modes of these devices, from which we extract Young's modulus and internal stress to design the OMC as a MWOC. We visualize and thus confirm the corresponding mode shapes via laser doppler vibrometry.

HL 18.2 Tue 10:15 POT/0051

Sensing local temperature changes of a silicon nitride nanomembrane under large-amplitude vibration — •Valentin Barth, Mengqi Fu, and Elke Scheer — University of Konstanz, Konstanz, Germany

In MEMS and NEMS, changes in environmental conditions (e.g., a global change in temperature [1]) can alter the motion properties of silicon nitride (SiN) membranes. Vibrational motion may cause the membrane to experience local heating effects.

SiN square membranes (side length: 450 μm, thickness: 500 nm) are used and driven with a piezoelectric actuator. The motion is monitored using digital holographic microscopy. The measurements are carried out with a strong drive, resulting in vibration amplitudes on the order of hundreds of nanometers. Local temperatures are measured via the Seebeck effect using permalloy ($Ni_{81}Fe_{19}$) and gold as thermocouple, which provides a sensitivity of 20 μV/K and is suitable for micrometer-scale measurements [2]. To improve the signal-to-noise ratio and suppress unwanted contributions, the measurement is performed with a lock-in amplifier, where the temperature signal is demodulated at twice the drive frequency. The measured temperature depends on both the position of the thermometer and the vibration amplitude, with values reaching up to 0.5 mK. Besides the temperature signal of the membrane, signals caused by vibrations from neighboring membranes (distanced 1.5 mm) are also detected.

HL 18.3 Tue 10:30 POT/0051

FEBID and FIBID nanowire field emitters integrated with microcantilevers - fabrication and characterization — •Ewelina Gacka[1,2], Gregor Hlawacek[1], Krzysztof Kwoka[2], Tomasz Piasecki[2], Bartosz Pruchnik[2], René Hübner[1], and Teodor Gotszalk[2] — [1]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328, Dresden, Germany — [2]Department of Nanometrology, Wroclaw University of Science and Technology, 50-370, Wroclaw, Poland

Because micro- and nanomechanical systems are continuously evolving, there is a need to leverage various fabrication technologies. A scanning electron microscope with a gallium focused ion beam, as well as a helium ion microscope, were used to integrate platinum-carbon (Pt-C) and tungsten-carbon (W-C) nanowire field emitters with microcantilevers, serving as deflection sensors. Pt-C and W-C nanocomponents were fabricated using an additive, direct-writing method - focused-electron-/ion-beam-induced deposition (FEBID/FIBID)[1,2]. After growth calibration, the field emission behavior was studied in situ inside a vacuum chamber. The deposited Pt-C and W-C materials were characterized using Kelvin probe force microscopy and transmission electron microscopy. [1] T. Piasecki et al., Nanotechnology 35 (2024), doi: 10.1088/1361-6528/ad13c0. [2] E. Gacka et al., Measurement 234 (2024), doi: 10.1016/j.measurement.2024.114815.

HL 18.4 Tue 10:45 POT/0051

Optimization of Faraday Cage Angled Etching and Its Application Prospects in Silicon Carbide — •Wuzheng Ge[1,2], Ciaran Fowley[1], Jens Zscharschuch[1], Claudia Neisser[1], Artur Erbe[1,2], Philipp Bredol[3], Felix David[3], and Eva Weig[3] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, 01328 Dresden, Germany — [2]Dresden University of Technology, Faculty of Electrical and Computer Engineering, 01069 Dresden, Germany — [3]Technical University of Munich, Chair of Nano and Quantum Sensors, 85748 Munich, Germany

This work presents the optimization of a Faraday Cage Angled Etching (FCAE) approach for ICP-RIE. By reshaping the plasma potential through the cage's mesh geometry, FCAE steers ions along the cage-wall normal, enabling controllable ion incidence angles. Reproducible 3D triangular cross-section structures were demonstrated on silicon, confirming the effectiveness of ion-direction tuning. The results were also applied to silicon carbide nanomechanical resonators. The enhanced directional ion flux enables direct fabrication of free-standing, stress-free structures in bulk, undoped SiC. This capability offers new pathways for advanced SiC-based MEMS.

HL 18.5 Tue 11:15 POT/0051

Probing Mechanical Nonlinearities with Quantum Dots — •Noah Spitzner, Jona Richter, Emeline Denise Sophie Nysten, Matthias Weiss, and Hubert Krenner — Universität Münster, Münster, Germany

The coupling of quantum dots to mechanical resonances is a well-established approach to investigate the behaviour of mechanical resonators and crystals. Within that approach, the quantum dots (QDs) act as point-like sensors sensitive to dynamical changes to their lattice constant. Vibrations in the host structure modulate the emission energy of the quantum dot, enabling readout of mechanical modes via ultrafast optical detectors. In our hybrid structures, mechanical excitation is achieved by integrating the QD-membrane onto a lithium niobate substrate equipped with finger-like electrodes called interdigitated transducers (IDTs). Applying a radio-frequency (RF) signal to the IDTs generates surface acoustic waves, which propagate on the surface of the substrate, coupling to quantum dots in their path.

This hybrid platform was taken a step further by structuring the QD-membrane into rings hosting mechanical resonances. Frequency sweeps of the RF signal applied to the IDT revealed sharp resonances in the emission-energy modulation exclusively for the quantum dots located within the rings. Interestingly, the resonances appear over a large region of SAW frequencies from 200 MHz to 900 MHz. Moreover, we detect clear signatures of a nonlinear mechanical response e.g. asymmetric lineshapes in the time-modulated optical signal of the QD when the external drive by the IDT is increased.

HL 18.6 Tue 11:30 POT/0051

Dry processing of 3C-silicon carbide nanostring resonators — •Felix David[1,2,3], Yannick Klass[1], Philipp Bredol[1,2,3], and Eva Weig[1,2,3] — [1]Technische Universität München, School of Computation, Information and Technology, Garching, Germany — [2]Technische Universität München, Zentrum für QuantumEngineering (ZQE), Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), München, Germany

We fabricate string resonators from strongly stressed 3C-silicon carbide (SiC) grown on a silicon substrate. In conventional fabrication processes, electron-beam lithography with PMMA is employed to define a metallic hard mask for the subsequent dry etching step via a liftoff process. This requires some wet-chemical process steps, such as HF etching and metal removal, which can destroy samples. Here, we describe an alternative process that avoids all wet-chemical process steps, enabling superior quality. It involves the use of a negative electron-beam resist as an etch mask, as well as the completely reactive-ion etching-based release of the nanostrings. The dry-processed nanostrings can be fabricated with a high yield and exhibit high mechanical quality factors at room temperature. Due to its high reliability, combined with high process speed, it also allows for quick adaptation to new projects, such as multilayer and hybrid mechanical systems.

HL 18.7 Tue 11:45 POT/0051

The best of two worlds: hexagonal boron nitride exfoliated on stressed silicon carbide string resonators — •Philipp Bredol[1], Felix David[1], Junhui Wu[2], Andrey N. Anisimov[2], Takashi Taniguchi[3], Kenji Watanabe[3], Georgy V. Astakhov[2], Artur Erbe[2], and Eva M. Weig[1] — [1]TU Munich, Chair of Nano and Quantum Sensors, 85748 Munich, Germany — [2]HZDR, Institute of Ion Beam Physics and Materials Research, 01328 Dresden, Germany — [3]National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan

The boron vacancy (VB) of hexagonal boron nitride (h-BN) is a promising single photon emitter for applications in quantum technologies. Nanomechanical control of the VB would greatly enhance its versatility in such applications, therefore nanomechanical h-BN resonators are of great interest. Here we demonstrate that h-BN can be exfoliated on a chip with a pre-stressed silicon carbide thin-film and subsequently patterned into nanomechanical string resonators with high tensile stress. The resulting h-BN covered string resonators have high mechanical quality factors due to dissipation dilution and show the optically detected magnetic resonance signature of the VB of h-BN. Our fabrication approach allows to decouple the choice of the defect hosting 2D-material from the engineering of the mechanical mode and paves the way to nanomechanical control of single photon emitters in h-BN and other 2D materials.

HL 18.8 Tue 12:00 POT/0051

Cavity optomechanics with van der Waals materials — •Aloysius Farrel[1,3], Lukas Schleicher[1,3], Irene Sánchez Arribas[1,3], Leonard Geilen[2,3], Alexander Musta[2,3], Alexander Holleitner[2,3], and Eva Weig[1,3] — [1]Chair of Nano and Quantum Sensors, TU Munich, Germany — [2]Walter Schottky Institute, TU Munich, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Freely suspended two-dimensional materials are promising platforms for hybrid quantum systems that combine mechanical, optical, and electronic properties. Coupling the optical and mechanical modes of the resonators would be the first step towards such hybrid quantum system.

Here, we present studies of the mechanical resonators with van der Waals materials, such as hBN, on a SiN membrane. We map the spatial mechanical modes of the freestanding and supported 2D materials. Furthermore, we observe an optical nonlinearity in our high-finesse fiber optic cavity setup, which could couple to the mechanical modes. This result helps us understand the optomechanical coupling of the system and leads the way for a hybrid quantum device by incorporating quantum emitters in the system.

HL 18.9 Tue 12:15 POT/0051

Imaging GHz surface acoustic waves in epitaxial graphene cavities — •Mingyun Yuan[1], Alberto Hernández-Mínguez[1], Yi-Ting Liou[2], Jens Herfort[1], Joao M. J. Lopes[1], and Paulo V. Santos[1] — [1]Paul-Drude-Institut, Leibniz Institut im Forschungsverbund e.V., Berlin, Germany — [2]Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany

The imaging of sound has fascinated scientists and the public alike, dating back to Chladni's demonstrations in the 19th century. Nowadays, it is possible to image mechanical vibrations at the nanoscale, enabling direct probing of propagation, scattering and diffraction for high-frequency acoustic waves with short wavelengths. Here, we present the imaging of GHz surface acoustic waves (SAWs) in an epitaxial monolayer graphene nanostructure, based on thermal decomposition of SiC, using atomic-force microscopy (AFM). We observe a near-perfect strain transfer that gives rise to rich acoustic patterns in the phononic cavity formed by the graphene nanostructure. Furthermore, the enhanced acoustic intensity in the graphene region indicates a waveguiding effect, with graphene serving as an atomically thin, embedded shorting layer. Within the cavity, signatures of quantum chaos are observed. The high spatial resolution of AFM enables the investigation of SAW strain transferred onto 2D materials with high precision. The results also demonstrate an epitaxial nanophononic platform for both functional acoustic devices and fundamental studies of quantum phenomena.

HL 18.10 Tue 12:30 POT/0051

Nonlinear vibrational dynamics locally probed by time-resolved electron diffraction — •Kai Nettersheim[1], Alexander Schröder[1], and Sascha Schäfer[1,2] — [1]Department of Physics, University of Regensburg, Regensburg, Germany — [2]Regensburg Center for Ultrafast Nanoscopy (RUN), Regensburg, Germany

Nonlinear dynamics of micro- and nanoscale electro-mechanical systems can be observed using electrical or optical methods. However, these approaches are often limited in their spatial resolution, which leaves the underlying mechanics only partially accessible. Recent advances in ultrafast electron microscopy (UTEM) enable the highly localized probing of nanoscale oscillators, allowing to retrieve detailed information about their atomic structure and material defects.

Utilizing stroboscopic UTEM imaging techniques, we present the characterization of nonlinear mode dynamics in free-standing silicon membranes employing an event-based electron detector with nanosecond temporal resolution [1]. The high-Q resonator is excited using an optical pulse train driving the sample into the nonlinear regime. Due to the use of event-based converged electron beam diffraction (CBED), phase-accurate measurements of the nanoscale structural motion are provided. Whereas at weak driving, the oscillator displays a simple Duffing-type bistability, higher harmonic overtones as well as period doubling dynamics emerge at higher driving amplitudes.

HL 20: Poster I

Time: Tuesday 18:00–20:00 Location: P1

HL 20.1 Tue 18:00 P1

Defect-Mediated Electronic Reconstruction in Li-TFSI-Passivated Layered InI Crystals — •Abdulsalam Aji Suleiman[1,2], Ali Karatutlu[1,3], and Aydan Yeltik[4] — [1]Department of Engineering Fundamental Sciences, Sivas University of Science and Technology, Sivas 58000, Türkiye — [2]Sivas Cumhuriyet University Nanophotonics Application and Research Center (CÜNAM), Sivas 58140, Türkiye — [3]Institute of Materials Science Nanotechnology, National Nanotechnology Research Center (UNAM), Bilkent University, Ankara 06800, Türkiye — [4]Department of Material Science and Nanotechnology Engineering, TOBB University of Economics and Technology, Ankara 06560, Türkiye

Layered indium iodide (InI) is a van-der-Waals semiconductor whose bandgap (1.6-2.8 eV) enables strong light-matter coupling but suffers from iodine-vacancy defects that limit stability. Surface passivation with lithium bis(trifluoromethanesulfonyl)imide (Li-TFSI) modifies near-surface electrostatics and bonding, improving optical and transport properties. Photoluminescence shows stronger emission and longer carrier lifetimes, consistent with reduced non-radiative recombination. Soft-X-ray absorption spectroscopy at the HESEB beamline probes F, N, O, C K-edges and I M4,5-edges, revealing how TFSI-ions coordination alters In-I bonding and orbital hybridization. These results link chemical passivation and defect energetics, outlining a route to stable halide-based optoelectronic devices.

HL 20.2 Tue 18:00 P1

Tensor network methods for electron-hole complex in nanoplatelets — •Bruno Hausmann and Marten Richter — Institut für Physik und Astronomie, Technische Universität Berlin, Germany

Nanoplatelets are colloidally grown, atomically thin, rectangular semiconductor nanostructures. Excitons in nanoplatelets are solutions of a four-dimensional Schrödinger equation. This is especially true as the structure is in between the weak and strong confinement regimes. Solving this equation is computationally expensive compared to the typical two-dimensional Wannier equation under weak confinement. Going beyond excitons to trions and biexcitons, the memory size of the discretized wavefunctions grows exponentially with the particle number. Tensor network methods have successfully been applied to solve high-dimensional eigenvalue problems. Here we adapt them to the eigenvalue equation for excitons and trions by decomposing the real-space wavefunctions into quantics tensor trains (QTT). Operators that transform the indices, e.g. shift operators in finite differences, become binary circuits, e.g. an addition network.

We were able to compute ground and excited states together with their energies for platelet dimensions between strong and weak confinement with a resolution (up to 2048 grid points per dimension) infeasible to implement without tensor networks. For illustration, eigenenergies, oscillator strengths, and various wavefunction projections were calculated.

HL 20.3 Tue 18:00 P1

Markovian vs. Full Quantum-Kinetic Approach to Phonon-Assisted Incoherent Exciton Formation in Atomically Thin Semiconductors — •Leonard Schneider, Andreas Knorr, and Henry Mittenzwey — Nichtlineare Optik und Quantenelektronik, Institut für Physik und Astronomie, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Excitonic coherence decay and incoherent exciton formation in atomically thin semiconductors such as monolayer transition metal dichalcogenides are strongly influenced by the coupling between charge carriers and lattice vibrations. Based on Heisenberg's equations of motion, we derive the microscopic dynamics of excitonic transitions and incoherent exciton occupations coupled via phonon-assisted processes. For a consistent quantum-kinetical approach, we go beyond the usual one-phonon processes and include up to two-phonon-assisted and phonon-population-assisted transitions, which corresponds to a truncation of the hierarchy problem within a fourth-order Born approximation. We numerically evaluate the full quantum kinetics for the dephasing- and incoherent-exciton-generation dynamics and compare it to the corresponding Markovian limit. The corresponding influence of memory effects and multi-phonon processes is discussed in detail.

HL 20.4 Tue 18:00 P1

Far- and near-field photoluminescence of interlayer excitons in MoS2/WS2 heterostructures — •Johannes Holters and Iris Niehues — Institute of Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster

Monolayers of transition-metal dichalcogenides show intense photoluminescence (PL) at room temperature due to their high exciton binding energies. Recently, heterostructures composed of two vertically stacked monolayers have gained significant attention because of the emergence of novel quantum phenomena within these materials. Of particular interest are interlayer excitons, where, in contrast to intralayer excitons, electron and hole reside in different layers of the heterostructure. Strain, nanobubbles, Moiré effects and other local inhomogeneities can localize the appearance of these interlayer excitons to several nanometer. Here we use a scattering-type scanning near-field microscope (s-SNOM) to investigate the photoluminescence (PL) of interlayer excitons in a MoS2/WS2 heterostructure with a spatial resolution below the diffraction limit. The obtained tip-enhanced PL (TEPL) images are compared to standard confocal microscopy images. Both intra- and interlayer excitons are visible in far- and near-field images. In the TEPL images an enhanced PL signal is observed in the form of arcs around nanobubbles. These features can be assigned to interference effects caused by the interaction of the far-field light with the tip. Additionally, it is found that the intensity of the interlayer exciton PL strongly depends on the polarization of the exciting laser as well as the distance between tip and sample in the TEPL setup.

HL 20.5 Tue 18:00 P1

Optical Properties of CrSBr/TMD heterostructures — •Nicole Engel[1], Luc Oswald[1], Sai Shradha[1], Lukas Krelle[1], Daria Markina[1], Zdenek Sofer[2], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt, Darmstadt, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Czech Republic

Monolayer transition metal dichalcogenides (TMDs) exhibit several fascinating properties. These characteristics can be further expanded by creating heterostructures with CrSBr. CrSBr is an antiferromagnetic semiconductor which exhibits promising magnetic interactions with monolayer TMDs. The magnetic order of CrSBr influences the optical properties of $MoSe_2$ and WSe_2, facilitating charge transfer processes [1,2]. This work investigates CrSBr/TMD heterostructures using low-temperature optical spectroscopy with applied magnetic fields to probe excitonic properties. Understanding the optical and valley properties of CrSBr/TMD heterostructures will be relevant for the development of spintronic and valleytronic devices and show a great potential for light harvesting and enhancement of emission from 2D-materials.

[1] C. Serati de Brito et. al., Nano Lett. 2023, 23, 11073-11081
[2] J. de Toledo et. al., Nano Lett. 2025, 25, 13212-13220

HL 20.6 Tue 18:00 P1

Optical Properties of Interlayer Excitons in Transition Metal Dichalcogenide Heterostructures — •Luc Frederik Oswald[1], Sai Shradha[1], Nicole Engel[1], Julian Führer[1], Md. Tarik Hossain[2], Lukas Krelle[1], Daria Markina[1], Andrey Turchanin[2], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt, Darmstadt, Germany — [2]Institute for Physical Chemistry, Friedrich Schiller University, Jena, Germany

Interlayer excitons (IXs) in van der Waals heterostructures arise from electrons and holes confined in different monolayers, forming long-lived quasi particles with strong spin-valley coupling. In $MoSe_2/WSe_2$ systems, type-II band alignment and conduction-band splitting give rise to multiple IX states whose optical signatures are highly sensitive to temperature, lattice vibrations, and magnetic fields. This work investigates the optical response of an hBN-encapsulated, $MoSe_2/WSe_2$ lateral-vertical heterostructure grown via chemical vapour deposition (CVD). A combination of temperature-dependent photoluminescence, excitation-spectroscopy approaches, and magneto-optical measurements is used to probe the formation, evolution, and valley properties of interlayer excitons in this hybrid geometry. Together, they reveal characteristic interlayer emission features, their excitation pathways, and signatures of spin-layer hybridization.

HL 20.7 Tue 18:00 P1

Study of irradiation-induced deep-level defects in transition metal dichalcogenides MX2 (M = Mo,W; X = S, Se) — •Andrii Bodnar, Łukasz Gelczuk, and Paweł Scharoch — Departament of Semiconductor Materials Engineering, Wroclaw University of Science and Technology, Wybrzeze Wyspianskiego 27, Wroclaw 50-370, Poland

This work presents comprehensive density functional theory (DFT) calculations investigating native point defects in pristine and alpha-particle-irradiated MX_2 materials, where M represents Mo or W and X represents S or Se. The calculations focused on identifying deep-level defects and their charge transition levels, with subsequent experimental validation through deep level transient spectroscopy (DLTS) measurements. The satisfactory agreement between state-of-the-art DFT-calculated defect levels and DLTS experiments confirmed the reliability of the computational methodology and enabled identification of the origins of experimentally observed defect levels.

The validated DFT approach employing the HSE06 hybrid functional, which accurately predicts band gaps and eliminates self-interaction errors present in other approaches, was applied to calculate charge transition levels of defects in bulk MX_2 that are experimentally challenging to measure directly using DLTS. Using DFT-generated data, deep-level defects induced by alpha-particle irradiation in bulk MX_2 were identified and defect evolution under different irradiation doses was tracked.

HL 20.8 Tue 18:00 P1

Influence of hBN encapsulation on the degradation process of Hittorf phosphorus — •Maximilian Scharpey[1], Daniel Wigger[2], Nicolas Pajusco[3], Iker Herrero[3], Rainer Hillenbrand[3], and Iris Niehues[1] — [1]Institute of Physics, University of Münster, Germany — [2]Department of Physics, University of Münster, Germany — [3]CIC nanoGUNE BRTA, Donostia-San Sebastián, Spain

The van-der-Waals material Hittorf phosphorus (HP, violet phosphorus) has attracted increasing interest due to its promising semiconducting properties including high charge carrier mobility, a tuneable bandgap, and high optical absorption in the visible [1]. However, its degradation poses significant challenges for device applications. Here, we investigate the influence of hexagonal boron nitride encapsulation on the optical properties of thin flakes of mechanically exfoliated HP. By comparing photoluminescence and nanoscale Fourier transform infrared spectroscopy of encapsulated and non-encapsulated HP samples over a period of days, we gained insight on the degradation process. In addition, we used scattering-type scanning near field optical microscopy to localize the origin sites of degradation under the encapsulation layer with a resolution beyond the diffraction limit. These findings contribute to a deeper understanding of the degradation process of HP, which will play a crucial role in stabilizing this material for future applications.

HL 20.9 Tue 18:00 P1

Graphene/WSe_2 heterostructures for optical investigation of proximity spin-orbit coupling — •Ernst Knöckl, Matthias Klein, Alexander Holleitner, and Christoph Kastl — Walter Schottky Institute, School of Natural Sciences, Technical University of Munich

We investigate proximity-induced spin-orbit coupling (SOC) in graphene/WSe_2 heterostructures using the circular photogalvanic effect (CPGE) as a symmetry-selective, experimentally simple optical probe of spin-valley-locked band textures [1]. By measuring helicity-dependent photocurrents as a function of gate voltage, excitation energy, and device geometry, we aim to disentangle Rashba and valley-Zeeman SOC contributions and to extract their magnitude and sign as a function of the graphene-WSe_2 twist angle. A key requirement is the fabrication of large, clean, and field-effect-gateable graphene/TMDC heterostructures. To this end, we demonstrate a modified dry-transfer process based on specifically prepared polydimethylsiloxane (PDMS) stamps [2]. We further determine the relative twist angle using Raman spectroscopy and second-harmonic generation (SHG) spectroscopy.

HL 20.10 Tue 18:00 P1

Transport measurements in thin layers of $HfTe_5$ — •Freddy Sack[1], Christopher Belke[1], Sonja Locmelis[2], Lina Bockhorn[1], and Rolf J. Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany — [2]Institut für Anorganische Chemie, Leibniz Universität, 30167 Hannover, Germany

Hafnium pentatelluride ($HfTe_5$) gained interest due to its topological insulator behavior and the pronounced anisotropy arising from highly disparate electron and hole masses. In recent works, a thickness dependent band gap was observed [1]. In contrast to the small band gap found in bulk $HfTe_5$, single layers are predicted to be quantum spin hall insulator with a large band gap [1-4]. In this study, we investigate temperature dependent transport properties of thin layers of $HfTe_5$ from 5 K to 270 K. Gate dependent measurements for different magnetic fields are utilized to characterize thin flakes with a thickness less than 50 nm and to investigate the resistance anomaly.

HL 20.11 Tue 18:00 P1

Spectroscopic Imaging Ellipsometry at Cryogenic Temperatures Reveals Peak Splitting in 2D Polar Silver — •Ulrich Limberg[1], Jakob Henz[1], Siavash Rajabpour[2], Alexander Vera[2], Arpit Jain[2], Joshua A. Robinson[2], Su Ying Quek[3], and Ursula Wurstbauer[1] — [1]Institute of Physics, Munster, Germany — [2]MatSE PennState, Pennsylvania, USA — [3]Centre of Advanced 2D Materials, Signapore, Signapore

Two-dimensional (2D) polar metals are a new class of atomically thin materials created by confinement heteroepitaxial growth, where metallic species such as silver are intercalated between epitaxial graphene and a 6H-SiC substrate [1]. Silver intercalation leads to two competing semiconducting monolayer phases, the metastable Ag(1) and the stable Ag(2), each showing distinct opto-electronic behaviour [2].

Spectroscopic imaging ellipsometry (SIE) enables spatially resolved analysis of the complex dielectric function of both phases. Using temperature-dependent SIE from 5 K to room temperature, we investigate the modification of the linear light-matter interaction of 2D polar Ag with temperature. At low temperatures, we detect a splitting of the characteristic absorption peak of Ag(2). The experimentally determined dielectric function agrees well with theoretical predictions [2].

HL 20.12 Tue 18:00 P1

Structural and Electrical Characterization of Graphene Thin Films from Dispersions — •Yasaman Jarrahi Zadeh[1], Lars Grebener[2], Shaghayegh Pourdahrany[3], Muhammad Ali[4], Nicholas Wilson[5], Mohaned Hammad[2], Günther Prinz[1], Martin Geller[1], Michael A. Pope[5], William Wong[3], Hartmut Wiggers[4], Doris Segets[2], and Axel Lorke[1] — [1]Faculty of Physics, and CENIDE, University of Duisburg-Essen, Germany — [2]Institute for Energy and Materials Processes, and CENIDE, University of Duisburg-Essen, Germany — [3]Department of Electrical and Computer Engineering, and WIN, University of Waterloo, Canada — [4]Institute for Combustion and Gas Dynamics, and CENIDE, University of Duisburg-Essen, Germany — [5]Department of Chemical Engineering, and WIN, University of Waterloo, Canada

Graphene powders were produced by microwave-plasma synthesis and sonicated into ethanol or water with carboxymethyl cellulose (CMC) or di-n-dodecyl dimethylammonium bromide (DDDA) stabilizers. Using ultrasonic spray coating or Langmuir deposition, thin films were deposited on sapphire and characterized by SEM, Raman spectroscopy, and transport measurements. Water-based CMC dispersions produced the most uniform films. Raman spectra showed good structural quality (judged by the intensity ratio $I_{2D}/I_G \sim 1.5$). CMC-stabilized spray-coated films (0.1 wt%) achieved the highest conductivity (2.5 mS) and mobility (11 cm^2/V.s). DDDA films were more porous with lower mobility, while multilayer Langmuir films reached higher mobility (19 cm^2/V.s) but reduced conductivity.

HL 20.13 Tue 18:00 P1

Raman polarization switching in CrSBr — Priyanka Mondal[1], Daria Markina[1], •Lennard Hopf[1], Lukas Krelle[1], Sai Shradha[1], Julian Klein[2], Mikhail Glazov[3], Iann Gerber[4], Kevin Hagmann[1], Regine v. Klitzing[1], Kseniia Mosina[5], Zdenek Sofer[5], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt — [2]Department of Materials Science and Engineering, Massachusetts Institute of Technology — [3]St. Petersburg, Russia — [4]Université de Toulouse, INSA-CNRS-UPS, LPCNO — [5]Department of Inorganic Chemistry, University of Chemistry and Technology Prague

In recent years, few-dimensional nanomaterials have sparked significant interest within the solid-state research community due to their novel properties and possible applications in quantum technologies. Layered CrSBr has attracted particular interest due to its quasi 1D nature, strong electron-phonon interaction and air-stability. This work probes the optical anisotropy using polarization resolved photoluminescence and Raman spectroscopy on mono and few-layer CrSBr. These techniques are sensitive to the crystal orientation and reveal the intricate dependence of phonon polarization on excitation energy. Additionally, a clear thickness dependence of the electronic and vibrational properties is found. These results shed light on the complex electron-phonon and photon-phonon interactions in CrSBr opening new avenues for future application in optoelectronic devices.

HL 20.14 Tue 18:00 P1

Tuning carrier type and electrical properties of 2D alloy transistion metal dichalcogenides — •Axel Printschler, Md Tarik Hossain, Nhat Lam Duong, Julian Picker, Rahul Sharma, Christof Neumann, Muhammad Sufyan Ramzan, Caterina Cocchi, and Andrey Turchanin — Friedrich Schiller University Jena, Germany

Two-dimensional (2D) transition metal dichalcogenide (TMD) alloys offer a powerful platform for engineering material properties beyond the limitations of their constituents. Controlling the electronic characteristics of TMDs is crucial for the development of advanced electronic and optoelectronic devices and functional circuitry. This study focuses on the electronic properties of monolayer $(V_xW_yMo_{1-x-y})S_2$ alloys synthesized via a liquid-precursor-based chemical vapor deposition (CVD) approach. We investigate the charge transport in these materials using field-effect transistor (FET) devices. Our electrical measurements demonstrate a controlled transition from n-type to p-type semiconducting behavior, culminating in a metallic state for high vanadium concentrations. This change is supported by density functional theory (DFT) calculations. The tunability, directly correlated with the alloy composition, provides a reliable strategy for tailoring the electronic character of 2D TMDs and underscores their significant potential for application in next-generation electronic devices.

HL 20.15 Tue 18:00 P1

Many-body effects and intervalley coupling mechanisms in monolayer transition metal dichalcogenides — •Oleg Dogadov[1,2], Henry Mittenzwey[3], Thomas Deckert[4], Micol Bertolotti[2], Daniele Brida[4], Giulio Cerullo[2,5], Andreas Knorr[3], and Stefano Dal Conte[2] — [1]Fritz Haber Institute, Berlin, Germany — [2]Politecnico di Milano, Milan, Italy — [3]Technische Universität Berlin, Berlin, Germany — [4]University of Luxembourg, Luxembourg — [5]CNR-IFN Milan, Italy

The strongly bound excitons and the spin-valley locking effect make monolayer (1L) transition metal dichalcogenides (TMDs) an ideal platform to study intra- and intervalley many-body effects. Despite extensive studies conducted during the last years, a unified description of the competing many-body interactions and intervalley coupling processes in 1L-TMDs is lacking. Here, we apply broadband helicity-resolved transient absorption spectroscopy combined with a microscopic theory based on the excitonic Bloch equations to investigate coherent optical response and valley polarization dynamics in 1L-WSe_2. We unambiguously unravel competing valley-dependent contributions of two- and four-particle correlations to the coherent optical response of the studied material. By exploring the valley (de)polarization dynamics, we dissect the roles of individual intervalley coupling mechanisms, including Coulomb exchange and Dexter-like interaction, as well as phonon-assisted scattering, providing a consistent picture of the processes governing spin-valley dynamics in 1L-TMDs.

HL 20.16 Tue 18:00 P1

Unconventional Nanopatterning of 2D Materials for Future Nanoelectronics — •Tawat Chen[1,2], Poonam Borhade[3], Ya-Ping Hsieh[4], and Mario Hofmann[1] — [1]Department of Physics, National Taiwan University, Taipei, 10617 Taiwan — [2]Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 3, 07743 Jena, Germany — [3]Institute of Physics, Academia Sinica, Taipei, 10617 Taiwan — [4]Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, 10617 Taiwan

Two-dimensional (2D) materials offer a promising pathway to surpass the physical scaling limits of silicon-based electronics in the post-Moore era. However, fabricating high-resolution nanofeatures on these materials using conventional photolithography is constrained by Rayleigh's diffraction limit and escalating processing costs. In this work, we demonstrate nanopatterning techniques that overcome these limitations. First, we utilize a self-expansion double patterning (SEDP) process to generate nanometer-scale features through a self-limiting, temperature-controlled oxidation mechanism, enabling the fabrication of graphene nanoribbons with precise control. Second, to achieve high-density patterning without standard lithography, we investigate the formation of porous anodic aluminum oxide (AAO) via anodization, successfully creating porous arrays with a diameter of 37 nm. Finally, we discuss the physical mechanisms governing these formation processes and their potential for the scalable, high-throughput fabrication of next-generation 2D material devices.

HL 20.17 Tue 18:00 P1

Universality of Raman spectroscopy for determining twist angle in diverse systems — •Ana Senkić[1], Nicolai Leonid Bathen[2], Thorsten Deilmann[1], Hendrik Lambers[1], Lara Blinov[1], Aleksandar Matković[3], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster, Münster, Germany — [2]Israel Institute of Technology, Haifa, Israel — [3]Chair of Physics, Department Physics, Mechanical Engineering, and Electrical Engineering, Montanuniversität Leoben, Leoben, Austria

Twisted bilayers of transition metal dichalcogenides form moiré superlattices, resulting in electronic moiré minibands [1]. Correlated phases hosted in these structures are prone to twist disorder given by lateral fluctuations of the moiré cell size [2]. We investigated this lateral twist inhomogeneity on twisted WSe2 bilayers using comprehensive correlative lateral force microscopy and Raman spectroscopy [3].

In this work, we expand the topic by investigating different twisted systems: artificially stacked fully encapsulated WSe2 bilayers, MoSe2/WSe2 heterobilayers and CVD-grown MoS2 bilayers. Moiré phonon frequencies obtained from Raman spectroscopy maps are utilized to determine the twist angle over micrometer-sized areas in these systems. Additionally, Raman mapping facilitates fast and non-destructive identification of homogeneous, high-quality regions in encapsulated and gated structures.

HL 20.18 Tue 18:00 P1

Nonlinear interference in a CrSBr BIC metasurface — •Fabian Glatz[1], Thomas Weber[2], Till Weickhardt[1], Luca Sortino[2], Andreas Tittl[2], and Giancarlo Soavi[1] — [1]Friedrich Schiller University Jena — [2]Ludwig Maximilians University of Munich

The active electrical [1] and all-optical [2] modulation of the nonlinear optical (NLO) response of layered materials has attracted great interest for nanophotonic applications. Ferroic layered materials, such as CrSBr, offer an alternative and powerful approach for NLO tuning thanks to temperature-dependent phase transitions [3]. Here, we present a new method where NLO modulation arises from interference effects between bound states in the continuum (BIC) resonances and the bulk NLO susceptibility of a CrSBr nanophotonic device. To achieve this, we patterned exfoliated CrSBr flakes into metasurfaces that exhibit BICs and investigated their NLO response. By varying the dimensions of the metasurface, we obtain direct control over the energy, linewidth and Q-factor of the BIC resonances [4]. When the energy of the BIC resonance is close to that of the CrSBr exciton, we further observe a strong modulation in third harmonic generation (THG), characterized by both constructive and destructive interference depending on the energy of the emitted TH signal. These results allow us to retrieve the real and imaginary parts of the BIC-resonance, and they further demonstrate a new powerful approach for NLO engineering at the nanoscale. *[1] Soavi et al. Nat. Nanotech. 13, (2018). [2] Klimmer et al. Nat. Photon. 15, (2021). [3] Wang et al. Nat. Com. 14, (2023). [4] Weber et al. Nat. Mater. 22, (2023).*

HL 20.19 Tue 18:00 P1

Surface acoustic wave spectroscopy on low dimensional semiconductor materials — •Paul Hollatz, Felix Ehring, Paromita Bhattacharjee, Emeline Nysten, and Hubert Krenner — Intitute of Physics, University of Münster, Germany

For future technologies, low-dimensional quantum materials such as 2D transition metal dichalcogenides (TMDCs), 1D Nanowires, or 0D Quantum Dots (QDs) are of highest relevance.

Studying the properties of such semiconductor nanomaterials can be achieved by various methods, including the combination of surface acoustic wave (SAW) spectroscopy and photoluminescence (PL) measurements, which provides unique access to carrier dynamics.

In this approach, SAWs operating in the MHz to GHz regime enable on-chip integration due to their micro- to nanometer wavelengths.

Here, we show that interaction of a SAW with co-integrated materials via its strain and the electrical field enables contact-free sensing and manipulation of their optical properties.

When combined with time-integrated and time-resolved PL measurements, it reveals excitation pathways and charge-carrier behaviour, offering deeper insight into the fundamental processes that govern these materials and paving the way for advanced optoelectronic applications.

HL 20.20 Tue 18:00 P1

Interfacial Electronic Coupling in WS2-PyMACl van der Waals Heterostructures — •Mohammed Adel Aly[1,2], Dominik Muth[3], Bettina Wagner[4], Martin Koch[2], Johanna Heine[4], and Marina Gerhard[3] — [1]Institute of Physics and Center for Nanotechnology, University of Münster, 48149 Münster, Germany — [2]Department of Physics and Marburg Centre for Quantum Materials and Sustainable Technologies, Semiconductor Photonics Group, Philipps-Universität Marburg, 35032 Marburg, Germany — [3]Department of Physics and Marburg Centre for Quantum Materials and Sustainable Technologies, Semiconductor Spectroscopy Group, Philipps-Universität Marburg, 35032 Marburg — [4]Department of Chemistry and Marburg Centre for Quantum Materials and Sustainable Technologies, Philipps-Universität Marburg, 35032 Marburg, Germany

Interfacial coupling in mixed van der Waals systems enables tuning of the optical response of 2D semiconductors. We investigate heterostructures based on monolayer WS2 and few-layer organic crystalline pyrenemethylammonium chloride (PyMACl). Time-resolved photoluminescence shows a pronounced shortening of the PyMACl emission lifetime, indicating efficient interfacial coupling. Polarization-resolved measurements show a clear polarization anisotropy in WS2 within the heterostructure, pointing to symmetry breaking induced by the organic crystal. These observations demonstrate electronic coupling across the interface and highlight ionic organic crystals as functional substrates for tailoring excitonic behavior in 2D materials.

HL 20.21 Tue 18:00 P1

Optical Properties of a Transition-metal Dichalcogenide - ZnO Nanowire Field-effect Transistor — •Yashvi Bulsara[1], Maximilian Tomoscheit[1], Omid Ghaebi[1], Edwin Eobaldt[1], Carsten Ronning[1], and Giancarlo Soavi[1,2] — [1]Institute of Solid State Physics, University of Jena — [2]Abbe Center of Photonics, University of Jena

Transition-metal dichalcogenide (TMD) monolayers combined with zinc-oxide (ZnO) nanowires (NW) represent a promising platform for electrically tunable nanophotonic devices. ZnO NWs can be used as nanoscale lasers, supporting waveguiding, field amplification and being the gain medium at the same time. A further major step towards the success and broad applicability of NW lasers, is the possibility to actively tune their laser properties via external stimuli, such as the piezo-electric effect[1]. Recently, we have demonstrated that coupling of ZnO NWs to monolayer TMDs leads to an increase of the lasing intensity threshold[2]. Building on this approach, in this poster I will propose a device where the laser emission of a ZnO NW can be electrically tuned by coupling it to a TMD based field-effect transistor. Besides the main idea and device architecture, I will present preliminary results of device fabrication and characterization.

HL 20.22 Tue 18:00 P1

Optical Properties of He^+-Irradiated CrSBr — •Alison Pfister[1], Daria Markina[1], Shengqiang Zhou[2], Regine von Klitzing[1], Kseniia Mosina[3], Zdenek Sofer[3], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 6-8, D-64289 Darmstadt, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, Bautzner Landstraße 400, 01328 Dresden, Germany — [3]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Technicka 5, 166 28 Prague 6, Czech Republic

CrSBr, a van der Waals layered magnet, exhibits rich interactions among quasiparticles, involving photons, excitons, and spins. Although antiferromagnetic in its bulk pristine form with ferromagnetic intralayer order, irradiation with He^+ ions drives CrSBr into a ferromagnetic state, enabling novel optical behaviour without applying an external magnetic field. We probe the optical response using polarization-resolved Raman spectroscopy together with absorption and photoluminescence excitation (PLE) measurements. Pronounced changes in Raman intensity and polarization alongside marked variations in absorption near the Curie temperature, and resonant features in PLE spectra were observed. Analysis of Raman tensor evolution and anomalous temperature-dependent behaviour of excitons in absorption highlights intricate coupling between lattice, electronic, and magnetic states, positioning CrSBr as an attractive platform for exploring quasiparticle physics in 2D magnets and related quantum technologies.

HL 20.23 Tue 18:00 P1

Creating Chalcogenide Aeromaterials through Atomic Layer Deposition — •Vladimir Ciobanu[1], Alejandra Ruiz-Clavijo[2], Tudor Braniste[1], Sebastian Lehmann[2], Niklas Wolff[3], Dongho Shin[2], Eduard Monaico[1], Rainer Adelung[3], Lorenz Kienle[3], Kornelius Nielsch[2], and Ion Tiginyanu[1] — [1]Technical University of Moldova, Chisinau, Moldova — [2]Leibniz Institute of Solid State and Materials Research, Dresden, Germany — [3]Kiel University, Kiel, Germany

In this work, we report the development of SnS2 and SnSe2 aeromaterials synthesized via ALD on sacrificial ZnO microtetrapod templates. The ALD process enables conformal coating of the 3D ZnO microtetrapod network with precise thickness control. The resulting SnS2 and SnSe2 shells retain the original tetrapodal morphology after selective ZnO removal in acid, forming a hollow microtubular structure with the wall thickness of about 50 nm and very high porosity. Structural characterization by XRD revealed that the as-deposited films are amorphous, while post-deposition annealing in a S or Se atmosphere at 250 °C induces crystallization of SnS2 or SnSe2. SEM demonstrated uniform coverage and preservation of the porous aeromaterial network. TEM revealed the presence of SnSx or SnSex phases with multidomain. These results highlight the

capability of ALD to fabricate crystalline, compositionally controlled, and geometrically complex chalcogenide aeromaterials with strong potential for photoactive and catalytic applications. Acknowledgements: We thank the BMFTR and NARD for the funding of ProMoMo project DEHYCONA.

HL 20.24 Tue 18:00 P1

HL 20.25 Tue 18:00 P1

Investigating few-layer 3R-MoS_2 on top of laser-written waveguides — •Elisabeth Grune[1], Alina Schubert[1], Karoline Becker[1], Rico Schwartz[1], Andreas Thies[2], Alexander Szameit[1], Takashi Taniguchi[3], Kenji Watanabe[3], Matthias Heinrich[1], and Tobias Korn[1] — [1]Insitute of Physics, University of Rostock, Rostock, Germany — [2]Ferdinand-Braun-Institut, Leibniz-Institut für Höchstfrequenztechnik, Berlin, Germany — [3]National Institute for Material Science, Tsukuba, Japan

The properties of 3R-MoS_2, ranging from photoluminescence to second-harmonic generation, have attracted increasing scientific interest in recent years. Our goal is to couple these optical properties evanescently to an laser-written optical waveguide running along the substrate's surface. As a first step, we manufactured a system containing an hBN-encapsulated few-layer 3R-MoS_2 flake on top of a surface waveguide and investigated its photoluminescence signal in several optical geometries at room temperature as well as under cryogenic conditions. We find that when exciting the sample from above, the waveguide itself emits an unexpectedly high background fluorescence signal compared to the 3R-MoS_2 flake. We also use the waveguide itself to excite the flake, yet find that the previous fluorescence also dominates the spectrum. We discuss strategies for mitigating improving the present structures.

HL 20.26 Tue 18:00 P1

Transport simulations of bilayer graphene/WSe_2 electron-hole double quantum dots with spin-orbit coupling — •Nikita Berg[1,2], Hubert Dulisch[1,2], Roxana Anghel[1,2], Simone Sotgiu[1,2], Christian Volk[1,2], and Christoph Stampfer[1,2] — [1]JARA-FIT and 2nd Institute of Physics, RWTH Aachen University — [2]Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich

The electron-hole (e-h) symmetry in bilayer graphene (BLG) gives rise to robust spin-valley blockade in double quantum dots (DQDs) operated in the e-h regime. This enables the system to serve as a sensitive probe for blockade-breaking mechanisms. BLG/WSe_2 heterostructures offer electrostatic tunability of proximity-induced spin-orbit coupling (SOC) through the layer selectivity of the electron and hole wave functions in BLG. In this system, one possible spin-blockade-breaking mechanism arises from Rashba-type SOC, which can mediate spin-flip tunneling between the dots.

We present a master-equation-based steady-state transport simulation framework that accounts for coherence effects in e-h BLG double quantum dots. Using this approach, we show that Rashba-mediated spin-flip tunneling produces a distinctive dependence of the e-h blockade lifting on the angle of the applied in-plane magnetic field. This predicted angular dependence provides a clear and experimentally testable signature of induced Rashba spin-orbit coupling in BLG/WSe_2 heterostructures.

HL 20.27 Tue 18:00 P1

Active Fabri-Perot interferometer cavity stabilization for high-resolution spectroscopy of low-light single-photon emitters — •F. Stechemesser[1], F. Schaumburg[1], C. Dietrich[2], H. Mannel[1], A. Rodriguez[2], J. König[2], C. Steiner[3], P. Pesch[3], A. Lorke[1], G. Prinz[1], M. Geller[1], and A. Kurzmann[2] — [1]Faculty of Physics, University of Duisburg-Essen and CENIDE, Germany — [2]Physikalisches Institut Fachgruppe Physik, Universität zu Köln, Germany — [3]Fachgruppe Physik, RWTH Aachen, Germany

Single-photon emission from solid-state quantum emitters, such as quantum dots and defects in 2D materials, with narrow linewidths is one of the key ingredients for future applications in quantum information processing. In photoluminescence spectroscopy, the linewidths of such emitters can be determined using a grating spectrometer. However, in resonance fluorescence and at low laser excitation intensity, such spectrometers reach their limits regarding resolution and optical sensitivity. We introduce an actively stabilized, narrow-linewidth (free spectral range of 30 GHz) Fabry-Perot interferometer (FPI) that is stabilized using the light from a frequency-tunable diode laser. The quantum emitter photons are sent through the FPI, which is scanned across the emitter resonances. This approach enables measurements on a single photon detector (APD) with extended integration times. The single photon sensitivity of an APD can then be used to resolve low-intensity optical resonances of the different quantum emitters with a resolution down to 60 MHz. We show first results of single photon emission from InAs quantum dots and defects in WSe_2 monolayers.

HL 20.28 Tue 18:00 P1

Temperature-Dependent Studies of Interlayer Exciton in PbI2/WS2 Heterostructure — •Tobias Manthei[1], Bhabani Sahoo[1], Ajay Kumar[2], Abhishek Misra[2], Chirag Palekar[1], and Stephan Reitzenstein[1] — [1]Institut für Physik und Astronomie, Technische Universität Berlin, Hardenbergstrasse 36, 10623 Berlin, Germany — [2]Department of Physics, Indian Institute of Technology Madras, Chennai 600036, India; Center for 2D Materials Research and Innovation, IIT Madras, Chennai 600036, India

We present temperature-dependent studies of interlayer exciton in PbI2/WS2 heterostructure. The interlayer exciton formed in such heterostructures consist of electron and hole situated at gamma point in Brillouin zone of respective materials. Hence these dipolar exction are twist angle independent and momentum direct while emitting at room temperature. Taking advantage of the stable nature of the interlayer exciton we investigated radiative lifetime along with polarisation as function of the temperature. We observe relatively long radiative lifetime at low temperature compared to room temperature. Furthermore, we measured the polarisation of the interlayer exciton, which suggests that the emission is elliptically polarised, with peak splitting occurring at high temperatures. This provides insight into spin-valley dynamics. Our studies establish solid foundation for further light-matter interaction experiments related to room temperature interlayer excitons integrated in microcavity.

HL 20.29 Tue 18:00 P1

Effective Theory of Feshbach Resonances in Two-Dimensional Semiconductors — •Maximilian Wolf and Richard Schmidt — Institut für Theoretische Physik, Universität Heidelberg, 69120 Heidelberg, Germany

Feshbach resonances in two-dimensional semiconductor bilayer systems have recently been demonstrated through experiments and first-principles calculations. Motivated by these findings, we introduce an effective model that captures the essential physics of these resonances. We show how the model parameters can be fixed directly from experimental data, enabling us to derive analytical scattering phase shifts and propagators in the few-body limit. With these results, observables at finite chemical potential can be computed using standard many-body techniques. As an example, we evaluate the exciton absorption spectrum in TMD materials and compare our predictions with experimental observations.

HL 20.30 Tue 18:00 P1

Manipulation of hybrid interlayer excitons in homobilayer MoS_2 — •Ankur Arora, Mathias Federolf, Atanu Patra, Subhamoy Sahoo, Monika Emmerling, Anuj Kumar Singh, Simon Betzold, and Sven Höfling — Lehrstuhl für Technische Physik, Julius-Maximilians-Universität Würzburg, Würzburg, Germany

Van der Waals (vdW) heterostructures of transition metal dichalcogenide materials provide a versatile platform for novel excitonic phenomena. Homobilayer MoS_2 is particularly attractive, as its hybrid interlayer excitons (hIX) possess a permanent dipole moment with high oscillator strength, even at room temperature and exhibit tunability via the quantum-confined Stark effect under an external DC electric field. In this work, we investigated the optical properties of hIX in homobilayer MoS_2, which is electrically contacted with few-layer graphene (FLG) and encapsulated in hexagonal boron nitride (hBN). The hBN encapsulation improves the optical response by narrowing the excitonic linewidths, revealing the effect of the dielectric environment. By applying a vertical electric field, we show the Stark splitting of the peaks of the hIX. The vdW heterostructure is transferred onto a distributed Bragg reflector (DBR) with pre-patterned contacts forming a half-cavity design. This architecture serves as a critical first step toward the fabrication of a full microcavity, enabling the exploration of strong light-matter coupling. Our results pave the way for electrically tuning these dipolar hIX polaritons inside a microcavity for fundamental studies on exciton condensates and exciton polariton-induced superconductivity.

HL 20.31 Tue 18:00 P1

SH modulation in a TMD-graphene heterostructure — •Raja Hoffmann[1], Lisa Suchomel[1], Omid Ghaebi[1], Till Weickhardt[1], and Giancarlo Soavi[1,2] — [1]Friedrich-Schiller-Universität Jena, Germany — [2]Abbe Center of Photonics, Jena, Germany

One of the most fascinating properties of layered materials is arguably the possibility to combine them in heterostructures with engineered electronic and optical properties. In the field of nonlinear optics, a clear example is the emergence of second harmonic generation (SHG) in layered heterostructures realized by combining centrosymmetric materials. In such samples, interface broken space inversion symmetry can be engineered in different ways depending on the choice of materials and twist angle. An interesting example, which has been investigated recently in Ref.[1], are heterostructures composed of bilayer TMDs and monolayer graphene. As charges move from the TMD into the graphene, an imbalance between the bottom and top layers in the TMD bilayer leads to breaking of the inversion symmetry.

Building on these previous seminal results, we further investigate a bilayer TMD-monolayer graphene gated device, focusing in particular on both gate and all-optical tuneability of its engineered SHG. With this, we aim to add another prototype sample to the growing list of nonlinear nanophotonic devices based on layered materials and displaying ultrafast tunable optical properties [2,3].

HL 20.32 Tue 18:00 P1

Electrical and optical studies of twisted graphene bilayers — •Anselm Watschke, Monica Kolek Martinez de Azagra, and Thomas Weitz — I. Physikalisches Institut, University of Goettingen

As a van der Waals heterostructure, twisted bilayer graphene shows rich angle-dependent electronic behavior, including magic-angle superconductivity [1] and near-30° interlayer decoupling [2], motivating efforts to tune its electrical properties through multiple degrees of freedom. Furthermore, in situ quantum twisting microscope measurements revealed the angle dependent tunneling current for small regions of twisted bilayer graphene [3].

In this work, we fabricated devices incorporating a locally twisted bilayer graphene region, enabling simultaneous investigation of the off-angle regime and adjacent monolayer domains. Encapsulation in hexagonal boron nitride was used to maintain the intrinsic behavior of graphene, and vibrational and electronic properties were subsequently examined through Raman spectroscopy and gate-tunable transport measurements.

HL 20.33 Tue 18:00 P1

Laser induced oxidation of thin layered MoS2 — •Aniketa Anampally, Gerhard Berth, Klaus Jöns, and Henry Hübschmann — Paderborn University, Germany

Transition metal dichalcogenides (TMDs) have gained great attention within the growing field of 2D materials. Due to their inherent semiconductor properties, materials like molybdenum disulfide (MoS2) have been implemented in many components of photonic and optoelectronic devices [1,2]. Precise structural modification has been proven to exhibit significant benefits to build tailored devices on the nanoscale [3]. In this work nonlinear microscopy is utilized for in-situ probing and laser oxidation of mechanically exfoliated 2H-MoS2. Precise locally resolved oxidation has been performed by second harmonic microscopy. The arising layer number dependency of this treatment is investigated further supported by polarization resolved analysis.

HL 20.34 Tue 18:00 P1

Optimization of quantum dot in nanowire for efficient emission in telecom spectral range — •Tomasz Gzyl[1], Giada Bucci[2], Valentina Zannier[2], Paweł Mrowiński[1], Anna Musiał[1], Elisa García-Tabarés[3], Ileana Florea[4], Beatriz Galiana[3], Lucia Sorba[2], Wojciech Rudno-Rudziński[1], and Grzegorz Sek[1] — [1]Wrocław University of Science and Technology, 50-370 Wrocław, Poland — [2]NEST Istituto Nanoscienze CNR and Scuola Normale Superiore, 56127 Pisa, Italy — [3]Universidad Carlos III de Madrid, 28903 Getafe, Spain — [4]CNRS-CHREA, 06560 Valbonne, France

One of the promising platforms for realization of a single photon source emitting in telecom wavelengths is an InAs(P) quantum dot (QD) embedded in a nanowire (NW), designed to enhance extraction efficiency and directionality of QD emission. Chemical Beam Epitaxy technique is employed to grow the QD within novel zinc-blende InP NW or wurzite InAsP NW. Here, we present numerical simulations of the QD-NW system, using finite-difference time-domain method to find optimal NW geometry for maximal extraction efficiency, within numerical aperture of 0.4 used in experiment and taking into account parameters space limited by the growth technology. To verify the calculations and further guide the growth of optimized structures, we performed microphotoluminescence measurements as a function of excitation power on samples with different composition and NW shell diameter. The structural quality of the samples was confirmed using Scanning Transmission Electron Microscopy with Energy Dispersive X-ray Spectroscopy.

HL 20.35 Tue 18:00 P1

Electrostatic Inter-Layer Coupling Between Self-Assembled Quantum Dot Layers — •Jan Lange[1], Lukas Berg[1], Laurin Schnorr[1], Charlotte Rothfuchs-Engels[2], Nikolai Bart[2], Severin Krüger[2], Sven Scholz[2], Arne Ludwig[2], Andreas Wieck[2], and Thomas Heinzel[1] — [1]Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany — [2]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität, Bochum, Germany

In this study, transient capacitance spectroscopy is used to examine the coupling between self-assembled quantum dots (SAQDs) - made of InAs in a GaAs heterostructure - in spatially separated layers. A rate equation model was developed, incorporating self-consistent band bending calculations, to describe the impact of the inter-layer coupling on the charge transfer processes. Here, also effects caused by the wetting layer are described and included into the model. The findings indicate that the coupling arises from the electrostatic field generated by the charged quantum dots in the adjacent layer as well as charge in a wetting layer, providing a quantitative explanation for the altered electron capture and emission dynamics.

HL 20.36 Tue 18:00 P1

Illumination Response of Electron Capture and Emission Dynamics in Self-Assembled Quantum Dots — •Till Draxler[1], Jan Lange[1], Julia Avdeev[1], Sven Scholz[2], Arne Ludwig[2], Andreas Wieck[2], and Thomas Heinzel[1] — [1]Condensed Matter Physics Laboratory, Heinrich-Heine University Düsseldorf — [2]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum

InAs Self Assembled Quantum Dots (SAQDs) are nanoscale semiconductor structures that confine charge carriers in all three spatial dimensions, leading to discrete, atom-like energy levels. Using Deep Level Transient Spectroscopy (DLTS) the influence of infrared irradiation with photon energies in respect to the bandgap energies of GaAs and InAs on the electron transfer dynamics is studied. To maintain a proper illumination of the SAQDs, semi-transparent NiCr Schottky gates are manufactured instead of classical Au gate.

HL 20.37 Tue 18:00 P1

Optimized quantum dot emitters for telecom applications: from growth to diode integration — •Tobias Bruggesser, Ponraj Vijayan, Patrick Pietrantuono, Sergej Vollmer, Philipp Noack, Justus A. Unfried, Ulrich Pfister, Michelle Weiss, Simone L. Portalupi, Michael Jetter und Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen, University of Stuttgart, Germany

Quantum communication and quantum computing applications require a reliable high-purity single photon source. Stranski-Krastanov grown indium arsenide (InAs) quantum dots (QDs) are among the most widely studied candidates, as they possess high purity, brightness, and indistinguishability. When embedded in a GaAs semiconductor matrix, these QDs emit in the near-infrared region (≈ 900 nm), and this can be shifted to the technologically important telecom C-band (1530-1565 nm) by introducing an InGaAs metamorphic buffer (MMB) beneath the QDs to engineer the strain. Our group has previously developed a thin InGaAs MMB based on a non-linear grading of the indium content with a so-called jump-convex-inverse (jci) design. This design is compatible with optical device fabrication, as it can be incorporated into a high-quality 1λ-cavity structure. In this work, we present our approach towards integrating these telecom C-band emitting InAs QDs into a p-i-n diode structure. Our goal is to control the charge carrier environment of the QDs, improve their optical properties, and achieve fine-tuning of the emission energy via the quantum-confined Stark effect.

HL 20.38 Tue 18:00 P1

Design and optimization of photonic nanostructures for embedding GaAs quantum dots emitting at 780 nm — •Mrunmayee Deodhar[1], Ponraj Vijayan[1], Katharina Dahler[1], Ulrich Pfister[1], Michelle Weiss[1], Melina Peter[2], Ailton José Garcia Jr.[2], Thomas Oberleitner[2], Michael Jetter[1], Simone Luca Portalupi[1], Armando Rastelli[2], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, Germany — [2]Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, 4040 Linz, Austria

Droplet-etched GaAs quantum dots (QDs) are a promising source for single and highly indistinguishable photons. Their optical properties like a narrow wavelength distribution, short decay times, linewidths close to the Fourier limit, and the resulting highly indistinguishable photons make them highly appealing for

several quantum technologies. We demonstrate the integration of these QDs into photonic nanostructures such as single-mode waveguides, multimode interference splitters, and Bragg grating waveguides. We also present simulations and describe the fabrication process used to realize these photonic nanostructures.

HL 20.39 Tue 18:00 P1

Auger-recombination in no-wetting layer InAs self-assembled quantum dots — •M. Rasulyar[1], H. Mannel[1], F. Rimek[1], A. Ludwig[2], A. Lorke[1], and M. Geller[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, 47057 Duisburg, Germany — [2]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, 44780 Bochum, Germany

The Auger-Meitner effect is a non-radiative recombination pathway in which the energy of an electron-hole pair is transferred to a third carrier. In colloidal quantum dots, this mechanism is known to suppress radiative emission, while in self-assembled InAs/GaAs quantum dots, both non-radiative Auger processes [1] and radiative Auger-like channels [2] have been reported. However, as Auger recombination is a dephasing effect in quantum dot-based single-photon devices, we study the influence of the confining potential on the non-radiative Auger recombination rate.

We investigate the Auger-Meitner dynamics in a no-wetting layer quantum dot incorporated in a gate-tunable p-i-n diode. Under resonant excitation of the trion transition, we observe a pronounced quenching of the resonance-fluorescence signal. The intensity reduction is quantitatively explained by the competition between the electron emission rate and the electron tunneling-in rate. The Auger recombination rate is in the order of $1\,\mu s^{-1}$ and in accordance with previous measurements with a rate of $\gamma_a = 2.3\,\mu s^{-1}$ [1]. [1]A. Kurzmann et al., Nano Lett. 16, 3367 (2016). [2]M. Löbl et al., Nat. Nanotechnol. 15, 558-562 (2020). [3]M. Löbl et al., Commun. Phys. 2, 93 (2019).

HL 20.40 Tue 18:00 P1

Single-electron charging events on double quantum dots in InSb nanowires — •Kanji Furuta[1], Marcus Liebmann[1], Fenja Thomsen[1], Sasa Gazibegovic[2], Diana Car[2], Erik Bakkers[2], and Markus Morgenstern[1] — [1]II. Phys. Inst. B, RWTH Aachen Univ., Germany — [2]Dept. of Appl. Phys., Eindhoven Univ., The Netherlands

As a step to develop a single-electron counting tip for a scanning tunneling microscope, we investigate the charge states of a double quantum dot (DQD) formed in an InSb nanowire by monitoring the current through a floating-gate-coupled sensor quantum dot (QD). The DQD and sensor QD are defined electrostatically by bottom finger gates below hexagonal boron nitride (h-BN) used as the gate dielectric. Time-resolved measurements of the sensor QD current reveal single-electron charging events in the DQD. The asymmetric capacitive coupling of the floating gate allows us to identify which dot acquires an electron. The time traces of the double quantum dot movement of individual electrons are analyzed using full counting statistics, from which the Fano factor and factorial cumulants [1] are extracted.

HL 20.41 Tue 18:00 P1

Towards a Quantitative Framework for Capacitance-Voltage Spectroscopy in Quantum Dot Ensembles — •Phil Julien Badura[1], Nico Frédéric Brosda[1], Ismail Bölükbaşı[1], Ibrahim Engin[1], Patrick Lindner[1], Sascha René Valentin[1], Andreas Dirk Wieck[1], Björn Sothmann[2], and Arne Ludwig[1] — [1]Fakultät für Physik und Astronomie, Experimentalphysik VI, Ruhr-Universität Bochum, Bochum, Germany — [2]Fakultät für Physik and CENIDE, Universität Duisburg-Essen, Lotharstraße 1, D-47048 Duisburg, Germany

This study investigates an inhomogeneous ensemble of quantum dots coupled to a charge reservoir using capacitance-voltage spectroscopy. Experimental measurements reveal shifts in capacitance peak positions influenced by AC frequency and temperature, with frequency-dependent shifts remaining unexplained by existing models. To address this, we develop a master-equation-based theoretical model incorporating energy-dependent tunneling effects, which successfully reproduces the experimental data. Our findings emphasize the role of energy-dependent tunneling in distinct regimes: at low temperatures, energy-level dispersion dominates, while at high temperatures and frequencies, shifts arise from optimized sequences of in- and out-tunneling events.

HL 20.42 Tue 18:00 P1

Towards the integration of telecom C-band QDs into photonic integrated circuits — •Michelle Weiss, Ulrich Pfister, Ponraj Vijayan, Simon Oberle, Justus Unfried, Philipp Noack, Tobias Bruggesser, Sergej Vollmer, Raphael Joos, Michael Jetter, Simone L. Portalupi, and Peter Michler — Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), University of Stuttgart, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, Germany

Photonic integrated circuits (PICs) pave the way to the realization of several quantum technologies on a small footprint, which makes them highly desirable for applications in quantum communication, computing, simulation and sensing. Silicon and silicon nitride are leading materials for PICs due to the high quality optical components and low optical propagation losses. Due to the indirect bandgap of silicon most of the single-photon sources (SPSs) are based on probabilistic implementations. However, the probabilistic generation of the photons can limit the scalability and requires the use of high laser powers, which is a potential drawback regarding the integration of on-chip detectors. In this regard, In(Ga)As quantum dots (QDs) are promising candidates as on-demand SPSs with high single-photon purity. For their integration on low-loss PICs, several approaches already exist, like monolithic integration techniques and hybrid approaches used for interfacing with silicon-based platforms. We present the progress on various PIC integration techniques for InGaAs QDs grown on a metamorphic buffer layer and so emitting in the telecom C-band.

HL 20.43 Tue 18:00 P1

Aharonov-Bohm interferometry with interacting quantum dots — •Oliver Oing, Alexander Hahn, Jürgen König, and Fred Hucht — Theoretische Physik, Universität Duisburg-Essen

We describe an Aharonov-Bohm interferometer consisting of two leads and two tunnel-coupled quantum dots with on-site Coulomb interaction using first order perturbation theory in the tunnelling strength. In earlier work, a diagrammatic approach was chosen. The complexity of the diagrams for arbitrary parameters limited the calculations to symmetric systems in energies and couplings. By developing a systematic routine in *Mathematica* to generate all possible diagrams, we can explore a wider range of system configurations. Eleven system parameters can be arbitrarily tuned, namely the finite Coulomb interactions, the quantum dot level energies as well as the tunneling strengths, magnetic flux, bias voltage and temperature, enabling us to describe both symmetric and asymmetric systems. A finite bias voltage makes it possible to explore the non-linear response regime. The routine calculates density matrix elements and uses these to obtain the occupations of the quantum dots, the current and the conductance through the system. With this, we compare to analytic results and numerically exact results obtained with the TraSPI method [1].

HL 20.44 Tue 18:00 P1

Characterization of Quantum Dots after Rapid Thermal Annealing in Photonic Layer Structures — •Jasper Ullrich, Severin Krüger, Elias Kersting, and Arne Ludwig — Universitätsstraße 150, Bochum 44801

Rapid thermal annealing (RTA) is an effective post-growth technique for engineering the structural and optoelectronic properties of InGaAs quantum dots (QDs). Short, high-temperature pulses induce controlled interdiffusion that blueshifts the emission wavelength, reduces inhomogeneous broadening, and modifies carrier confinement. In this work, we investigate how specific annealing conditions*temperature, duration, and ambient environment*govern these changes and, in particular, how they influence the oscillator strength of confined excitonic transitions. We expect to show that optimized RTA parameters significantly enhance radiative coupling of QDs, leading to increased oscillator strength and faster emission dynamics. These results would provide a systematic framework for tailoring the optical performance of InGaAs QDs for quantum-light sources, high-speed emitters, and infrared photonic devices.

HL 20.45 Tue 18:00 P1

Ohmic contact for charge tuning devices — •Krupali Dobariya[1], Tom Fandrich[1], Yiteng Zhang[1], Arijit Chakraborty[1], Sulabh Shrestha[1], Doaa Abdelbarey[1], Eddy P. Rugeramigabo[1], Michael Zopf[1,2], and Fei Ding[1,2] — [1]Leibniz Universität Hannover Institut für Festkörperphysik, Appelstraße 2, 30167 Hannover, Germany. — [2]Leibniz Universität Hannover Laboratorium für Nano- und Quantenengineering, Schneiderberg 39, 30167 Hannover, Germany.

Semiconductor quantum dots have shown unique properties as deterministic single photon and entangled photon pair sources. Their outstanding optical properties have the potential for use in quantum applications like quantum communication, quantum key distribution and quantum computing. Nevertheless, due to the stochastic nature of the self-assembly growth process, quantum dots typically emit photons with a broad wavelength distribution across the entire chip, posing challenges for applications requiring specific wavelengths. To address this issue, various tuning techniques have been developed. Electrical tuning, in particular, has emerged as an effective method for adjusting the wavelength and mitigating charge noise in semiconductor quantum dots. Here we study the impact of contact fabrication on the emission properties of GaAs quantum dots. We aim to optimize the process of forming ohmic contacts to n- and p-doped GaAs, placing special emphasis on the selection of materials and the reduction of contact resistance. The quality and performance of the electrical contacts are evaluated through the photoluminescence characterization.

HL 20.46 Tue 18:00 P1

Mixed-dimensional Silicon Junctionless Nanowire Transistors with Hexagonal Boron Nitride Gate Dielectrics — •Ahmed Elwakeel[1,2], Sayantan Ghosh[1,2], Alessandro Puddu[1,2], Madhuri Chennur[1,2], Slawomir Prucnal[1], Yordan Georgiev[1], Ahmad Echresh[1], and Artur Erbe[1,2] — [1]1Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [2]Technische Universität Dresden, 01069 Dresden, Germany

The investigation of two-dimensional hexagonal boron nitride (hBN) as a gate dielectric arises from the intrinsic limitations of conventional oxide layers in aggressively scaled devices. Owing to its atomically thin structure, excellent insulating characteristics, and inherently clean surface free of dangling bonds, hBN enables improved electrostatic control and effective channel passivation. In Junctionless Nanowire Transistors (JNTs), which remain strong contenders for extending Moore's Law, the use of hBN offers the potential to suppress interface trap states and enhance carrier transport. In this work, a top-down fabrication approach was employed to define the n-type doped silicon nanowires (C = 1E19 cm-3). Two distinct JNT devices were prepared: one with native oxide and another incorporating a thermally grown oxide. Subsequently, exfoliated hBN flakes were dry-transferred onto both samples as a gate dielectric. The hBN-integrated JNTs with thermally grown oxide exhibited pronounced improvements in subthreshold swing, on-state current, and the ION/IOFF ratio.

HL 20.47 Tue 18:00 P1

Importance of Aluminium Quality for High-Quality Quantum Emitter — •Severin Krüger[1,2], Elias Kersting[1], Phil Badura[1], and Arne Ludwig[1] — [1]Ruhr-Universität Bochum, Bochum, Germany — [2]Sparrow Quantum Aps, Copenhagen, Denmark

InAs quantum dots are regarded as excellent candidates for single photon emitters due to their high photon rates, good single photon properties, and compatibility with scalable and integratable photonic platforms.

Despite remarkable progress for quantum dots emitting at 950 nm, achieving the same results for quantum dots emitting in the important optical fibre transparency window around 1.3 *m has remained a major challenge.

Here we present a routine we used to monitor and improve the quality of aluminium containing layers grown in our MBE. We find that high quality Al in MBE significantly improves the interface quality and smoothness of Al(Ga)As layers by reducting the surface roughness.

These improvements enabled the growth of pristine distributed Bragg reflectors beneath a defect free, charge tunable quantum dot device, emitting near transform-limited single photons in the O-band at 1.3 um.

HL 20.48 Tue 18:00 P1

RoHS-Compliant Nanocrystal LEDs for Flexible Near-Infrared Biomedical Emitters — •Simon Letzer[1], Andrey Iodchik[2], Rabiul Islam[1], Vladimir Lesnyak[2], and Caroline Murawski[1] — [1]Institute of Solid State Electronics, TU Dresden, Germany — [2]Physical Chemistry, TU Dresden, Germany

The near-infrared (NIR) biological window enables deep-tissue access for non-invasive imaging and health monitoring. Wearable emitters for this range require flexible and efficient materials, yet organic LEDs lose performance above 850 nm. Colloidal nanocrystals (NCs) offer a promising alternative for NIR emission, although most efficient systems contain Hg, Cd, or Pb, restricting their use in biomedical settings. We therefore investigate RoHS-compliant NCs for solution-processed NIR emitters. As a baseline, we employed CdHgSe/CdZnS core/shell NCs, which have already demonstrated strong performance in LEDs and provide a reliable platform for optimizing device processing [1]. Film quality is strongly influenced by concentration, solvent, dispense time, spin profile, and baking conditions. High-boiling-point solvents produced uniform macroscopic films, while low-temperature baking and high spin speeds improved nanoscale smoothness. Building on these conditions, we fabricated our first RoHS-compliant devices based on CuInS2/ZnS NCs. Processing parameters were refined for this material, and different transport layers and device architectures were evaluated. These results demonstrate a viable path toward cadmium-free NIR emitters for wearable biomedical sensors.

HL 20.49 Tue 18:00 P1

Stark Tuning of CsPbBr3 Quantum Dots — •Christopher Borchers[1], Johann Dzeik[1], Maximilian Heller[1], Frederik Benthin[1], Eddy Rugeramigabo[1], Chenglian Zhu[2,3], Ihor Cherniukh[2,3], Gabriele Rainò[2,3], Maksym Kovalenko[2,3], Michael Zopf[1,4], and Fei Ding[1,4] — [1]Leibniz Universität Hannover, Institut für Festkörperphysik, Appelstraße 2, 30167 Hannover — [2]Institute of Inorganic Chemistry, Department of Chemistry and Applied Biosciences, ETH Zürich, CH-8093 Zürich, Switzerland — [3]Laboratory for Thin Films and Photovoltaics, Empa - Swiss Federal Laboratories for Materials Science and Technology, CH-8600 Dübendorf — [4]Laboratory of Nano and Quantum Engineering, Leibniz University Hannover, Schneiderberg 39, D-30167 Hannover, Germany

CsPbBr3 perovskite quantum dots are bright, solution-processable nanocrystal emitters with size-tunable color and high oscillator strength. Furthermore, they can be fabricated and processed in a cheap and facile way. We investigate electric-field tuning of single dots through the quantum-confined Stark effect to minimize exciton fine-structure splitting and tune separate emitters into resonance with each other. This opens up possibilities of creating entangled photon pairs of super- and subradiance with perovskite quantum dot based photonic devices.

HL 20.50 Tue 18:00 P1

Low temperature dry etching of InAlAs/InP nanostructures for telecom band single photon sources — •Ankita Choudhary[1], Chenxi Ma[1], Yiteng Zhang[1], Eddy Patrik Rugeramigabo[1], Michael Zopf[1,2], and Fei Ding[1,2] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover, Germany — [2]Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, Schneiderberg 39, 30167 Hannover, Germany

Epitaxial InP-based quantum dots are excellent candidates for telecom band single photon sources for long-distance quantum communication. Enhancing photon extraction requires integration into photonic nanostructures through high resolution lithography and dry etching. Conventional chlorine-based ICP-RIE etching of InP is challenging due to competing thermal demands that lead to uncontrollable volatilisation of chlorine byproducts at high temperatures, while low-temperature cyclic methods result in defect-rich interfacial layers.Here we demonstrate low temperature chlorine based etching that circumvents byproduct volatilisation and stoichiometric imbalance and eliminates defect layer formation without intermediate chemical treatments. we demonstrate the fabrication of a submicron truncated cone with smooth sidewalls, enhancing spontaneous emission directionality. The fabricated nanostructure shows 3-4 times improved extraction efficiencies compared to as-grown samples, with an NA of 0.7 detection optics. This process provides a robust pathway for fabricating high-quality photonic nanostructures for quantum telecommunications.

HL 20.51 Tue 18:00 P1

Lateral Electric Field Tuning of Quantum Dots — •Johann Dzeik[1], Christopher Borchers[1], Chenxi Ma[1], Ankita Choudhary[1], Xian Zheng[1], Yiteng Zhang[1], Tom Fandrich[1], Arijit Chakraborty[1], Michael Zopf[1,2], and Fei Ding[1,2] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover, Germany — [2]Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, Schneiderberg 39, 30167, Hannover, Germany

Quantum dots are among the most promising material systems for single photon sources in quantum communication and computation. However, they exhibit a stochastic distribution of emission wavelengths and fine-structure splitting, necessitating post-growth tuning that must be compatible with their fabrication and photonic environment. In this study, we use planar electrodes in parallel and quadrupolar configurations at varying distances to investigate the influence of electric fields on the emission wavelength and fine-structure splitting of GaAs/AlGaAs quantum dots.

HL 20.52 Tue 18:00 P1

SUPER Scheme in Telecom-Wavelength Quantum Dots — •Zenghui Jiang — Leibniz Universität Hannover, Institut für Festkörperphysik, Appelstraße 2, 30167 Hannover

Co-authors: Vikas Remesh, Frederik Benthin,Thomas Bracht, Michael Jetter, Simone Portalupi, Doris Reiter, Peter Michler, Michael Zopf, Fei Ding

Abstract:

To obtain the best photon properties from quantum dots (QDs), direct driving between the S-shell and the ground state i.e., resonant excitation is typically required. However, laser filtering under resonant excitation is extremely challenging because the QD emission and the excitation laser lie at essentially the same wavelength. The recently proposed and experimentally demonstrated SUPER scheme addresses this challenge by using two relatively detuned laser pulses to directly drive the two-level system. Since the excitation and emission wavelengths are well separated, the scattered excitation laser can be spectrally filtered much more easily. In our work, we implement a pulse shaper based on a spatial light modulator to generate two well-defined laser pulses from a single broadband pulse for the SUPER scheme. In addition, we investigate SUPER excitation using two narrow-linewidth continuous-wave lasers as a comparison, enabling a clearer understanding of the excitation dynamics and the differences relative to pulsed operation.

HL 20.53 Tue 18:00 P1

Andreev Spin Qubits in Hole-Gas Based Nanowires with Mixed Superconducting Pairing — •Markus Plautz — Norwegian University of Science and Technology, Norway

Ge-based lower-dimensional hole gases proximitized by superconductors represent a promising platform for future quantum technologies, largely related to the complicated p-wave nature of the orbital wavefunctions of the valence band. While standard models often treat the induced superconductivity as purely s-wave, recent microscopic theories indicate that the proximity effect in these sys-

tems is far more complex. They reveal that the strong spin-orbit interaction can induce non-trivial mixed pairing correlations, featuring coexisting s- and p-wave terms.

We calculate the Andreev reflection phases and determine the Andreev bound state (ABS) energy spectrum in the presence of Zeeman and spin-orbit fields. In particular, we show how these odd-parity correlations influence the spin splitting, leading to distinct changes in the qubit energy levels. Furthermore, we discuss the coherent control of the qubit subspace by considering a time-dependent perturbation of the spin-orbit coupling. By deriving the exact transition matrix elements, we construct an effective Hamiltonian for the ASQ and investigate how this mechanism can be utilized to coherently drive the qubit.

HL 20.54 Tue 18:00 P1

Nonequilibrium transport in designed random obstacle arrays — •Frederik Bartels[1], Johannes Strobel[1], Beate Horn-Cosfeld[1], Mihai Cerchez[1], Klaus Pierz[2], Hans Werner Schumacher[2], Dominique Mailly[3], and Thomas Heinzel[1] — [1]Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany — [2]Physikalisch-Technische Bundesanstalt (PTB), Bundesallee 100, 38116 Braunschweig, Germany — [3]CNRS, Université Paris-Saclay, C2N Marcoussis, 91460 Marcoussis, France

Nonequilibrium transport phenomena in two-dimensional electron systems include Hall field induced resistance oscillations (HIROs), zero resistance states (ZRS), phase inversion of SdH oscillations, and modifications of the giant negative magnetoresistance (GNMR). In our recent work [1], we studied HIROs in two-dimensional electron gases dominated by scattering at artificially introduced, randomly distributed circular obstacles. For sufficiently high obstacle densities, these scatterers dominate the HIROs. The HIRO period increases with obstacle density, indicating a localization of the Hall field around the obstacles and providing an alternative explanation of the scaling factor γ in terms of spatially varying Hall fields. Here, we extend these studies to cross-shaped obstacle geometries designed to enhance backscattering - the central mechanism in the theory of HIROs [2]. The findings may help to establish a more unified understanding of nonlinear resistance oscillations in two-dimensional systems with artificial scatterers. [1] Bartels *et al.* Phys. Rev. B **111**, 165301 (2025), [2] Yang *et al.* Phys. Rev. Lett. **89**, 076801 (2002)

HL 20.55 Tue 18:00 P1

Tenfold Conductance Enhancement in Graphene Nanoscrolls via Interlayer Hopping — •Jia-Cheng Li[1], Yu-An Cheng[2], Ying-Je Lee[2], Xuan-Fu Huang[2], Yu-Jie Zhong[2], Carmine Ortix[3], and Ching-Hao Chang[2] — [1]Program on Key Materials, Academy of Innovative Semiconductor and Sustainable Manufacturing, National Cheng Kung University, Tainan 70101, Taiwan — [2]Department of Physics, National Cheng Kung University, Tainan 70101, Taiwan — [3]Institute for Theoretical Solid State Physics, IFW Dresden, Helmholtzstraße 20, 01069 Dresden, Germany

Rolling a graphene nanoribbon into a nanoscroll, a radial superlattice, offers a simple yet powerful way to control electronic transport at the nanoscale. In this work, we show that a one-turn nanoscroll exhibits a dramatic enhancement of quantum conductance compared to a flat ribbon, reaching nearly an order of magnitude in our tight-binding transport calculations. This effect does not rely on curvature-induced gauge fields or external perturbations. Instead, it arises purely from interlayer hopping at the overlapping edges of the scroll, which hybridizes the zigzag edge states and reconstructs the low-energy band structure. The resulting collapse of the flat bands reduces the density of states and shifts the Fermi level upward at fixed carrier density, activating multiple propagating modes. As the number of turns increases, these effects gradually weaken. Our findings identify nanoscrolls as a tunable geometry-driven platform for engineering transport in low-dimensional carbon systems.

HL 20.56 Tue 18:00 P1

Top-Down Fabrication and characterization of Al-Si-Al Nanowire Schottky barrier field-effect transistors — •Banafsheh Aghvami[1], Alessandro Puddu[1,2], Ahmed Elwakeel[1,2], Sayantan Ghosh[1], Ahmad Echresh[1], and Artur Erbe[1,2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstrasse 400, Dresden, 01328, Germany — [2]Technische Universität Dresden, Dresden, 01069, Germany

In Schottky barrier field-effect transistors (SBFETs), the channel length plays a crucial role in device performance. Shorter channels lead to lower channel resistance, stronger electrostatic gate control, reduced threshold voltage, and improved ON/OFF current ratios. However, to achieve sub-100 nm channel lengths using conventional top-down patterning approaches is extremely challenging due to resolution limits, line-edge roughness, and probable alignment errors. In contrast, the Al-Si-Al solid-state exchange process via rapid thermal annealing (RTA) enables the formation of well-defined and self-aligned short silicon channels. In this study, electron beam lithography (EBL) is used to define nanowire structures into HSQ resist. Then, the patterned structures will be transfered into the silicon layer by Inductively Coupled Plasma-Reactive Ion Etching (ICP-RIE). The Aluminium metal contacts will be formed by sputtering deposition. Scanning Electron Microscopy (SEM) will be employed to analyse the Al-Si-Al heterostructure. In addition, the performance of fabricated SBFETs will be evaluated by electrical characterisation using back-gated configuration.

HL 20.57 Tue 18:00 P1

Organic LEDs for optogenetic cochlear implants — •Nirbhika Nandakumar and Caroline Murawski — Dresden University of Technology, Dresden, Germany

Recent studies have highlighted the potential of optogenetic cochlear implants (oCIs) to surpass the spatial resolution limitations of conventional electrical stimulation by utilizing confined light to activate genetically modified auditory neurons [1]. Existing oCI prototypes predominantly use micro-LEDs, which can generate high optical power but are constrained by thermal load, rigidity, and limited scalability toward dense stimulation arrays [2]. In this work, we investigate organic light-emitting diodes (OLEDs) as alternative light sources for next-generation oCIs. Bottom-emitting OLEDs were fabricated and experimentally characterized with respect to spectral emission, efficiency, and achievable optical power density. The micro-cavity was designed by complementary optical simulations to generate a forward-directed, spatially confined illumination capable of efficiently reaching the intended spiral ganglion neurons. An implant design is proposed based on the geometry of the cochlea, required pixel size, and spacing. The combined experimental and simulation results establish OLEDs as promising alternatives to micro-LEDs for integration into future oCI architectures.

HL 20.58 Tue 18:00 P1

Creation and characterization of color centers in hexagonal Boron Nitride — •Dennis Heinz Bruno Mors[1,2], Iris Niehues[1], and Daniel Wigger[3] — [1]Institute of Physics, University of Münster, 48149 Münster, Germany — [2]Faculty of Science and Technology, University of Twente, 7522 NB Enschede, Netherlands — [3]Department of Physics, University of Münster, 48149 Münster, Germany

Color centers (CCs) in hexagonal boron nitride (hBN) are promising candidates for stable and bright quantum light sources, despite their unknown origin due to their single-photon emission properties even at room temperature. To explore their potential, we investigate various material sources for their ability to host CCs. We employ mechanical exfoliation to reduce the thickness of bulk crystals to a few layers, resulting in thin hBN flakes that are then transferred onto Si or SiO_2 samples. To enhance the yield of CCs, we thermally anneal the hBN. We then examine our samples using confocal photoluminescence to identify the CCs in the host crystal. Additionally, we utilize a scattering-type scanning near-field optical microscope (sSNOM) to study the photoluminescence (PL) emission characteristics of these quantum emitters. By using a sharp metallic tip, we concentrate the illuminating light field into a nanofocus, enabling us to achieve nanoscale resolution beyond the diffraction limit.[1]

HL 20.59 Tue 18:00 P1

Spectral wandering of single-photon emitters in the van der Waals material hBN — •Akhilesh Dubey, Robert Schmidt, Johannes Kern, Steffen Michaelis de Vasconcellos, and Rudolf Bratschitsch — Institute of Physics and Center for Nanotechnology, University of Münster, 48149 Münster, Germany

Single-photon emitters in hexagonal boron nitride (hBN) exhibit favorable photophysical optical properties at both room and cryogenic temperatures. However, their performance is limited by various line broadening mechanisms. Here, we present a low-temperature study of the photoluminescence of hBN emitters, investigating linewidth reduction and spectral diffusion at cryogenic temperatures. We believe that the spectral wandering is due to migrating charges in the vicinity of the nanoscale emitter, which could be mitigated by applying an external electric field. Our results essential for developing nanoscale quantum photonic devices based on robust hBN emitters.

HL 20.60 Tue 18:00 P1

2D Lattices of Rb Quantum Emitters on Isolating Substrates — •David Bergmann, Katharina Lorena Franzke, Wolf Gero Schmidt, and Uwe Gerstmann — Paderborn University, Paderborn, Germany

Entanglement plays a decisive role in modern application of quantum information, such as memory atoms and quantum emitters. The central challenge in this context is to address, control and protect systems of many qubits against decoherence.[1] Recently, efficient generation of entangled multiphoton graphs from single ^{87}Rb atoms was reported, overcoming the limitations encountered by probabilistic schemes.[2]

In this theoretical work, we investigate the applicability of different isolating materials to be used as substrate for a 2D lattice or clusters of ^{87}Rb atoms. In contrast to MgO, frequently used in previous investigations [3], NaCl was found to be a substrate that minimizes substrate-mediated interaction between neighboring Rb atoms. It is thus expected to allow entanglement of several individ-

ual atoms as single emitters in the same cavity. Therefore, the system Rb/NaCl promises improved scalability and opens new possibilities for quantum computation and communications.

Dry transfer of 2D van der Waals heterostructures for quantum sensing — •Timo Strobl, Korbinian Felber, Paul Konrad, Andreas Sperlich, and Vladimir Dyakonov — Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

A highly dynamic research area is dedicated to the development of quantum sensors based on solid-state spin defects. This field was previously focused on three-dimensional (3D) material systems, which posed challenges in positioning spin centers close to the sample surface. The recent discovery of V_B^- spin defects in the 2D van der Waals (vdW) material hexagonal boron nitride (hBN) provided a new approach to overcome this inherent positioning limitation. These defects are suitable for sensing local magnetic fields, temperature, and lattice strain when utilizing the method of optically detected magnetic resonance (ODMR). Hence, these functional hBN layers constitute a powerful tool for investigating fundamental 2D material properties.

To apply the potential in this area, the fabrication of a van der Waals heterostructure is necessary, combining the spin-active hBN with another 2D material. The precise fabrication by stacking these multilayer 2D materials via established dry-transfer polymer techniques is an essential prerequisite for such quantum sensor structures. The preparation procedures presented here provide essential insights required to implement in situ quantum sensing of 2D materials utilizing hBN.

HL 20.62 Tue 18:00 P1

Development of open-source DRC scripts for physical verification of integrated circuits with FinFET technology. — •Lev Churkin — Moscow, Russia

The development of open-source DRC scripts for FinFET technologies necessitates a fundamental shift from planar-based verification. It must encapsulate the three-dimensional nature of the transistor, enforcing complex rules for fin formation, cut patterning, and their strict alignment. Furthermore, rules must integrate with multi-patterning lithography, addressing color decomposition and spacing constraints to prevent printability errors. This requires checking more than simple geometrics. Consequently, a modern DRC script is a complex software model, which needs to manage the interdependencies of density, stress engineering, and manufacturing variability at a more advanced level.

HL 20.63 Tue 18:00 P1

Exciton dressing by extreme nonlinear magnons in a layered semiconductor — •Geoffrey M. Diederich — University of Maryland Baltimore County, 1000 Hilltop Circle, Baltimore MD, USA

Collective excitations presenting nonlinear dynamics are fundamental phenomena with broad applications. A prime example is nonlinear optics, where diverse frequency-mixing processes are central to communication and attosecond science, and extreme (>sixth-order) harmonic generation provides broad wavelength conversion. Leveraging recent progress in van der Waals magnetic semiconductors, we demonstrate nonlinear optomagnonic coupling. In the layered antiferromagnetic semiconductor CrSBr, we observe exciton states dressed by up to 20 harmonics of magnons, resulting from their extreme nonlinearities. We also create tunable optical sidebands via sum- and difference-frequency generation between two optically bright magnon modes under symmetry-breaking magnetic fields. Moreover, we can tune the observed difference-frequency generation mode into resonance with one of the fundamental magnons, which results in parametric amplification of magnons. Our findings realize the modulation of the optical-frequency exciton with the extreme nonlinearity of magnons at microwave frequencies, which could find applications in magnonics and hybrid quantum systems, and provide a method for optomagnonic neuromorphic computing devices.

HL 20.64 Tue 18:00 P1

Synthesis and characterization of new materials from the Sb-Ag-Te system — •Trayana Dolchinkova, Vladislava Ivanova, and Yordanka Trifonova — University of Chemical Technology and Metallurgy, Department of Physics, 8 Kl. Ohridski Blvd., 1797 Sofia, Bulgaria

New bulk chalcogenide materials from the Sb-Ag-Te system were synthesized by single-temperature synthesis in a closed volume. The density of the bulk samples was estimated using the pycnometer technique. Some physicochemical properties such as compactness, the molar volume and the free volume percentage of the materials were calculated, and their dependences on composition were determined. XRD analysis was performed to determine the structure and phase composition of the synthesized samples. A scanning electron microscope were used to study the surface morphology and EDS determined the chemical composition of the bulk samples.

Conclusions were drawn based on the results obtained regarding the influence of Ag content on the properties of the bulk samples.

HL 20.65 Tue 18:00 P1

Investigation of the Thermoelectric Properties of Single-Crystalline and Polycrystalline Bi1-xSbx (x =0, 0.1, 0.15) Alloys — •Fangyi Hu, Yuan Yu, and Matthias Wuttig — I. Physikalisches Institut (IA), RWTH Aachen University, 52074 Aachen, Germany

Thermoelectric (TE) materials can directly convert heat into electricity and vice versa, providing a sustainable and clean energy solution. Bi1-xSbx, a low-temperature n-type TE alloy with great potential between 20-200 K, has drawn increasing attention in cooling applications. Single crystals and polycrystals exhibit different performance and application prospects. In most cases, particularly below 200 K, single-crystal Bi-Sb shows much higher TE performance than polycrystals. However, polycrystalline Bi-Sb offers lower fabrication cost, better mechanical strength, and easier processing, making it attractive for large-scale use. This study compares the TE properties of Bi-Sb alloys in these two forms and clarifies their intrinsic relationship. Single-crystalline and polycrystalline Bi1-xSbx (x = 0, 0.1, 0.15) were prepared by Bridgman and melt-air-cooling methods, respectively. TE properties, with and without magnetic fields, were measured using Thermal Transport Option in a physical property measurement system (PPMS). Microstructures and bonding mechanisms were analyzed via atom probe tomography. By establishing the bonding-structure-property connection, we aim to reveal the origin of the performance difference between the two forms. These results provide insights into improving ZT in polycrystalline Bi-Sb alloys, which are more suitable for practical deployment.

HL 20.66 Tue 18:00 P1

Oxygen Vacancy-Mediated Non-Volatile Memory in RF-Sputtered Ga_2O_3 films — •Aman Baunthiyal, Jon-Olaf Krisponeit, Marco Schowalter, Alexander Karg, Andreas Rosenauer, Martin Eickhoff, and Jens Falta — Institute of Solid State Physics, University of Bremen, Bremen, Germany

To address the memory bottleneck in conventional electronics, resistive switching (RS) has emerged as a promising route for next-generation memory technologies. Among various materials used in RS devices, β-Ga_2O_3 offers advantages such as high breakdown strength and defect-mediated conductivity. However, its direct growth on metal electrodes with controlled microstructure, crucial for scalable vertical devices, remains largely unexplored. Here, we investigate RF-sputtered Ga_2O_3 deposited on smooth Ru(0001) films for non-volatile RS applications.

XRD and TEM confirm the temperature-dependent structural evolution of Ga_2O_3 and its correlation with the I–V response. Devices grown at intermediate temperatures (~400°C) show the best switching window (up to 10^4), with thinner films enabling low set voltages (~1.5 V) [1] but poorer stability. In contrast, thicker layers require higher voltages (~4 V) yet offer better reliability [2]. This behaviour arises from temperature-driven grain growth and the $\gamma \rightarrow \beta$ phase transition [3], which creates mixed phases and grain boundaries that govern oxygen-vacancy-mediated filament dynamics.

Stable n-Type OECTs with BBL: Unlocking Complementary Circuits — •Clemens Rössler[1,2], Laura Teurle[1,2], Hans Kleemann[1,2], and Karl Leo[1,2] — [1]Dresden Integrated Center for Applied Physics and Photonic Materials — [2]TU Dresden

Organic mixed ionic-electronic conductors (OMIECs) have emerged as a key materials platform for next-generation bioelectronics, energy-efficient signal processing, and neuromorphic computing. Among the most versatile OMIEC devices is the organic electrochemical transistor (OECT), whose ability to couple ionic and electronic transport enables low-voltage operation and is particularly advantageous for solid-state electrolyte systems that enable densely integrated circuitry. While p-type materials such as PEDOT:PSS have driven much of the field's progress, the lack of stable and high-performance n-type counterparts remains a critical bottleneck - limiting the realization of complementary circuits, low-power logic, and more complex bioelectronic architectures. In this talk, I present recent progress on n-type OECTs based on the ladder polymer poly(benzimidazobenzophenanthroline) (BBL). I will discuss how we have developed and optimized n-type OECTs that exhibit remarkable stability and a unique electrochemical conditioning behaviour. Spectroscopic, AFM, and transfer curve analyses show that BBL combines excellent optical and morphological stability with a high mobility capacitance product, indicating efficient ion penetration and intrinsically high electronic mobility.

HL 22.2 Wed 9:45 POT/0006

A Nonlinear Organic Infrasound Sensor — •Maarten Mittmann[1], Carsten Habenicht[1], Andreas Hofacker[1], Richard Kantelberg[1], Stefan Jacob[2], Hans Kleemann[1], and Karl Leo[1] — [1]Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Dresden University of Technology, 01062 Dresden, Germany — [2]National Metrology Institute (PTB), 38116 Braunschweig, Germany

Most works on speech recognition using reservoir computing focus on the nonlinear transformation of the data, which is fed electronically from a conventional sensor to the device. However, this approach necessitates two separate devices, consuming power and possibly requiring additional signal processing steps. In this work, we demonstrate that an efficient interface between acoustic stimulation and nonlinear, electronic output can be established using a free-standing viscoelastic film containing a poly(3,4-ethylenedioxythiophene) hexafluorophosphate ($PEDOT:PF_6$) fiber organic electrochemical transistor (OECT). Upon application of a constant drain-source and gate-source voltage, the system shows a time-dependent, nonlinear modulation of the drain current when excited acoustically. This nonlinearity opens possibilities of combining the existing system with a reservoir computing approach to perform complex tasks like infrasound source discrimination and anomaly detection. The devices show great sensitivity within the order of magnitude of $10^2\ mV\ Pa^{-1}$ in the infrasound frequency regime thanks to the amplification via the gate electrode.

HL 22.3 Wed 10:00 POT/0006

Is Printed Electronics a Sustainable Technology? A Framework to Efficiently Implement an Early-Stage Life-Cycle-Analysis — •Laura Teuerle, Tommy Meier, Klara Hänisch, Finn Jaekel, Yeohoon Yoon, Andreas Wendel, and Hans Kleemann — Dresden Integrated Center for Applied Physics and Photonic Materials, TU Dresden, Germany

The rise of microelectronic system has been the major driving focus of the global economy for the last couple of decades. As we are now transitioning to the era of the internet-of-things, with an increasing number of small autonomous electronic circuits, e.g, for sensing, we need to urgently consider the environmental impact of this development due to the unsustainable use of natural resources. Thus, to ensure the environmental sustainability of the development, future electronics must prioritize both performance and environmental impact, explaining the interest in flexible and printed electronics. However, the sustainability claims often connected to the field of flexible and printed electronics must be substantiated using analytic methods, providing the motivation for quantitative Life-Cycle Assessment (LCA). Here we demonstrate our approach to implement an LCA for an early-state research topic such as Organic Electrochemical Transistors (OECTs). Using hands-on examples, we will show how to set up an inventory database (the core of the LCA) using a process-of-record (PoR). By making LCA a standard tool in printed electronics, the community can move beyond sustainability claims to measurable environmental impact, driving truly responsible innovation in electronics.

HL 22.4 Wed 10:15 POT/0006

Obtaining In-Vivo Data for AI Applications Using Implantable Biocompatible Materials — •Finn Jaekel[1], Richard Kantelberg[1], Hans Kleemann[1], Daniel Freund[2], Julia Henne[2], Dennis Wahl[2], Eberhard Grambow[3], Sebastian Hinz[2], Clemens Schafmayer[2], Jochen Hampe[4], and Karl Leo[1] — [1]Institut für Angewandte Photophysik, Technische Universität Dresden, Dresden, Germany — [2]Klinik und Poliklinik für Allgemeine Chirurgie, Thorax, Gefäß- und Transplantationschirurgie, Universitätsmedizin Rostock, Rostock, Germany — [3]Klinik für Herz-, Thorax- und Gefäßchirurgie (HTG), Universitätsmedizin Göttingen, Göttingen, Germany — [4]Universitätsklinikum Carl Gustav Carus Dresden, Dresden, Germany

Artificial intelligence can be of great use in biomedical applications, especially when implemented in implantable hardware solutions. However, robust, biomedical AI applications crucially depend on real, high-quality, physiological training and input datasets, which are scarce in practice. In this presentation, we provide a prototypical use-case scenario by demonstrating in-vivo impedance measurements in a porcine small-intestinal anastomosis using printed, fully biocompatible organic sensors. Ischemia was induced locally, and manual evaluation shows a characteristic signature in the recorded impedance spectra, confirming that the system captures physiologically relevant data. This positions the technology in a realistic sensor to AI analysis pipeline, where automated detection of ischemia can be used to create an early warning system of anastomotic failure.

HL 22.5 Wed 10:30 POT/0006

Towards Fully Biodegradable and Sustainable Organic Electrochemical Transistors Printed on Leaf-Derived Substrates — •Bilge Kahraman, Rakesh R. Nair, Hans Kleemann, and Karl Leo — Dresden Integrated Center for Applied Physics and Photonic Materials, Technische Universität Dresden, 01187 Dresden, Germany.

The rapid proliferation of disposable electronics has exacerbated electronic waste and its associated environmental burden. Here, we demonstrate fully screen-printed organic electrochemical transistors (OECTs) fabricated on robust biodegradable leaf-derived substrates using non-toxic carbon and PEDOT:PSS-based inks. Magnolia grandiflora leaves were skeletonized to function as sequestering matrices for hydroxypropylcellulose (HPC) based resin, which was subsequently crosslinked to create robust flexible, compostable substrates. Life-cycle assessment (LCA) reveals that the combination of leaf-skeleton-based substrates and carbon gate electrodes for electronic device fabrication reduces CO_2-equivalent emissions by up to four orders of magnitude compared to conventional glass substrates and gold electrodes (19,400 times lower for substrates; 680 times lower for electrodes). The printed OECTs exhibit steady-state performance comparable to devices made on glass using commercial PEDOT:PSS formulations, with on/off ratios > 10^4 and transconductance values exceeding 1 mS. This work presents a viable path toward truly green bioelectronic devices that can be manufactured for disposability and safely returned to the environment after use.

HL 22.6 Wed 10:45 POT/0006

Flexible Organic Photodiodes Based on Advanced Encapsulation Strategies — •Rabiul Islam[1,2], Siddhartha Saggar[1,2], Jakob Wolansky[3], Darius Pohl[4], Markus Löffler[4], Bernd Rellinghaus[4], Johannes Benduhn[3], and Caroline Murawski[1,2] — [1]Institute of Solid-State Electronics, Technische Universität Dresden, Dresden, Germany — [2]Kurt Schwabe Institute for Sensor Technologies, Waldheim, Germany — [3]Dresden Integrated Center for Applied Physics and Photonic Materials, Technische Universität Dresden, Dresden, Germany — [4]Dresden Center for Nanoanalysis (DCN), Technische Universität Dresden, Dresden, Germany

Organic photodiodes (OPDs) are promising for biomedical applications due to their flexibility, spectral tunability, and biocompatibility, yet their moisture sensitivity demands robust encapsulation for long-term operation. Conventional flexible substrates offer limited device protection in humid conditions; to overcome this, we employed a parylene-C/ALD-deposited Al2O3/ZrO2 hybrid substrate, providing flexibility and strong barrier properties. We fabricated flexible OPDs with an ultrathin (7 nm) silver electrode on a hybrid substrate, which remained stable after 10,000 bending cycles and demonstrated high mechanical robustness. Using PM6:PC71BM as the active layer, the OPDs achieved responsivity of 0.26 A/W at -0.1 V under 639 nm illumination, retained 86% of their initial performance after 12 days in deionized water, and remained functional after one hour of machine washing, showing that parylene/nanolaminate-based ultra-flexible OPDs enable long-term operation in aqueous environments.

HL 23: Transport Properties

Time: Wednesday 9:30–12:15 Location: POT/0051

HL 23.1 Wed 9:30 POT/0051

Nonlinear charge transport in single crystalline slabs of Bi2Se3 — •Igor Veremchuk[1], Pavlo Makushko[1], Anita Guarino[2], Muhammad Waqee Ur Rehman[2], Rosalba Tatiana Fittipaldi[2], Tobias Kosub[1], Alexej Pashkin[1], Fabian Ganss[1], Proloy T. Das[1], Rui Xu[1], Rhonald Burgos Atencia[3], Debottam Mandal[3], Antonio Vecchione[2], Carmine Ortix[3,2], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., 01328 Dresden, Germany — [2]CNR-Institute for SuPerconductors, Innovative materials, and devices, Salerno, Italy — [3]Dipartimento di Fisica "E. R. Caianiello", Universita di Salerno, IT-84084 Fisciano (SA), Italy

Nonlinear charge transport is central to next-generation high-frequency electronics, enabling efficient rectification and frequency conversion up to the THz range. Nonlinear responses are observed in various material systems often focusing on thin films including Bi [1], Te [2], and Bi2Se3 [3]. In this study, we will report experimental observations of nonlinear charge transport in Bi2Se3 single crystals, which is explained based on peculiarities of the structural properties of layered Bi2Se3 materials. Our findings can be applied to a broad range of van der Waals centrosymmetric compounds.

HL 23.2 Wed 9:45 POT/0051

Comparing thermal conductivity predictions from open source phonon transport solvers — •Sally Issa, Martí Raya-Moreno, and Nakib H. Protik — Humboldt-Universität zu Berlin, Germany

Phonon transport continues to be an active field of research, both for probing materials physics and developing applications for thermoelectricity and thermal management. Due to their parameter-free nature, ab initio approaches are one of the preferred means for solving the phonon transport problem, offering excellent predictive capabilities, especially for novel materials. Over the last decade, the workflow combining density functional theory (DFT) and the Peierls Boltzmann transport equation (BTE) has gained popularity. Indeed, practitioners in the field have several publicly available BTE code packages to choose from, for example, ShengBTE, AlmaBTE, phonop3py, elphbolt, Phoebe, etc., that use this workflow. Nevertheless, the doubt regarding the comparability of these different codes still remains. At present, a detailed comparative study is missing in the literature. In this work, we fill this gap and carry out a comparison of the phonon thermal conductivity predicted by various codes. For a fair comparison, we use the same DFT generated interatomic force constants from the Alma database [1] for all considered codes. We carefully check the convergence of the thermal conductivity with respect to the wave vector mesh density and compare the results over a range of temperature points.

[1] ALMA database: https://almabte.bitbucket.io/database/

HL 23.3 Wed 10:00 POT/0051

Influence of Thermal Annealing on CMOS-Integrated Graphene Field-Effect Transistors — •Daniel Nickel[1], Daniele Capista[1], Rasuole Lukose[1], Christian Wenger[1,2], and Mindaugas Lukosius[1] — [1]IHP - Leibniz Institute for High Performance Microelectronics, Im Technologiepark 25, 15236 Frankfurt (Oder), Germany — [2]BTU Cottbus Senftenberg, Platz der Deutschen Einheit 1, 03046 Cottbus, Germany

This work investigates the influence of consecutive annealing on CMOS-integrated graphene field-effect transistors (GFETs) with annealing temperatures (T_a) from 150 °C up to 300 °C. The GFETs were fabricated on 200 mm SiO_2/Si wafers with Pd/Au and Ni edge contacts, tungsten backgate and Si_3N_4 passivation. Annealing was carried out in 150 sccm nitrogen flow for 1 h using a 10 °C/min ramp. Electrical transfer measurements show that maximum p- and n-type field-effect mobilities occur at T_a = 200 °C for Pd/Au ($\mu_p \approx 950$ cm^2/Vs, $\mu_n \approx 1650$ cm^2/Vs) and at T_a = 150 °C for Ni ($\mu_p \approx 450$ cm^2/Vs, $\mu_n \approx 890$ cm^2/Vs). Raman analysis indicates an improved graphene quality with increasing T_a. Raman mapping reveals that for Pd/Au, the FWHM of the 2D peak reaches a minimum at T_a = 200 °C, followed by a slight increase in compressive strain at higher T_a. For Ni, broader 2D and G peak distributions and a reduction in p-doping with increased T_a is observed. Raman data measured near the Ni contacts reveal reduced p-doping, whereas doping near the Pd/Au contacts remains largely unaffected. Funding was provided by EU Horizon 2020 Graphene Flagship grants 101189797 and 101120938.

HL 23.4 Wed 10:15 POT/0051

Elucidating mobile charge carriers in granular matter by transient surface photovoltage analysis — •Christoph Merschjann[1], Albert These[2], Christoph Brabec[2,3], Thomas Dittrich[1], and Pablo Jimenéz-Calvo[2,4] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen — [3]Helmholtz-Institute Erlangen-Nürnberg, Erlangen — [4]Max-Planck-Institute of Colloids and Interfaces, Potsdam

Among the most important properties of novel functional materials are their charge transport characteristics, including *n* vs. *p* type conductivity, carrier concentrations, and respective mobilities. However, new solid-state materials are typically first synthesized in granular form, and often this is also the intended morphology for applications (batteries, photocatalysts, etc.). This makes most electrical characterization techniques (e.g. impedance, Hall, time-of-flight photocurrent) extremely challenging, as they rely on current measurements throughout the bulk of the sample. To overcome this drawback, we use contactless transient surface photovoltage (TR-SPV) to detect charge-density shifts on the nanometer scale and in a time range from nanoseconds to seconds. Comparing the results with diffusive charge-transport models of moderate complexity, we are able to deduce the type and mobility of photoinduced charge carriers in a prominent example material, graphitic polymeric carbon nitride (PCN). We encourage transferability of this SPV analysis to other 2D layered systems like metal- or covalent-organic frameworks (MOF / COF).

HL 23.5 Wed 10:30 POT/0051

Deep-learning Hamiltonian Acceleration of Electrical Transport Predictions using the Non-Perturbative *ab initio* Kubo-Greenwood Method for Strongly Anharmonic Materials — •Juan Zhang[1,2], Kisung Kang[3], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at the FHI of the Max Planck Society, Berlin — [2]Department of Optical Science and Engineering, Fudan University, Shanghai — [3]School of Materials Sciences and Engineering, Chonnam National University, Gwangju

Thermal insulators, e.g., needed for efficient thermoelectric materials, feature strong anharmonicity. As a consequence, a perturbative approach of electron-phonon interactions and even the phonon concept for describing vibrations may become invalid. The non-perturbative *ab initio* Kubo-Greenwood (aiKG) method provides an approach for evaluating electron and hole mobilities [1]. However, it requires substantial computational costs due to its high requirements with respect to statistical averages, large supercells, and extrapolation strategies to the zero-frequency limit. This work introduces an AI-assisted aiKG framework for the FHI-aims code, which incorporates the neural-network model, DeepH [2], trained to predict the Kohn-Sham Hamiltonian. Using the thermal insulator KI, we demonstrate the capabilities and predictive power of the approach, which substantially accelerates the calculation of large supercell electronic band structures, temperature-dependent spectral functions, and carrier mobilities with high accuracy.

HL 23.6 Wed 10:45 POT/0051

Quantum oscillations in the correlated metal $CaVO_3$ — Olivio Chiatti[1], Mahni Müller[1], Maria Espinosa[1], Tatiana Kuznetsova[2], Roman Engel-Herbert[2,3], and •Saskia F. Fischer[1,4] — [1]Novel Materials Group, Humboldt-Universität zu Berlin, 10099 Berlin, Germany — [2]Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA 16802, USA — [3]Paul-Drude-Institut für Festkörperelektronik, 10117 Berlin, Germany — [4]Center for the Science of Materials Berlin, Humboldt-Universität zu Berlin, 12489 Berlin, Germany

Transparent conductive materials are in great demand in the optoelectronic industry for their high-performance and cost-effectiveness. Strong electron-electron interactions in correlated metals can enhance the carrier effective mass and allow to achieve both high-optical transparency and high-electrical conductivity [1].

Here, we study the electric transport properties of thin $CaVO_3$ epitaxial films grown on $LaAlO_3$ substrates by hybrid molecular beam epitaxy, with residual a high resistivity ratio (RRR) up to 98 [2]. Magnetortransport measurements were performed between 2 and 200 K in magnetic fields up to 64 T. Films with high RRR show quantum oscillations below 10 K. The analysis of the Shubnikov-de Haas oscillations provides parameters within a multi-carrier model and the implications for the complex Fermi surface of $CaVO_3$ are discussed.

Modeling the impact of dynamic disorder on optical conductivity of semiconductors using a Kubo approach — •Frederik Vonhoff[1], Michel Panhans[2], David R. Reichman[3], Frank Ortmann[2], and David A. Egger[1] — [1]Physics Dep., TUM School of Natural Sciences, Technical University of Munich, 85748

Garching, Germany — [2]Dep. of Chemistry, TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany — [3]Dep. of Chemistry, Columbia University, New York, NY 10027, USA

Semiconductor devices rely critically on efficient charge-carrier transport, making it essential to understand the underlying transport mechanisms. The optical conductivity is a key transport observable, both experimentally and theoretically, for identifying the scattering mechanisms and transport regimes. However, modeling the transport properties of semiconductors with strong nuclear vibrations is challenging due to the resulting dynamic disorder in the electronic structure [1, 2]. Addressing these challenges, we develop a dynamic-disorder-driven microscopic method to compute optical conductivities in one- and three-dimensional semiconductor model systems by integrating time-dependent electronic Hamiltonians in Kubo transport theory. By systematically varying the static and dynamic disorder strength, we investigate the transition from localization to transient localization to and diffusive behavior, providing insights into scattering mechanisms active in emerging semiconductor materials such as halide perovskites.

HL 23.8 Wed 11:30 POT/0051

Self-Trapped Exciton Diffusion in a Lead-Free Two- Dimensional Hybrid Perovskite — •Jan-Heinrich Littmann[1], Lukas Gümbel[1], Philip Klement[1], Meng Yang[2], Markus Stein[1], Johanna Heine[2,3], and Sangam Chatterjee[1] — [1]Institute of Experimental Physics I and Center for Materials Research (ZfM), Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany — [2]Department of Chemistry and Material Sciences Center, Philipps-Universität Marburg, Hans-Meerwein- Straße, 35043 Marburg, Germany — [3]Institute of Chemistry, Carl von Ossietzky Universität Oldenburg, Ammerländer Heerstraße 114-118, 26129 Oldenburg, Germany

Self-trapped excitons (STEs) in low-dimensional metal-halide perovskites arise from lattice distortions. The mobility of such excitations is expected to be limited, however, remains vastly unexplored experimentally.

Here, we directly image STE transport in a lead-free perovskite using spatially and temporally resolved photoluminescence microscopy. The STEs exhibit measurable mobility and propagate over micrometer distances despite their strongly-localized nature. At low temperatures, their motion is limited and nearly temperature independent. Transport becomes thermally activated above 150k and overcomes local energy barriers. Together this infers trap-limited diffusion. These results establish that STEs are mobile under suitable conditions and provide a quantitative framework for STE transport in lead-free perovskite materials.

HL 23.9 Wed 11:45 POT/0051

Electron-phonon interactions in VASP — •Manuel Engel[1], Henrique Miranda[1], Atsushi Togo[2], Laurent Chaput[3], Martijn Marsman[1], and Georg Kresse[1,4] — [1]VASP Software GmbH, Vienna, Austria — [2]National Institute for Materials Science, Tsukuba, Japan — [3]Lorraine University, Nancy, France — [4]University of Vienna, Vienna, Austria

Understanding electron-phonon interactions with first-principles accuracy is essential for predicting temperature-dependent electronic properties in semiconductors and complex materials. In this work, we present new capabilities implemented in VASP that enable a fully ab initio treatment of electron-phonon coupling using the projector-augmented wave (PAW) method. These developments provide a consistent framework for evaluating band-gap renormalization, phonon-induced linewidths, and finite-temperature electronic transport properties within density functional theory.

Our approach combines perturbative electron-phonon matrix elements with dense Brillouin-zone sampling achieved through interpolation techniques compatible with PAW-based orbitals and higher-level density functionals. We demonstrate accurate predictions of zero-point and thermal band-gap shifts across a range of materials. In addition, we incorporate the electron-phonon scattering rates directly into Boltzmann transport calculations under relaxation-time approximations. This enables temperature-dependent mobilities and conductivities to be computed from first principles.

HL 23.10 Wed 12:00 POT/0051

Investigation of exciton diffusion in GaAs nanowires via cathodoluminescence spectroscopy — •Mikel Gómez Ruiz, Vladimir Kaganer, Jesús Herranz, Lutz Geelhaar, Oliver Brandt, and Jonas Lähnemann — Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, 10117 Berlin, Germany

Semiconductor nanowire (NW) structures emitting at tailored wavelengths have attracted notable interest for integration with silicon-on-insulator waveguides. For many of these applications, the efficiency with which carriers are injected into the active region of the sample is relevant.

In this context, carrier transport in phase-pure GaAs nanowires is investigated by spatially-resolved cathodoluminescence spectroscopy. Emission intensity profiles along the nanowire axis are measured to study carrier transfer from the GaAs segment to the axial interfaces at both ends of the nanowire. These interfaces are formed at the top with the axially grown (Al,Ga)As shell and at the bottom with the Si substrate. The recorded intensity profiles are predominantly asymmetric, indicating that carrier recombination at the two interfaces occurs in a different fashion.

These profiles are analyzed using a mathematical model that accounts for carrier generation, diffusion, and recombination. Fitting this model to the experimental profiles reveals a diffusion length exceeding one micron at 10 K, an unprecedented value for GaAs nanowires. This reflects the high crystal quality of our nanowires.

HL 24: 2D Materials IV – Emerging materials and properties

Time: Wednesday 9:30–12:45 Location: POT/0081

HL 24.1 Wed 9:30 POT/0081

Atomic layer deposition of few-layer 1T-TiS_2 and ternary $MoTiS_2$ — •Christian Petersen[1,2], Christian Tessarek[1,2], Marco Schowalter[1,2], Andreas Rosenauer[1,2], and Martin Eickhoff[1,2] — [1]Institute of Solid State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359 Bremen, Germany — [2]MAPEX Center for Materials and Processes, University of Bremen, Bibliothekstraße 1, 28359 Bremen, Germany

Theoretical calculations and experimental data concerning electronic and structural properties of 1T-TiS_2 are sparse in comparison to other transition metal dichalcogenides (TMD) such as MoS_2. The available data is contradicting and attributes 1T-TiS_2 a plethora of different properties ranging from a semi-metal like behaviour to different charge density wave phases (2×2 and $\sqrt{7} \times \sqrt{3}$) and even a band gap of up to 2.5 eV. In general, there is a lack of experimental data due to difficulties in synthesis and stabilization of 1T-TiS_2 which rapidly oxidizes in ambient conditions.

In this study, plasma-enhanced sub-atomic layer deposition (ALD) [1] in combination with in situ X-ray photoelectron spectroscopy (XPS) is employed to directly study the effects of the growth conditions on the chemical composition of 1T-TiS_2 while circumventing the problem of oxidation in ambient. To further characterize the 1T-TiS_2 film ex situ, Raman spectroscopy and atomic force microscopy (AFM) is utilized. Additionally, $MoTiS_2$ was synthesized by substitution of ALD cycles of the Ti precursor (TDMAT) by the Mo precursor (BTBMMo).

HL 24.2 Wed 9:45 POT/0081

The effect of Lithium intercalation on line defects in the MoS2 monolayer — •Asghar Ali Jan and Peter Kratzer — University of Duisburg-Essen, Duisburg, Germany

MoS2 can be an effective anode material in lithium-ion batteries, as it is scalable at room temperature and has weak van der Waals forces, allowing lithium ions to intercalate between the sheets. Additionally, when using MoS2 as an anode in a lithium-rich environment, the phase transition from the most stable H phase to the T' phase must also be considered. Certain defects, such as sulfur vacancies and grain boundaries, are often present in experimentally synthesized MoS2 layers. These grain boundaries introduce metallic states within the bulk band gap. As a result, the conductivity of MoS2 is reduced. Up to now, the H-to-T' phase transition in MoS2 has been extensively studied, but generally without considering the possible presence of defects such as grain boundaries. Therefore, we have investigated the interaction of lithium intercalation with the grain boundaries present in a MoS2 monolayer. For example, we examine how the presence of lithium near a mirror twin boundary (MTB) affects the one-dimensional line of charge trapped in the MTB. It is also important to consider the grain boundary formed when a T' phase created from the H phase due to lithium intercalation directly meets the remaining H phase that does not interact with lithium. Our density functional theory calculations provided insights about the stability and electronic properties of these line defects in the presence of lithiation.

HL 24.3 Wed 10:00 POT/0081

Wafer-scale growth of hexagonal boron nitride thin films using pulsed laser deposition — •Daniel Klenkert[1,2], Benedikt Winter[1], Paul Konrad[2], Andreas Sperlich[2], Vladimir Dyakonov[2], and Jens Ebbecke[1] — [1]Technology Campus Teisnach Sensor Technology, Deggendorf Institute of Technology, 94244 Teisnach — [2]Experimental Physics 6, Julius-Maximilians-University Würzburg, 97074 Würzburg

Hexagonal boron nitride (hBN) has attracted significant attention due to its wide bandgap, high thermal conductivity and its ability to host optically active defects, which are promising as single photon emitters and for quantum sensing applications. Thus far the sample preparation of hBN usually relies on tape exfoliation or high temperature chemical vapor deposition. Here we report on our progress using an alternative approach to prepare thin films of hBN on different substrates: pulsed laser deposition. This enabled the preparation of microcrystalline hBN layers on large scale wafer substrates at temperatures below 850°C. The stoichiometry preserving properties of pulsed laser deposition also allows for the preparation of carbon doped thin films. These are especially interesting for research on carbon related, optically active defects, which are noted for their high brightness and single photon purity.

HL 24.4 Wed 10:15 POT/0081

Doping-Induced Modulation of Structural and Electronic Properties in Transition Metal Dichalcogenides — •Cem Sanga[1,3], Nadire Nayir[1,3], Yusuf Kerem Bostan[2], Fahrettin Sarcan[2], Diwakar Singh[4], and Tanushree Choudhury[4] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, 10117 Berlin, Germany — [2]Department of Physics, Faculty of Science, Istanbul University, Vezneciler, Istanbul, 34134, Turkey — [3]Department of Physics Engineering, Istanbul Technical University, Maslak, Istanbul, 34467, Turkey — [4]Department of Metallurgical Engineering and Materials Science, Indian Institute of Technology Bombay, Mumbai, Maharashtra 400076, India

Transition metal dichalcogenides (TMDCs) hold promise for electronic applications, yet their performance is limited by inadequate doping strategies. This density functional theory investigation examines substitutional and interstitial doping in MoS_2 and WS_2 using chlorine and oxygen dopants. Formation energy calculations reveal chlorine preferentially occupies sulfur vacancy sites in MoS_2. Electronic structure analysis demonstrates that strategic doping enables bandgap engineering in TMDC systems.

HL 24.5 Wed 10:30 POT/0081

Opposite In-Plane Electrical Anisotropy in $ZrSe_3$ and ZrS_3 Flakes — •Davin Höllmann[1], Lars Thole[1], Sonja Locmelis[2], and Rolf J. Haug[1,3] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany — [2]Institut für Anorganische Chemie, Leibniz Universität Hannover, 30167 Hannover, Germany — [3]Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, 30167 Hannover, Germany

The anisotropy in form of quasi one-dimensional (1D) chains in transition metal trichalcogenides (TMTCs) makes them stand out compared to other more conventional two-dimensional (2D) materials [1]. Through width-dependent [2] and direct measurements, we investigated the electrical properties of $ZrSe_3$ and ZrS_3 flakes, in particular, the influence of the anisotropic effective electron masses [3] in the 2D plane. Flakes with a height of 26 nm were exfoliated from the respective bulk materials grown by a chemical vapour transport method.

Despite their identical quasi 1D layered crystal structure, $ZrSe_3$ and ZrS_3 exhibit inverted in-plane electrical anisotropy. While $ZrSe_3$ exhibits the highest conductivity across the 1D chains with an anisotropy ratio of 0.60, ZrS_3 is shown to favour electron transport along the 1D chains with a ratio of 1.69. Using DFT, we attribute this to the different chalcogen contributions at the conduction band minimum.

Observation of Bernal Stacking in Few-Layer Graphene on C face Silicon Carbide — •Jonas Rose, Oliver Brandt, Michael Hanke, Joao Marcelo Lopes, Philipp John, and Hans Tornatzky — Paul-Drude-Institut, Berlin

Epitaxial growth of few-layer graphene (FLG) on SiC(000$\bar{1}$) (C face) is widely assumed to yield films with rotational disorder, in contrast to the well-ordered Bernal (AB) stacking typically associated with SiC(0001) (Si face) growth. In this work, we show that surface graphitization on the C face of SiC can, under appropriate conditions, produce FLG with genuine AB stacking and remarkably low mosaic spread. Using detailed Raman spectroscopy, supported by complementary structural characterization, we identify clear spectral signatures of Bernal ordering, including a well-defined 2D-band lineshape. These findings demonstrate that ordered stacking is achievable on the C face under controlled sublimation conditions. We will present our full spectroscopic analysis and discuss its implications for the structural and electronic properties of the grown FLG.

Influence of Defects, Doping and Layer Twisting on Phonon Dispersions in Bilayer Graphene and MoS_2 from Machine-Learned Force Fields — •Sabuhi Badalov and Harald Oberhofer — Chair for Theoretical Physics VII and Bavarian Center for Battery Technologies, University of Bayreuth

In two-dimensional (2D) layered materials, phonon dispersion plays a central role in determining transport and electronic properties. In bilayer systems, phonon dispersion is highly sensitive to the stacking configuration, twist angle, defects, and doping types. Using *state-of-the-art* machine learning force fields trained on the *first-principles* data, we perform large-scale phonon calculations for bilayer graphene and MoS_2 to investigate how layer twist and defect density alter phonon spectra and interlayer vibrational modes. We also analyze the influence of p- and n-type doping on phonon dispersions and their interactions with the underlying electronic structure. Our results reveal characteristic shifts in low-energy acoustic and optical branches that are directly linked to microscopic structural motifs, including *Moiré*-induced phonon properties. These findings provide microscopic input for future calculations of electron-phonon coupling and possible phonon-mediated superconducting states in twisted and doped 2D materials and establish machine learning force fields as a powerful framework for exploring phonon-electron interaction in quantum materials.

HL 24.8 Wed 11:30 POT/0081

Efficient GW band structure calculations using Gaussian basis functions and application to atomically thin transition-metal dichalcogenides — •Rémi Pasquier[1], María Camarasa-Gómez[2,3], Anna-Sophia Hehn[4], Daniel Hernangómez-Pérez[5], and Jan Wilhelm[1] — [1]Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, 93053 Regensburg, Germany — [2]Centro de Física de Materiales (CFM-MPC), CSIC-UPV/EHU, Paseo Manuel de Lardizabal 5, 20018 Donostia-San Sebastián, Spain — [3]Departamento de Polímeros y Materiales Avanzados: Física, Química y Tecnología, Facultad de Química, UPV/EHU, 20018 Donostia-San Sebastián, Spain — [4]Institute of Physical Chemistry, Christian-Albrechts-University Kiel, Max-Eyth-Strasse 1, 24118 Kiel, Germany — [5]CIC nanoGUNE BRTA, Tolosa Hiribidea 76, 20018 San Sebastián, Spain

The GW approximation is widely used to compute self-energies and related electronic properties but remains computationally demanding, motivating the development of more efficient approaches. We present a space-time GW algorithm for periodic systems in a Gaussian basis with spin-orbit coupling, enabling accurate and efficient quasiparticle band-structure calculations for atomically thin materials. For monolayer MoS_2, $MoSe_2$, WS_2, and WSe_2, the resulting GW band gaps agree on average within 50 meV with plane-wave reference values. Full G_0W_0 band structures can be computed in less than two days on a laptop (Intel i5, 192 GB RAM) or under 30 minutes using 1024 cores.

HL 24.9 Wed 11:45 POT/0081

Investigating the Ferroelectric Potential Landscape of 3R-MoS_2 through Optical Measurements — •Jan-Niklas Heidkamp[1], Johannes Schwandt-Krause[1], Swarup Deb[1,2,3], Takashi Taniguchi[4], Kenji Watanabe[4], Rico Schwartz[1], and Tobias Korn[1] — [1]Institute of Physics, University of Rostock, Rostock, Germany — [2]Homi Bhabha National Institute, Mumbai, India — [3]Saha Institute of Nuclear Physics, Kolkata, India — [4]National Institute for Material Science, Tsukuba, Japan

In recent years, sliding ferroelectricity has emerged as a topic of significant interest due to its possible application in non-volatile, reconfigurable storage devices. This phenomenon is unique to two-dimensional van der Waals materials, where out-of-plane ferroelectric polarization switching is induced by relative in-plane sliding of adjacent layers. The intrinsic stacking order influences the resulting polarization, creating distinct polarization regions separated by domain walls. These can be manipulated using an applied vertical electric field, enabling a switchable system that retains the environmental robustness of van der Waals materials. This study investigates 3R-MoS_2 using various optical measurement techniques at room temperature and reveals apparent signal changes corresponding to different ferroelectric stacking orders and variations in layer count. Our findings demonstrate that fast optical mapping at room temperature is a reliable method for probing ferroelectric potential steps in 3R-stacked MoS_2 samples, thereby facilitating the identification of the ferroelectric configuration.

HL 24.10 Wed 12:00 POT/0081

Robust Orbital-Selective Flat Bands in Transition-Metal Oxychlorides — Xiangyu Luo[1], •Ludovica Zullo[2], Sahaj Patel[1], Dongjin Oh[1], Qian Song[1], Asish K. Kundu[3], Anil Rajapitamahuni[3], Elio Vescovo[3], Natalia Olszowska[4], Rafal Kurleto[4], Dawid Wutke[4], Giorgio Sangiovanni[2], and Riccardo Comin[1] — [1]Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139, USA — [2]Universität Würzburg, 97074 Würzburg, Germany, ct.qmat — [3]National Synchrotron Light Source II, Brookhaven National Laboratory, Upton, NY, USA — [4]Solaris National Synchrotron Radiation Centre, Jagiellonian University, Czerwone Maki 98, 30-392 Krakow, Poland

Flat electronic bands, which amplify electron correlations by quenching kinetic energy, provide an ideal foundation for exotic quantum phases. Here, we unveil an intrinsic orbital-selective flat-band mechanism in the van der Waals materials $NbOCl_2$ and $TaOCl_2$, directly observed by angle-resolved photoemission spectroscopy (ARPES) and understood through density functional theory (DFT) and Wannier analysis. Crucially, we experimentally demonstrate that this momentum-independent flat band exhibits remarkable robustness, surviving from the bulk crystal down to the few-layer limit at room temperature. Our theoretical analysis traces its origin to the hybridization between Nb-dz^2 orbital chains and the Lieb-like dx^2-y^2 sublattice, which is further reinforced by Peierls dimerization. Our findings uncover a new orbital-selective design principle for realizing flat bands in quantum materials.

HL 24.11 Wed 12:15 POT/0081

Tuning the Metal-to-Semiconductor Transition in Bilayer PtTe2 via Electric Field Control — •Sharieh Jamalzadeh Kheirabadi, Farzan Gity, Paul K.Hurley, and Lida Ansari — Tyndall National Institute, University College Cork, Cork, Ireland

Abstract: One effective method to induce a bandgap in graphene is applying a perpendicular electric field to its bilayer structure [1]. This process works by breaking the inversion symmetry of BL gra-phene with an external electric field, leading to electrostatic screening between the two layers and splitting the π and π^* bands that intersect at the Fermi level [2]. Platinum ditelluride (PtTe2) has garnered significant interest due to its unique physical and chemical properties [3,4]. PtTe2 retains its semi-metallic properties for thicknesses down to BL but transits to a semiconductor when re-duced to a monolayer due to the quantum confinement effect [5]. We demonstrate that a bandgap emerges in BL-PtTe2 when an electric field is applied perpendicular to the layers, ultimately transforming the system into a semiconductor. We have identified reliable critical electric fields within the range of 2-3 MV/cm to achieve a bandgap comparable to conventional semiconductors in BL-PtTe2. Further, we have investigated the effect of a vertical electric field on a BL-PtTe2 based field effect transistor using density functional theory (DFT) and non-equilibrium Green*s function (NEGF) methods. The results demonstrate device performance compatible with low-power require-ments for ION and IOFF, as projected in the IRDS 2028 roadmap [6].

Circular Dichroism ARPES Reveals Orbital Chirality in Single-Layer TMDs — •Shubham Patel, Luke Pimlott, and Habib Rostami — Department of Physics, University of Bath, Claverton Down BA2 7AY, United Kingdom

The electron wavefunctions in momentum space are fundamental to understanding the microscopic physical properties of solids. Circular dichroism (CD), a key feature observable in angle-resolved photoemission spectroscopy (ARPES) [1]. Recent experimental investigations have indicated a direct relationship between CD-ARPES and the Berry curvature of electronic bands [2], motivating theoretical efforts to interpret CD within this framework. The Berry curvature-based approach fails to capture certain critical sign-reversal features near the time-reversal-invariant K(K') points. Moreover, this method lacks dependence on the photon energy of the incident light, as it is derived purely from the momentum-space wavefunction characteristics. In the present work, we adopt this plane wave approximation to compute CD-ARPES spectra and find excellent agreement with experimental observations. We solve tight-binding Hamiltonian for single-layer TMDs, and generalize the dipole matrix elements. This formalism successfully captures the sign-changing behavior of CD near the K(K') points, a feature absent in the Berry curvature approach, and provide a control on tunability of the dichroic response with the photon energy. Notably, our theoretical approach offers an alternative explanation that differs from the Berry curvature-based framework.

HL 25: Focus Session: Young Semiconductor Forum

The young semiconductor forum gives a platform for post-docs at all career stages to present themselves and their scientific ideas. It consists of an oral session with invited talks about their work and/or scientific vita. With this format, we hope to attract both postdocs and senior researchers and decision makers to join this forum: for postdocs, to give them a platform to present themselves, and for professors, to meet the next generation of scientists.

Organized by Rudolf Bratschitsch, Alexander Holleitner, and the AGyouLeaP (Lucas Kreuzer and Aisha Aqeel)

Time: Wednesday 9:30–12:15 Location: POT/0251

Invited Talk HL 25.1 Wed 9:30 POT/0251

Quantum dots for single-electron current sources — •Johannes C. Bayer, Thomas Gerster, Dario Maradan, Niels Ubbelohde, Klaus Pierz, Hans W. Schumacher, and Frank Hohls — Physikalisch-Technische Bundesanstalt, 38116 Braunschweig, Germany

Generating accurate currents can be achieved in an elegant and direct way by applying a periodic signal to a tunable barrier quantum dot. Such devices are called single-electron pumps (SEPs) due to their capability of emitting a well defined number of n electrons per cycle of an external drive. With driving frequency f and elementary charge e this leads to a controlled and clocked current of $I = nef$, thereby providing a suitable basis for a quantum current standard. While individual SEPs can already achieve errors in the sub-ppm range for currents of the order $I \approx 100$ pA [1], implementing larger systems consisting of multiple well-performing SEPs remains a challenging task. We here present DC transport as well as pumping characteristics of multiple SEP devices toward scaling to higher currents.

Optical readout of reconfigurable in-plane magnetic domains in CrSBr — •Aleksandra Łopion[1], Pierre-Maurice Piel[1], Manuel Terbeck[1], Jan-Hendrik Larusch[1], Jakob Henz[1], Marie-Christin Heissenbüttel[2], Thorsten Deilmann[2], Michael Rohlfing[2], Zdenek Sofer[3], and Ursula Wurstbauer[1] — [1]Physikalisches Institut and Center for Soft Nanoscience (SoN), University of Münster, Wilhelm Klemm Str. 10, Münster, 48149, Germany — [2]Institut für Festkörpertheorie, University of Münster, Wilhelm Klemm Str. 10, Münster, 48149, Germany — [3]Department of Inorganic Chemistry, University of Chemistry and Technology, Prague Technická 5, Prague, 616628, Czech Republic

Two-dimensional van der Waals (vdW) magnets have overcome the Mermin-Wagner expectation by hosting long-range order while remaining tunable through stacking, strain, gating, and external fields. Their reconfigurability and hysteresis are attractive for information technologies, particularly when antiferromagnetic (AFM) multistability is accessed and read optically. We discover a reconfigurable multilayer magnetic domain structure in the A-type antiferromagnetic semiconductor. The layered out-of-plane domain structure can be tuned by external stimuli and read out via domain-modulated optical contrast. This coupled magnetic-optical functionality demonstrates the possibility of encoding, processing, and storage of information in magnetic textures with a photonic-compatible readout. The domain landscape highlights CrSBr as a platform for "intelligent matter" and a building block for ultracompact opto-spintronic memories and neuromorphic hardware.

Invited Talk HL 25.3 Wed 10:30 POT/0251

Ferroelectric switching in Mn-doped epitaxial $BaTiO_3$ films and superlattices on silicon — •Alfredo Blázquez Martínez[1], Valentin Väinö Hevelke[1,2], Ibukun Olaniyan[1,2], Minh-Anh Luong[1,3], Ines Häusler[1], Sven Wiesner[1], Christoph T. Koch[4], Dong-Jik Kim[1], and Catherine Dubourdieu[1,2] — [1]Helmholtz-Zentrum Berlin fur Materialien und Energie, 14109 Berlin, Germany — [2]Freie Universität Berlin, 14195 Berlin, Germany — [3]CEMES-CNRS and Université de Toulouse, F-31055 Toulouse, France — [4]Humboldt-Universität zu Berlin, 12489 Berlin, Germany

The integration of epitaxial ferroelectric oxides on silicon remains a key challenge for realizing energy-efficient and CMOS-compatible nanoelectronic devices. Among these materials, barium titanate ($BaTiO_3$) is a prototypical perovskite ferroelectric with a high remanent polarization and a low coercive field. Molecular beam epitaxy (MBE) enables the growth of high-quality epitaxial $BaTiO_3$ on Si, yet these films typically show high leakage currents, which preclude polarization measurements and the realization of functional devices on Si. Here, we demonstrate robust ferroelectric hysteresis in epitaxial $BaTiO_3$ films grown on p-type Si using Mn doping. The introduction of a suitable amount of Mn suppresses leakage currents by up to seven orders of magnitude. We will then discuss the properties of (Mn-doped $BaTiO_3/SrTiO_3)_n$ superlattices hosting vortex polar textures of a few nanometers in diameter. This work highlights Mn-doping as an effective path to reduce leakage currents in epitaxial $BaTiO_3$ heterostructures to enable future topotronic devices integrated monolithically on semiconductors.

Invited Talk HL 25.4 Wed 11:15 POT/0251

Tunability of quantized Hall plateaus — •Serkan Sirt[1], Vladimir Umansky[2], and Stefan Ludwig[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — [2]Weizmann Institut of Science, Rehovot, Israel

The textbook single-particle description of the quantum Hall effect based on the Landauer-Büttiker picture explains the extent of quantized Hall plateaus as a function of magnetic field in terms of disorder-broadened Landau levels. In contrast, the screening theory includes electron-electron interactions and predicts the formation of extended Hall plateaus based on the confinement potential, without the need for disorder [1].

To test these contrasting models, we investigate the tunability of the plateaus in gate-defined Hall bars. We employ a global top gate to deplete the two-dimensional electron system and an additional screen gate on the sample surface, separated by an insulating layer, to define the Hall bar. Varying the gate voltages allows us to tune the edges of the Hall bar continuously from hard to soft confinement. We find that, for softer confinement, the plateaus become wider by extending to lower magnetic fields. These results support the screening theory and are inconsistent with the Landauer-Büttiker picture.

This work establishes a new method for controlling and manipulating quantized Hall plateaus, which may become relevant for quantum Hall metrology and quantum technology applications.

How to achieve high gain in organic photodetectors? — •Johannes Benduhn — Institute of Applied Physics, TU Dresden, Germany — German Centre for Astrophysics, Görlitz, Germany

Organic photodetectors (OPDs) match their inorganic counterparts in performance, with additional features like semitransparency, flexibility, and narrowband detection, opening new sensing applications. However, high-gain OPDs are challenging due to disorder. This work discusses two alternative principles to achieve gain.

The first approach uses unbalanced charge-carrier transport. Photo-generated charges accumulated near one of the contacts generate a local field that triggers charge injection of charges from the external circuit into the active layer. Under dark conditions, this injection is absent; therefore, these devices reach impressive EQE values of 1,000-10,000 %. However, the underlying microscopic mechanisms remain unclear. Here, we precisely tune the interface layers via vacuum deposition, enabling us to reveal the injection mechanism.

Another solution is photoactive transistors. We introduce vertical organic-permeable base transistors (OPBTs) that operate at low driving voltages and achieve high switching speeds. We report, for the first time, a photogating effect in OPBTs. By leveraging the unique structure of OPBTs and conducting a detailed investigation into the underlying charge-storing mechanism, we have achieved record responsivity values reaching 10^9 A/W, specific detectivities of 10^{15} Jones (based on noise measurements), and retention times exceeding 10^5 s. [1]

HL 26: Poster II

Time: Wednesday 9:30–11:30 Location: P1

HL 26.1 Wed 9:30 P1

Quantum Dots in Nonlinear Mechanical Resonators — •Jona Richter, Noah Spitzner, Emeline Nysten, Matthias Weiss, and Hubert Krenner — Universität Münster, Münster, Germany

Surface acoustic waves are employed in a broad range of technologies, including radio-frequency filters in wireless communication systems and life-science applications. In the presented work, SAWs are utilized to drive mechanical modes in a quantum-dot membrane patterned into rings on a lithium niobate substrate. Generation of the SAWs is achieved by fabricating a comb-shaped interdigital transducer on the substrate. When an RF signal is applied, the piezoelectric response of the lithium niobate converts the electrical excitation into coherent acoustic waves propagating on the surface of the substrate. The propagating SAW induces a periodic modulation of the QD lattice constant, resulting in a corresponding modulation of the emission energy at the driving frequency. This mechanism enables the use of individual QDs as point-like nanoscale sensors, which can be probed through photoluminescence spectroscopy using ultrafast optical detection. When sweeping the RF frequency over a range of 200-900 MHz, pronounced resonances in the emission-energy modulation are observed, but only for QDs located within the ring structures. Both time-integrated as well as time-resolved measurements exhibit clear signatures of nonlinear mechanical behavior for example a hysteresis.

HL 26.2 Wed 9:30 P1

Gallium Nitride arrays for proton imaging — •Nico Frédéric Brosda[1], Matilde Siviero[2], Maxime Hugues[2], Stéphane Higueret[3], Nicolas Arbor[3], Andreas Wieck[1], and Jean-Yves Duboz[2] — [1]Ruhr University Bochum, Faculty of Physics and Astronomy, Experimental Physics VI, D-44780 Bochum, Germany — [2]Université Côte d'Azur, CNRS, CRHEA, 06560, Valbonne, France — [3]Université de Strasbourg, CNRS, IPHC UMR 7178, F-67000 Strasbourg, France

The MATRIX project is advancing proton therapy for cancer treatment by developing novel, highly durable detectors designed to improve real-time control of irradiation doses. Proton detection is performed by measuring the charge generated within the active regions of PIN GaN diodes. These GaN-based devices are fabricated as linear arrays containing 128 diode elements, as well as two-dimensional imaging arrays with up to 11 × 11 elements, covering an area of 1 cm^2 and achieving spatial resolutions of up to 500 μm. Owing to microelectronic fabrication techniques, even higher resolutions can be realized when required. The spatial performance of these detectors was validated through proton radiography of test objects using a 24 MeV beam, benchmarked against non-pixelated Gafchromic film. Measurements with phantoms of varying thickness further demonstrated the detector's capability for energy-resolved proton imaging. With achieved frame times of 1 ms, the MATRIX detector also provides a first proof of concept for real-time proton beam monitoring.

HL 26.3 Wed 9:30 P1

Impact of Ge-doping on the photoelectrochemical response of cubic (Ga,In)N photoelectrodes — •Sundas Hamid[1,2], Marius Wasem[1,2], Mario F. Zscherp[1,2], Silas A. Jentsch[1,2], Jörg Schörmann[1,2], Sangam Chatterjee[1,2], and Matthias T. Elm[1,2] — [1]Center for Materials Research, Heinrich-Buff-Ring 16, 35392 Giessen — [2]Institute of Experimental Physics I, Heinrich-Buff-Ring 16, 35392 Giessen

(Ga,In)N is a promising electrode material for electrochemical water splitting as the amount of indium determines the band gap of the semiconductor alloy. In this study we focus on the influence of germanium doping on the photoelectrochemical response of cubic (In,Ga)N photoanodes, which were grown by molecular beam epitaxy (MBE). Different methods like open circuit potential, cyclic voltammetry and electrochemical impedance spectroscopy were used to analyse charge carrier transport and the properties of the electrode electrolyte interface, such as flat band potential. The non-intentionally doped samples show a high photocurrent, indicating less recombination and efficient charge separation, while doping decreases the photoelectrochemical response. Despite the lower photocurrent, the doped samples show higher electrochemical stability displaying structural strength and chemical resistance at the interface. The results show that a trade-off between stability and activity needs to be achieved by controlling doping and indium concentration to develop durable and efficient III-nitride photoanodes for solar water splitting.

HL 26.4 Wed 9:30 P1

First Principle Calculations of Scandium-Aluminium-Nitrides — Max Grossmann, Malte Grunert, and •Wichard beenken — Technische Universität Ilmenau, Institut für Physik, Theoretische Physik I, Ilmenau, Germany

We have calculated the crystal structures and optical spectra of $Sc_xAl_{1-x}N$ compounds in trigonal/hexagonal and tetragonal/cubic lattices. For increasing Scandium content, we could confirm the experimentally found first order phase transition from Wurtzit to Rock-Salt structure. Furthermore we found a second order phase transition to the theoretically predicted metastable hexagonal-MgO-structure. Thereby, we studied various possible superstructures for rational Scandium to Aluminium proportions in detail. Using LDA, *GW*, and BSE methods, we calculated band structures and optical dielectric functions for selected $Sc_xAl_{1-x}N$ compounds with high precision.

HL 26.5 Wed 9:30 P1

Tracing Charge Carrier Transport in Freestanding Core-Shell GaN Nanowires on n-Si(111) Substrates — •Juliane Koch[1], Patrick Häuser[2], Peter Kleinschmidt[1], Lisa Liborius[2], Nils Weimann[2], and Thomas Hannappel[1] — [1]Technische Universität Ilmenau, Fundamentals of Energy Materials, Ilmenau, Germany — [2]University of Duisburg-Essen, Components for High Frequency Electronics (BHE) and CENIDE, Duisburg, Germany

Precisely engineered heterojunctions are essential for advancing nanoscale systems with superior electrical performance. The structure and electrical behavior of nanostructured devices must be examined with high spatial resolution.

This study investigates the charge carrier transport in freestanding core-shell GaN nanowires (NW) grown via polarity- and site-controlled metal-organic vapor phase epitaxy with a site-dependent AlN interlayer on pre-structured n-type Si(111) substrates. Multi-tip scanning tunnelling microscopy and electron beam-induced current mapping were utilized to probe local transport phenomena with high precision. Transport pathways of charge carriers within the NWs and across key interfaces were resolved. Distinct I-V characteristics appeared for different facets, while scanning transmission electron microscopy revealed no direct shell-core contact. Consequently, current transport is governed by three serially connected diodes: shell-shell, shell-core, and NW-substrate junctions. These results reveal mechanisms shaped by geometry and interfaces, advancing understanding of charge carrier dynamics in III-N nanostructures.

HL 26.6 Wed 9:30 P1

Optical loss characterization in UV multimode AlGaN waveguides with and without a backside absorbing layer — •Leonardo Wildenburg[1], Verena Kowallik[1], Tim Wernicke[1], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH), Berlin, Germany

Photonic integrated circuits (PICs) in the UV range enable complex optical functions on a chip-scale platform, e.g. for the detection of gases and biomolecules by absorption or Raman spectroscopy. The implementation of UV PICs requires wide-bandgap materials to ensure optical transparency. Among the available material systems, one promising candidate is AlGaN due to its application in UV-LEDs and laser diodes. In this work, the optical losses near 265 nm of n-$Al_{0.76}Ga_{0.24}N$ waveguides with a width of 200 μm are investigated using a monolithically integrated UV-LED and UV-photodetector. The influence of straylight from the substrate backside was investigated with and without an absorbing 200 nm thin SiN layer. When operating the LEDs at a constant output power of 0.2 mW, the photocurrent decreases exponentially with increasing waveguide length according to Beer-Lambert-law. The reduction of scattered light was confirmed by measurements of photodetectors of the same wafer, but not connected to the emitting LED by a waveguide. Thus, optical losses of (40 ± 5) cm^{-1} with an absorbing layer and (33 ± 5) cm^{-1} without were measured for the n-$Al_{0.76}Ga_{0.24}N$ waveguides. It was also determined that the optical losses strongly depend on the amount of scattered light from the UV-LED signal.

HL 26.7 Wed 9:30 P1

Optimization of etching processes for quantum well structures to enhance IR emission — •Daniel Janzen[1], Peter Zajac[1], Sascha R. Valentin[2], Arne Ludwig[1], and Andreas D. Wieck[1] — [1]Ruhr-Universität Bochum, Bochum, Germany — [2]Gesellschaft für Gerätebau mbH, Klönnestr. 99, 44143 Dortmund

The precise control of etching processes is crucial for the properties of quantum well structures, especially in terms of IR emitter efficiency. This study examines how different etching techniques affect surface quality, defect formation, and electrical properties of the epitaxially grown GaSb layers. A critical aspect is the formation of oxides and metallic antimony, which can lead to leakage currents and short circuits. Through Atomic Force Microscopy (AFM) the influence of etching parameters are investigated. Reducing defect states and optimizing material passivation could contribute to the long-term improvement of emission efficiency. This research bridges materials science and semiconductor physics by discussing strategies to optimize surface states for IR emitters. The findings are relevant not only for quantum optics but also for sensor applications and industrial semiconductor fabrication.

HL 26.8 Wed 9:30 P1

Hydrogen Annealing of Silicon Micro- and Nanostructures through Rapid Thermal Processing — •Kyra Malcherek, Thomas Grap, and Markus Kaiser — Helmholtz Nano Facility, Forschungszentrum Jülich, Germany

As semiconductor devices continue to scale into the lower nanometer range, achieving smooth surfaces becomes increasingly important for device performance. In particular, silicon nanowires used in Gate-All-Around Metal-Oxide-Semiconductor Field-Effect Transistors (GAA-MOSFETs) require these characteristics to ensure uniform electrostatic control over the channel. Therefore, Hydrogen Annealing of silicon is a promising process to enable shape transformation and surface smoothing.

In this study, we characterized the effects of Hydrogen Annealing. Silicon microstructures showed a significant reduction in surface roughness and rounded corners after the process. In addition, stable crystal facets were formed and identified as (111) and (113) planes. The influence of the relevant process parameters - temperature, annealing time, hydrogen flow and pressure - were investigated. The radius of curvature increases with both temperature and annealing time, whereas hydrogen flow and pressure show no significant influence.

The process was further applied to silicon-on-insulator nanostructures, creating free-floating silicon nanowires after oxide etching. Subsequent hydrogen annealing effectively smoothed and rounded the structures, demonstrating its potential for the fabrication of GAA-MOSFETs.

HL 26.9 Wed 9:30 P1

Processing and Characterization of Mid Infrared Emitters from III-V Epitaxy — •Peter Zajac[1], Sascha R. Valentin[1], Timo A. Kurschat[1], Rainer Krage[1], Arne Ludwig[2], and Andreas D. Wieck[3] — [1]Gesellschaft für Gerätebau mbH, Klönnestr. 99, 44143 Dortmund, Germany — [2]Arbeitsbereich Epitaxie, Experimentalphysik VI, Ruhr-Universität Bochum, 44801 Bochum, Germany — [3]ehem. Lehrstuhl für Angewandte Festköperphysik, Ruhr-Universität Bochum, 44801 Bochum, Germany

A layer structure optimized for mid-infrared emission, containing W-type quantum wells has been realized with III-V epitaxy on GaSb. The processing workflow presented here, from the MBE-grown wafer sample to an emitting device, includes mesa etching, photolithography and electrical contacting. The contribution outlines the challenges faced in progressing towards the first prototype, including the optimization of the wet-etching process with respect to the observed trench formation and surface roughness. The electrical characterization includes contact resistance and I-V measurements. Electroluminescence spectroscopy is performed for optical characterization.

HL 26.10 Wed 9:30 P1

GaAs nanowire networks by electrochemical etching as a universal platform for oxide and nitride architectures — •Eduard Monaico[1], Sebastian Lehmann[2], Elena Monaico[1], Xinzhi Li[2], Veaceslav Ursaki[1], Ion Tiginyanu[1], and Kornelius Nielsch[2] — [1]Technical University of Moldova, Chisinau, Moldova — [2]Leibniz Institute of Solid State and Materials Research, Dresden, Germany

GaAs nanowire networks obtained by electrochemical etching provide a versatile platform for semiconductor-oxide-nitride architectures with controlled geometry and crystallinity. Depending on the orientation of the GaAs substrate ((100), (111)B, (001)), the resulting nanowires can be tilted, vertical, or oriented parallel to the surface. Formed by selective electrochemical dissolution rather than epitaxial growth, they retain the structural quality of the bulk crystal, offering a low-defect scaffold suitable for subsequent transformations.

In this work, we explore their conversion into oxides and nitrides. Thermal treatment in argon with 3% oxygen led to selective formation of Ga2O3 on the nanowires while preserving the GaAs substrate, confirmed by SEM, EDX, XRD, and Raman analysis. Preliminary nitridation tests also show the feasibility of forming GaN-based architectures. These findings highlight the potential of electrochemically derived GaAs nanowire networks as a universal platform for oxide and nitride structures relevant to optoelectronics, photonics, and sensing technologies.

We thank the BMFTR and NARD for the funding of ProMoMo project DEHYCONA.

HL 26.11 Wed 9:30 P1

Influence of AlInP(100) Surface Reconstruction on TiO_2/III–V Interface Chemistry and Band Alignment — Mohammad Amin Zare Pour[1,2], Christian Höhn[3], Negin Mogharehabed[1], Roel van de Krol[3], Thomas Hannappel[2], and •Agnieszka Paszuk[1] — [1]BMFTR Junior Research Group PARASOL, Technische Universität Ilmenau, Germany — [2]Fundamentals of Energy Materials, Technische Universität Ilmenau, Germany — [3]Institute for Solar Fuels, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Germany

TiO_2/III–V heterointerfaces are crucial for photoelectrochemical devices, as their chemistry and band alignment govern photogenerated charge-carrier transfer. The TiO_2/InP(100) heterointerface was recently studied using XPS/UPS and *ab initio* molecular dynamics simulations [Adv. Funct. Mater. 2025, 2506105]. ALD-grown TiO_2 on phosphorus-terminated (P-rich) InP(100) shows strong interface-induced band bending, $InPO_x$ formation related to the P-rich surface, and Cl incorporation from $TiCl_4$, reflecting precursor-dependent chemistry. Here, we relate these findings to AlInP(100) surfaces prepared with either P-rich or indium-rich termination, as well as with a thin oxide layer. By comparing oxide states and valence-band positions with those of InP, we analyze how surface reconstruction governs the formation and energetic alignment of TiO_2/III–V heterointerfaces. These insights highlight how AlInP surface preparation controls the formation and electronic structure of TiO_2/III–V interfaces.

HL 26.12 Wed 9:30 P1

Measuring the Temperature Distribution of GaSb Wafers during MBE Growth — •Timo A. Kurschat[1], Sascha R. Valentin[1], Peter Zajac[1], Rainer Krage[1], Arne Ludwig[2], and Andreas D. Wieck[3] — [1]Gesellschaft für Gerätebau mbH, Klönnestr. 99, 44143 Dortmund — [2]Arbeitsbereich Epitaxie, Experimentalphysik VI, Ruhr-Universität Bochum, 44801 Bochum — [3]ehem. Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, 44801 Bochum

During epitaxial growth the substrate temperature is one of the essential parameters. To obtain high-resolution temperature maps we use a single-lens reflex (SLR) camera with the infrared filter removed. The sensor is sensitive up to a wavelength of about 1 μm and can therefore be used as a pyrometer. With wafer rotation disabled, temperatures down to T_S = 400 °C can be measured. With rotation and a reduced exposure time of 0.25 s images can still be obtained at the growth temperature of T_S = 680 °C.

To optimize the temperature distribution, so called washers are used during growth that cover parts of the wafer. With the original washers, the center of our quarter 2" wafers is more than 20 K hotter than the corners. Without a washer the profile inverts. Therefore we designed a new washer which greatly improves the homogeneity.

On the other hand an inhomogeneous temperature profile can be used to optimize growth parameters, which we show with photoluminescence measurements of quantum wells and atomic force microscope images.

HL 26.13 Wed 9:30 P1

Impact of Al containing nucleation layers on Si(100)/GaP heterointerface — •Kai Daniel Hanke[1], Angieszka Paszuk[1,2], Peter Kleinschmidt[1], and Thomas Hannappel[1] — [1]Technische Universität Ilmenau, Fundamentals of Energy Materials, Ilmenau, Germany — [2]Technische Universität Ilmenau, BMFTR Junior Research Group PARASOL, Ilmenau, Germany

Monolithically grown III-V-on-silicon (100) tandem solar cells show great promise for applications such as direct solar water splitting. A critical interface in these devices is the Si/GaP heterointerface, at which defects originate and subsequently propagate through the entire III-V epitaxial stack. Minimizing defect formation at this initial interface is therefore essential for achieving high-efficiency water-splitting performance. The use of TMAl during the pulsed nucleation of the GaP layer has previously been shown to lower defect densities, particularly stacking faults, stacking-fault pyramids (SF/SFP), and threading dislocations (TDs). In this study, we investigate the effect of TMAl on the formation of SF/SFP and on the density of TDs. We further analyze how TMAl modifies the interfacial energetic band alignment using X-ray photoelectron spectroscopy, and study its impact on surface anisotropy and interface-related optical transitions by low-temperature reflection anisotropy spectroscopy. Defect densities are quantified by electron channeling contrast imaging, a scanning electron microscopy technique that exploits electron channeling at an acceleration voltage of 30 kV.

HL 26.14 Wed 9:30 P1

Enhanced Field Emission Current Density in Chemically Engineered Multiwall Carbon Nanotube Neodymium Oxide Heterostructures — •Anima Mahajan[1], Menaka Jha[2], and Santanu Ghosh[1] — [1]Department of Physics, Indian Institute of Technology, Hauz Khas, New Delhi -110016, India. — [2]Institute of Nano Science & Technology, Knowledge City, Sector-81, Mohali, Punjab- 160062, India.

The MWCNT, neodymium oxide (Nd*O*), and MWCNT-Nd*O* heterostructure were successfully fabricated through a facile three-step synthesis process: the synthesis of MWCNT rods by the chemical vapor deposition technique, the synthesis of the Nd*O* nanoparticles by using the micellar-assisted solid-state route, and the fabrication of the MWCNT-Nd*O* heterostructure. Moreover, the MWCNT-Nd*O* heterostructure exhibits enhanced field emission properties, with a lower turn-on field of 2.4 V/*m compared to pure MWCNT and Nd*O*, which have turn-on fields of 3.6 and 3.8 V/*m, respectively. The MWCNT*Nd*O* heterostructure exhibits an enhancement in current density of approximately 6365% compared to pure Nd*O* and around 172% relative to pristine MWCNT. The emission current stability at a preset value of 6 V/*m over an 8-hour duration is found to be fairly good, characterized by current fluctuations within * 3% of the average value. The enhanced field emission (FE) performance of the MWCNT-Nd*O* heterostructure is attributed to its high enhancement factor (β) of ~3.3*10*.

HL 26.15 Wed 9:30 P1

Low temperature photoluminescence excitation spectroscopy on thin film zinc phthalocyanine — •Josephine Braun, Sebastian Hammer, and Jens Pflaum — Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

The optical properties of molecular semiconductors are determined by the electronic properties of the molecular constituents and their respective intermolecular (IM) interaction [1]. To disclose the IM interaction, polymorphic materials like Zinc-phthalocyanine (ZnPc) provide perfect prototypical systems [2]. Its luminescence in the α-phase is dominated by excimer emission [3], wheras the β-phase luminescence is governed by a highly temperature sensitive Frenkel exciton emission. While temperature dependent luminescence studies provide insight into the IM interaction potential, the excitation spectrum does the same without being prone to effects of excitonic relaxation. In this contribution we investigate the excitonic system of ZnPc thin films in the α- and β-phase via temperature dependent photoluminescence excitation (PLE) and photoluminescence (PL) spectroscopy between 4 K and 300 K. We show, that while the PL spectra exhibits strong variability with temperature, the PLE spectra show only minor changes. This suggests that rather than a large modulation of the IM interaction with temperature, exitonic relaxation processes are at the heart of ZnPc's pronounced spectral luminescence changes.

HL 26.16 Wed 9:30 P1

Host-Emitter Interactions in Single-Gaussian Deep-Blue Europium(II) OLED Emitters — •Mahmoud Soleimani[1,2], Paulius Imbrasas[2], Jan-Michael Mewes[2], Felix Kaden[2], Sebastian Schellhammer[1], Toni Bärschneider[2], Carsten Rothe[2], and Sebastian Reineke[1] — [1]Institute of Applied Physics (IAP), Technische Universität Dresden, Germany — [2]beeOLED GmbH, Dresden, Germany

Lanthanide-based emitters offer a promising approach to stable and efficient deep-blue organic light-emitting diodes (OLEDs). While divalent europium [Eu(II)] and trivalent cerium [Ce(III)] can provide ideal emission colors with near-unity exciton utilization, their integration into thin-film architectures remains insufficiently understood. In particular, the compatibility of lanthanide complexes with organic host materials and possible lanthanide-specific interactions are open questions. To shed light on and gain a deeper understanding of these aspects, we combine photoluminescence spectroscopy and density functional theory to evaluate the behavior of a literature-reported Eu(II) emitter and to introduce two new carborate-based Eu(II) complexes. These novel materials exhibit deep-blue single-Gaussian 4f-5d emission. Our experimental and theoretical analysis provides a framework for understanding electron confinement and shielding in Eu-based emitters, establishing design principles for a new class of stable, efficient deep-blue OLED materials.

HL 26.17 Wed 9:30 P1

Flexible OLED-OPD System in a Rolled Geometry for Angle-Resolved Optical Sensing — •Shujun Pei, Jan Schardt, Markus Köpke, and Martina Gerken — Chair for Integrated Systems and Photonics, Faculty of Engineering, Kiel University, Kiel, Germany

We investigate an integrated sensing platform combining an organic light-emitting diode (OLED) and multiple organic photodetector (OPD) pixels fabricated on a single flexible PET substrate. After fabrication, the substrate is rolled manually such that the OLED and OPDs face each other across the inner circumference of a cylindrical channel. This geometry enables angle-dependent optical paths through fluids flowing inside the tube, providing a basis for reconstructing absorption and scattering profiles relevant for chemical and biomedical sensing.

To independently assess OLED-OPD performance, devices were characterized on separate flat substrates. OPD responsivity was quantified using a calibrated LED solar simulator and direct OLED illumination. Distance-dependent photocurrent measurements reveal the expected decay consistent with Lambertian emission and simple geometric coupling between the OLED and OPD pixels. Numerical modeling, including finite emitter and detector areas as well as realistic alignment offsets, closely reproduces the measured photocurrent trends.

These results demonstrate the feasibility of compact, flexible OLED-OPD assemblies for multi-angle optical sensing and provide a foundation for future device refinement.

HL 26.18 Wed 9:30 P1

Organic Narrowband Near-infrared Photodiodes for Breath Monitoring — •Sudhi Mahadevan[1,2], Siddhartha Saggar[1,2], Rabiul Islam[1,2], and Caroline Murawski[1,2] — [1]Institute of Solid-State Electronics, Technische Universität Dresden, 01062 Dresden, Germany — [2]Kurt Schwabe Institute for Sensor Technologies, Kurt-Schwabe-Straße 4, 04736 Waldheim, Germany

For clinical diagnosis of various diseases, breath analysis has become a powerful non-invasive tool, which demands the development of reliable and efficient sensing technologies. However, conventional respiratory monitors hinder users' mobility, provide discomfort, and affect natural breathing patterns. Recent progress in organic and wearable optoelectronics presents an opportunity to develop thin, flexible, and imperceptible sensors. In this work, we report high-performance near-infrared (NIR) organic photodiodes (OPD), using a PM6:Y6 blend combining a polymer donor with an NIR-absorbing small molecule processed from the green solvent o-xylene. In this simplified device architecture, the hole-blocking functionality is incorporated directly into the active layer, reducing fabrication complexity and enabling cost-effective production. A narrow-band optical response at 800 nm is achieved via an organic photo-filtering layer that allows only long-wavelength photons into the active layer. The optical breath sensor will integrate organic light-emitting diodes (OLEDs) to emit light onto the chest, while an OPD will capture changes in diffusely scattered light from the skin during breathing. This work aims to advance organic electronic devices into the NIR spectrum for non-invasive medical diagnosis applications.

HL 26.19 Wed 9:30 P1

Wavelength-selective, ultraviolet (Mg,Zn)O photodiodes — •Jonas Elz, Holger von Wenckstern, and Marius Grundmann — Leipzig University, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group, Leipzig, Germany

Ninety-five percent of the UV radiation that reaches the Earth's surface is in the UVA band (315-400 nm). In order to assess the potential harmful effects of UVA radiation on the human epidermis with compact, wearable devices, semiconductor technology can be used. Magnesium zinc oxide is a suitable material for detectors in such devices because it exhibits a bandgap between 3.3 and 4.8 eV.

One photodiode design uses a filter and an active layer with different material compositions to achieve sensitivity in different optical bands [2].

In this study, we use combinatorial pulsed laser deposition to fabricate metal-semiconductor-metal photodiodes that are sensitive to different wavelength ranges. With the same mask system and similar targets as in [3], we achieve multiple compositions of filter and active layers on a single substrate.

Determination of activation energies in vertical co-doped κ-Ga_2O_3 Schottky barrier diodes — •Elise Morawe, Sofie Vogt, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik Halbleiterphysik, Leipzig, Germany

The predicted spontaneous polarization of κ-Ga_2O_3 renders this polymorph of Ga_2O_3 highly interesting for, e.g., high electron mobility transistor devices [1]. As shown by Kneiß et al., vertical Schottky barrier diodes can be realized on pulsed laser deposition (PLD) grown κ-Ga_2O_3 thin films [2]. For that, the addition of tin in the process is mandatory to induce the surfactant-mediated growth of the κ phase [3]. We present κ-Ga_2O_3 thin films grown by PLD on indium tin oxide (ITO) layer on different substrates: c-sapphire and yttria-stabilized zirconia (YSZ). We discuss the influence of co-doping of the κ-Ga_2O_3 thin films with ZrO_2 or SiO_2 in addition to SnO_2 on the performance of Schottky barrier diodes. Furthermore, the activation energies of Sn, Zr and Si in the κ-Ga_2O_3 are determined by thermal admittance spectroscopy.

HL 26.21 Wed 9:30 P1

How To Tame Your Iodine in Reactive Sputtering and Similar UHV Thin Film Deposition Processes — •Christiane Dethloff, Sebastian Köpp, Sofie Vogt, Lukas Trefflich, Holger von Wenckstern, and Marius Grundmann — Felix-Bloch-Institute for Solid State Physics, Universität Leipzig, Germany

Sputtering in reactive atmospheres involves several challenging conditions, like target poisoning, or a hysteresis of the reactive gas partial pressure, leading to an unstable operation regime [1]. In order to investigate and control these process conditions, and therefore tune the properties of the resulting thin film, a controlled flux of the reactive species is crucial. Commonly, this is achieved by mass flow controllers, when O and N are the reactive gases [2]. However, in the case of an iodine enriched atmosphere this is hardly feasible, due to the corrosive effect and low inlet pressures.

We present an optical measurement setup, enabling real-time measurements of the iodine content in an iodine enriched Ar flow from an iodine vaporizer into a deposition chamber. Our investigations comprise the growth and characterization of functional p-type copper iodide (CuI) thin films by reactive magnetron sputtering under a well defined iodine flux.

Investigation of vertical α-Ga_2O_3/$(Al_xGa_{1-x})_2O_3$ diodes grown by pulsed laser deposition — •Veronika Lunova, Sofie Vogt, Paul Bokemeyer, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group, Leipzig, Germany

With a bandgap of 5.3 eV and a dielectric breakdown field of 10 MV/cm, α-phase gallium oxide is a promising ultra-wide bandgap semiconductor for high-power electronics [1]. Furthermore, alloying with isostructural α-Al_2O_3 is possible without a miscibility gap and allows for even higher band gaps and electrical breakdown fields [2]. In this work, we present a systematic investigation of vertical Schottky diode structures based on α-$(Al_xGa_{1-x})_2O_3$ thin films grown by pulsed laser deposition (PLD). The heterostructures consist of an undoped α-Ga_2O_3 buffer layer, highly doped intermediate layers, and an $(Al_xGa_{1-x})_2O_3$ layer. Achieving sufficient conductivity in $(Al_xGa_{1-x})_2O_3$ remains a major challenge; thus, we investigate donor activation as a function of aluminum content [3]. The structural quality and electrical properties of the resulting heterostructures were investigated, with focus on the influence of Al incorporation on crystal structure, carrier activation, and vertical transport behavior.

HL 26.23 Wed 9:30 P1

Titania-based aerodynamic nanomaterials produced by atomic layer deposition — •Tudor Braniste[1], Vladimir Ciobanu[1], Sebastian Lehmann[2], Phil Goldberg[2], Kornelius Nielsch[2], Niklas Wolff[3], Lorenz Kienle[3], Rainer Adelung[3], and Ion Tiginyanu[1] — [1]Technical University of Moldova, Chisinau, Moldova — [2]Leibniz Institute for Solid State and Materials Research, Dresden — [3]Institute for Materials Science, Kiel University, Germany

In this work, we report on a technology for the production of TiO2, Zn2TiO4, and Mg2TiO4 aero-nanomaterials. Titanium and magnesium oxides were deposited using atomic layer deposition (ALD) onto a sacrificial network of ZnO microtetrapods. After deposition, the sacrificial ZnO layer was removed using two different technological routes. The first route involves removing the zinc oxide in a citric acid solution at room temperature, followed by critical-point drying of the titania-based material. The second route consists of removing the ZnO substrate in a hydrogen atmosphere at high temperature. At temperatures as high as 850 °C in an atmosphere of H2 + Ar (2% + 98%), the ZnO core decomposes, and the resulting aero-nanomaterial consists of hollow microtetrapods with porous microtubular arms composed of Zn2TiO4 or (ZnMg)TiO2. Scanning and transmission electron microscopy, as well as X-ray analysis, were used to elucidate the morphology, composition, and crystal structure of the produced aeromaterials. The investigations revealed the influence of annealing temperature and the sequence of technological steps on the morphology and properties of the resulting materials.

HL 26.24 Wed 9:30 P1

Band-Gap Trends in Halide Double Perovskites from Quasiparticle Self-Consistent GW — •Louis Meier[1], Timur Biktagirov[1], Volodymyr Vasylkovskyi[2], Anastasiia Kultaeva[2], and Wolf Gero Schmidt[1] — [1]Physics Department, Paderborn University, 33098 Paderborn, Germany — [2]Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

Halide double perovskites represent a chemically versatile class of optoelectronic materials with tunable band gaps dependent on their cation and halide composition. Their diversity requires a first-principles framework that can predict these trends consistently. Semilocal density functional theory (DFT) underestimates band gaps, while many-body GW results depend sensitively on the DFT starting point. In this contribution, we assess the quasiparticle self-consistent GW (QSGW) method as a unified, starting-point-independent approach for predicting the electronic structure of the $Cs_2MM'X_6$ family (M = Bi, Tl; M' = Ag, Cu; X = Cl, Br), focusing on trends with composition and spin-orbit coupling.

HL 26.25 Wed 9:30 P1

Atomistic Modeling of A- and X-Site Mixing in Halide Perovskites using Cluster Expansion — •Hilde Bellersen[1], Ana M. Valencia[2], and Caterina Cocchi[1] — [1]Friedrich-Schiller-Universität Jena, Germany — [2]Carl von Ossietzky Universität Oldenburg, Germany

Designing stable and efficient halide perovskites involves navigating a vast space of possible chemical substitutions. To address this challenge, we combine density-functional theory calculations with a machine-learning-based cluster expansion framework [1] to efficiently explore multi-component perovskite alloys. Our training structures systematically sample A-site mixing (FA, MA, Cs), X-site mixing (I, Br, Cl), as well as simultaneous A- and X-site co-mixing, with the lattice parameters adjusted according to Vegard's law. These configurations provide the basis for constructing cluster expansion models capable of capturing key energetic trends across the full compositional space. Such models can be used to identify stability landscapes and quantify the influence of configurational effects. We present the methodology, dataset construction, and first insights from the ongoing model development, highlighting the importance appropriate settings to ensure model accuracy, as well as the potential of this approach to guide the design of complex halide perovskite alloys.

HL 26.26 Wed 9:30 P1

Cavity-enhanced microscopy: absorption measurements of single perovskite nanocubes and photo-switchable lipids — •Ayesha Khan[1], Ines Amersdorffer[1,2], David Hunger[3], and Thomas Hümmer[1,2] — [1]Qlibri GmbH, Munich, Germany — [2]Ludwig Maximilian University of Munich, Munich, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany

Optical studies of nano-scale systems through spectroscopy and imaging can reveal intrinsic optical properties of materials including resolving the exitonic fine structure of systems. However, due to diminutive absorption of nano-scale systems, it is challenging to perform absorption spectroscopy.

For a nano-scale system placed inside an optical resonator, the light passes through the sample thousands of times, enhancing the absorption and thus, allowing measurements.

Here we demonstrate the use of a fiber-based, open-access microcavity to perform direct measurements of the absorption of single perovskite nanocubes. We further image and obtain hyperspectral maps of perovskite nanocubes.

We also present the use of the cavity microscope to image label-free Azo-PC phospholipid bilayers in both cis and trans state and show the diffusion of the two states.

The successful measurements of different nano-scale systems promise that fiber-based microcavities can become standard tools for absorption measurements of these systems.

HL 26.27 Wed 9:30 P1

Excitonic Reststrahlen Effect in $(PEA)_2PbI_4$ — •Michael Pfeufer, Patrick Grenzer, Friedrich Schöppler, and Tobias Hertel — Institute of Physical and Theoretical Chemistry, Julius-Maximilains-University Würzburg, Germany

Layered Ruddlesden-Popper perovskites with their natural quantum well structure allow for strongly confined excitons with very high oscillator strengths. In this work, evidence of an excitonic Reststrahlen effect, a phenomenon in which strong exciton resonances push the real permittivity below zero, was identified and characterized in phenethylammonium lead iodide $(PEA)_2PbI_4$. Transfer-matrix method simulations of the thin film were employed to fit temperature-dependent transmission measurements to an isotropic Lorentz oscillator model and to extract the dielectric function of the material. Additionally, we show that the behaviour of the Reststrahlen band in thickness-dependent transmission spectra is consistent with that found in other materials featuring a Reststrahlen-like response. Electric field calculations inside the material slab suggest natural exciton-polaritonic formation in the material, as well as longitudinal modes near the zero crossing of the real permittivity.

HL 26.28 Wed 9:30 P1

Optical Composition-Property Relationships in a Lead-Free Isostructural 2D Hybrid Metal-Halide Series — •Nils Kasten[1], Jan-H. Littmann[1], Meng Yang[2], Natalie Dehnhardt-Fehst[2], Lukas Gümbel[1], Ralph Kusche[2,3], Markus Stein[1], Johanna Heine[2,3], and Sangam Chatterjee[1] — [1]Institute of Experimental Physics I and Center for Materials Research (ZfM), Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany. — [2]Department of Chemistry and Material Sciences Center, Philipps-Universität Marburg, Hans-Meerwein-Straße, 35043 Marburg, Germany. — [3]Insitute of Chemistry, Carl von Ossietzky Universität Oldenburg, Ammerländer Heerstraße 114-118, 26129 Oldenburg, Germany.

Organic–inorganic metal halides have achieved notable success in photovoltaics. Among these, metal-halide perovskites represent a versatile class of compounds, exhibiting diverse optoelectronic behaviour, ranging from narrow-band emission to broadband white-light photoluminescence (PL), typically arising from self-trapped excitons (STEs). These characteristics render them relevant for optoelectronic applications. In this study, we investigate a lead-free isostructural series of two-dimensional hybrid metal halides, $[(R)\text{-1-(4-F)PEA}]_4[E_2X_{10}]$; (R)-1-(4-F)PEA = (R)-1-(4-fluoro) phenylethylammonium, where E = Sb, Bi and X = Cl, Br, I. All compounds share a common structural framework, which allows us to isolate the effects of metal-cation and halide-anion substitution on the optical response. We employ PL and Raman spectroscopy to characterize these compounds.

HL 26.29 Wed 9:30 P1

Stokes, Anti-Stokes and selective excitation of Si-vacancies in SiC — •Emilian Eisermann, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

Our group has demonstrated a room temperature continuous-wave maser that uses the silicon vacancy (V2) in silicon carbide (4H-SiC) (arXiv:2312.08251). Stimulated emission arises from an optically pumped population inversion in these spin defects. However, only a low output power could be achieved and laser heating caused instabilities. To enhance the maser characteristics, we investigate the fundamental pumping behavior of V2 (zero phonon line at 916.2 nm). Hereby, we distinguish between common Stokes excitation (CSE) (<916.2 nm), Anti-Stokes excitation (ASE) (>916.2 nm) and selective excitation (=916.2 nm). Using electron paramagnetic resonance spectroscopy, we resolve microwave absorption and emission signals due to the optical polarization of Zeeman split states. By analyzing these features, we calculate the population inversion and hence the pump efficiency. At low temperatures selective excitation is particular efficient and CSE outcompetes ASE, which requires thermally driven phonons. At room temperature, the increased phonon activity and the shortened T_1 lifetime cause ASE (λ=950 nm) to have an efficiency of around 50 % compared to CSE. ASE however allows for a very targeted excitation of V2 and we identify an optical pumping sweet spot that is promising for future maser implementations.

HL 26.30 Wed 9:30 P1

Double Gaussian Defect Cavity Design for Semiconductor Based Entangled Photon Sources — •Xian Zheng, Fei Ding, and MIchael Zopf — Institute of Solid State Physics, Leibniz University of Hannover, Appelstr. 2, 30167 Hannover, Germany

Polarization-entangled photon pairs are essential resources for quantum communication and quantum networks, enabling protocols such as quantum key distribution, teleportation, and entanglement swapping. However, simultaneously controlling cavity spectrum, field profile, and balanced coupling to multiple radiative transitions in a solid-state emitter remains challenging. In this work, we design a double-Gaussian defect cavity as a flexible platform to engineer semiconductor quantum-dot entangled photon sources. Two Gaussian-shaped, microsphere-like thickness modulations are embedded inside a DBR cavity and sculpt the axial and lateral field distributions, providing independent knobs, such as cavity height and defect width, to simultaneously tune the cavity resonance close to emission lines, such as biexciton and exciton emission and optimize the emission wavelength. Using FDTD simulations and time-domain exponential decay fitting, we extract the quality factor, mode volume, and Purcell enhancement, and quantify their dependence on the geometric parameters. The resulting design framework provides practical guidelines for tailoring cavity*quantum-dot coupling in double-Gaussian defect geometries and supports the development of bright, on-demand entangled photon sources suitable for future integrated quantum-network architectures.

HL 26.31 Wed 9:30 P1

Low-density InAs quantum dots for telecom O-band single-photon emission — •Elias Kersting, Nikolai Spitzer, Hans Georg Babin, Severin Krüger, Phil Julien Badura, and Arne Ludwig — Ruhr-Universität Bochum, EP6 , Bochum, Germany

InAs quantum dots (QDs) grown by molecular beam epitaxy (MBE) are promising candidates for single-photon sources (SPS), particularly for quantum communication. Emission in the telecom O-band (1260 - 1360 nm) is especially desirable due to the low transmission loss in optical fibers. However, conventional Stranski-Krastanov (SK) InAs QDs face challenges in achieving low and well-controlled densities in the range of 0.1- 10 QDs/um^2, as well as in precisely tuning the emission wavelength. We present an alternative approach to address this issue based on local droplet etching (LDE), in which nanoholes in a GaAs matrix are filled with InAs to form QDs. The quantum dot density is defined by the nanohole pattern, enabling precise and scalable control. A strain-reducing layer (SRL) shifts the emission wavelength into the telecom O-band. Homogeneous low-density (~2 QDs/um^2) growth is achieved through shutter-synchronized deposition, making this approach well suited for scalable SPS fabrication. We detail the fabrication method and present structural and optical characterization results.

HL 26.32 Wed 9:30 P1

Effect of TiO_2 thin films on shallow NV centers in co-doped diamond. — •Arthur Witte, Dominic Reinhardt, Peter Schlupp, Holger von Wenckstern, Jan Meijer, and Marius Grundmann — Universität Leipzig, Felix-Bloch Institute for Solid State Physics, Germany

The nitrogen vacancy (NV) center is a color center in diamond, that was proposed as a platform for solid state quantum computing. Essential for this idea is the spin-dependent photoluminescence of the negatively charged NV center, through which an optical spin polarization can be achieved and its relatively long spin coherence time at room temperature. Much research has been done in this direction: to engineer the required negative charge of the NV centers, co-doping of the diamond with donors was developed [1]. Shallow NV centers are subject to surface effects that cause charge instabilities, as well as magnetic and electronic noise. Various surface treatments have been explored to mitigate these effects, including the deposition of a passivation layer on the diamond surface. We combine surface engineering and charge engineering by co-doping and study the effects of these methods on the charge state and T_2 time of shallow NV centers. This is done by sputtering transparent titanium dioxide layers of varying thickness onto a diamond with shallow NV centers in differently co-doped environments. Additionally, effects of annealing of the layer on both the layer itself and the NV properties are discussed.

HL 26.33 Wed 9:30 P1

High-Resolution Lift-Off Process for Sub-100-nm Metal Features using a PMMA Bilayer Stack — •Melina Sporkett[1], Lina Trippelsdorf[1,2], Thomas Grap[1], Florian Lentz[1], and Markus Kaiser[1] — [1]Helmholtz Nano Facility, Forschungszentrum Jülich, Germany — [2]Peter Grünberg Institute, Forschungszentrum Jülich, Germany

A reliable and reproducible lift-off process is essential for the fabrication of high-resolution metal structures in micro- and nanotechnology. This has become increasingly important due to recent advances in quantum computing. In quantum devices, these nanoscale electrodes and interconnects are needed to realize the electrical connections to qubits.

In this study, we present a PMMA bilayer lift-off process that enables the reliable fabrication of structures below 100 nm, including fine lines and spaces. The resist stack consists of a copolymer bottom layer that creates a defined undercut and a thin PMMA/CSAR top layer. Through specifically optimized electron-beam lithography and development using a methoxypropanol-based developer, a clearly defined resist profile was achieved. Subsequent metal deposition using Ti/Au electron beam evaporation enabled the fabrication of lines with a width of only 30 nm.

These results demonstrate a robust and practical process for fabricating ultra-fine metallic interconnects for nanoelectronic applications.

HL 26.34 Wed 9:30 P1

Diamond devices for high contrast electrical readout of NV centers — •Melina F. V. Pees[1], Lina M. Todenhagen[1], Joachim P. Leibold[2], Dominik B. Bucher[2], and Martin S. Brandt[1] — [1]Walter Schottky Institut, TU Munich, Am Coulombwall 4, 85748 Garching — [2]Department of Chemistry, TU Munich, Lichtenbergstr. 4, 85748 Garching

Nitrogen-vacancy (NV^-) centers in diamond enable optically and electrically detected magnetic resonance (ODMR and EDMR/PDMR, respectively) and are a promising semiconductor platform for spin-based sensing. Metal contacts often influence the NV^- charge state, change current flow near the surface and worsen the spin contrast in resonance measurements. In this work we investigate shallow, implanted NV ensembles under Ti/Pt/Au contacts using combined photoluminescence, photocurrent and ODMR/EDMR measurements as a function of applied bias voltage, nitrogen implantation depth and position relative to the metallized surface. We have recently shown that Pt, just as other metals, strongly influences the charge state of the NV centers underneath the contacts, leading to mostly neutral or positively charged centers. Here, we show that via application of bias voltages, the negative charge state can be partially recovered, leading to an increase in the spin contrast. This approach allows to stabilize the NV^- charge state and improves the suitability of such diamond devices for quantum sensing applications.

HL 26.35 Wed 9:30 P1

Fabrication of SNSPDs on TF-LNoI for measurement device independent QKD — •Simon Palitza[1,2,3], Bilal Malik[1,2,3], and Carsten Schuck[1,2,3] — [1]Department for Quantum Technology, University of Münster — [2]Center for NanoTechnology - CeNTech, Münster — [3]Center for Soft Nanoscience - SoN, Münster

Thin-Film Lithium Niobate on Insulator (TF-LNoI) has been recognized as a promising platform for realizing low-loss propagation and high-speed modulation of optical signals in photonic integrated circuits. However, quantum technology applications, such as quantum key distribution (QKD) also require integrating single photon detection capabilities with nanophotonic functionalities. Here we show how crucial optical circuit components of a QKD-receiver can be co-integrated with Nb-based Superconducting Nanowire Single Photon Detectors (SNSPDs) on the TF-LNoI-platform. We specifically assess the influence of ubiquitous lithium diffusion on SNSPD performance and explore mitigation strategies in the design and nanofabrication process flow, such as introducing diffusion barrier layers. Combining efficient measurement capabilities with the stability and low loss routing of optical signals in monolithic LNoI-circuits provides a viable way towards realizing quantum communication protocols, such as measurement device independent QKD.

HL 26.36 Wed 9:30 P1

Role of a Quarter-Wave Plate in Resonant Laser Spectroscopy: Signature of Spin-Orbit Interactions of Light — •Wenze Lan, Anton Lögl, and Bernhard Urbaszek — Institute for Condensed Matter Physics, Technische Universität Darmstadt, 64289 Darmstadt, Germany

Resonant laser spectroscopy is a powerful technique for probing the intrinsic optical transitions, coherence properties, and spin dynamics of single quantum emitters. Although polarization-based dark-field confocal microscopy enables nearly background-free detection of resonant fluorescence [1], the role of an additional quarter-wave plate in further improving extinction has remained unclear. Here, we elucidate the mechanism by which a commercial quarter-wave plate enhances polarization extinction in a simple confocal geometry. Under cross-polarization conditions, the transmitted beam exhibits a robust first-order Hermite-Gaussian mode, which explains the improved background suppression and we identify it as a direct signature of spin-orbit interactions of light [2-3]. Our findings inspire applications in polarization optics, nanophotonics, and quantum photonics. [1] Rev. Sci. Instrum. 84, 073905 (2013); [2] J. Opt. 15, 014001 (2013); [3] Nat. Photon. 9, 796-808 (2015).

HL 26.37 Wed 9:30 P1

Phonon-Polaritons in MOVPE-grown hexagonal Boron Nitride — •Oskar Schröer[1], Maximilian Scharpey[1], Lena Miler[2], Johannes Binder[2], Andrzej Wysmołek[2], Daniel Wigger[3], and Iris Niehues[1] — [1]Institute of Physics, University of Münster, Germany — [2]Faculty of Physics, University of Warsaw, Poland — [3]Department of Physics, University of Münster, Germany

Two-dimensional materials composed of atomically thin layers have attracted great interest due to their unique optical and electronic properties. Using a scattering-type scanning near-field optical microscope (s-SNOM), surface phonon polaritons (SPhPs) are observable in the insulating polar van-der-Waals material hexagonal boron nitride (hBN) [1]. While most works focus on exfoliated single-crystalline layers of hBN, we show that SPhPs can also be excited in hBN grown by metalorganic vapor phase epitaxy (MOVPE). Here, grain boundaries and defects play a major role for the propagation properties of the polaritons. By evaluating the real-space interference patterns, we extract dispersion relations and compare propagation characteristics for the two sample types. The results contribute to a deeper understanding of light-matter interactions in polar van der Waals materials and may pave the way towards improved control and manipulation of light-matter excitations on the nanometer scale.

HL 26.38 Wed 9:30 P1

Predicting nonlinear optical properties from the linear response: Generalized Miller Formulae — •Maximilian Tim Meyer and Arno Schindlmayr — Universität Paderborn, Department Physik, 33095 Paderborn, Germany

Predicting the nonlinear optical response of real materials from first principles remains a major challenge, since quantitative calculations require strong simplifications and large computational resources. As a shortcut, Miller's rule provides an empirical relation between the linear and second-harmonic coefficients. It can be extended to higher-order nonlinearities and is now accepted as a useful tool for guiding experiments and computational materials discovery. However, its theoretical foundation had long been limited to a simple derivation for the classical Lorentz model with a weak anharmonic perturbation, whose properties differ from those of real quantum-mechanical electrons. We have developed a mathematical framework which enabled us to prove that Miller's rule is nevertheless equally valid for weakly anharmonic quantum-mechanical oscillators [1]. For three-dimensional anharmonic oscillators, we further derived generalized Miller formulae that express all orders of the nonlinear response to an arbitrary multi-frequency field exactly in terms of the linear optical susceptibility [2]. These generalized formulae are applicable to a much broader range of nonlinear optical processes and systems. The practical implementation is illustrated by means of a numerical example. [1] Meyer and Schindlmayr, J. Phys. B **57**, 095001 (2024). [2] Meyer and Schindlmayr, Dynamics **5**, 34 (2025).

HL 26.39 Wed 9:30 P1

Revisiting Cross-Polarized Resonant Excitation: Spin-Orbit Interaction in Confocal Dark-Field Microscopy — •Anton Lögl, Wenze Lan, and Bernhard Urbaszek — Institute for Condensed Matter Physics, Technische Universität Darmstadt, 64289 Darmstadt, Germany

Resonant excitation is a key experiment for accessing and probing the optical properties of semiconductor quantum emitters. The typical epifluorescence geometry of the cryostat environment presents an experimental challenge: separating the much weaker emission of the sample from the much stronger excitation, typically addressed using a cross-polarization scheme [1]. It is well known that confocal microscopy in combination with a dark-field technique can surpass the intrinsic extinction limit of commercial polarizers [1, 2]. In this work, we investigate the spin-orbit interaction of light observed when a polarized Gaussian beam is reflected from a mirror surface within such a microscope arrangement. We revisit the model from [2] and demonstrate that slight modifications allow us to phenomenologically model all of our results within the linear and circular polarization basis. Our results pave the way for improved characterization and optimization of optical setups used to measure the optical properties of various quantum emitters. Simultaneously, our results highlight how poorly understood the physical principles of one of the most common characterization techniques in resonant spectroscopy are.

Optical properties of $(Ti_xGa_{1-x})_2O_3$ — •Leonard Käferstein, Clemens Petersen, Daniel Splith, Holger von Wenckstern, Chris Sturm, and Marius Grundmann — Felix Bloch Institute for Solid State Physics, Leipzig University, Leipzig, Germany

The high bandgap energy in the order of 5.3 eV and its high predicted electrical breakdown field of about 10 MV cm^{-1} make α-Ga_2O_3 a quite promising material for transparent electronic devices and high power applications [1]. Alloying αGa_2O_3 with Ti leads to a decrease of the band gap. Here we report on the optical properties, especially the dielectric function, of $(Ti_xGa_{1-x})_2O_3$ determined by spectroscopic ellipsometry as a function of the cation composition.

A $(Ti_xGa_{1-x})_2O_3$ thin film with a lateral composition gradient was deposited by combinatorial pulsed laser deposition [2]. X-ray diffraction indicates a transformation from the tetragonal rutile phase for large Ti concentration ($x > 0.55$) toward a rhombohedral phase for $x < 0.4$. As $(Ti_xGa_{1-x})_2O_3$ is optically uniaxial and the optic axis is within the surface plane, generalized spectroscopic ellipsometry was applied. In the transparent spectral range, we determined a decrease from positive birefringence for high x towards negative birefringence for $x \approx 0$. As expected, we observe a redshift of the bandgap energy with increasing Ti-content from 5.1 eV for $x \approx 0$ down to 4.3 eV for $x \approx 0.85$.

***In situ* investigation of PEC devices by time-resolved photoluminescence** — •Peter Kleinschmidt, Ali Omar, Sahar Shekarabi, David Ostheimer, and Thomas Hannappel — TU Ilmenau, Institute of Physics, Fundamentals of Energy Materials, 98693 Ilmenau

Direct, unassisted photoelectrochemical (PEC) water splitting is a promising approach for the generation of solar hydrogen. At present, PEC devices still suffer from rapid degradation during operation in the electrolyte. In PEC devices, the control of the dynamics of minority charge carriers is crucial for efficient operation. *In situ* time-resolved photoluminescence (TRPL) measurement provides a direct access to charge carrier lifetimes in the PEC environment. We demonstrate that *in situ* TRPL reveals early-stage, localized degradation in PEC devices under operating conditions long before any decline in conventional performance metrics, such as a reduction in hydrogen evolution current density, becomes detectable. With this method, we investigate the effect of different surface treatments of dual junction PEC devices, in particular the functionalization with passivation layers and catalysts, on the stability and overall performance.

HL 26.42 Wed 9:30 P1

Propagation of Bloch surface polaritons in ZnO — Sebastian Henn, •Dmitry Sayenko, Marius Grundmann, and Chris Sturm — Felix Bloch Institute for Solid State Physics, Leipzig University, Leipzig, Germany

Here we present the long-range propagation of Bloch surface polaritons (BSP) in ZnO, which are formed through the strong interaction between light and excitons. Of special interest are BSP particles as they are bosonic quasi-particles and inherit the long-range propagating properties of the involved photons. In contrast to typically used microcavities, BSPs are formed at the surface of a photonic crystal, and thus the fabrication of these structures requires less technical effort and the properties of the BSP are surface-sensitive. In our studies, we realized BSPs in a photonic crystal made of distributed Bragg reflector made of yttria-stabilized zirconia (YSZ) and Al_2O_3. As an active medium, we used a ZnO surface layer, allowing strong coupling up to 430 K [1]. For the coupling of the BSPs to the vacuum modes, a 1D grating was etched onto the surface. By employing non-resonant excitation and varying the distance of the excitation with respect to the grating, the propagation length of BSPs was determined. We found that the propagation length of the BSP is about five times larger than would be expected for a pure photonic mode traveling through the ZnO layer [2]. We attribute this enhancement of the propagation lenght to the extended field distribution within the structure.

Comparative *ab initio* characterization of $LiNbO_3$, Li_3NbO_4 and $LiNb_3O_8$ — •Frederik Schmidt and Arno Schindlmayr — Universität Paderborn, Department Physik, 33095 Paderborn, Germany

Ferroelectric lithium niobate ($LiNbO_3$) is an important material for nonlinear optical technologies. It is part of the Li_2O–Nb_2O_5 system, whose two components can not only form $LiNbO_3$ but also other phases with different Li:Nb ratios, such as Li_3NbO_4 or $LiNb_3O_8$. Both are studied as possible materials for lithium-ion batteries on their own, but they may also occur as unwanted secondary phases during the growth of lithium niobate crystals when pure $LiNbO_3$ is preferred. As a consequence, it is important to detect and identify the different phases. In this work, we employ *ab initio* methods including density-functional theory, the *GW* approximation and the Bethe-Salpeter equation in order to characterize the three compounds with identical computational techniques and convergence parameters. In particular, we compare the density of states, electronic band structure and optical absorption spectrum of Li_3NbO_4 and $LiNb_3O_8$ to $LiNbO_3$. Despite qualitative similarities, our results reveal quantitative differences in the electronic and optical properties that should be clearly measurable in experiments. Compared to $LiNbO_3$, the electronic band gap of Li_3NbO_4 is 1.0 eV larger and that of $LiNb_3O_8$ is 0.4 eV smaller. The optical absorption edges also vary correspondingly.

HL 26.44 Wed 9:30 P1

Improving the optical readout of NV-centers in diamond by oxide surface coating — •Klemens Wurl, Michael Bar, Holger von Wenchstern, and Marius Grundmann — Universität Leipzig, Felix-Bloch Institute, Germany

Successful quantum computing has many advantages compared to regular computing, especially in simulations. It is proposed that nitrogen-vacancy (NV) centers in diamond could be used as qubits at room temperature, which would make everyday applications of quantum computing easier compared to solutions that rely on superconductivity.[1] The quantum states of the NV-centers can be controlled by optical excitation via laser and spin-state manipulation by microwave radiation.[2] The main objective of this research is to improve the optical readout of the NV-center by the use of solid immersion lenses (SIL). For this purpose, transition metal oxides are used, which are optically transparent and do not exhibit photoluminescence for the given wavelength. PLD is used for the surface coating, but the optical properties are limited by particle density. Therefore, peripheral target ablation was used to decrease the particle density as it allows for higher control of the plasma plume deflection. The influence of O_2 partial pressure and fluence will be investigated in order to record the corresponding growth window for decreased particle expulsion as well as increased optical transparency and refractive index.

Two-color sensitive II-VI wide-bandgap diodes with PbTe quantum dots for visible and infrared detection and emission — •Jakub Gluch[1], Sergij Chusnutdinow[1], Michal Szot[1,2], Piotr Wojnar[1], and Grzegorz Karczewski[1] — [1]Institute of Physics, Polish Academy of Sciences, 02-668 Warsaw, Poland — [2]International Research Center MagTop, 02-668 Warszawa, Poland

We present the results of research on p-n diode working as two-color photodetector, made from combined narrow- and wide-bandgap semiconductors. With the use of molecular beam epitaxy (MBE) we managed to create diode structures (p-ZnTe/(Active Layers - AL)/n-CdTe) with lead telluride (PbTe, 0.32 eV in 300K) quantum dots embedded in cadmium telluride matrix (CdTe, 1.49 eV in 300K). To create quantum dots we first grown 20 alternating layers of PbTe and CdTe on top of p-type layer, which followed by thermal annealing which break down PbTe layers in to dots. We performed current-voltage measurements for the basic characteristics followed by an optical measurements to obtain diode spectral response curves with respect to different temperatures in the visible and infrared ranges (350 - 3500nm in 300K). In photoluminescence measurement we observe emission from PbTe quantum dots. We confirmed junction formation in the diode by electron beam induced current (EBIC) measurements. On cross sections of this structures, we observed formation of double p-n junction at the interface of p-type layer and AL, and AL and n-type layer. Measurements show promising possibilities for creating infrared LED and at the same time photodetector with wide spectrum of detectivity.

HL 26.46 Wed 9:30 P1

Microscopic reverse-bias electroluminescence spectra and spectral images of 850 nm oxide-confined VCSELs during burn-in — •Arndt Jaeger[1], Nikolay Ledentsov Jr.[2], Sebastian Haberkern[1], Helmut Meinert[1], Alexander Moll[1], Dominik Ölke[1], Ilya E. Titkov[2], Oleg Yu. Makarov[2], and Nikolay Ledentsov[2] — [1]Esslingen University of Applied Sciences, Flandernstrasse 101, 73732 Esslingen, Germany — [2]VI Systems GmbH, Hardenbergstrasse 7, 10623 Berlin, Germany

850 nm vertical-cavity surface-emitting lasers (VCSELs) are studied during high-current burn-in operation utilizing both reverse-bias electroluminescence (ReBEL) spectra and spectral images. High-resolution spectral images are generated by means of a confocal scanning optical microscope using interference filters whereas microscopic spectra are obtained with a fiber-coupled sensitive USB spectrometer. Recently unfiltered ReBEL images have proven to be sensitive to operation-induced changes of VCSELs because defect states evolved during high-current stress trigger avalanche breakdown and give rise to ReBEL emission. In particular, local current crowding during high current burn-in leads to spatial distributions of ReBEL emission being characteristic to the aging status and contain spectral portions due to quantum well as well as AlGaAs barrier emissions. In contrast, electroluminescence spectra measured under near flat-band conditions exhibit only quantum well emission at 848 nm.

HL 26.47 Wed 9:30 P1

Optical Properties of a Transition-metal Dichalcogenide - ZnO Nanowire Field-effect Transistor — •Yashvi Bulsara[1], Maximilian Tomoscheit[1], Omid Ghaebi[1], Edwin Eobaldt[1], Carsten Ronning[1], and Giancarlo Soavi[1,2] — [1]Institute of Solid State Physics, University of Jena — [2]Abbe Center of Photonics, University of Jena

Transition-metal dichalcogenide (TMD) monolayers combined with zinc-oxide (ZnO) nanowires (NW) represent a promising platform for electrically tunable nanophotonic devices. ZnO NWs are naturally nanoscale lasers, supporting waveguiding, field amplification and being the gain medium at the same time. A further major step towards the success and broad applicability of NW lasers is the possibility to actively tune their laser properties via external stimuli, such as the piezo-electric effect[2]. Recently, we have demonstrated that coupling of ZnO NWs to monolayer TMDs leads to an increase of the lasing intensity threshold[3]. Building on this approach. in this poster I will propose a device where the laser emission of a ZnO NW can be electrically tuned by coupling it to a TMD based field-effect transistor. Besides the main idea and device architecture, I will present preliminary results of device fabrication and characterization. [1] M. Zapf, Nano Lett., 2017, 17 (11), 6637-6643 [2] E. Eobaldt, Nanoscale, 2022,14, 6822-6829.

HL 26.48 Wed 9:30 P1

PT-Symmetry in Excitonic Spectra of TMDC Monolayers under Influence of Magnetic Fields — •Michiel Snoeken, Andreas Knorr, and Henry Mittenzwey — Nichtlineare Optik und Quantenelektronik, Institut für Physik und Astronomie (IFPA), Technische Universität Berlin, D-10623 Berlin, Germany

Excitons in TMDC monolayers under the influence of an in-plane magnetic field are theoretically studied. We demonstrate that in-plane magnetic fields induce a hybridization between spin-bright and spin-dark exciton transitions, resulting in

a brightening of spin-dark excitons in optical experiments. We provide a thorough analytical characterization of the spectrum and demonstrate that, upon including dissipation, such a system can be interpreted as a gain-loss system as described in PT-symmetric quantum mechanics.

HL 26.49 Wed 9:30 P1

Calculation of thermodynamic potentials and heat capacities of ScN , YN and Au_2InYb — •Clemens Vogel and Jens Kortus — TU Bergakademie Freiberg, Institut für Theoretische Physik

ScN and YN can be incorporated in AlN to improve piezoelectric pro-perties and electromechanical coupling. The Heusler phase Au_2InYb is of interest due to its potential for thermoelectric properties. In this work we computed the thermodynamic potentials, the entropy, the specific heat capacities C_p and C_V, and the thermal expansion coefficient. The calculations were performed using DFT/DFPT in Quantum ESPRESSO (PBE-XC) using the quasi-harmonic approximation for phonons. C_p and C_V were determined over the range of 3-600 K, as well as entropy and thermal expansion coefficient; C_p exceeds the Dulong-Petit limit. For Au_2InYb, the projected density of states was also calculated, which reveals a strong $4f$ density of states near the Fermi level and indicating valence fluctuation (in agreement with experimental findings); the calculated heat capacities agree very well with the experimental measurements.

HL 26.50 Wed 9:30 P1

Super-Resolution Terahertz Spectroscopy via Near-Field Electro-Optic Sampling — •Kevin Berwagner, Moritz Heindl, Fabian Brütting, and Georg Herink — Universität Bayreuth

Electro-optic sampling of THz radiation transmitted through a specimen provides a non-invasive way to analyze materials, however, the spatial resolution is typically constrained by the diffraction limit of the THz beam to a few hundred microns.

In this contribution, we will present our progress in developing a novel method for sampling pulsed terahertz fields with potentially sub-micron spatial resolution. Specifically, the approach is based on local imaging of THz nearfields via an electro-optic material in close contact with the specimen. In contrast to established near-field approaches, the method does not require the scanning of local probes such as SNOM or micro-antennas. We analyze phase-matching conditions and effective resolutions, and we demonstrate the super-resolution capabilities.

HL 26.51 Wed 9:30 P1

Highspeed ultrafast spectroscopy via active synchronization of dual-comb lasers — •Simeon Schmitt, Julia Lang, and Georg Herink — University of Bayreuth, Germany

Dual-comb lasers enable ultrafast spectroscopic measurements at high speeds by generating optical delays without the motion of mechanical elements. According to the asynchronous optical sampling (ASOPS) scheme, pulses from two mode-locked lasers with detuned repetition rates are combined to automatically scan relative delays throughout the pulse period. In contrast, here, we present a novel approach which features flexible active synchronization of both lasers: Employing precisely timed electrical signals and fast electro-optical modulators, we achieve full control over the overall scanning process. This concentrates the scanning range to the region of interest by limiting it to several picoseconds, resulting in record fast scanning rates. Furthermore, the scanning resolution can be arbitrarily adjusted up to tens of THz by varying the repetition rate difference. We adopt this process to realize ultrafast acquisition speeds for rapid THz time domain spectroscopy and present first measurements.

HL 26.52 Wed 9:30 P1

Ultrafast negative thermal expansion in NbO_2 — •Florian Baltrusch[1], Marc Herzog[1], Florin Boariu[2], Matthias Rössle[2], Jutta Schwarzkopf[3], and Matias Bargheer[1,2] — [1]Institut für Physik und Astronomie, Universität Potsdam, Potsdam, Germany — [2]Helmholtz-Zentrum Berlin, Berlin, Germany — [3]Leibniz-Institut für Kristallzüchtung, Berlin, Germany

Niobium dioxide (NbO_2) exhibits negative thermal expansion (NTE), meaning it contracts upon heating rather than expanding like most materials. Below 200 K, bulk NbO_2 shows a monotonic contraction of the tetragonal c-axis, while the a/b-axes expand. This behaviour not only enables zero-expansion composites but also provides an unconventional elastic driving mechanism for magneto-elastic materials on picosecond timescales.

In epitaxial thin films, however, the lattice response is modified by substrate constraints via the Poisson effect. Temperature-dependent XRD measurements show that the film response depends strongly on the thermal-expansion mismatch between film and substrate during equilibrium heating.

Using ultrafast X-ray diffraction (UXRD), we directly observe ultrafast NTE in NbO_2 thin films. On picosecond timescales, the substrate remains effectively "frozen", allowing us to isolate the intrinsic response of the NbO_2 layer. This enables us to determine the timescale of contraction, which provides crucial insights about its driving mechanism.

HL 26.53 Wed 9:30 P1

Development of single-shot spectral referencing to increase signal-to-noise ratio in broadband 2D electronic spectroscopy — •Lotte Polling, Anton Trenczek, Pavel Trofimov, Trideep Kawde, and Hélène Seiler — FU Berlin

Two-dimensional optical spectroscopy is a powerful technique for resolving couplings between electronic states. Its implementation relies on the availability of a broadband light source in the visible range, typically generated using non-collinear optical parametric amplifiers or gas-filled hollow-core fibers. These sources exhibit shot-to-shot spectral fluctuations which can be as high as 10-15% depending on the laser source. Here, we introduce a setup for single-shot spectral referencing with the end goal of significantly increasing the signal-to-noise ratio in broadband 2D electronic spectroscopy measurements.

HL 26.54 Wed 9:30 P1

Ultrafast Lattice Dynamics in Gold Beyond the Kinematic Approximation — •Helena Hollstein[1,2], Sebastian Hammer[2], and Heinrich Schwoerer[1] — [1]Max-Planck-Institut für Struktur und Dynamik der Materie, 22761 Hamburg, Germany — [2]Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

In the interpretation of electron diffraction experiments, the kinematic scattering approximation and simple phonon models are often used to reduce computational cost when modeling structural dynamics [1]. However, even for well-studied benchmark systems such as polycrystalline gold thin films, it often remains unquestioned how reliably these assumptions hold under strong nonequilibrium excitation [2].

In this work, we investigate a 20 nm gold thin film under optical excitation using ultrafast electron diffraction (UED) and static temperature dependent electron diffraction to extract transient atomic displacements and determine phonon excitation by analyzing the Debye-Waller effect. We compare our experimental findings of lattice heating dynamics with simulated diffraction patterns that rely on kinematic scattering and harmonic phonon models. We hereby assess to what extent the commonly used theoretical frameworks cease to describe the structural response accurately. Our findings demonstrate that neglecting possible anharmonic potentials, phonon-phonon coupling and multiple scattering-effects can lead to systematic misinterpretations of ultrafast lattice dynamics and thermophysical material properties.

HL 26.55 Wed 9:30 P1

Ultrafast dynamics of exciton–exciton interaction in monolayer MoS_2 investigated by high-order pump–probe micro-spectroscopy — •Ruidan Zhu, Patrick Grenzer, Simon Büttner, Matthias Hensen, Tobias Hertel, and Tobias Brixner — Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

Exciton–exciton interaction (EEI), as a many-body effect, sets a fundamental limit to optimizing the photoluminescence efficiency of light-emitting devices based on 2D materials under high exciton densities [1]. A detailed understanding of the underlying EEI mechanisms provides crucial insight for the optimization of the device performance. However, EEI dynamics are challenging to probe directly as their signatures are mixed with the dominant single-exciton background in conventional ultrafast measurements. Here, we apply our recently developed high-order pump–probe spectroscopy [2] in a cryo-microscope to study exciton interaction in freestanding and supported MoS_2 monolayers. We aim to separate different EEI-related processes (fifth and higher orders of the system's nonlinear response) from the single-exciton dynamics (third order) and further investigate how the dielectric environment influences EEI dynamics. We present our current progress toward isolating EEI dynamics.

Impulsive Stimulated Raman Scattering: Highspeed Detection Strategies — •Laura Hüllmandel, Julia A. Lang, and Georg Herink — Universität Bayreuth

Pulse interaction of femtosecond pulses inside Ti:Sapphire lasers is mediated by Raman-active modes with terahertz beats causing bound states of solitons at fixed time delays [1]. In this contribution, we employ extra-cavity impulsive stimulated Raman scattering (ISRS) to quantitatively determine the phase-shifts involved to further our understanding of the intra-cavity formation of so-called "soliton molecules". We compare spectral-shift and interferometric methods for phase-sensitive detection and achieve efficient noise reduction of multiplicative $1/f$ noise sources – where lock-in amplification is ineffective – through rapid scan-averaging and balanced detection.

High Harmonic Hall Currents Driven by Curved Conducting Nanoarchitecture — •Ching-Hao Chang[1,2], Botsz Huang[1,2], Wei-Xiang Yin[1,2], and Xiao Zhang[3] — [1]Department of Physics, National Cheng Kung University Tainan, Taiwan — [2]Center for Quantum Frontiers of Research and Technology (QFort), National Cheng Kung University Tainan 70101, Taiwan — [3]Institute for Theoretical Solid State Physics Leibniz Institute for Solid State and Materials Research Dresden Helmholtzstr. 20, D-01069 Dresden, Germany

We theoretically establish a realizable non-perturbative mechanism for generating high harmon- ics (up to 6th order) in Hall currents within curved two-dimensional nanoarchitectures. Unlike previously explored perturbative mechanisms based on inversion symmetry breaking or Berry curvature, the high-harmonic generation demonstrated here is driven by magnetic-field dipoles induced purely by nanoscale curvature under an applied uniform magnetic field. We develop a theory showing that these harmonics originate from unique snake orbits induced by the interplay between an alternating electric field and curvature-induced magnetic-field dipole. Moreover, we establish quantitative control over harmonic suppression and enhancement by tuning the amplitude and orientation of the magnetic field, uncovering distinct symmetry-based even/odd harmonic selection rules. These findings provide a tunable platform for engineering nonlinear currents in curved electronics, with potential applications in developing high-frequency Hall sensors and THz devices.

HL 29.2 Wed 15:15 POT/0006

Gate-tunable isospin switching in graphene Mach-Zehnder electronic interferometers — •Antonio Lacerda-Santos, Lilian Seyve, Yassine Setti, Bikash Barik, Leo Pugliese, Preden Roulleau, and Cosimo Gorini — SPEC, CEA, CNRS, Université Paris-Saclay, 91191 Gif-sur-Yvette, France

Graphene has become an exciting platform for electron (quantum) optics experiments [1]. Compact electronic interferometers can be realised via p-n interfaces, which in quantizing magnetic fields host counter-propagating chiral edge states. In a paradigmatic architecture with a single junction, such quantum Hall states form a Mach-Zehnder interferometer [2, 3]. The precise position of such edge states is set by the electrostatics of a given device [4], which can be determined to great accuracy with the self-consistent Schrödinger-Poisson solver Pescado [5].

We perform electrostatic and quantum transport simulations accompanying conductance measurements in a graphene Mach-Zehnder interferometer, and show that remote gates can be used to control the position of the p-n junction on sub-nanometer scales. Such a fine control does not meaningfully affect the edge state positions and lengths, but induces valley-isospin oscillations. The interferometer thus behaves as a tunable valley-isospin transistor.

Phase-coherent autonomous nonequilibrium demon — •José Balduque[1,2] and Rafael Sánchez[1,2,3] — [1]Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Madrid, Spain. — [2]Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, Madrid, Spain — [3]Instituto Nicolás Cabrera (INC), Universidad Autónoma de Madrid, Madrid, Spain.

Mesoscopic conductors enable the efficient management and useful conversion of not only thermal resources but also nonequilibrium electron distributions. The latter scenario makes it possible to define demonic modes of operation, in which the entropy of a subsystem is autonomously reduced without extracting net particles or energy from the subsystem that provides the nonequilibrium resource [1]. We propose an implementation of such a nonequilibrium demon, or N-demon, in a multiterminal system that exploits carrier coherence. This is achieved by directly coupling the demonic subsystem to an isothermal two-terminal conductor via a scanning tip, enabling the local injection of electrons in a nonthermal distribution that participates in the phase-coherent interference processes governing the system's transport response [2]. In this way, we uncover an extrinsic, nonlocal, and phase-tunable transport response induced by the demon [3].

Exploring the Influence of Electron Density on the Giant Negative Magnetoresistance — •Lina Bockhorn[1], Christian Reichl[2], Werner Wegscheider[2], and Rolf J. Haug[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Germany — [2]Laboratorium für Festkörperphysik, ETH Zürich, Switzerland

Ultra-high mobility two-dimensional electron gases exhibit a robust negative magnetoresistance at zero magnetic fields, characterized by a temperature-independent peak around $B = 0$ T and a temperature-dependent giant negative magnetoresistance (GNMR) at higher fields [1-4]. By varying the electron density in situ, we gain valuable insights into the nature of GNMR. Our study shows a significant dependence of GNMR on electron density, suggesting that scattering potential variations [5] may not be fully addressed in current theoretical models. By examining these dependencies for different temperatures, we enhance the understanding of unresolved aspects of GNMR theory, potentially bridging the gap between experimental observations and theoretical predictions.

HL 29.5 Wed 16:00 POT/0006

A topological field-effect memristor — •Fabian Hartmann[1], Manuel Meyer[1], Selena Barragan[1], Sergey Krishtopenko[1,2], Jean-Baptiste Rodriguez[3], Eric Tournie[3], Benoit Jouault[2], Gerald Bastard[1], Frederic Teppe[2], Lukas Worschech[1], Victor Lopez-Richard[4], and Sven Höfling[1] — [1]Lehrstuhl für Technische Physik, Julius-Maximilians-Universität Würzburg — [2]L2C, CNRS-Université de Montpellier, France — [3]IES, Université de Montpellier, France — [4]Departamento de Fisica, Universidade Federal de Sao Carlos, Brazil

Quantum and neuromorphic computing rely on unconventional materials and device functionalities, yet achieving resilience to imperfections and reliable operation remains a major challenge. This has motivated growing interest in topological materials that provide robust and low-power operation while preserving coherence. However, integrating topological transport with memory functionality into a reconfigurable device has remained elusive. Here, we realize a topological field-effect memristor in which topological protection preserves edge state coherence, enabling the coexistence of coherent transport and non-volatile memory functionality. Utilizing inverted InAs/GaInSb/InAs trilayer quantum wells, we realize a quantum spin Hall insulator that exploits its intrinsic floating-gate behavior. This feature allows one to reconfigure the conventional field-effect transistor operation into memristive functionality with broad electric-field tunability. One resistance state is entirely governed by dissipationless, coherent transport.

HL 30: 2D Materials V – Magnetic, spintronic, and topological properties (joint session HL/TT)

Dual proximity engineering of spin-orbit and magnetic effects in graphene heterostructures — •Christoph Kastl — Walter Schottky Institute, School of Natural Sciences, Technical University of Munich — Munich Center for Quantum and Technology (MCQST)

The coexistence of induced spin-orbit coupling (SOC) and magnetic exchange fields is predicted to drive graphene into topological phases, such as the quantum anomalous Hall state. Here, I will discuss the prospect of using monolayer graphene proximitized by WSe_2 (SOC) and $Cr_2Ge_2Te_6$ (magnetic exchange) for such dual proximity control. To determine the type and strength of the induced SOC, I will compare Landau fan analysis, where level anticrossings can serve as direct signatures of spin-orbit splittings, to optoelectronic measurements on graphene/WSe_2 heterostructures, where the photogalvanic effect can provide an indirect fingerprint of SOC. Low-temperature magnetotransport measurements of the heterostructures with combined magnetic and SOC proximity reveal a large and gate-tunable anomalous Hall effect persisting at zero magnetic field, signaling an intrinsic Berry curvature arising from the interplay of SOC and magnetism. These results highlight the coexistence of spin-orbit and magnetic proximity effects in graphene-based van der Waals heterostructures and establish a route toward topological graphene phases.

HL 30.2 Wed 15:30 POT/0081

Twist angle and pressure tuning of proximity-induced spin-orbit coupling in graphene/WSe_2 heterostructures — Tobias Rockinger[1], Bálint Szentpéteri[2], Szabolcs Csonka[2], Marina Marocko[1], Julia Amann[1], Ziyang Gan[3], Antony George[3], Andrey Turchanin[3], Kenji Watanabe[4], Takashi Taniguchi[4], Dieter Weiss[1], Péter Makk[2], and •Jonathan Eroms[1] — [1]Department of Physics, University of Regensburg, Germany — [2]Department of Physics, Budapest University of Technology and Economics, Budapest, Hungary — [3]Institute of Physical Chemistry, Friedrich Schiller University Jena, Germany — [4]National Institute for Materials Science, Tsukuba, Japan

Proximity-induced spin-orbit interaction in heterostructures of graphene and transition metal dichalcogenides has been studied intensely in the past few years. However, present experiments still suffer from poor reproducibility, as one key parameter, the twist angle between the crystal axes of both materials, has not been systematically controlled during fabrication. Band structure calculations, on the other hand, have predicted a decisive influence of this parameter. In our experiments, we control the twist angle during fabrication by aligning fractured or CVD grown edges and resolving the ambiguity of zigzag and armchair directions using a crystallographic etching process. We employ weak antilocalization to extract the spin-orbit coupling parameters quantitatively, and report excellent reproducibility and a good match to theoretical predictions. We also confirm the influence of high pressure on the proximity effect.

HL 30.3 Wed 15:45 POT/0081

Nonlinear optical probing of local quantum geometry — •Nele Tornow[1], Paul Herrmann[1], Clemens Schneider[2], Jan Wilhelm[2], and Giancarlo Soavi[1,3] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — [2]Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy, Regensburg, Germany — [3]Abbe Center of Photonics, Friedrich Schiller University Jena, Jena, Germany

With its direct relation to many phenomena in solid matter, quantum geometry has become a concept of increasing interest in solid state physics. However, measurements of the local quantum geometry, *e.g.,* Berry curvature, has been possible to date only *via* angle-resolved photoemission spectroscopy [1]. On the other hand, in one of our recent theoretical works [2] we have shown that there is a link between linear circular dichroism and derivatives of Berry curvature in 3D crystals with preserved time-reversal symmetry (TRS).

In this presentation I will further demonstrate both, experimentally and with analytical solutions of semiconductor Bloch equations, that in a 2D semiconductor with broken TRS, the emerging second-harmonic circular dichroism can be used as a direct probe of the Berry curvature at the opposite ± K valleys, providing a new all-optical approach to access the local quantum geometry in 2D materials.

Proposal for Resolving Quantized Landau Orbits via Elastic XUV Scattering — •Sabrina Meyer[1], Andreas Knorr[1], Stephen Hughes[2], and Lara Greten[1,2] — [1]Institut für Physik und Astronomie, Technische Universität Berlin, Germany — [2]Department of Physics, Queen's University, Kingston, Canada

In a strong perpendicular magnetic field, a two-dimensional electron gas is quantized into discrete Landau levels. We propose a method to extract the spatial structure of Landau orbits via scattering with extreme ultraviolet radiation, whose wavelength naturally matches the Larmor radius. In a microscopic theory, we derive the far-field spectrum emitted by the optically induced current density. Contributions from Landau orbits within this spectrum are suppressed due to scattering effects imposed by the sample geometry. By normalizing against the zero-magnetic-field reference, however, we define a Landau level scattering spectrum that isolates Landau orbit information. This gives access to the probability density distributions of individual Landau level wave functions featuring radial maxima at the quantized Larmor radii.

HL 30.5 Wed 16:30 POT/0081

Berry Phase Shift in Folded Bilayer Graphene — •Hannes Kakuschke, Lina Bockhorn, and Rolf J. Haug — Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany

Mono- and bilayer systems of graphene have been extensively researched due to their unique magnetic und electronic transport properties. In more recent works, folded graphene [1-5] has gained interest as a platform for topological phenomena, such as zero-line modes [4]. However, these systems rely on self-assembled folded graphene, found by chance during exfoliation or induced by tearing [1-5]. Our dry-transfer approach allows us to fold graphene around hBN in a controllable manner, decoupling the overlapping graphene regions. In these samples, we observe a Berry phase shift from 2π to π near the edge of folded bilayer graphene, attributed to local strain fields and stacking shifts.

Probing spin-orbit coupling in graphene/WSe_2 heterostructures by the circular photogalvanic effect — Ernst Knöckl, •Matthias Klein, Alexander Holleitner, and Christoph Kastl — Walter Schottky Institute, School of Natural Sciences, Technical University of Munich

We investigate proximity-induced spin–orbit coupling (SOC) in graphene/WSe_2 heterostructures using the circular photogalvanic effect (CPGE) as a symmetry-selective and experimentally accessible probe of spin–valley-locked band textures [1]. By measuring helicity-dependent photocurrents as a function of gate voltage, excitation energy, and device geometry, we aim to disentangle Rashba and valley-Zeeman SOC contributions and to extract their magnitude and sign as a function of the graphene–WSe_2 twist angle. The observed trends in CPGE sign reversals and scaling behavior provide quantitative indications of interfacial symmetry breaking and moiré-enhanced spin–valley coupling, supported by comparison to microscopic transport models. These results are expected to establish CPGE as a promising metrological probe of proximity SOC in 2D heterostructures and to complement ongoing efforts in twist-angle-dependent spin–orbit engineering in graphene/TMD systems [2,3].

HL 30.7 Wed 17:00 POT/0081

Study of the non-trivial spin texture in Tellurium and the consequences in charge-spin interconversion — •Andrés Martínez-García[1], Daniel Gosálvez-Martínez[1], Carlos Sabater[1], and Juan José Palacios[2] — [1]Departamento de Física and Instituto Universitario de Materiales de Alicante (IUMA), Universidad de Alicante, Alicante, Spain. — [2]Departamento de Física de la Materia Condensada and Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, Madrid, Spain.

Tellurium is a chiral semiconducting material with a narrow band gap that can be synthesized with well-defined handedness in nanowires and flakes, making it an excellent platform for studying chirality-related charge-spin interconversion in nanodevices. The coupling between charge and spin degrees of freedom is closely connected to the spin texture in momentum space. In this work, we demonstrate that tellurium exhibits a nontrivial radial spin texture at the top of the valence band, where the spin polarization aligns parallel to the HK direction of the Brillouin zone, while spins in the perpendicular ZHL plane display a nontrivial winding. We investigate the electronic transport and resulting spin

polarization within the Landauer transport formalism using first-principles calculations. This approach allows us to map the transport properties along each crystallographic direction and to identify correlations between the spin polarization of the induced current and the underlying momentum-space spin texture. Our results provide microscopic insight into chirality-driven spin responses in tellurium and highlight its potential for spintronic applications.

Time: Wednesday 15:00–16:15 Location: POT/0251

HL 31.1 Wed 15:00 POT/0251

Escaping AB caging via Floquet engineering: photo-induced long-range interference in an all-band-flat model — Aamna Ahmed, •Mónica Benito, and Beatriz Perez-Gonzalez — Institute of Physics, University of Augsburg, 86159 Augsburg, Germany

Flat-band lattices hosting compact localized states are highly sensitive to external modulation, and the tailored design of a perturbation to imprint specific features becomes relevant. Here we show that periodic driving in the high-frequency regime transforms the all-flat-band diamond chain into one featuring two tunable quasi-flat bands and a residual flat band pinned at zero quasienergy. The interplay between lattice geometry and the symmetries of the driven system gives rise to drive-induced tunneling processes that redefine the interference conditions and open a controllable route to escaping Aharonov-Bohm (AB) caging. Under driving, the diamond chain effectively acquires the geometry of a dimerized lattice, exhibiting charge oscillations between opposite boundaries. This feature can be exploited to generate two-particle entanglement that is directly accessible experimentally. The resulting drive-engineered quasi-flat bands thus provide a versatile platform for manipulating quantum correlations, revealing a direct link between spectral fine structure and dynamical entanglement.

HL 31.2 Wed 15:15 POT/0251

Floquet theory for the quantum-to-classical crossover of light-matter models — •Beatriz Perez Gonzalez[1], Sigmund Kohler[2], and Mónica Benito[1] — [1]Institute of Physics (University of Augsburg), Augsburg, Germany — [2]Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), Madrid, Spain

Rabi-type Hamiltonians, comprising either a time-periodic driving or a quantized electromagnetic field, have become ubiquitous across physics. Despite the well-established physics of both the semi-classical and quantum descriptions, when and how classical Floquet physics emerges from a fully quantum treatment remains the subject of active debate [1] and study [2].

We present a unified framework for the quantum-to-classical mapping, emphasizing the gauge-invariant formulation of the quantum Rabi Hamiltonian. This allows a systematic comparison of quasienergies, spectra, entanglement, and dynamics across high- and low-frequency regimes, and clarifies how Floquet frames correspond to gauge choices once photonic Fock states are interpreted as Fourier harmonics. We further assess the suitability of quantum high-frequency expansions and benchmark them against alternative methods for deriving effective Hamiltonians, including Schrieffer-Wolff transformations and projector-based approaches.

HL 31.3 Wed 15:30 POT/0251

Understanding optically detected magnetic resonance (ODMR) of InSi-Sii-defects — •Kevin Lauer[1,2], Bernd Hähnlein[1], Mario Bähr[1], Kai Kühnlenz[1], Philipp Kellner[1], Dirk Schulze[2], Stefan Krischok[2], Alexander Rolapp[3], Christian Möller[1], and Thomas Ortlepp[1] — [1]CiS Forschungsinstitut für Mikrosensorik GmbH, Konrad-Zuse-Str. 14, 99099 Erfurt, Germany — [2]Technische Universität Ilmenau, Institut für Physik, Weimarer Str. 32, 98693 Ilmenau, Germany — [3]IMMS Institut für Mikroelektronik- und Mechatronik-Systeme gGmbH, Konrad-Zuse-Str. 14, 99099 Erfurt, Germany

Defects from the acceptor-interstitial silicon (ASi-Sii)-defect category were found to be promising candidates for qubits in silicon-based quantum technology [1]. To further explore their qubit properties optically detected magnetic resonance (ODMR) measurements are carried out on quenched indium-doped silicon samples featuring InSi-Sii-defects. Depending on the antenna design (omega or rod) four different ODMR signals are found in the spectra. An approach to understand these spectra in frame of a triplet system formed by two holes at the InSi-Sii-defect will be discussed. On that basis possible electronic level schemes are proposed.

[1] K. Lauer et al., 'Examining the properties of the ASi-Sii-defects for their potential as qubits', presented at the GADEST but unpublished, Bad Schandau: ResearchGate, May 2024. doi: 10.13140/RG.2.2.18793.51048.

HL 31.4 Wed 15:45 POT/0251

Time-bin encoded quantum key distribution over 120 km with a telecom quantum dot source — •Jingzhong Yang[1], Jipeng Wang[1], Joscha Hanel[1], Zenghui Jiang[1], Raphael Joos[2], Michael Jetter[2], Eddy. Patrick Rugeramigabo[1], Simone. Luca Portalupi[2], Peter Michler[2], Xiao-Yu Cao[3], Hua-Lei Yin[3,4], Shan Lei[5], Jingzhong Yang[1], Michael Zopf[1], and Fei Ding[1] — [1]Leibniz University of Hannover, Hannover, Germany — [2]University of Stuttgart, Stuttgart, Germany — [3]Nanjing University, Nanjing, China — [4]Renmin University of China, Beijing, China — [5]Anhui University, Hefei, China

Quantum key distribution (QKD) with deterministic single photon sources has been demonstrated over intercity fiber and free-space channels, but mainly on polarization encoding schemes. In contrast, time-bin encoding offers inherent robustness and has been widely adopted in mature QKD systems using weak coherent laser pulses.

In this work, we presents the first demonstration of the time-bin encoded quantum key distribution (QKD) using the telecom single photons from a quantum dot. A maximum tolerable transmission distance of 127 km is identified as the system error ratio approaches the security threshold. The result demonstrates the feasibility of realizing robust and scalable quantum communication network based on solid-state single-photon technology.

HL 31.5 Wed 16:00 POT/0251

high-efficiency photonic interfaces for VV centres in silicon carbide — •Nien-Hsuan Lee[1,2], Jonas Schmid[1,2], Berke Demiralp[3], Felix David[1], Kevin Menguelti[3], Stephan Kucera[1], Eva Weig[3,4,5], and Florian Kaiser[1,2] — [1]Luxembourg Institute of Science and Technology, Belval, Luxembourg — [2]University of Luxembourg, Belval, Luxembourg — [3]Technical University of Munich, Garching, Germany — [4]Munich Center for Quantum Science and Technology, Munich, Germany — [5]TUM Center for Quantum Engineering, Garching, Germany

In this work, we present a systematic investigation of etching processes aimed at optimising photonic structures for VV centres in bulk SiC. A wide range of fabrication parameters is explored, including metallic and non-metallic etch masks, plasma chemistries, and etching strategies to reduce surface and sidewall roughness while improving reproducibility. Structural and optical characterisation of the resulting waveguides enables identification of key loss mechanisms and the critical parameters governing high-efficiency photon transmission. Building on these process developments, we demonstrate a new generation of free-standing SiC waveguides with high wafer-scale uniformity and excellent reproducibility, enabling very high coupling efficiencies. Furthermore, we introduce a nanocone photonic structure in SiC, which simulations indicate can achieve more than a ten-fold enhancement in photon collection efficiency compared with unstructured bulk SiC. These results provide a scalable and reproducible photonic platform for wafer-scale integration of SiC colour centres for quantum communication.

HL 32: 2D Materials 2 (joint session DS/HL)

HL 33: Nitrides I – Growth and fabrication

Time: Wednesday 16:30–17:45 Location: POT/0006

HL 33.1 Wed 16:30 POT/0006

Homoepitaxial growth of AlN by plasma-assisted molecular beam epitaxy — •Xin Du, Hossein Yazdani, and Yongjin Cho — Paul-Drude-Institut für Festkörperelektronik (PDI), Leibniz-Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5–7, 10117 Berlin, Germany

Wurtzite AlN can be considered an electrical insulator because of its ultrawide bandgap of 6.2 eV. However, it can become electrically active as either *n*-type or *p*-type through direct chemical doping or polarization doping when alloyed with the other group-III cations. This broad tunability in electrical conductivity, combined with its high thermal conductivity of about 340 W/m·K, makes AlN highly attractive for power electronics and deep-UV optoelectronic devices. Interest in AlN has considerably increased with the recent development of high-quality AlN bulk substrates with dislocation densities below 10^4 cm^{-2}. To fully leverage the high structural quality of these substrates in subsequent epitaxial layers, the native oxide must be removed before growth. Although Al-assisted deoxidation of AlN substrates has recently been shown to be effective for MBE growth, achieving consistently complete oxide removal and subsequently high-quality AlN homoepitaxy remains challenging. In this talk, we show how various cleaning methods and MBE growth conditions influence AlN homoepitaxy. This work serves as a seeding study at PDI for future investigations aimed at achieving reliable doping control in AlN with minimized compensating defects.

HL 33.2 Wed 16:45 POT/0006

Phase transition regions of epitaxially sputtered TiAlN layers on TiN and AlN buffer layers — •Emine Kaynar, Florian Hörich, Jürgen Bläsing, Fabian Grossmann, Usha Velpuri, Armin Dadgar, André Strittmatter, and Arne Busse — Institut für Physik, Otto-von-Guericke Universität Magdeburg, Magdeburg, Germany

For manufacturing vertical GaN-based power devices on Si substrates, it is advantageous to replace insulating AlN/AlGaN layers at the Si interface. AlN/AlGaN layers are currently required to ensure high-quality GaN on Si. TiAlN alloys offer a tunable bandgap from metallic conduction up to 6 eV and thermal robustness, making them promising alternatives to insulating Al(Ga)N buffers when epitaxial growth on Si is feasible. In this work, TiAlN layers were epitaxially grown on n-type Si (111) using TiN and AlN buffers prepared by a two-step sputtering process at growth temperatures below 900 °C. Highly crystalline cubic TiN (ω-FWHM ~ 0.3°, RMS < 1 nm) served as a conductive template. By tuning the power ratio between Ti and Al targets, Al content was systematically controlled, enabling direct mapping of the cubic-wurtzite transition. On TiN buffers, cubic TiAlN remained stable up to x ~ 0.4. On wurtzite AlN buffers, the opposite transition from wurtzite to cubic occurred as Ti incorporation increased. For all AlN-buffered samples, ω-FWHM stayed below 1° and RMS roughness remained < 5 nm. These results demonstrate precise phase control and high crystalline quality, positioning TiAlN as a strong candidate for conductive buffer layers in vertical GaN-on-Si device architectures.

HL 33.3 Wed 17:00 POT/0006

Epitaxial Growth of ZrN on Si(111) — •Muthukani Kathiresan, Usha Velpuri, Arne Busse, Florian Hörich, Jürgen Bläsing, Armin Dadgar, and André Strittmatter — Institut für Physik, Otto-von-Guericke Universität Magdeburg, Magdeburg, Germany

Transition metal nitrides can add new functionalities to GaN devices. These range from conducting buffer layers for the growth of vertical GaN devices on Si, as template for the growth of N-polar GaN up to enhanced piezo- and ferroelectric properties when alloyed with AlN. Transition-metal nitrides (TMNs) such as ZrN, HfN, TiN and ScN crystallize in the rock-salt structure and exhibit metallic conductivity except for ScN which is semiconducting. For nitride growth, ZrN is particularly attractive due to its favorable lattice relationship, exhibiting an in-plane mismatch of only 1.35% between ZrN (111) and GaN (0001). Additionally, ZrN layers can be deposited by sputtering, whereas layer growth by MOVPE suffers from the low-vapor pressure of available precursors.In this work, we present recent progress in the sputter epitaxy of ZrN on Si (111). For 100-nm-thick films grown at 900 °C in N2/NH3, we achieved an ω-FWHM of 0.5°. Introducing NH3 promoted a transition from a columnar grain structure to a compact, two-dimensional morphology, with a surface roughness of 1.7 nm. The thermal stability of these layers was assessed through annealing at 1100 °C under NH3, which led to reduced film density by void formations, revealed by X-ray reflectivity (XRR) measurements and scanning electron microscopy (SEM).

HL 33.4 Wed 17:15 POT/0006

In-situ fabrication of $In_{0.3}Ga_{0.7}N$ pseudo-substrates on GaN (0001) templates via a three-step protocol in plasma-assisted molecular beam epitaxy — •Huaide Zhang, Aidan Campbell, Jingxuan Kang, Jonas Lähnemann, Oliver Brandt, and Lutz Geelhaar — Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, 10117, Berlin, Germany

The considerable lattice mismatch between GaN and InN introduces significant strain into (In,Ga)N epitaxial layers grown on GaN templates. This strain impedes the incorporation of In and induces a strong piezoelectric field in (In,Ga)N/GaN quantum wells, which diminishes the internal quantum efficiency. Furthermore, the accumulated strain can prompt plastic relaxation of the lattice, generating additional threading dislocations. The high In content required for (In,Ga)N-based light-emitting diodes (LEDs) operating in the amber/red spectral range necessitates, hence, a substrate with an adjusted lattice constant. In this work, we present a three-step growth method for fabricating a highly relaxed $In_{0.3}Ga_{0.7}N$ pseudo-substrate directly on GaN(0001) templates which is conducted entirely within a plasma-assisted molecular beam epitaxy system. In contrast to other approaches, our method does not require any ex-situ patterning, providing thus advantages in terms of scalability and cost. The resulting structure demonstrates superior characteristics in key properties, including In content, degree of strain relaxation, and surface smoothness compared to existing alternatives.

HL 33.5 Wed 17:30 POT/0006

Influence of A-Site Cations on Structure, Defect Density and Photoactivity of Tantalum-Based Perovskite Oxynitride Photoelectrodes — •Gabriel Grötzner[1,2], Aleksandr Kochergov[1,2], Oliver Brune[1,2], Laura I. Wagner[1,2], Saswati Santra[1,2], Verena Streibel[1,2], and Ian D. Sharp[1,2] — [1]Walter Schottky Institute, Technische Universität München, Germany — [2]Physics Department, TUM School of Natural Sciences, Technische Universität München, Germany

Perovskite oxynitrides are emerging materials for photoelectrochemical (PEC) water splitting, yet the influence of the A-site cation on their material properties remains poorly understood. Here, we investigate a series of $ATaON_2$ thin films (A = La, Ce, Pr, Nd, Gd, ordered by decreasing ionic radius) to elucidate the role of the A-site cation on structural, optoelectronic, and PEC properties. X-ray diffraction analysis reveals a systematic lattice contraction with decreasing ionic radius of the A-site cation. This structural change is accompanied by an increase in optical band gap from 1.8 eV to 2.2 eV and a reduction in sub-bandgap absorption, indicating lower defect densities for smaller A-site cations. Electrical measurements show reduced conductivity for $GdTaON_2$ compared to $LaTaON_2$, consistent with defect suppression. By changing the A-site cation from La to Gd, the photocurrent density in PEC measurements doubles, despite an increase in optical band gap, which indicates the beneficial impact of reduced defect-mediated recombination. These insights offer design principles for defect and band-structure engineering in perovskite oxynitride photoanodes.

HL 34: Quantum Dots and Wires: Telecom Wavelength

Time: Wednesday 16:30–17:45 Location: POT/0051

HL 34.1 Wed 16:30 POT/0051

All-photonic quantum teleportation at telecom wavelength with frequency converted photons from remote quantum dots — •Tim Strobel[1], Michal Vyvlecka[1], Ilenia Neureuther[1], Tobias Bauer[2], Marlon Schäfer[2], Stefan Kazmaier[1], Nand Lal Sharma[3], Raphael Joos[1], Jonas H. Weber[1], Cornelius Nawrath[1], Weijie Nie[3], Ghata Bhayani[3], Caspar Hopfmann[3], Christoph Becher[2], Peter Michler[1], and Simone Luca Portalupi[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQ^{ST}) and SCoPE, University of Stuttgart, Stuttgart, Germany — [2]Fachrichtung Physik, Universität des Saarlandes, Saarbrücken, Germany — [3]Institute for Integrative Nanosciences, Leibniz IFW Dresden, Dresden, Germany

A future terrestrial quantum internet relies on distant quantum network nodes connected via optical fiber channels. In this context, semiconductor quantum dots (QDs) are promising sources of quantum light. Here, we report on an all-photonic quantum teleportation experiment with photons from remote QDs emitting at ca. 780 nm. The polarization state of a single photon emitted by one QD is prepared and interfaced with one photon of an entangled pair from a second QD in a Bell state measurement. This process teleports the polarization state onto the second photon of the entangled pair. Polarization-preserving

quantum frequency converters eliminate the frequency mismatch between photons, allowing for interference at telecom wavelengths. Teleportation succeeds with post-selected fidelities up to 0.721(33).

HL 34.2 Wed 16:45 POT/0051

Telecom C-band Quantum Dots Coupled to Gaussian-shaped Microlens Cavities — •Michelle Pfahl[1], Raphael Joos[1], Lena Engel[1], Johannes Michl[2], Katharina Dahler[1], Ponraj Vijayan[1], Tobias Huber-Loyola[2], Michael Jetter[1], Simone L. Portalupi[1], Sven Höfling[2], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart — [2]Julius-Maximilians-Universität Würzburg, Physikalisches Institut, Lehrstuhl für Technische Physik, Am Hubland, 97074 Würzburg

Single-photon sources emitting in the telecom C-band are a key resource for applications in quantum communication and quantum cryptography, as they enable long-distance quantum networks. Semiconductor quantum dots (QDs) are particularly well suited for this since they have a high quality optical emission and can achieve high efficiency when coupled to microcavities. Here, we investigate telecom C-band InAs QDs, which are embedded in a resonator made of distributed Bragg reflectors (DBRs), with the upper dielectric DBR being shaped into Gaussian lenses using an etching process. This structure promises Purcell enhancement, which reduces the decay time of the QDs and enables efficient collection of the emitted photons. We investigate the optical modes of the resonators by an in-depth characterization of microlenses with different design parameters. Furthermore, the quantum-optical properties of the QDs coupled to cavities are analyzed by means of autocorrelation and decay time measurements.

HL 34.3 Wed 17:00 POT/0051

InGaAs/GaAs preparation at 1.55 micrometer telecom wavelengths — •Juwana Jose, André Strittmatter, Armin Dadgar, Jürgen Bläsing, and Usha Velpuri — Otto von guericke university, Magdeburg, Germany

Quantum key distribution is a secure way of generating and sharing encryption keys using photons. Single photons as qubits for key generation is an efficient method of secure data transmission. It guarantees absolute eavesdropping detection since it is impossible to copy a quantum state. Qubit transmission at telecom wavelengths of 1.55 micrometer using InGaAs quantum dots on GaAs substrates is a challenge. We explore the conventional Stranski-Krastanow growth mode to shift the wavelengths far beyond the spectral 1.3-1.4 *m region. Photoluminescence experiments on high-density QD ensembles show remarkable intensities in a wavelength range of 1.5-1.6 micrometer at room-temperature. This luminescence shifts by xx nm into the blue upon cooling down to 15 K. By tailoring the thickness of the initial InGaAs deposition to the 2D/3D transition region low QD densities of 108 cm-2 and below are achieved. Single photon emission experiments will be conducted after preparation of individual QD emitters.

HL 34.4 Wed 17:15 POT/0051

Integration of telecom C-band quantum dot-based single-photon emitters onto silicon photonic platform using micro-transfer printing — •Simon Oberle[1], Ponraj Vijayan[1], Alessandro Buzzi[2], Hugo Larocque[2], Michael Jetter[1], Simone Luca Portalupi[1], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), University of Stuttgart — [2]Research Laboratory of Electronics (RLE), Massachusetts Institute of Technology

Silicon photonics for telecommunications applications has garnered much attention recently. The optical transparency and the large refractive index contrast of silicon at telecommunication wavelengths allow the implementation of high-density photonic integrated circuits. One disadvantage of silicon photonics is the lack of mature deterministic light sources. One potential solution is the integration of III-V material, which offers outstanding optical emission properties, on a silicon platform. The direct growth of III-V materials on silicon the most scalable and therefore desired approach. However, it is challenging because of the material polarity difference and the lattice mismatch between GaAs and silicon. An alternative approach is the hybrid integration of III-V structures using micro-transfer printing, which enables integration of prefabricated devices onto silicon. Our group has previously developed telecom C-band emitting InAs quantum dots grown on InGaAs. Here, we report our approach to designing and fabricating structures for the hybrid integration of these QDs onto a silicon platform using micro-transfer printing.

HL 34.5 Wed 17:30 POT/0051

Automated optical imaging for telecom Quantum Dot deterministic fabrication — •Eden Arbel[1], Lukas Wagner[1], Peter Gierss[1,2], Ponraj Vijayan[1], Michal Vyvlecka[1], Michael Jetter[1], Simone L. Portalupi[1], and Peter Michler[1] — [1]Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQ^{ST}) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — [2]Physikalisch Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig

Semiconductor quantum dots (QDs) are promising sources of single- and entangled-photon pairs. Due to its low absorption in silica fibers, operation in the telecom C-band (1530-1565nm) is desired. Integrating these QDs into Circular Bragg Grating cavities (CBGs) enhances extraction efficiency and enables Purcell enhancement. Our method employs wide-field imaging for deterministic preselection of QDs for subsequent CBG fabrication. The QD positions are referenced using e-beam-written markers. Smart preselection of suitable candidates, embedded in an automated setup, promises higher yield and efficiency, with the potential for AI integration. We demonstrate that deterministically processed CBGs exhibit significant improvements in brightness and enhance the decay time of the two-level state. With higher throughput and continually improving quality of telecom QD samples, this approach will enable to provide single-photon sources tailored to specific needs of various applications, such as quantum memories or long-distance quantum communication.

HL 35: Optical Properties II

Time: Wednesday 16:30–19:00 Location: POT/0251

HL 35.1 Wed 16:30 POT/0251

Polarization-Angle-Resolved Raman Spectroscopy for Reliable Raman Tensor Analysis — •Hans Tornatzky[1], Jonas Rose[1], Luca Choi[2], Moritz Meissner[1], Zbigniew Galazka[3], and Markus R. Wagner[1,2] — [1]Paul Drude Institut — [2]Technische Universität Berlin — [3]Institut für Kristallzüchtung

Phonons are fundamental to materials, shaping the physical properties that underlie device functionality. Accurate knowledge of their quantitative description, specifically the Raman tensor, is essential for a detailed understanding of materials and for reliable modeling and optimization of structures and devices.

This talk presents state-of-the-art approaches for determining relative Raman tensor elements using polarization-angle-resolved Raman (PARRS) spectroscopy, alongside discussion of major challenges and sources of error encountered in the process. We also introduce a newly developed fitting procedure that enables robust disentanglement of strongly overlapping signals arising from different modes, permitting precise extraction of their characteristics – energy, FWHM, symmetry, and tensor elements – with enhanced reproducibility.

These techniques are demonstrated across several materials recently studied by our group, including rutile GeO_2, Ga_2O_3, and $LaInO_3$.

HL 35.2 Wed 16:45 POT/0251

Characterization of Exciton-exciton entanglement in different phases: A many-body investigation in low dimensions — •Fangzhou Zhao[1], Carlos Mejuto-Zaera[2], Vojtech Vlcek[3], and Angel Rubio[1] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Laboratoire de Physique Théorique, LPT, CNRS, Toulouse, France — [3]UCSB, Santa Barbara, USA

There have been emerging experimental investigations on exciton-exciton correlations, especially in moiré superlattices. However, theoretical understanding of exciton-exciton interactions - which requires an accurate treatment of four-point Green's functions and the validity of a bosonic description of excitons- remains relatively underdeveloped. We construct an exactly solvable one-dimensional model to investigate exciton-exciton correlations and entanglement using many-body exact techniques. We identify phase boundaries separating excitonic phases with different degrees of binding, and extrapolate the data to the thermodynamic limit to infer properties in large systems. We also apply a wavefunction projection technique to characterize the strength of entanglement between excitons, as well as the strength of entanglement between the electron and hole inside an exciton. Our results show that, over a broad parameter range, excitonic correlations remain weak, validating the applicability of many-body perturbation theory in most cases. We also explored the quantum confinement effect of multi-exciton state in 1D systems and uncovered the conditions under which the confinement effects emerge.

HL 35.3 Wed 17:00 POT/0251

Excited-state trions in a quantum well — Sourabh Jain[1], Mikhail Glazov[2], and •Ashish Arora[1] — [1]Indian Institute of Science Education and Research, Pune 411008 India — [2]St. Petersburg, Russia

Recently, excited-states of trions were discovered in a layered semiconductor raising strong interest in many-body physics of Coulomb-bound quasiparticles in solids [1]. Here, we report on the observation of an excited 2s state of a trion in a GaAs quantum well (QW) using magneto-optical Kerr effect (MOKE) spectroscopy under out-of-plane magnetic fields up to 6 T [2]. This resonance ap-

pears slightly below the 2s exciton in energy. Strikingly, the 2s trion is found to be bound only for magnetic fields larger than 1 T. The signature of the 2s trion is absent in the magneto-reflectance spectra, while it is detectable in the MOKE spectra signifying the importance of the powerful technique. Similar to the 1s states, the 2s trion shows an opposite degree of magnetic-field-induced polarization compared to its exciton counterpart, in agreement with our theoretical calculations. This transfer of oscillator strength between the complexes establishes an optical fingerprint of the 2s excited trion. Our work addresses a four-decade old problem of excited-state trions in a quantum well, and opens scope for further investigations of many-body physics in solids. [1] Phys. Rev. Lett. 123, 167401 (2019) [2] Phys. Rev. Lett. 134, 246902 (2025)

HL 35.4 Wed 17:15 POT/0251

Directional lasing and optical coupling in indium phosphide nanowires — •Lukas Raam Jäger[1], Wei Wen Wong[2], Hark Hoe Tan[2], and Carsten Ronning[1] — [1]Friedrich-Schiller-Universität Jena, Fürstengraben 1, 07743 Jena, Germany — [2]The Australian National University, Canberra ACT 2600, Australia

Indium phosphide (InP) nanowires (NWs) are promising nanoscale light sources due to their strong optical confinement and compatibility with selective-area epitaxy. We investigate optical coupling in vertically standing lasing InP NWs using finite-difference time-domain simulations and angle-resolved photoluminescence. Single NWs lase in the TE01 mode for diameters above about 250 nm and exhibit far-field patterns shaped by interference of emission from the top and bottom facets. Coupled NW structures enable controlled emission engineering. In NW pairs, coupling splits the TE01 mode into two hybrid modes with orthogonal directional lobes, in good agreement with experiment. Mode selection is highly sensitive to subtle geometric differences, while asymmetric pumping has negligible effect. Extending this concept to arrays of NW pairs shows that array-level interference can further narrow the emission lobes. Triplet NW structures exhibit three distinct hybrid modes with characteristic far-field patterns. These results demonstrate designable directional nanoscale emitters based on coupled NW lasers.

HL 35.5 Wed 17:30 POT/0251

Optical emission of monolayer-hybridized nanowire lasers — •Moritz Willems, Edwin Eobaldt, Alexander Zaunick, Aurelia Eberhard, Lukas Jäger, Xiao Chen, and Carsten Ronning — Friedrich Schiller Universität, Jena, Deutschland

Semiconductor Nanowires have attracted substantial scientific interest as foundation for nanoscale coherent light sources and all-optical circuits, based on to their remarkable waveguide properties and their intrinsic ability to lase. 2D-Materials offer a functional environment that enables influencing the lasing characteristics, including emission wavelength and lasing threshold, of ZnO nanowires. These hybrid structures thus allow for electrical and optical charge and energy transfer. Deterministic nanowire integration is achieved through stage-assisted transfer using PDMS and tip-assisted nanomanipulation. Comparative micro-photoluminescence measurements are used to investigate how the 2D-materials influence and modify the lasing behaviour of individual nanowires.

HL 35.6 Wed 17:45 POT/0251

Bandgap and exciton engineering in two-dimensional transition $Mo_{1-x}W_xSe_2$ alloys for next-generation photonics. — •Muhammad Hussain[1], Omid Ghaebi[1], Mohammad Monfared[2], Marco Gruenewald[1], Umer Ahsan[3], Fedor Lipilin[3], Jan Luxa[3], Zdenek Sofer[3], Ulf Peschel[2,4], and Giancarlo Soavi[1,4] — [1]Institute of Solid-State Physics, Friedrich Schiller University Jena, Germany — [2]Institute of Condensed Matter Theory and Optics, Friedrich Schiller University Jena, Germany. — [3]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Czech Republic — [4]Abbe Center of Photonics, Friedrich Schiller University Jena, Germany

Alloys of 2D transition metal dichalcogenides (TMDs), provide a unique platform for bandgap engineering at the atomic scale. In this work, we investigate the nonlinear optical response of $Mo_{1-x}W_xSe_2$ alloys focusing in particular on second harmonic generation (SHG) and two-photon photoluminescence (TP-PL) [1]. We find that alloyed TMDs exhibit enhanced nonlinearities compared to their pristine counterparts. By combining SHG and TP-PL and the respective optical selection rules, we are able to extract the energy difference between 1s and 2p exciton states in samples of different alloy composition. By doing this, we find that the exciton binding energy in such alloys varies with the W composition (x). This can be used as a knob to tune not only the optical bandgap, but also the exciton binding energy by changing the alloy composition.

HL 35.7 Wed 18:15 POT/0251

Photoluminescence of single color centers in hBN below the diffraction limit — •Iris Niehues[1], Daniel Wigger[2], Korbinian Kaltenecker[3], Annika Klein-Hitpass[1], Johannes Binder[4], Andrzej Wysmołek[4], and Rainer Hillenbrand[5] — [1]Institute of Physics, University of Münster, Germany — [2]Department of Physics, University of Münster, Germany — [3]Department of Physics, Ludwig-Maximilians-Universität München, Germany — [4]Faculty of Physics, University of Warsaw, Poland — [5]CIC nanoGUNE BRTA, Spain

Color Centers in hexagonal boron nitride (hBN) are promising quantum light sources due to their stable single-photon emission at room temperature. Using a scattering-type near-field optical microscope, we investigate photoluminescence (PL) properties of hBN grown via metalorganic vapor phase epitaxy. Our experiments employ the microscope in tapping mode to detect PL signals influenced by the metallic AFM tip. We demonstrate near-field optical excitation and emission via the tip's nanofocus, creating a sub-diffraction limited tip-enhanced (TE)PL hotspot [1]. Additionally, an "arc" forms around the emitter, explained by constructive interference between direct beams between the optics and the emitter and indirect beams scattered from the tip. This tip-assisted (TA)PL method can be used to map in-plane dipole orientations of hBN color centers at the nanoscale.

HL 35.8 Wed 18:30 POT/0251

Role of lattice temperature for the optical properties of boron nitride — •Peter Kratzer[1] and Andre Schleife[2] — [1]Faculty of Physics, University Duisburg-Essen, 47057 Duisburg, Germany — [2]Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, Urbana, USA

We carried out a computational study of boron nitride both in its cubic (c-BN) and hexagonal (h-BN) polytypes as a prototypical system for the renormalization of optical properties in semiconductors by lattice vibrations. While band-gap renormalization due to electron-phonon coupling is a well-explored concept in semiconductor physics, this topic has gained renewed attention in the context of pump-probe spectroscopies where high fluences may lead to local lattice excitation. With this motivation, we performed first-principles calculations of c-BN and h-BN supercells using the DFT+GW method, treating lattice excitation via explicit atomic displacements. Finally, the frequency-dependent dielectric function and the optical absorbance are obtained including many-particle effects on the level of the Bethe-Salpeter equation. The results show that the atomic displacements in the 2x2x2 supercells used in this study have little effect in c-BN but lead to a considerable narrowing of the optical gap in h-BN. In h-BN, the band splitting due to 'frozen' phonons gets even amplified on the GW level of theory. The binding energy of approximately 0.5eV of the exciton derived from the band edges, however, is found to be only weakly affected by the atomic displacements.

Financial support from CRC 1242 is gratefully acknowledged.

HL 35.9 Wed 18:45 POT/0251

Half-saddle excitons in monolayer SnS2: a first-principles study — •Vinicius Alves Bastos[1], Fulvio Paleari[2], Eleonora Luppi[3], Marco Gibertini[1,2], and Alice Ruini[1,2] — [1]Dipartimento di Scienze Fisiche, Informatiche e Matematiche, UNIMORE, Modena (Italy) — [2]CNR-Nano, Modena (Italy) — [3]Laboratoire de Chimie Théorique, Sorbonne Université and CNRS, Paris (France)

Monolayer SnS2 has been demonstrated as a visible-light absorber with promising characteristics for applications in fuel cells and thin film photovoltaics [1]. Motivated by that, we have performed a first-principles study of bound excitons in this system within the GW-BSE formalism [2]. We have gone beyond previous works by analysing the exciton symmetries, electron-hole contributions, and transition dipoles. We find a richer structure of bound excitons than previously reported, e.g., deeply bound dark excitons with binding energies of about 0.9 eV and a very strong bright exciton at 2.9 eV, in good correspondence with the experimental absorption peak. Also, the bound excitons are localized around the direct band gap at the M point, which exhibits a saddle point at the top valence band and a minimum at the bottom conduction band. Consequently, we show that linearly polarized light can be used to completely select two of the three inequivalent M saddles, as previously demonstrated in graphene [3]. Surface acoustic wave-controlled photocurrent in few-layer WSe2 — •Benjamin Mayer, Felix Ehring, Matthias Weiss, Hubert Krenner, Ursula Wurstbauer, and Emeline Nysten — Institute of Physics, University of Münster, Germany

Surface acoustic waves (SAWs) offer a versatile platform for nanoscience applications [1]. Their ability to integrate GHz-frequency control and sensing schemes at micron-scale wavelengths on a chip opens cross-disciplinary applications and enables the SAW electric field to drive acousto-electric currents in low-dimensional materials, including semiconducting transition metal dichalcogenides (TMDCs) [2]. Here, we study the AEC and the underlying charge-carrier dynamics in mechanically exfoliated 2D tungsten diselenide (WSe2) placed on two gold electrodes integrated into hybrid lithium-niobate-based SAW devices (150-250 MHz). Our multifunctional acousto-optoelectric setup combines current-voltage characterization, SAW-direction dependent AEC measurements and spectrally resolved scanning photocurrent (PC) spectroscopy. This allows detailed investigation of how electrical contacts affect the performance of our archetypical acoustophoto-electric device. Thus, we establish a qualitative model of the tunneling barrier and band bending induced by Schottky barriers at the Au-TMDC interface [3]. Further, tuning the optical excitation wavelength provides spectral access to energy-dependent photocurrent contributions and reveals how they are modulated by the SAW.

HL 36.2 Wed 17:45 POT/0081

Shift current tuned via twisting angle in moiré system — •Michele Bagaglini[1,2], Cesare Tresca[2], and Gianni Profeta[1,2] — [1]Dipartimento di Scienze Fisiche e Chimiche, Università degli Studi dell'Aquila, L'Aquila, Italy — [2]CNR-SPIN c/o Dipartimento di Scienze Fisiche e Chimiche, Università degli Studi dell'Aquila, L'Aquila, Italy

In recent years the interest in the two-dimensional bulk photovoltaic effect (BPVE) has been increasing in non-centrosymmetric materials. Research on 2D solar cells and optoelectronic device is focusing on these materials due to their highly efficient response. The shift current (SC) is one of the most important effect to the BPVE. The SC is second-order non-linear response that arises from the different real-space centres position of charge, a 'shift', between the valence and conduction bands. In the literature, several studies already exist on the SC in monolayer and untwisted bilayer transition-metal dichalcogenide (TMD) systems, where promising peaks have been reported from DFT calculations. In this study we focus on the evolution of the SC with the twisting angle in moiré twisted two-dimensional materials, specifically in multilayer MoS2 systems. In our case, given the large size of the systems for small twist angles, we employ a tight-binding (TB) approach with Slater-Koster (SK) parameterization to compute the SC. We show that a multiband approach improves the accuracy and allows one to reproduce the dispersions obtained from first-principles calculations.

HL 36.3 Wed 18:00 POT/0081

Theoretical investigation of the flexo-photovoltaic effect — •Juan Jose Esteve-Paredes[1], Maria N. Gastiasoro[2], and Julen Ibanez-Aspiroz[1] — [1]Materials Physics Center, University of the Basque Country, Donostia-San Sebastian, Spain — [2]Donostia International Physics Center, Donostia-San Sebastian, Spain

The bulk photovoltaic effect (BPVE) refers to the generation of a direct current in a bulk crystal under illumination. This phenomenon arises in non-centrosymmetric materials and is described by a finite electronic second-order conductivity. In recent years, experimental works have reported the realization of the BPVE in centrosymmetric media, where this effect is conventionally forbidden, by generating large strain gradients through application of local pressure with nanoscale tips [1,2]. This new effect, named the flexo-photovoltaic effect, has attracted interest regarding its microscopic origin. In this talk, we theoretically investigate this effect and demonstrate that a flexo-photovoltaic effect can indeed be predicted by considering local lattice deformations in several-layer centrosymmetric crystals, giving rise to the appearance of a finite BPVE conductivity. We employ a Slater-Koster approach to model the electronic band structure and wavefunctions within a supercell geometry and compute the associated linear and second-order optical responses. We discuss the tunability and scaling of this effect in relation to the magnitude and spatial extent of the mechanical deformation, and discuss how our theoretical predictions compare with existing experimental observations. HL 36.4 Wed 18:15 POT/0081

All-in-one Optoelectronic Synaptic Device with Van der Waals materials-based floating gate — •Thi Phuong Anh Bach and Sangeun Cho — Division of System Semiconductor, Dongguk University, Seoul, South Korea

Optoelectronic synaptic devices that integrate nonvolatile memory with light matter interactions offer high processing efficiency and low energy consumption for neuromorphic computing. Two-dimensional materials and their van der Waals heterostructures provide strong electronic and optical properties, while floating-gate structures emulate synaptic plasticity and enable a path toward brain-inspired, beyond-von-Neumann computation. Herein, we demonstrate a multifunctional optoelectronic synapse device based on rhenium disulfide (ReS2)/hexagonal boron nitride (hBN)/indium selenide (InSe) vdW FG structure. The device exhibits a high On/Off current ratio (>10^6), large memory window, multi-level storage behavior and excellent data retention (~10000 s) under various electrical and optical stimuli. By leveraging the thickness tunable bandgap of InSe FG and the dynamic tunneling process of photogenerated carriers across the vdWhs interface, the device capable to work under a wide range from visible to near-infrared laser with excellent synaptic plasticity. The device replicates classical conditioning (Pavlov's dog experiment) and advanced signal-discrimination learning, and also supports reconfigurable inverter logic via electrical and optical inputs, along with neuromorphic image recognition, demonstrate its multifunctionality.

HL 37: Nitrides II – Designed properties and LED

Time: Thursday 9:30–11:00 Location: POT/0006

HL 37.1 Thu 9:30 POT/0006

Designing Visible-Spectrum Nitride Alloys from First Principles — •Jan M. Waack[1,2], Michael Czerner[1,2], and Christian Heiliger[1,2] — [1]Institut für theoretische Physik, Justus-Liebig-Universität Gießen, Germany — [2]Center for Materials Research (LaMa), Justus-Liebig-Universität Gießen, Germany

Precise band-gap engineering across the full visible spectrum is essential for emerging applications such as integrated RGB LEDs. This tunability can be achieved through alloying narrow-band-gap materials like InN or ScN with wide-band-gap semiconductors such as GaN or AlN. Among these systems, random alloys including (In,Ga)N and (Al,Sc)N require advanced theoretical treatments–such as the coherent potential approximation (CPA) and special quasi-random structures (SQS)–to capture their configurational disorder accurately.

In this work, we combine first-principles density functional theory with efficient electronic-structure methods such as LDA-1/2 and the mBJ functional to provide a comprehensive dataset for both random and ordered alloy phases. We report key structural properties including lattice parameters and bond lengths as well as elastic constants, phonon modes, thermodynamic stability, and electronic characteristics such as band gaps and Bloch spectral functions. These results offer a robust theoretical foundation for experimental detection of ordering phenomena and for the rational design of nitride alloys with tailored optical and electronic properties.

HL 37.2 Thu 9:45 POT/0006

Detailed nano-characterization of structural and optical properties of a red-emitting InGaN LED — •N. Dreyer[1], F. Bertram[1], G. Schmidt[1], J. Christen[1], Z. Chen[2], and X. Wang[2] — [1]Otto-von-Guericke-University Magdeburg, Germany — [2]Peking University, Beijing, China

A fully processed and operating red InGaN LED was grown by MOVPE on a GaN/sapphire template. The active region, which consists of three identical stacks, is surrounded by *n*- and *p*-GaN with an EBL. Each stack contains three quantum wells with different indium concentrations: two with a low indium concentration for strain relaxation, and one subsequently grown red-emitting quantum well (RQW). The structure was characterized using scanning transmission electron microscopy (STEM) and the orientation of the Burgers vector (edge- or screw type dislocation) was determined. Cross-sectional cathodoluminescence performed directly in STEM shows broad band-to-band recombination in the *n*-GaN at $T = 17$ K which is caused by band gap renormalization and conduction band filling. Line shape analysis of this emission band yields a charge carrier density of 6×10^{18} cm^{-3}. The vertical evolution of the RQW emission exhibits a shift of 123 meV within the active region. Furthermore, the lateral homogeneity

of the RQW emission will be examined. A blue-shift of the RQW emission of up to 365 meV was found around defects. The vertical and lateral trapping processes of excess carriers will be discussed in detail. The capture length of the bottom RQW was found to be 78 nm using highly spatially resolved vertical linescans across the active region.

HL 37.3 Thu 10:00 POT/0006

Determination of optical losses in AlGaN-based multimode waveguides — •Verena Kowallik[1], Martin Guttmann[2], Leonardo Wildenburg[1], Tim Wernicke[1], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute for Physics & Astronomy, Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH), Berlin, Germany

Many applications for ultraviolet photonic integrated circuits (UV PICs), such as biochemical sensing, atomic clocks, and UV Raman spectroscopy, require materials with a large bandgap energy to facilitate low optical losses. One possible candidate are AlGaN alloys which are already successfully employed for the fabrication of UV light emitting diodes (UV-LEDs) and UV lasers. However, the optical properties of AlGaN materials, especially the absorption losses have not yet been studied in detail in the UVC spectral range. In this work, the absorption losses in 200 μm wide n-$Al_{0.76}Ga_{0.24}N$ waveguides were investigated using monolithically integrated UV-LEDs emitting at 262 nm and detectors. By Monte Carlo ray-tracing simulations, we identified different contributions of the optical losses, namely, the propagation losses and scattering losses. Here, we implemented the waveguide surface roughness determined from atomic force microscopy images. Also, we investigated the portion of rays reaching the detector without beeing guided in the waveguide, e.g. scattered at the substrate's backside or the AlN/sapphire interface.

HL 37.4 Thu 10:15 POT/0006

Influence of the AlGaN multi-quantum well design on the efficiency of 233 nm far-UVC LEDs grown by MOVPE — •Rebekah Seonggyeong Kim[1], Marcel Schilling[1], Massimo Grigoletto[1,2], Jakob Höpfner[1], Tim Wernicke[1], and Michael Kneissl[1,2] — [1]Technische Universität Berlin, Institute of Physics and Astronomy, Berlin, Germany — [2]Ferdinand-Braun-Institut (FBH), Berlin, Germany

Light emitting diodes (LEDs) emitting in the far ultraviolet-C (far-UVC) spectral range are promising for applications like skin safe disinfection and gas sensing. The composition and thickness of the AlGaN-multi quantum wells and barriers are crucial for the efficiency of the LEDs. In this work we investigate the impact of the last quantum well barrier's (LB) thickness (0 nm to 10 nm) and aluminum mole fraction (76% - 86%) onto the electrooptical performance of the LEDs. The LEDs with an aluminum mole fraction of 80 % and a thickness of 5 nm exhibit the highest external quantum efficiency (EQE) of 0.32 % at 16 mA (on-wafer).

HL 37.5 Thu 10:30 POT/0006

In-rich InGaN quantum well growth for green InGaN LED — •Christoph Berger, Armin Dadgar, and André Strittmatter — Otto-von-Guericke-University, Magdeburg, Germany

Achieving high-efficiency green InGaN LEDs remains challenging due to material issues like phase instability, metallic inclusions and interface roughening. We present an optimized MOVPE growth approach that significantly improves the optical and morphological quality of green LEDs. After each QW, a growth interruption combined with a controlled temperature ramp is introduced before starting the GaN barrier growth. This sequence allows to get rid of excess indium that accumulates on the surface during QW growth, leading to smoother interfaces, a removal of indium-rich defects visible in Nomarski microscopy and consequently, a substantial suppression of a grayish appearance of the wafer. We further combine this process with hybrid MQW designs, where blue QWs are grown below a green top QW, leading to an improvement of the efficiency of the LED. The impact of different growth sequences and layer designs on the optical and structural characteristics of green LEDs will be discussed.

HL 37.6 Thu 10:45 POT/0006

Nano-characterization of polarization-doped deep UV LED structures using highly spatially resolved cathodoluminescence spectroscopy — •E. Bäker[1], F. Bertram[1], G. Schmidt[1], N. Dreyer[1], J. Christen[1], T. Kolbe[2], S. Hagedorn[2], H.K. Cho[2], J. Rass[2], S. Einfeldt[2], and M. Weyers[2] — [1]Otto-von-Guericke-University Magdeburg, Germany — [2]Ferdinand-Braun-Institut (FBH), Germany

AlGaN-based deep UV LEDs emitting below 250 nm are of great interest for many applications. Especially in the far-UVC, efficient p-doping poses major challenges, which can be effectively overcome by the concept of polarization doping. This study compares far-UVC LEDs with different AlGaN composition gradients used for polarization doping. The LEDs were grown by MOVPE on optimized AlN/sapphire templates. While the n-side of the diode uses conventional Si-doping, the p-side utilizes an AlGaN-layer with constant [Ga]-gradient. Diodes with different [Ga]-gradients but identical thicknesses are analyzed, with the Ga mole fraction increasing linearly from 0.02 to 0.45 and from 0.02 to 0.81, respectively. Using low temperature cathodoluminescence spectroscopy directly performed in a scanning transmission electron microscope, a nano-scale correlation of the optical properties with the real structure is obtained. Cross-sectional CL line scans show the different emission of the gradient layer. While the sample with the shallow gradient shows continuous emission spectral red-shift from 240 nm to 260 nm, the sample with the steep gradient shows an abrupt jump from 273 nm to 312 nm, indicating lattice relaxation.

HL 38: Materials and Devices for Quantum Technology II

Time: Thursday 9:30–12:45 Location: POT/0051

HL 38.1 Thu 9:30 POT/0051

Shadow masks for all-in-situ fabrication of InAs nanowire Josephson junctions — •Christian Schäfer, Lennart Grosch, Yurii Kutovyi, Nils von den Driesch, Thomas Schäpers, and Alexander Pawlis — PGI 9 / PGI 10 / JARA-FIT, Forschungszentrum Jülich, 52428 Jülich, Germany

Josephson junctions based on semiconductor/superconductor hybrid structures offer unique features for quantum circuits, such as gate-controllable supercurrent and quantized Andreev bound states. Clean interfaces between nanowire and superconductor are essential to leverage both effects, driving the development of in-situ contact fabrication. Shadow wall epitaxy offers both, a scalable and all-in-situ solution for nanowire growth and contact formation. Micrometer-high pre-fabricated walls shadow the molecular beams of In and As depending on their relative orientation. Since As on its own has a low sticking coefficient and In forms isolated droplets, partially shadowed regions are insulating and do not form InAs crystals. Despite the significant lattice mismatch between InAs and the GaAs substrate, we observe growth of lateral 1D-nanowires between walls spaced less than one micrometer. The same mask can additionally be used to perform selective deposition of any superconductor. We explore different mask designs to optimize electrical device isolation, nanowire growth, and junction geometry. Since no transfer or post-processing after growth is necessary, associated defects and degradation are avoided. Shadow wall epitaxy enables scalable in-situ fabrication of InAs nanowire junctions.

HL 38.2 Thu 9:45 POT/0051

Semiconductor–superconductor membranes for nanoelectronic devices — •Thies Jansen[1], Christian Reichl[2], and Thomas Sand Jespersen[1,3] — [1]Technical University of Denmark, Anker Engelunds Vej 101 2800 Kongens Lynby — [2]ETH Zürich Laboratorium für Festkörperphysik — [3]Center for Quantum Devices Niels Bohr Institute, University of Copenhagen

Semiconductor-superconductor hybrid materials have become the workhorse platform for quantum devices, owing to their clean and highly transparent semiconductor-superconductor interfaces. Indium arsenide–aluminum (InAs-Al) nanowires and quantum wells are currently the dominant material systems, each offering distinct advantages: nanowires allow transfer to arbitrary substrates, while quantum wells provide two-dimensional design flexibility. Here, we introduce a new platform that combines the strengths of both systems: a semiconductor-superconductor membrane. We present the fabrication of these membranes and their initial electrical characterization through low-temperature transport measurements. The membranes are gate-tunable, and their material properties closely resemble those of both InAs nanowires and InAs quantum wells.

HL 38.3 Thu 10:00 POT/0051

Secondary electron detector for deterministic single ion implantation — •Priyal Dadhich, Nico Klingner, and Gregor Hlawacek — Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf(HZDR), Dresden, Germany

Fault tolerant quantum computers based on donor-ion solid-state qubits require highly localized placement of single donors. To achieve this, we are developing a new setup for deterministic single-ion implantation in a FIB. To detect each implanted ion, we aim to use the secondary electrons (SEs) emitted during ion impact. A windowless silicon drift detector (SDD), biased up to +10 kV, accelerates and collects these SEs. The resulting electron-hole pairs allow us to quantify the number of emitted electrons via pile-up analysis. A critical challenge for this detection approach is the intrinsic SE emission probability. As governed by Poisson statistics, the average SE yield strongly affects detection confidence. Current work examines material-dependent absolute SE yields and practical methods to enhance SE emission while maintaining efficient extraction. Given the low SE

yield per impact, optimizing the extraction geometry is crucial. A C++ simulation code using the ion-optics library IBSIMU [1] has been developed for this customised problem, to maximize SE collection and study backscattering, including possible methods to recollect backscattered electrons. References: [1] T Kalvas et. al. Rev. of Sci. Inst., 81(2), 2010.

HL 38.4 Thu 10:15 POT/0051

Spin-orbit-enabled realization of arbitrary two-qubit gates on moving spins — •David Fernández-Fernández[1], Yuta Matsumoto[2], Lieven M.K. Vandersypen[2], Gloria Platero[1], and Stefano Bosco[2] — [1]Instituto de Ciencia de Materiales de Madrid, CSIC, Spain — [2]QuTech and Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands

Shuttling spin qubits across semiconductor quantum dot arrays is emerging as a key primitive for scalable quantum information processing, enabling on-chip inter-node quantum communication and modular architectures. By analyzing the shuttling of two spin qubits towards each other using a conveyor-mode protocol, we show that controlling only two experimentally accessible parameters, the shuttling velocity and the waiting time at minimum interdot separation, is sufficient to synthesize a broad class of entangling gates. Moderate SOI provides direct access to both CPHASE(θ) and SWAP$^{\alpha}$ families, as well as native fermionic-simulation gates, all with fidelities above 99.99% neglecting decoherence. We further quantify gate accessibility through a Weyl-chamber analysis and demonstrate that strong SOI or engineered helical magnetic fields can unlock nearly complete (~ 99.98%) coverage of all locally inequivalent 2Q operations, including quantum gates such as the Berkeley gate. This work provides a realistic and scalable route toward single-step 2Q gates on mobile spin qubits, with immediate implications for distributed quantum computing, quantum simulation, and shuttling-assisted error-correcting architectures.

HL 38.5 Thu 10:30 POT/0051

Topological Superconductivity in the Presence of Contact Potentials — •Leonard Kaufhold — Institute for Theoretical Physics, Cologne, Germany

The research on Majorana bound states (MBS) has brought forth a multitude of proposed platforms and devices that are, in principle, capable of realizing such states as topological edge modes. These devices usually rely on the superconducting proximity effect induced in semiconductors with strong spin-orbit coupling or, more recently, in topological insulators. The material interface however induces another effect that can be as much as one order of magnitude larger than the electronic band gap at the surface. Due to the mismatch of work functions between the materials, a dipole layer forms at the interface, effectively creating a contact potential that modifies the electronic band structure far beyond the minimal models typically used to describe the formation of MBS. In this presentation, we will focus on different nanowire-based architectures consisting of a topological insulator in contact with an s-wave superconductor, and discuss on a theoretical level the effect of contact potentials on the formation and stability of MBS. We further outline under which parameter conditions these interface-induced effects become experimentally relevant.

HL 38.6 Thu 10:45 POT/0051

Hexagonal Germanium Nanowires as a Spin Qubit Platform — •Anirban Das[1], Baksa Kolok[1,2], Daniel Varjas[1,3], and Andras Palyi[1,2] — [1]Department of Theoretical Physics, BME, Budapest, Hungary — [2]HUN-REN-BME-BCE QTRG, BME, Budapest, Hungary — [3]IFW Dresden and Würzburg-Dresden Cluster of Excellence ct.qmat, Dresden, Germany

Hexagonal germanium (2H-Ge) offers strong spin-orbit interaction and optical activity, making it an appealing platform for semiconductor spin qubits. Recent progress in growing hexagonal Si_xGe_{1-x} nanowires enables controlled geometries suitable for quantum devices. In contrast to cubic Si or Ge, 2H-Ge supports direct band-gap transitions, opening a pathway towards a novel spin-photon interface.

We study the electronic and spin properties of 2H-Ge nanowires using a multiband k·p Hamiltonian describing low-energy states near the Γ point. By discretizing the model with open boundaries, we construct nanowires oriented perpendicular to the c-axis and compute their band structure. We analyze confinement-induced gap variations and the influence of transverse electric fields, from which we extract Rashba coefficients. Magnetic fields are included via a Peierls substitution to investigate anisotropic spin responses. The resulting effective g-tensor shows strong directional dependence, revealing regimes favorable for qubit operation in hexagonal Ge nanowires.

This research is supported by the European Union within the Horizon Europe research and innovation programme via the ONCHIPS project under grant agreement No 101080022.

HL 38.7 Thu 11:15 POT/0051

Low-Loss LNOI PIC Components for Quantum Interference Applications — •Mohammad Malik[1,2,3], Simon Palitza[1,2,3], and Carsten Schuck[1,2,3] — [1]Department for Quantum Technology, University of Münster — [2]Center for NanoTechnology - CeNTech, Münster — [3]Center for Soft Nanoscience - SoN, Münster

Lithium niobate on insulator (LNOI) exhibits significant potential as a platform for integrated photonics owing to its strong electro-optic response, broad transparency window, and intrinsic nonlinear properties. For on-chip quantum key distribution (QKD) and related quantum photonic applications, the precise fabrication of photonic integrated circuit (PIC) components with minimal loss and high fidelity remains a key challenge. Here, we demonstrate directional couplers (DCs) and multimode interferometers (MMIs) that achieve a 50/50 splitting ratio with insertion losses below 1.5 dB at a wavelength of 1550 nm. These results are obtained using in-house fabrication techniques, including electron-beam lithography and inductively coupled plasma reactive ion etching, enabling accurate and reproducible realization of crucial PIC components. Building on these results, we will discuss progress towards integrating superconducting nanowire single-photon detectors (SNSPDs) on the LNOI platform for realizing on-chip Hong-Ou-Mandel interference as required for integrated quantum technology applications, including measurement device independent QKD.

HL 38.8 Thu 11:30 POT/0051

Scalable and individual control of Si qubits via magnetic skyrmions — •Leander Reascos[1], Raluca Boltje[1], Kai Litzius[1], Felix Büttner[1,2], and Mónica Benito[1] — [1]Institute of Physics, University of Augsburg, 86159 Augsburg, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, 14109 Berlin, Germany

Scalable, precise control of spin qubits is essential for large-scale quantum processors with millions of qubits. Electron-spin qubits in semiconductor quantum dots are promising due to their small size, high fidelities, long coherence times, and CMOS compatibility. However, current electric-dipole spin resonance (EDSR) schemes rely on static micromagnets, which suffer from fabrication-induced inhomogeneities and limited tunability. We propose using gate-tunable nanoscale magnetic skyrmions as on-chip magnetic field sources to replace micromagnets. By controlling skyrmion geometry, the local magnetic field at a quantum dot can be tuned post-fabrication to adjust both the qubit frequency and the EDSR driving gradient. Using micromagnetic simulations and analytical modeling, we show how skyrmion geometry maps directly onto the qubit's Zeeman splitting and Rabi frequency. These results highlight skyrmion-based control as a promising route towards scalable, frequency-selective spin-qubit architectures with enhanced tunability.

HL 38.9 Thu 11:45 POT/0051

Strain modulation in Germanium: an overview for quantum applications — •Meera None[1], Ignatii Zaitsev[1], Davide Spirito[2], Patricio Farrell[3], Christian Merdon[3], Yiannis Hadjimichale[3], Daniel Fritsch[4], Marvin Hartwig Zoellner[1], and Costanza Lucia Manganelli[1] — [1]IHP-Frankfurt (Oder)-Germany — [2]BC-Materials-Leioa, Spain — [3]WIAS-Berlin — [4]Zuse-Berlin

Germanium (Ge) is a promising platform for hole-based quantum devices due to its high hole mobility, strong spin-orbit coupling, and compatibility with CMOS technology. We investigate strain engineering in an ideal structure with two silicon nitride (SiN) stressors on a Ge substrate, using FEM to study how stress level, stressor height, and design influence mechanical deformation. The resulting strain tensors, including often neglected shear components, are inserted into a fully coupled 6x6 Bir-Pikus Hamiltonian to compute heavy hole (HH) and light hole (LH) band shifts under uniaxial and biaxial stress. Our results show tunable HH-LH splitting from 36 to 165 meV for SiN stressors between 1 and 4 GPa, demonstrating that SiN stressors offer a practical, scalable route to engineer Ge band structure for quantum wells and hole spin qubits.

HL 38.10 Thu 12:00 POT/0051

Optical probing of strain fields in isotopically pure Si-28 using donor-bound excitons — •Nico Eggeling[1], Phillip Külper[1], N.V. Abrosimov[2], Jens Hübner[1], and Michael Oestreich[1] — [1]Leibniz Universität Hannover, Germany — [2]IKZ Berlin, Germany

The successful demonstration of all optical qubits in isotopically pure Si-28 utilises the donor-bound exciton transition of phosphorus dopants [1]. As a current obstacle for large-scale implementation, the challenge remains to harness inhomogeneities resulting from simple imperfections in the crystal lattice, over dopant-dependent lattice deformations, to even the hydrostatic pressure due to the sample's own weight or adjacent interfaces. We present results from spatially resolved measurements of the donor-bound exciton, revealing a distinct strain distribution in a bulk Si-28 sample at cryogenic temperatures. These are explained in the context of the Pikus-Bir formalism for silicon [2], leading to strain estimates that are well matched to the known extrinsic factors.

HL 38.11 Thu 12:15 POT/0051

Development of heavy noble gas field ion sources using an iridium coated single crystalline tungsten emitter — •Amina Zid[1,2], Gregor Hlawacek[1], Nico Klingner[1], Arnaud Houel[2], and Anne Delobbe[2] — [1]Institute for Ion Beam Physics and Material Research, Helmholtz-Zentrum Dresden-Rossendorf — [2]ORSAY PHYSICS, 95, 3ème Avenue - ZA Saint-Charles, 13710 Fuveau, France

Gas Field Ion Sources (GFIS) provide high brightness, high current density and excellent spatial resolution[1]. Conventional GFIS use light noble gases: helium enables 0.5 nm imaging resolution, while neon allows high-resolution milling beyond Liquid Metal Ion Source (LMIS) capabilities. However, low maximum current limits material removal rates, and the light ions cause deep implantation and bubble formation, reducing efficiency for large-volume or high-aspect-ratio milling. To overcome these limits, we investigate GFIS operation in a Focused Ion Beam (FIB) using heavier noble gases.

Additionally an iridium-coated tungsten tip is investigated. Iridium forms the strongest bond with tungsten[2], enabling higher electric fields and thus higher stable beam currents. Our emitter operates from a single emission point rather than the typical trimer used in Helium Ion Microscopy. This work presents the first FIB performance evaluation of this emitter with argon and xenon, including comparison to helium and neon-based GFIS.

Finding the kinked propagation of the I3 defect in hexagonal silicon using a machine-learned potential — •Jolijn Dellevoet — Eindhoven University of Technology, Eindhoven, The Netherlands

Hexagonal silicon-germanium (hex-SiGe) alloys have recently emerged as promising direct-bandgap semiconductors suitable for on-chip optical communication, offering a path to reduce heat production in microchips. Currently, the hex-SiGe crystal is grown in core-shell nanowire structures, but their crystal quality is hindered by the formation of I3 defects. During growth, these defects nucleate and can propagate into otherwise pristine crystal. This propagation has been observed experimentally but not reproduced in atomistic simulations, leaving the underlying mechanism unclear. This presentation reveals, at atomic resolution, a kinking mechanism that enables the I3 defect boundary to propagate within hex-Si. This mechanism and its corresponding energy landscape are obtained by using the nudged elastic band (NEB) method in combination with the machine-learned PACE potential. Although the calculations are currently limited to Si systems, future studies could focus on extending the calculations to SiGe systems. The temperature and boundary length dependence of the transition rate can ultimately be used to optimize growth conditions of the hex-SiGe core-shell nanowires.

HL 39.1 Thu 9:30 POT/0081

Ab initio investigation of electronic, magnetic, optical properties and proximity effect in MoS_2/CrSBr van der Waals heterostructures — •Athanasios Koliogiorgos and Karel Carva — Charles University, Prague, Czech Republic

CrSBr-MoS_2 heterostructures combine the properties of the antiferromagnetic semiconductor CrSBr and the TMD semiconductor MoS_2, yielding a promising platform for spintronic and valleytronic applications. In connection with experimental work, using density functional theory with GGA+U and hybrid HSE06 functionals, we explore the structural, electronic, magnetic and optical properties of MoS_2/CrSBr systems, where CrSBr is 1-4 layers thick and MoS_2 a monolayer. We observe induced magnetization in the MoS_2 layer via proximity effect, strongly dependent on the interlayer distance. Other proximity effects include charge transfer, bandgap renormalization and spin splitting in the band structure, while the density of states reveals a weakly hybridized system, retaining the characteristics of the separate parts. Work function and band alignment show that the material behaves as a Type-II heterostructure. The calculation of the absorption coefficient reveals distinct peaks corresponding to the CrSBr and MoS_2 layers, in agreement with the experimental photoluminescence spectrum.

HL 39.2 Thu 9:45 POT/0081

Proximity-Induced Raman Signatures in a $NbSe_2$-CrSBr Superconductor-Magnet Heterostructure — •Elena Vinnemeier[1], Jan-Hendrik Larusch[1], Kai Rossnagel[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster, Münster, Germany — [2]Institute of Experimental and Applied Physics, Kiel University, Kiel, Germany

Interfacing superconducting $NbSe_2$ with the antiferromagnetic semiconductor CrSBr provides a van der Waals platform to study proximity effects in quantum devices. The superconductivity-magnetism interplay enables Josephson junctions and superconducting quantum interference devices with field-tunable critical current and spin filtering. We study proximity effects of the spin ordered CrSBr on the specific collective modes in $NbSe_2$ in the superconducting phase at 4K and the charge-density wave phase at 15K. A magnetic field tunes CrSBr from antiferromagnetic to ferromagnetic order. The Raman response of the heterointerface, relative to bare $NbSe_2$, reveals proximity effects from the ferromagnetic CrSBr layer at the interface. Modifications of the $NbSe_2$ collective excitation spectrum demonstrate strong interaction between the proximitized magnetic order in CrSBr and correlated phases in $NbSe_2$. This project was supported by the EIC pathfinder grant 101130224 "JOSEPHINE".

HL 39.3 Thu 10:00 POT/0081

Exciton dominated anisotropic dielectric tensor in CrSBr — •Jan-Hendrik Larusch[1], Pierre-Maurice Piel[1], Aleksandra Łopion[1], Thomas Kliewer[1], Zdeněk Sofer[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, University of Münster, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Prague, Czech Republic

CrSBr is an air-stable magnetic vdW semiconductor with a direct bandgap; its anisotropic spin, lattice, and charge, drive anisotropic light-matter interaction $\varepsilon(\omega)$. We directly determine the full dielectric tensor of exfoliated CrSBr by spectroscopic imaging ellipsometry (SIE). In the paramagnetic phase, SIE verifies $\varepsilon_{xx} \times \varepsilon_{yy} \times \varepsilon_{zz}$. Room-temperature comparison of Mueller-matrix and generalized ellipsometry guides cryogenic SIE, enabling us to track changes across the Curie and Néel temperatures as the system evolves from paramagnetic over intralayer ferromagnetism to A-type antiferromagnetism. In the AFM phase, polarization-resolved magneto-reflectance with fields along c (hard), b (easy), and a (intermediate) axis yields critical fields of roughly 2.2, 1.05, and 0.3 T for transition to FM order sensed by distinct optical fingerprints. Together, these measurements quantify the anisotropic light-matter interaction and its dependence on magnetic order, linking exciton-dominated emission/absorption to the full dielectric tensor [1]. [1] J. Klein et al. ACS Nano 17, 5316-5328 (2023).

HL 39.4 Thu 10:15 POT/0081

Optical Probing of Interfacial Magnetic Properties of the CrSBr-$MnPS_3$ hetero-interface — •Thomas Kliewer[1], Aleksandra Łopion[1], Pierre-Maurice Piel[1], Jan-Hendrik Larusch[1], Zdeněk Sofer[2], and Ursula Wurstbauer[1] — [1]University of Münster, Germany — [2]University of Chemistry and Technology Prague, Czech Republic

CrSBr and $MnPS_3$ are both 2D antiferromagnetic semiconductors with different magnetic and optical properties. $MnPS_3$ has out-of-plane spin alignment while CrSBr's spins are aligned in-plane [1,2]. Interfacing these two materials is expected to result in complex interfacial spin-alignment, presumably with the stabilization of a non-collinear magnetic phase at the interface. CrSBr exhibits strong excitonic features coupled to the magnetic order [3]. This is used as a probe for the magnetic situation of the $MnPS_3$-CrSBr interface. The structures are characterized by polarization-resolved Raman spectroscopy measurements and the interfacial magnetic properties are probed by low-temperature magneto-photoluminescence and reflectance spectroscopies. We observed a peculiar influence of $MnPS_3$ on the optical response of CrSBr. A proximity-induced modification of the magnetic properties of CrSBr interfaced with $MnPS_3$ seems to induce long-range order, since the impact is observable on the CrSBr flake more than 10 μm away from the interfaced region. Our observations might be connected to the stabilization of an intermediate ordered magnetic state in CrSBr. [1] Wilson, et al. Nat. Mat. 20.12 (2021), [2] Kobets, et al. Low Temp. Phys. 35.12 (2009), [3] Heißenbüttel, et al. Phys. Rev. B 111.7 (2025)

HL 39.5 Thu 10:30 POT/0081

Coupling Between Vibrational, Electronic, and Magnetic States in CrSBr — •Daria Markina[1], Priyanka Mondal[1], Lukas Krelle[1], Sai Shradha[1], Mikhail M. Glazov[2], Regine von Klitzing[1], Kseniia Mosina[3], Zdenek Sofer[3], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 6-8, D-64289 Darmstadt, Germany — [2]St. Petersburg, Russia — [3]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Technicka 5, 166 28 Prague 6, Czech Republic

The van der Waals antiferromagnet CrSBr displays interplay between vibrational, electronic, and magnetic states, producing distinctive quasiparticle interactions. Using temperature-dependent polarization-resolved Raman spectroscopy with

optical absorption and photoluminescence excitation (PLE), we examine these effects across the magnetic phase transition. Under 1.96 eV excitation, the A_g^1, A_g^2, and A_g^3 Raman modes exhibit pronounced polarization and intensity changes near the Néel temperature, accompanied by modifications in excitonic oscillator strength and resonant PLE features. The distinct temperature evolution of Raman tensor elements indicates that individual phonons couple to specific excitonic and electronic states. The suppression of excitonic transitions above the Néel temperature links these effects to spin alignment, suggesting an indirect spin−phonon interaction mediated by exciton−phonon coupling. These findings establish CrSBr as a promising platform for studying quasiparticles in two-dimensional magnets and for potential quantum technologies.

HL 39.6 Thu 10:45 POT/0081

Evidence for a novel spin-density excitation in 2D magnetic semiconductor CrSBr — •Pierre-Maurice Piel[1], Jan-Hendrik Larusch[1], Aleksandra Łopion[1], Zdenek Sofer[2], and Ursula Wurstbauer[1] — [1]Institute of Physics, Muenster University, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Prague, Czech Republic

The van der Waals magnet CrSBr is an air-stable semiconductor with ferromagnetic layers, antiferromagnetic interlayer coupling, and a highly anisotropic bandstructure, resulting in quasi-one-dimensional excitonic states [1]. We probe the impact of magnetic order on excitons and collective modes using low temperature (4K) magneto photoluminescence and resonant Raman spectroscopy with special emphasize on the magnetic anisotropy and magnetic phase transitions. The excitonic signatures in photoluminesence show clear differences between antiferromagnetic and ferromagnetic regimes and reveal pronounced magnetic anisotropy. In resonant Raman, the first order Ag phonons remain essentially field independent, whereas additional modes appear only under excitonic resonance. We resolve a sharp mode near 248 cm-1 emerging in resonance with the A-exciton (~1.36eV) and a broad mode at 362 cm-1 occurring in A and higher-lying excitonic regimes. The mode's excitation energy and field dependence indicate selective access to different collective possibly spin-density excitations in CrSBr. [1] J. Klein et al., ACS Nano 17, 5316-5328 (2023).

HL 39.7 Thu 11:15 POT/0081

Tracking Magnetic Phase Evolution in CrSBr via Excitonic Emission and Absorption — •Lukas Krelle[1], Ryan Tan[1], Daria Markina[1], Priyanka Mondal[1], Kseniia Mosina[2], Kevin Hagmann[1], Regine von Klitzing[1], Zdenek Sofer[2], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 6-8, D-64289 Darmstadt, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Technicka 5, 166 28 Prague 6, Czech Republic

CrSBr is an air-stable magnetic van der Waals semiconductor, in which the interaction of excitons with the magnetic order enables the optical identification of different magnetic phases. Here, we study multi-layer samples of CrSBr inside a three-axis vector magnet and correlate magnetic order and optical transitions. We identify layer by layer switching of the magnetization through drastic changes of the optical absorption energy and strength as a function of the applied magnetic field. We find that ferromagnetic and antiferromagnetic order between layers can coexist in the same domain [1]. The photoluminescence evolution depends on the magnetic order and can differ for each emission. The intensity of energetically lower lying transitions reduces monotonously with increasing field strength whereas energetically higher lying transitions around the bright exciton increase in intensity close to the saturation field. Using this contrasting behavior we can therefore correlate transitions with each other. [1]: L. Krelle et al, ACS Nano 2025, 19, 33156

HL 39.8 Thu 11:30 POT/0081

Magnetically controllable exciton-polariton condensation in CrSBr microwires — •Christian Weidgans[1], Heng Zhang[1], Niloufar Nilforoushan[1,4], Julian Hirschmann[2], Marlene Liebich[1], Tobias Inzenhofer[1], Imke Gronwald[1], Josef Riepl[1], Kseniia Mosina[3], Zdeněk Sofer[3], Fabian Mooshammer[1], Florian Dirnberger[2], and Rupert Huber[1] — [1]University of Regensburg, Germany — [2]Technical University of Munich, Germany — [3]University of Chemistry and Technology Prague, Czech Republic — [4]Université Paris Cité, France

Coupling the macroscopic wave functions of quasiparticle condensates to other degrees of freedom, such as the electron spin, could offer valuable control knobs for future quantum applications. In particular, man-made condensates of light-matter hybrids known as exciton-polaritons have lacked a direct spin-related control mechanism. Here we demonstrate magnetically tunable exciton-polariton condensation in the antiferromagnetic semiconductor CrSBr, a van der Waals material with strongly linked optical and magnetic properties. Under photoexcitation, CrSBr microwires embedded in an optical cavity show the hallmarks of polariton condensation. The conditions for efficient optical pumping suggest a crucial role of recently discovered surface excitons. Applying an external magnetic field energetically shifts the photoemitting polariton states, enabling direct spin-based control. Our results highlight CrSBr microwires as a powerful platform for exploring magnetically tunable polariton condensates, their directional propagation and their potential for spin-based quantum devices.

HL 39.9 Thu 11:45 POT/0081

Preparation and characterization of CrSBr on opal substrtates — •Jannik Schürmann[1], Aleksandra Lopion[1], Ursula Wurstbauer[1], Alexey V. Scherbakov[2], and Giulia Magnabosco[3] — [1]University of Münster, Münster, Germany — [2]Technische Universität Dortmund, Dortmund, Germany — [3]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Ger- many

The magnetic semiconductor Chromium-Sulfur-Bromide (CrSBr) is a highly anistropic van der Waals material. To study the anisotropy of the phononic properties independent from the supporting substrate, the flakes can be detached from it either by suspending it over cavities or by transferring it to a substrate containing closely packed silica spheres (opals). This second approach was already applied to other, nonmagnetic vdW materials such as WSe2 allowing an in-depth pump-probe study of phonons in the material [1]. Accordingly, we transfer mechanically exfoliated CrSBr onto opal substrates using polycarbonate stamps (dry transfer) and thoroughly characterize the properties and qualities of the flakes on opals. Atomic force microscopy confirms that CrSBr is on top of the spheres and partially freestanding. PL and Raman measurements are performed to validate the behavior of the flake in comparison with fully supported one. The decoupled CrSBr flakes on opal substrates are suitable for pump-probe studies of phonon states in CrSBr.

Accurate electronic, optical, and magnetic properties of CrSBr via a tuned hybrid functional — •Daniel Hernangómez-Pérez[1], María Camarasa-Gómez[2], Javier Junquera[3], and Ashwin Ramasubramaniam[4] — [1]CIC nanoGUNE BRTA, Donostia, Spain — [2]Centro de Física de Materiales (CFM/MPC), Donostia, Spain — [3]Universidad de Cantabria, Santander, Spain — [4]University of Massachusetts Amherst, USA

CrSBr, a layered antiferromagnet, has attracted attention for its ambient stability, relatively high Néel temperature, and strong exciton-magnon coupling. While experiments have progressed rapidly, computational studies lag due to the high cost of many-body perturbation theory (MBPT). Here, we present a generalized Kohn-Sham density functional approach that accurately reproduces electronic bandstructures, optical spectra, exciton binding energies, and magnon spectra of bulk and few-layer CrSBr at much lower cost than MBPT. Using a minimal two-parameter set tuned to a few benchmarks, we achieve excellent agreement across a broad range of optoelectronic and magnetic properties.

HL 39.11 Thu 12:15 POT/0081

Tunable exchange interaction and hysteresis observed via excitons in a van der Waals antiferromagnet bilayer — •Priyanka Mondal[1], Sonu Verma[2], Wenze Lan[1], Lukas Krelle[1], Ryan Tan[1], Regine von Klitzing[1], Kseniia Mosina[3], Zdenek Sofer[3], Akashdeep Kamra[2], and Bernhard Urbaszek[1] — [1]Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 6-8, D-64289 Darmstadt, Germany — [2]Department of Physics and Research Center OPTIMAS, Rheinland-Pf\"alzische Technische Universit\"at Kaiserslautern-Landau,Germany — [3]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Czech Republic

Two-dimensional magnets have emerged as key platforms for exploring layer-dependent magnetic phenomena. CrSBr is a recently identified van der Waals magnet with strong excitonic features and layered antiferromagnetic (AFM) order. While pristine bilayers show no magnetic hysteresis, we find that a ~3° twist induces clear hysteresis and can even stabilize a zero-field ferromagnetic state[1]. Field-dependent photoluminescence tracks this behavior through hysteretic exciton energy shifts that match the magnetic configuration. A two-sublattice model explains the response via twist-reduced interlayer exchange, allowing both parallel and antiparallel spin states. The bilayer behaves as an effective monodomain, switching cleanly into the AFM state without forming spin textures. These results highlight twist engineering as a route to programmable magnetic memory in 2D magnets.

HL 40: Oxide Semiconductors: Transport and Spectroscopy

Time: Thursday 9:30–12:30 Location: POT/0251

HL 40.1 Thu 9:30 POT/0251

Unraveling metal-induced redox mechanisms on SrTiO3 via combined in-situ laser reflectometry and x-ray photoelectron spectroscopy — •Georg Hoffmann, Shi-Hui Liu, Serkan Sirt, Oliver Bierwagen, and Roman Engel-Herbert — Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, 10117 Berlin, Germany

SrTiO3 has long served as a key platform for emergent phenomena in perovskite oxides such as polar discontinuity driven two-dimensional electron gases (2DEGs) when interfaced with LaAlO3 [1]. Recently, increasing attention has been brought to 2-DEGs that emerge at SrTiO3 surfaces from redox-reactions induced by amorphous metal deposition on top [2]. Studying these processes, however, requires complex in-situ techniques like photoelectron spectroscopy (XPS) with long measurement cycles. Here, we introduce laser reflectometry (LR) as a complementary technique that enables monitoring of redox-reactions at oxide/metal interfaces. We show that LR in an oxide molecular beam epitaxy setup can distinguish between Al deposition on non-reactive substrates and Al oxidation, e.g. through oxygen scavenging from SrTiO3. Atomic force microscopy, Capacitance-Voltage profiling, and XPS measurements corroborate our findings. Our results demonstrate how LR can guide future investigations of redox-reactions at oxide/metal interfaces.

HL 40.2 Thu 9:45 POT/0251

Resonant Raman studies in rutile-Germaniumdioxide — •Kenneth Brandt[1,3], Moritz Meissner[1,3], Zbigniew Galazka[2], Tobias Schultz[2], Markus Wagner[1,3], and Hans Tornatzky[1,3] — [1]Paul-Drude-Institut, Berlin — [2]Leibniz-Institut für Kristallzüchtung, Berlin — [3]Technische Universität Berlin

Ultra-wide bandgap (UWBG) semiconductors are a new research area of interest, with promised applications in power electronics. Germaniumdioxide in the rutile phase (r-GeO_2) has been characterised to be such an UWBG Material with a Bandgap at about 4.5 eV. To be able to create homojunction devices, the material needs to be ambipolar dopable, which poses a challenge for β-Ga_2O_3, as p-type doping has yet to be achieved, while r-GeO_2 is predicted to be ambipolar dopable. Raman measurements show a non typical intensity relationship, in which explicitly the E_g mode does not follow the expected $I \propto \omega^4$ relation of the Raman-Scattering processes but decreases in intensity with higher excitation energies. We are performing resonant Raman studies, with excitation energies ranging from 1.2 eV provided by a tunable Ti:Sa Laser, as well as multiple additional single line Lasers with energies up to 5.1 eV, to investigate the atypical Raman response and electron-phonon coupling.

To quantise the measurements CaF_2 is used as a calibration standard and GaAs is included in the measurement series to compare with literature.

HL 40.3 Thu 10:00 POT/0251

Theoretical Description of a Photo-induced Hidden State in Bismuth Vanadate — •Philip Schwinghammer[1], Verena Streibel[1,2], Frederico Delgado[1], Franziska S. Hegner[1], Viktoria Kunzelmann[1,2], Konrad Merkel[1], Frank Ortmann[1], Ian Sharp[1,2], and David A. Egger[1] — [1]TUM School of Natural Sciences, Technical University of Munich, Germany — [2]Walter Schottky Institute, Technical University of Munich, 85748 Garching, Germany

Bismuth Vanadate has attracted attention in recent years as a promising photoactive material and complex model system. In order to understand new experimental results which show a light-sensitive structure at room temperature, we perform a detailed analysis of the chemical bonding and impact of the exchange-correlation functional. In addition to the use of hybrid functionals, spin-orbit coupling (SOC) stabilizes the experimentally observed monoclinic structure over its high-symmetry tetragonal counterpart. The physical mechanism behind the stabilization is explained through the increase of both covalent and ionic bonding as symmetry breaking causes shortening of select Bi-O bonds. These mechanisms are strongly affected by photo-induced excitation of charge carriers, as the states responsible for the monoclinic distortion are depleted. The alteration of the structure through light may then affect the photo-catalytic efficiencies of the material, as we also find significant differences in the optoelectronic properties of the monoclinic and tetragonal structures.

HL 40.4 Thu 10:15 POT/0251

E-field modulated phase change properties in highly epitaxial VO2 thin film monitored via Raman spectra and IR transmission — •Sonika Singh[1], Rajendra Singh[2], and Ankur Goswami[3] — [1]IIT Delhi, New Delhi, India — [2]IIT Delhi, New Delhi, India — [3]IIT Delhi, New Delhi, India

VO2 is a highly explored smart oxide semiconductor showing metal insulator transition (MIT) at near room temperature ~67 oC. It is observed that optoelectronic properties of highly epitaxial VO2 thin films offer several advantages as compared to polycrystalline film in terms of E-MIT and thermal switching. Here we investigate E-MIT on epitaxial VO2 deposited using PLD technique. Prior to electrical measurement, electrical contacts with 8 *m separation distance were made using Ti/Au metallization. The dual voltage sweep carried over the device demonstrated a high thermal switching ratio (around 30) between high resistive and low resistive state. Furthermore, the dual current sweep was performed on the devices reflected snapback transition signifying uncontrolled and rapid phase transition of VO2. Additionally, E-field dependent Raman spectroscopy revealed modulation of phase transition of VO2 monitored via Raman peaks and triggered via square signal of E-field. These findings suggest that epitaxial thin film of VO2 can be explored for further studies involving modulation of phase change properties via E-field that find direct applications in neuromorphic devices, THz transmissions, thermal switches.

HL 40.5 Thu 10:30 POT/0251

Spatially Resolved Phase Transition and Characterization in Gallium Oxide — Umutcan Bektas[1], Paul Chekhonin[2], Nico Klingner[1], Azat Abdullayev[3], Alexander Azarov[4], René Hübner[1], Zhandos Utegulov[3], Andrej Kuznetsov[4], and •Gregor Hlawacek[1] — [1]Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328, Dresden, Germany — [2]Resource Ecology, Helmholtz-Zentrum Dresden-Rossendorf, 01328, Dresden, Germany — [3]Department of Physics, Nazarbayev University, 010000, Astana, Kazakhstan — [4]Centre for Materials Science and Nanotechnology, University of Oslo, N-0316, Oslo, Norway

In this study, we investigate ion-irradiated β-Ga_2O_3 samples (varying ions and fluences) alongside α- and κ-Ga_2O_3 thin films. Using focused ion beam (FIB) irradiation, we locally modified the samples under controlled conditions by tuning beam current, size, spacing, scan type, and ion species. Structural changes in the irradiated regions were characterized via electron backscatter diffraction (EBSD) and transmission electron microscopy (TEM). Our results demonstrate that ion induced transition to the γ polymorph can be achieved also through FIB irradiation, enabling the fabrication of in-plane polymorph patterns on the nanometer scale. Furthermore, time-domain thermoreflectance (TDTR) measurements further revealed the thermal conductivity of irradiated regions, highlighting opportunities to optimize heat transport in Ga_2O_3 power electronic devices. This research is supported by the tax funds on the basis of the budget passed by the Saxonian state parliament in Germany.

HL 40.6 Thu 10:45 POT/0251

Bandgap, exciton dynamics, and anisotropic thermal transport in rutile-GeO_2 — •Markus R. Wagner[1,2], Luca S. M. Choi[2], Nils Bernhard[2], Pouria Emtenani[2], Felix Nippert[2], Moritz Meissner[1], Hans Tornatzky[1], and Zbigniew Galazka[3] — [1]Paul-Drude-Institut für Festkörperelektronik — [2]Technische Universität Berlin, Institut für Physik und Astronomie — [3]Leibniz-Institut für Kristallzüchtung

Rutile germanium dioxide (r-GeO_2) is a promising ultra-wide bandgap material, predicted to support ambipolar doping and display high thermal and electronic conductivity, making it a strong candidate for power electronics. However, essential aspects of its properties, such as exciton and phonon dynamics as well as the role of defects and impurities, remain only partially explored. Here, we present our recent spectroscopic studies on r-GeO_2. High-resolution spectroscopy of free exciton ground and excited states enables us to determine exciton binding energies and the temperature dependence of the bandgap. Polarization-resolved photoluminescence reveals pronounced differences between near-UV and visible emission bands, which we analyze regarding thermal quenching, recombination dynamics, and charge transfer through temperature- and power-dependent PL, TRPL, and PLE. Using time-domain thermoreflectance down to cryogenic temperatures, we establish the temperatur dependence of thermal conductivity and anisotropy, supported by Boltzmann transport calculations. Finally, polarization-resolved Raman spectroscopy identifies all first-order Raman-active phonons and their relative tensor elements.

HL 40.7 Thu 11:15 POT/0251

MESFETs based on α-$(Al_xGa_{1-x})_2O_3$ thin films — •Sebastian Köpp, Sofie Vogt, Holger von Wenckstern, and Marius Grundmann — Leipzig University, Leipzig, Germany

We present the electrical properties and key parameters of metal-semiconductor field effect transistors (MESFET) on α-$(Al_xGa_{1-x})_2O_3$. The functional thin films were grown by pulsed laser deposition. The transistors were investigated in dependence on the Al content up to x=0.1. The devices exhibit an electrical breakdown field larger than that of comparable transistors on binary α-Ga_2O_3, demonstrating the advantages of the $(Al_xGa_{1-x})_2O_3$ alloy system.

With its ultra-wide bandgap of 5.3 eV to 5.6 eV [1,2] and a high predicted breakdown field of 10 MV/cm [3], α-Ga_2O_3 is a promising material for high-power devices, as well as deep-UV photodetectors. α-Ga_2O_3, being isostructural to aluminium oxide, allows for heteroepitaxial growth on cost-efficient sapphire substrates, and also opens up the option of α-$(Al_xGa_{1-x})_2O_3$ alloys [4], with even higher dielectrical breakdown field than binary Ga_2O_3.

Group-III doping study of p-type oxide tin monoxide — •Nicola Gutmann, Georg Hoffmann, Aidan Campbell, and Oliver Bierwagen — Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Germany.

The use of transparent conducting oxides has so far been limited to n-type materials, hindering the development of transparent oxide-based pn-junctions and CMOS devices. In contrast, SnO shows natural p-type conduction with reported hole mobilities up to 21 cm^2/Vs [1] and well-performing p-type transistors demonstrated.

Adjustment of hole concentration by doping with Ga, Na, K and Y has been demonstrated [2]. Al is theoretically predicted to be an n-type dopant [3], which would enable SnO-based pn-homojunctions.

In this work, we comparatively explore doping of suboxide molecular beam epitaxy grown SnO by the group-III elements Al, Ga and In.

HL 40.9 Thu 11:45 POT/0251

Realization of highly rectifying pn-heterojunctions and junction field-effect transistors on pulsed laser deposited α-Ga_2O_3 thin films — •Paul Bokemeyer, Clemens Petersen, Holger von Wenckstern, Marius Grundmann, and Sofie Vogt — University Leipzig, Felix-Bloch-Institut für Festkörperphysik, Germany

The wide band gap of about 5.3 eV[1] and a high expected breakdown field of up to 10 MV/cm[2], renders the corundum α-phase of Ga_2O_3 interesting for high power electronics. We present lateral p^+n-heterojunction diodes on α-Ga_2O_3:Sn grown by pulsed laser deposition (PLD) using a two step approach[3]. ZnCoO (ZCO) and NiO deposited by PLD at room temperature were used as p^+-type materials. Further, the influence of a remote oxygen plasma treatment prior to the deposition of the p-type layers on the device performance was investigated. High current rectification ratios of 8.2 (ZCO) and 7.8 (NiO) orders of magnitude at ± 3V were achieved. Additionally, both p-type materials were used as gate materials in the fabrication of α-Ga_2O_3:Zr junction-field-effect-transistors (JFETs), yielding on/off current ratios of more than 9 orders of magnitude and subthreshold-swings down to 119 mV/dec. Furthermore, breakdown was detected at drain voltages of up to 476 V which is estimated to a field of 1.7 MV/cm [4].

Defect-Induced Resistive Switching in Titanate-based Perovskites — •Parrydeep Kaur Sachdeva[1], Wahib Aggoune[1,2], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at FHI of MPG, Berlin — [2]Institut für Physik and CSMB, Humboldt-Universität zu Berlin, Berlin

Perovskites possess strong potential for exhibiting ferroelectric resistive switching (RS), a functionality recently realized yet not understood in titanate perovskites [1]. Controlled deviation from stoichiometry has revealed high RS, indicating a defect-mediated origin. Using hybrid functional DFT calculations, we show that the Ti antisite defect (Ti-interstitial with Ca-vacancy) can induce ferroelectricity in $CaTiO_3$ which is an incipient ferroelectric, stabilized in a nonpolar state by strong octahedral tilts. The Ti-interstitial atom breaks this balance by its off-center displacement and induces a local polarization. This polarization is switchable between different off-center positions of the defect, with energy barriers in the range of 0.25 eV. Additionally, the Ti antisite defect gives rise to mid-gap states, with a charge density mainly localized around the Ti-interstitial atom. Switching the defect between equivalent off-center positions switches the polarization direction and alters the spatial distribution of the charge state. This can influence the material's overall response under external stimuli. These results are discussed with respect to the experimentally observed resistive switching in titanate-based perovskites [1], as reported by Leibniz-Institut für Kristallzüchtung (IKZ) Berlin.

HL 40.11 Thu 12:15 POT/0251

ZnM_2O_4 (M = Co, Rh, Ir) spinels as potential p-type transparent conducting oxides — •Daniel Fritsch — Institute of Physics and Astronomy, University of Potsdam, Karl-Liebknecht-Str. 24/25, 14476 Potsdam, Germany

ZnM_2O_4 (M = Co, Rh, Ir) spinels are under investigation as potential p-type transparent conducting oxides (TCOs) [1]. Here we extend our previous investigation of $ZnRh_2O_4$ into the whole series of ZnM_2O_4 (M = Co, Rh, Ir) spinels.

To this end, we perform *first-principles* calculations based on density functional theory employing a recently developed *self-consistent* hybrid exchange and correlation functional [2], and compare the results to more standard HSE06 hybrid functional calculations. In order to judge the results on the electronic and optical properties, additional calculations based on many-body perturbation theory, i.e. G_0W_0 calculations, have been performed and allow for a more detailed analysis of the applicability of ZnM_2O_4 (M = Co, Rh, Ir) spinels as potential p-type TCOs.

The obtained structural, electronic, and optical properties will be discussed alongside earlier experimental and theoretical investigations, and will open a pathway to potential applications of ZnM_2O_4 (M = Co, Rh, Ir) spinels.

HL 42: Nitrides III – Emerging thin films and electrochemistry

Time: Thursday 11:15–12:45 Location: POT/0006

Invited Talk HL 42.1 Thu 11:15 POT/0006

Transition Metal Nitride Semiconductors for Photoelectrochemical Energy Conversion — •Verena Streibel[1,2], Laura I. Wagner[1,2], Elise Sirotti[1,2], David A. Egger[2], and Ian D. Sharp[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Garching, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Garching, Germany

Transition metal nitride thin films are emerging as promising materials for (photo)electrochemical applications. However, their synthesis and defect control remain challenging. Here, we use reactive co-sputtering to synthesize and engineer nitride thin films with precise control over composition and doping in the Ti-Ta-N,[1] Zr-Ta-N,[2,3] and Hf-Ta-N materials space. Starting from orthorhombic Ta_3N_5, we show that substitutional Ti doping improves photoconversion efficiency by modulating defects and recombination dynamics. While high Ti doping forms a secondary TiN phase, Zr and Hf yield tunable solid solutions in the Zr-Ta-N-(O) and Hf-Ta-N-(O) systems, exhibiting bandgap modulation and large refractive indices. Notably, a new bixbyite-type ternary compound, $ZrTaN_3$, forms at a 1:1 Zr:Ta ratio, showing strong visible light absorption and photoanodic activity. DFT calculations reveal a tunable direct bandgap driven by cation ordering.[3] Our findings establish composition engineering as a key strategy for tailoring band structure and charge transport in emerging nitride semiconductors.

HL 42.2 Thu 11:45 POT/0006

Analysis of the interface properties of cubic nitride thin films grown on 3C-SiC/Si templates using electrochemical impedance spectroscopy — •Hannes Hergert[1,2], Mario F. Zscherp[1,2], Silas A. Jentsch[1,2], Jörg Schörmann[1,2], Sangam Chatterjee[1,2], Peter J. Klar[1,2], and Matthias T. Elm[1,2] — [1]Center for Materials Research, Heinrich-Buff-Ring 16, 35392 Giessen — [2]Institute of Experimental Physics I, Heinrich-Buff-Ring 16, 35392 Giessen

Due to its lack of internal polarization fields cubic gallium nitride (c-GaN) is a promising semiconductor material for a variety of applications, such as high-power electronics or optoelectronic devices. High quality c-GaN can successfully be grown by molecular beam epiatxy on 3C-SiC/Si templates making use of a c-AlN buffer layer, which accommodates lattice mismatch between c-GaN and the 3C-SiC template. A reliable characterization of the interface properties as well as the electrical transport properties of c-GaN is crucial for optimizing the thin film growth as well as for designing advanced functional devices. In this work we employ electrochemical impedance spectroscopy (EIS) for characterizing the transport throught c-GaN/AlN/3C-SiC/Si sample structures with different c-GaN thicknesses and for analyzing the properties of the interface, such as the trap density.

HL 42.3 Thu 12:00 POT/0006

Investigating Charge Transport Limitations in $LaTiO_2N$ Thin Films for Photoelectrochemical Water Splitting — •Oliver Brune[1,2], Gabriel Grötzner[1,2], Katarina S. Flashar[1,2], Saswati Santra[1,2], Ian D. Sharp[1,2], and Verena Streibel[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Garching, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Garching, Germany

Photoelectrochemical water splitting offers a sustainable route to hydrogen production. On the photoanode side, $LaTiO_2N$ is a promising candidate due to its visible-light absorption, favorable band alignment and n-type semiconducting properties. However, its performance is limited by inefficient charge transport, the origin of which remains unclear. In this work, we synthesize $LaTiO_2N$ thin films by spin coating and reactive sputter deposition, both followed by ammonia annealing, yielding films with controlled structure and composition as confirmed by XRD and ERDA/RBS. Synchrotron-based XAS, XPS, UV-Vis spectroscopy, and PEC measurements reveal that a larger degree of nitridation in $LaTiO_2N$ correlates with higher short-range order and crystallinity, a decreasing bandgap, and an increase in photocurrent density. To elucidate charge transport mechanisms and carrier dynamics, we use Hall effect and temperature-dependent photocurrent measurements. Our findings establish a direct link between synthesis parameters, defect chemistry, and charge-carrier dynamics in $LaTiO_2N$, providing a foundation for overcoming transport limitations in oxynitride-based photoanodes for solar hydrogen production.

HL 42.4 Thu 12:15 POT/0006

Epitaxial YbN thin films grown by nitrogen plasma-assisted molecular beam epitaxy — Yitong Chen[1,2], •Anna Meléndez Sans[1,3], Shin-ichi Kimura[2,4,5], Liu Hao Tjeng[1], and Simone Altendorf[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Department of Physics, Graduate School of Science, The University of Osaka, Toyonaka, Japan — [3]Institut de Ciència de Materials de Barcelona, Bellaterra, Spain — [4]Graduate School of Frontier Biosciences, The University of Osaka, Suita, Japan — [5]Institute for Molecular Science, Okazaki, Japan

Rare-earth mononitrides display interesting magnetic and semiconducting properties due to the strongly correlated and localized 4*f* electrons. However, extreme air sensitivity and poor stoichiometry hindered research on bulk samples when they were first discovered. Modern advancements in UHV-based thin film growth techniques have opened the possibility to synthesize and study high quality samples.

Unlike most of the rare-earths, which can break the molecular nitrogen bond, Yb does not react with nitrogen gas and therefore requires an activated nitrogen source for the synthesis of YbN.

Here we present our growth study on YbN thin films grown by nitrogen plasma-assisted molecular beam epitaxy, using different substrates (MgO and $LaAlO_3$) and growth conditions. The films were characterized *in situ* with photoelectron spectroscopy, confirming their semiconducting character and the Yb valence as 3+. Photon-energy dependence of the valence band spectra revealed a significant hybridization of the Yb 4*f* and N 2*p* states.

HL 42.5 Thu 12:30 POT/0006

Novel $TbTa(O,N)_3$ perovskite oxynitride for photoelectrochemical energy conversion — •Aleksandr Kochergov[1,2], Gabriel Grötzner[1,2], Oliver Brune[1,2], Frans Munnik[3], Saswati Santra[1,2], Verena Streibel[1,2], and Ian D. Sharp[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Germany — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Perovskite oxynitride semiconductors have emerged as promising candidates for photoelectrochemical (PEC) water splitting, given their smaller band gaps (~ 2 eV) compared to more extensively studied metal oxides. Previous studies show that in rare-earth lanthanide tantalum perovskite oxynitrides, PEC photocurrent density increases with the increment of the A-site cation atomic number [1]. However, no studies have investigated A-site cations heavier than gadolinium (Gd). This work presents a method for synthesizing the novel perovskite oxynitride $TbTa(O,N)_3$ as thin film via spin coating followed by a sequential two-step annealing procedure in air and ammonia. X-ray diffraction shows that proper NH_3 annealing conditions are crucial for obtaining the $TbTa(O,N)_3$ perovskite structure. The resulting films are investigated for their structural, compositional, and optoelectronic properties. The results suggest a 2.3 eV band gap and n-type conductivity. Given these favorable properties, the viability of $TbTa(O,N)_3$ as photoanode is evaluated.

The influence of air and light exposure on alkali-metal doped $Cu(In,Ga)Se_2$ absorber materials measured with in-situ TRPL and XPS — •P. Stötzner, S. Sobisch, A. Stauffenberg, H. Kempa, R. Scheer, and S. Förster — Martin-Luther-Universität Halle-Wittenberg, Germany

Copper indium gallium diselenide ($Cu(In,Ga)Se_2$/CIGSe) is a promising thin-film solar cell absorber. Alkali-metal doping, especially in combination with heavy alkali metals, enhances solar cell efficiencies. However, air and light exposure (ALE) of the absorber reduces the solar cell efficiency. This is a result of the diffusion of sodium and oxygen toward the absorber surface, which is accompanied by a degradation of the charge-carrier lifetime of doped CIGSe absorbers [1,2].

Here, we study the ALE effect for CIGSe doped with K and cominations of Na and K as well as Na and Rb. Our studies combine X-ray photoelectron spectroscopy

(XPS) and in-situ time-resolved photoluminescence (TRPL) conducted in one ultrahigh vacuum system, addressing changes in the chemical composition and charge-carrier lifetime. The setup is completed by a high-pressure gas cell enabling for controlled exposure to specific environments.
We find that the charge-carrier lifetime of non-doped absorbers is unaffected by ALE and all alkali-metal doped absorbers degrade due to ALE. XPS shows that the most heaviest alkali metal present and oxygen are accumulated at the surface. While this effect is reversable over time, the degradation of the charge-carrier lifetime is permanent.

HL 45.2 Thu 15:15 POT/0006

Thermal Broadening Statistics of Photoluminescence in Tunable Lead Halide Perovskite Nanocrystals — •Luca B. Reim, Leo Luber, and Alexander S. Urban — Nanospectroscopy Group, Nano-Institute Munich, Department of Physics, Ludwig-Maximilians-Universität München, Königinstraße 10, 80539 Munich

Halide perovskite nanocrystals (NCs) exhibit excellent optoelectronic properties, including high quantum yields and composition-dependent, narrow photoluminescence (PL) that critically depend on control over NC size and uniformity. Understanding the mechanisms governing PL linewidths is therefore essential for evaluating material quality and device performance.

We synthesized size-tunable $CsPbBr_3$ nanocubes under ambient conditions using machine-learning-optimized reaction protocols.[1] The NCs were drop-cast onto substrates and investigated via temperature-dependent PL spectroscopy in a closed-cycle cryostat from 9-300 K. To quantitatively analyze the spectral evolution, we applied a novel fitting approach that enables the extraction of size dispersion, temperature-dependent exciton populations, and signatures of the local energetic environment. The latter is strongly influenced by nanocrystal quality and ligand coverage and provides a sensitive probe of inhomogeneous broadening mechanisms.

These results offer detailed insight into the fundamental limits of emission linewidths in perovskite NCs and support the targeted optimization of materials for optoelectronic applications such as LEDs.

HL 45.3 Thu 15:30 POT/0006

Investigation on the efficiency limiting processes of 3C-SiC photoelectrodes using intensity modulated techniques. — •Marius Wasem[1,2], Mario F. Zscherp[1,2], Silas A. Jentsch[1,2], Jörg Schörmann[1,2], Sangam Chatterjee[1,2], and Matthias T. Elm[1,2] — [1]Center for Materials Research, Heinrich-Buff-Ring 16, 35392 Giessen — [2]Institute of Experimental Physics I, Heinrich-Buff-Ring 16, 35392 Giessen

Cubic silicon carbide (3C-SiC) is a compelling photoelectrode for photoelectrochemical water splitting due to its near-ideal band gap energy and excellent chemical stability. Here, we present the characterization of the photoelectrochemical response of epitaxially grown n- and p-type 3C-SiC using different electrochemical methods. A pH neutral phosphate buffer solution was used as electrolyte. The suitable operating conditions, such as potential range and light intensity, were determined using chopped light voltammetry. Insights of the charge carrier dynamics were gained by combining electrochemical impedance spectroscopy (EIS), intensity-modulated photocurrent spectroscopy (IMPS) and intensity-modulated photovoltage spectroscopy (IMVS). While EIS is a common and widely used method, the latter two methods are rarely discussed in the photoelectrochemical community. Here we show how a combination of all three methods enables the differentiation and quantification of key processes (recombination processes, surface effects, charge carrier lifetime) to validate the efficiency of 3C-SiC photoelectrodes.

HL 45.4 Thu 15:45 POT/0006

Nano-sensing of AC-Fields with Perovskite Quantum Dots and Electro-Switching of Luminescence — •Emanuel Eckl[1], Fabian Brütting[1], Moritz B. Heindl[1], Maryna Bodnarchuk[2], Mariia Svyrydenko[2], Maksym Kovalenko[2], and Georg Herink[1] — [1]University of Bayreuth, Bayreuth, Germany — [2]ETH Zürich, Zürich, Switzerland

Perovskite quantum dots (PQDs) currently attract significant research interest, particularly owing to their broad tunability of optoelectronic properties with applications in energy conversion, solid-state lighting and sensing technologies.

In this study, we investigate the potential of PQDs as nano-sensors for transient electric fields up to multi-Terahertz (THz) frequencies [1]. Combining electro-absorption, lifetime and photoluminescence measurements of inorganic and hybrid lead-halide PQDs, we demonstrate a massive electro-switching effect observed via luminescence. The emission modulation is directly correlated with reduced photoluminescence lifetimes and can be attributed to a switching of radiative quantum efficiency. Furthermore, we present evidence for a memory effect that exhibits significantly delayed responses in comparison to the well-understood quasi-instantaneous Quantum-Confined Stark Effect that is also observable in these PQDs. In particular, the Stark effect is utilized for the purpose of validating and comparing our measurements to those of conventional inorganic CdSe QDs, previously employed in ultrafast imaging of THz near-fields.

HL 45.5 Thu 16:15 POT/0006

Resolving Ultrafast Conductivity Dynamics in 2D-Perovskites via correlative THz-NIR Spectroscopy — •Lion Krüger[1], Fabian Brütting[1], Michael Baumann[2], Moritz B. Heindl[1], Maximilian Spies[3], Anna Köhler[3], Alexander JC Kühne[2], and Georg Herink[1] — [1]Experimental Physics VIII, University of Bayreuth, Germany — [2]Institute of Organic and Macromolecular Chemistry, Ulm University, Germany — [3]Experimental Physics II, University of Bayreuth, Germany

Quasi-2D Metal-Halide Perovskites offer flexible tuning of optoelectronic properties via composition and quantum confinement.

In this contribution we present measurements of the ultrafast carrier dynamics and mobilities of 3D- and quasi-2D-methylammonium lead iodide (MAPI) using optical-pump terahertz-probe spectroscopy (OPTP). The comparison with corresponding optical transient absorption measurements allows for the extraction of an ultrafast feature on a picosecond timescale that is correlated with the delayed hot-carrier cooling, known from 3D hybrid perovskites. Here this "hot phonon bottleneck" manifests as a 2D-specific, intensity-dependent signature in the THz-conductivity and is attributed to transient exciton formation [1].

[1] Lion Krüger, Fabian Brütting, Michael Baumann, Moritz B. Heindl, Maximilian Spies, Anna Köhler, Alexander JC Kühne, Georg Herink. "Confinement-induced Ultrafast Conductivity in 2D Perovskites resolved by correlative Terahertz-NIR Spectroscopy". 2025. In review.

HL 45.6 Thu 16:30 POT/0006

Intra- and Interlayer Excitonic Finestructure of $(PEA)_2PbI_4$ — •Patrick Grenzer[1], Fabian Lie[2], Klaus H. Eckstein[1], Linn Leppert[2], and Tobias Hertel[1] — [1]Institute of Physical and Theoretical Chemistry, Julius-Maximilians-University Würzburg, Germany — [2]MESA+ Institute for Nanotechnology, University of Twente, Enschede, The Netherlands

Layered halide perovskites exhibit strongly bound excitons shaped by reduced dimensionality, dielectric confinement, and significant spinorbit coupling. Despite extensive work, the origin of the multiple resonances in absorption and PL of $(PEA)_2PbI_4$ remains subject to debate. We investigate the excitonic fine structure in high-quality, mechanically exfoliated single crystals by combining temperature- and polarization-resolved photoluminescence with first-principles GW+BSE calculations. The polarization dependence unambiguously assigns the observed features to distinct excitonic states and resolves the contributions from exchange interactions, crystal symmetry, and interlayer coupling. We further identify and spectroscopically separate intra- and interlayer excitons and their respective transition dipole moments. The results provide a consistent microscopic picture of the exciton manifold in $(PEA)_2PbI_4$ and clarify the origins of the multi-line structure characteristic of this material class.

HL 45.7 Thu 16:45 POT/0006

Dynamic Screening Effects on Auger Recombination in Metal-Halide Perovskites from First Principles — •Utkarsh Singh — Theoretical Physics Division, IFM, Linköping University, Sweden

Auger recombination is the dominant nonradiative loss in perovskite LEDs and nanolasers at carrier densities $> 10^{17}$ cm^{-3}.[1,2] Conventional first-principles treatments[3] use static dielectric screening $W(\mathbf{q}, 0)$ and neglect its frequency dependence in polar iodide perovskites.

I present a framework that incorporates the frequency-dependent screened interaction $W_{00}(\mathbf{q}, \omega)$, computed from low-scaling GW, into direct and phonon-assisted Auger amplitudes.[4] For γ-$CsPbI_3$ and γ-$CsSnI_3$, dynamic screening enhances the dielectric response at optical energies and reduces the room-temperature Auger coefficient by 50–60% compared with the static approximation.[5] The critical crossover density is shifted by a factor of 2, with implications for efficiency roll-off and lasing thresholds in optoelectronic devices.

These results establish dynamic screening as a quantitative determinant of Auger losses in polar semiconductors and provide a transferable framework for device modeling.

HL 45.8 Thu 17:00 POT/0006

Influence of static disorder on the low temperature photoexcitation dynamics in triple cation lead halide perovskites — •Alexander Schauerte[1], Anton Krüger[1], Isabel Allegro[2], Dominik Muth[1], Ian Howard[2], Uli Lemmer[2], and Marina Gerhard[1] — [1]Department of Physics and Marburg Centre for Quantum Materials and Sustainable Technologies, Hans-Meerwein-

Str. 4, Philipps-Universität Marburg, 35032 Marburg, Germany — [2]Light Technology Institute, Karlsruhe Institute of Technology, Kaiserstraße 12, 76131 Karlsruhe, Germany

We study the recombination dynamics of phase stable triple cation lead halide perovskites $Cs_{0.1}(MA_{0.17}FA_{0.83})_{0.9}Pb_{1-x}(I_{0.84}Br_{0.16})_{3-2x}$ with intentionally induced deficiencies of Pb over a broad temperature range using time-resolved photoluminescence (PL) spectroscopy. In the temperature range below 70 K, we find pronounced sub-nanosecond PL dynamics which are accompanied by an increase of the carrier diffusivity by more than one order of magnitude. The findings are attributed to the polaronic Mott transition, beyond which polaron radii overlap, leading to efficient transport and bimolecular recombination. Moreover, the observed energy dependent PL dynamics at low temperatures indicate the presence of a phonon bottleneck, which inhibits efficient cooling of the excited population. We find that a higher degree of static disorder slows down bimolecular recombination, while the phonon bottleneck effect is more pronounced, potentially because slower recombination does not effectively reduce the hot carrier population.

HL 46: Ultra-fast Phenomena II

Time: Thursday 15:00–17:15 Location: POT/0051

HL 46.1 Thu 15:00 POT/0051

Ultrafast study of out-of-plane charge carrier diffusion in perovskite thin films via pump-probe sSNOM — •Daniel Sandner[1], Branden Esses[2], Zhao Yang[3], Kai Zhu[3], Joseph Berry[2,3], Hristo Iglev[1], and Markus Raschke[2] — [1]Laser- and X-ray physics E11, TU Munich — [2]CU Boulder — [3]NREL

Despite substantial evidence for polaron formation in lead halide perovskites (LHPs), which exhibit excellent photovoltaic performance, the role of polarons in transport remains unclear. We've measured diffusion with high spatial resolution by monitoring the carrier density at the top of a thin film via the tip-localized response in pump-probe mIR-sSNOM, while exciting the sample from below. Due to the small penetration depth of the pump beam, most electrons and holes are initially located at the bottom of the perovskite layer. Consistent with previous studies, we find local variations in the diffusion coefficient. To link transport and local structure, we employ a vibrational mode as an indicator of lattice stiffness and polaron formation [JACS 2024, 146(29), 19852-19862].

HL 46.2 Thu 15:15 POT/0051

Coherent exciton-phonon coupling and many body interactions in halide perovskites probed by 2D electronic spectroscopy. — •Mohsin Sayar[1], Katrin Winte[1], Davide Caratti[2], David Cahen[2], Christoph Lienau[1], and Antonietta De Sio[1] — [1]Carl von Ossietzky Universität, Oldenburg, Germany. — [2]Weizmann Institute of Science, Rehovot, Israel

Exciton-phonon interactions are central to the unique optoelectronic properties of halide perovskites. Here we use temperature-dependent two-dimensional electronic spectroscopy (2DES) with 10 fs time resolution to study the exciton dynamics in bulk $CH_3NH_3PbBr_3$ crystals. The 2DES maps distinguish between exciton and free-carrier-induced contributions to the near-band-edge optical nonlinearity, revealing distinct signatures of exciton-exciton and exciton-carrier many-body interactions. The ultrafast dynamics further reveal coherent low-frequency phonon oscillations at $40 cm^{-1}$ and $67 cm^{-1}$, corresponding to Pb-Br-Pb bending and stretching modes that most strongly couple to the exciton. Additionally, we observe faster, 105 fs exciton amplitude oscillations across all three crystal phases, arising from coherent population oscillations between 1s and 2p excitonic states, off-resonantly driven by the low-frequency coherent phonon fields in the crystal. We rationalize these results within a phenomenological model accounting for both exciton-phonon coupling and 1s-2p exciton coupling via the phonon fields. Preliminary polarization-resolved 2DES data show that these phonon-induced exciton oscillations are retained upon spin-selective excitation.

Invited Talk HL 46.3 Thu 15:30 POT/0051

Antisymmetric vibrations in the excited state dynamics of quadrupolar dyes — Somayeh Souri[1], Katrin Winte[1], Daniel Lünemann[1], Daniel Timmer[1], Elena Mena-Osteritz[2], Sergei Tretiak[3], Christoph Lienau[1], and •Antonietta De Sio[1] — [1]Universität Oldenburg — [2]Universität Ulm — [3]Los Alamos National Laboratory

Non-equilibrium dynamics following photoexcitation in molecular materials arise from a complex interplay of electronic and vibrational motion, with antisymmetric vibrations playing a key role in ultrafast nonadiabatic dynamics, such as at conical intersections. Their direct spectroscopic identification is, however, challenging, since these modes are often Raman inactive and only weakly affect optical transitions. Here, we show experimental signatures of vibronic coupling to antisymmetric modes in the ultrafast symmetry-breaking dynamics of a quasi-quadrupolar dye[1,2] using two-dimensional electronic spectroscopy (2DES). The sub-50-fs 2DES maps reveal an asymmetric peak pattern with characteristic low-energy cross-peaks. We show that these peaks arise from stimulated emission from a double-minimum excited state potential energy surface induced by vibronic coupling to a ~1430 cm-1 antisymmetric mode[2]. Phenomenological essential state model simulations support the results. Our findings show that 2DES with sub-cycle vibrational resolution is a powerful method for identifying antisymmetric modes in the excited state dynamics prior to intramolecular vibrational relaxation and solvation. HL 46.4 Thu 16:15 POT/0051

Investigating exciton dynamics and exciton–exciton interactions via optical two-dimensional photoelectron spectroscopy — •Luisa Brenneis[1], Matthias Hensen[1], Julian Lüttig[2], and Tobias Brixner[1] — [1]Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Department of Physics, University of Ottawa, 150 Louis-Pasteur Pvt, Church St, Ontario K1N 6N5, Canada

Action-detected two-dimensional (2D) electronic spectroscopy has become a powerful technique to resolve exciton dynamics by measuring an incoherent signal proportional to the excited-state population generated by a multi-pulse sequence. However, processes that alter the excited-state population after the system's interaction with the pulse sequence, such as exciton–exciton annihilation, can obscure coupling signatures and single-exciton dynamics [1]. In optical 2D photoelectron spectroscopy (2DPES), typically a four-pulse sequence excites the system, followed by a time-delayed ionization pulse [2]. Here, we show how to disentangle exciton dynamics and interactions by varying the ionization pulse time delay. Exemplary simulations of a weakly coupled dimer demonstrate that short ionization delays reveal coupling signatures and single-exciton energy transfer, whereas longer delays reveal exciton–exciton annihilation. This concept is particularly promising for nanoscale surface studies, where 2DPES combined with photoemission electron microscopy enables spatially resolved exciton mapping.

Ab initio Theory of Coherent Phonon Damping in Semimetals — •Yiming Pan and Fabio Caruso — Institut für Theoretische Physik und Astrophysik, Christian-Albrechts-Universität zu Kiel, 24118 Kiel, Germany

Coherent phonon plays an important role in the structural properties of the crystal lattice and ultrafast light-induced phase transition. Following its excitation, atoms oscillate coherently along the excited modes with decaying amplitudes. This dynamical process is commonly modeled with damping oscillators with phenomelogical damping rates. In this work, we derive this model by employing quantum kinetic equations [1], and attribute the damping rate and frequency renormalization of coherent phonon to the imaginary and real parts of the phonon self-energy. To valdiate our approach, we perform first-principles calculation of the damping rate of A_{1g} phonon arising from electron-phonon coupling and phonon-phonon coupling in semimetals Bi and Sb. The numerical results agree with available temperature- and fluence-dependent experimental data, thereby providing a predictive framework for determining the timescales of structural dynamics in driven solids.

HL 46.6 Thu 16:45 POT/0051

Probing Ultrafast Electronic and Lattice Dynamics simultaneously at the Atomic Scale with Time-Resolved Diffraction Anomalous Fine Structure (TR-DAFS) — •Moritz Meissner[1,2,6], T. C. Rossi[2], M. Rössle[2], C. Petersen[3], H. von Wenckstern[3], R. Mandal[4], M. Levantino[5], and R. M. van der Veen[2,6] — [1]Paul-Drude-Institut für Festkörperelektronik — [2]Helmholtz Zentrum Berlin — [3]Universität Leipzig — [4]Institut des materiaux de Nantes Jean Rouxel — [5]European Synchrotron Radiation Facility — [6]Technische Universität Berlin

This work presents the first successful demonstration of Time-Resolved Diffraction Anomalous Fine Structure (TR-DAFS) measurements carried out in a pump-probe (stroboscopic) scheme. We show that TR-DAFS can directly probe ultrafast structural and electronic dynamics in crystalline materials. Investigating Zinc oxide (ZnO) enables direct comparison between TR-DAFS at the Zn K-edge with time-resolved X-ray absorption spectroscopy (TR-XAS) data. TR-DAFS represents a leap forward in the study of photoexcited materials at the atomic scale by providing access to different aspects of lattice dynamics in reso-

nant and non-resonant parts of the spectrum. Preliminary ab initio calculations show that the electronic changes visible in the resonant part of the spectrum are associated with an increase of carrier temperature in the photoexcited state. This dual sensitivity to electronic and lattice degrees of freedom makes TR-DAFS a game-changer in investigating ultrafast processes in complex materials and heterostructures as represented by the results of this work.

HL 46.7 Thu 17:00 POT/0051

Theoretical Modeling of Ultrafast Phase Transitions from the Femtosecond to the Picosecond Scale — Stefano Mocatti, Giovanni Marini, Pierluigi Cudazzo, and •Matteo Calandra — Department of Physics, University of Trento, Via Sommarive 14, 38123 Povo, Italy

In this talk, I will introduce a theoretical approach to ultrafast phase transitions that captures both electron/hole and phonon dynamics following laser pumping, on time scales ranging from a few femtoseconds to several picoseconds after irradiation.

At short times, the method relies on solving the Bloch equations coupled to Ehrenfest dynamics. It includes the electric field of the pump explicitly, as well as carrier-carrier, carrier-phonon, and phonon-phonon scattering, treated entirely from first principles.

At longer times before recombination, when carrier-carrier interactions generate a photoexcited quasi-equilibrium electron-hole plasma, the approach is based on a constrained density-functional perturbation theory (cDFPT) scheme that accounts for the presence of holes in the valence band and electrons in the conduction band (two-Fermi-level approach). In this framework, the calculation of forces, phonon dispersion, and carrier-phonon coupling becomes possible, as well as molecular dynamics with machine-learning potentials in the presence of an electron-hole plasma.

I will showcase applications of the method to several materials.

This work is funded by the European Union (ERC, DELIGHT, 101052708).

HL 47: 2D Materials VIII – Quantum emitters and defects

Time: Thursday 15:00–16:00 Location: POT/0081

HL 47.1 Thu 15:00 POT/0081

Tunable phonon sidebands of defect emitters in monolayer WSe_2 heterostructures — •Felix Schaumburg[1], Cornelius Diedrich[2], Alberto Rodriguez[2], Jeniffer König[2], Corinne Steiner[3], Patricia Pesch[3], Axel Lorke[1], Michael Lorke[1], Günther Prinz[1], Martin Geller[1], and Annika Kurzmann[2] — [1]Faculty of Physics, University of Duisburg-Essen and CENIDE, Germany — [2]II. Physikalisches Institut Fachgruppe Physik, Universität zu Köln, Germany — [3]Fachgruppe Physik, RWTH Aachen, Germany

Van der Waals heterostructures hosting single-photon emitters have emerged as a versatile platform for exploring material properties, like phonon interactions. We investigate single-photon emission from a heterostructure composed of a graphite back gate, hBN dielectric layers, and a monolayer of WSe_2. A 10 nm metallic top gate enables electrical tuning of the WSe_2 layer. The entire stack is strained using lithographically defined SiO_2 nanopillars. Optically active defect centers are introduced into the WSe_2 monolayer by electron-beam irradiation. These defect centers in the strained regions exhibit clear single-photon emission, confirmed by second-order correlation function values below 0.5. Voltage-dependent measurements reveal a pronounced Stark shift of the emission lines as well as electrically tunable phonon sidebands. The intensity evolution of these sidebands can be described within the framework of a Franck-Condon model. Our results demonstrate deterministic position control, electrical control, and phonon-sideband engineering of quantum emitters in WSe_2. This paves the way towards bright, electrically tunable emission in two-dimensional materials.

HL 47.2 Thu 15:15 POT/0081

Room Temperature Visualization of Exciton Confinement in Single Photon Emitters samples — •Lucas Liberal[1], Rafael Nadas[2], Frederico B. Sousa[1], Maria Clara Godinho[3], Gabriel Jacobsen[1], Takashi Taniguchi[4], Kenji Watanabe[4], Marcio Teodoro[1], Ado Jorio[3], and Leonardo Campos[3] — [1]Departamento de Física, Universidade Federal de São Carlos, São Carlos, Brasil — [2]Institut fur Physik, Humboldt-Universitat zu Berlin, Newtonstraße 15, Berlin, Germany — [3]Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brasil — [4]Research Center for Materials Nanoarchitectonics, NIMS, Tsukuba, Japan

Two-dimensional semiconductors such as monolayer WSe2 have attracted significant interest due to their remarkable quantum properties and their potential as scalable single-photon emitters. However, conventional microphotoluminescence (μ-PL) techniques are fundamentally limited by optical diffraction, preventing direct access to critical nanoscale features such as strain gradients and highly localized quantum confinement. In this study, we employ tip-enhanced photoluminescence with a spatial resolution of 10 nm to image, at room temperature, the emission landscape of monolayer WSe2 suspended over nanopillars. Our measurements reveal two distinct localization regimes consistent with leading theoretical models for single-photon activation: one arising from intervalley defect exciton hybridization and another driven purely by strain-induced confinement. These results provide practical guidelines for the deterministic nanoengineering of quantum light sources.

HL 47.3 Thu 15:30 POT/0081

Beyond static defects: temporal evolution of defect-driven reliability in WSe2 — •Madhuri Chennur[1,2], Ulrich Kentsch[1], Jens Zscharschuch[1,2], and Artur Erbe[1,2] — [1]Helmholtz-Zentrum Dresden Rossendorf, Institute of Ion Beam Physics and Materials Research, 01328 Dresden, Germany — [2]TUD Dresden University of Technology, 01062 Dresden, Germany

Two-dimensional (2D) semiconductors are emerging as promising candidates for CMOS-compatible nanoscale electronics, where defects increasingly dictate electron transport. In WSe2 transistors, chalcogen vacancies commonly degrade hole mobility, yet defect-rich surfaces or interfacial contact layers have enabled ultra-low-barrier p-type contacts. However, the electrical role of these defects is almost exclusively interpreted through static pre- and post-irradiation comparisons, leaving the time-dependent evolution of engineered defect and irradiation-induced trap dynamics essentially unexplored.

Here, we present a weeks-to-months time-resolved optical-electrical study of WSe2 FETs irradiated with a single-dose broad-beam irradiation, followed by temporal tracking of threshold voltage, subthreshold swing, and hysteresis under constant bias and ambient conditions. Raman and PL spectroscopy performed in parallel reveal lattice disorder, oxidation, and adsorbate uptake. We observe a reproducible transition with shifts in electrical parameters, demonstrating that defect is intrinsically dynamic, not static. This coupled temporal mapping provides missing insight into defect-aware reliability for realistic ambient and radiation-relevant 2D electronics.

HL 47.4 Thu 15:45 POT/0081

Physical Drivers of Metal Adsorption at 2D Interfaces for Memristive Applications — •Manoj Dey[1], Hamid Mehdipour[1,2], Peter Kratzer[2], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at the FHI of the Max Planck Society, Berlin — [2]Faculty of Physics, University of Duisburg-Essen, Duisburg

Two-dimensional (2D) materials with engineered defects are emerging as promising candidates for next-generation memristors. In these "atomristors," resistive switching (RS) arises from atomic-scale processes at the electrode-2D interface. Experiments show that adsorption and desorption of electrode metal atoms at vacancies play a key role in RS [1]. Here, we combine hybrid density functional theory with many-body dispersion corrections and the Sure Independence Screening and Sparsifying Operator (SISSO) method [2] to study metal adsorption on transition-metal dichalcogenides at gold interfaces. SISSO provides a predictive model for adsorption energies and uncovers the fundamental physical factors driving RS. Our sensitivity analysis shows how orbital hybridization and bonding interactions dominate the behavior, offering simple heuristics for understanding the atomic processes. We also build a materials-property map that highlights promising candidates and connects our predictions with experimentally demonstrated devices. Together, these results link fundamental material descriptors to RS behavior and offer clear guidance for designing future 2D atomristors.

HL 48: Heterostructures, Interfaces and Surfaces: Fabrication and Structure

Time: Thursday 15:00–17:15 Location: POT/0251

HL 48.1 Thu 15:00 POT/0251

Cross-sectional scanning tunneling microscopy (XSTM) study of nearly lattice-matched III-V semiconductor heterostructures — •Hitesh Kumar[1], Rüdiger Schott[2], Zijin Lei[2], Werner Wegscheider[2], and Stefan Fölsch[1] — [1]Paul Drude Institute for Solid State Electronics, Berlin, Germany — [2]Laboratory for Solid State Physics, ETH Zürich, Zürich, Switzerland

XSTM is a powerful technique for investigating the structural and electronic properties of III-V semiconductor heterostructures. These heterostructures are grown along the [001] direction by molecular beam epitaxy and accessible in cross-sectional view by cleaving the sample in ultrahigh vacuum to expose the (110) cleavage surface. We used this approach to study a GaSb-InAs-AlGaSb-InAs-InAsSb layered heterostructure grown on a Te-doped GaSb substrate. Voltage-dependent chemical contrast in STM imaging allows differentiation between anions and cations in the III-V semiconductors. Using this capability, we analyzed the degree of homogeneity in the ternary materials (Al-Ga mixing in the AlGaSb layer and As-Sb mixing in the InAsSb layer). With the help of scanning tunneling spectroscopy, we precisely determined the band gaps of the individual layers and locally probed the band lineup across the entire heterostructure. This allowed us to investigate the behavior of charge carriers governed by the band lineup. Specifically, we studied the spatial confinement and quantization of conduction band states in the InAs layer and their decay into the gap region of the adjacent layers.

HL 48.2 Thu 15:15 POT/0251

Theoretical Exploration of the Electronic Structure at Group-III Nitride Interfaces — •Maximilian Lauer[1,2], Christian Maas[1,2], Jan M. Waack[1,2], Michael Czerner[1,2], and Christian Heiliger[1,2] — [1]Institut für theoretische Physik, Justus-Liebig-Universität Gießen, Germany — [2]Zentrum für Materialforschung (ZfM), Justus-Liebig-Universität Gießen, Germany

Group-III nitrides are an essential group of materials at the forefront of modern optoelectronics. Recently, the metastable zincblende (In,Ga)N system emerged as a promising material for optoelectronic devices. Heterojunctions play a central role in device design, making a precise understanding of their electronic structure essential. Determining the band alignment at the interface is crucial for understanding its electronic properties.

Here, we show that the zb-GaN/zb-InN heterojunction exhibits a Type-I alignment with no states forming within the band gap at the interface. We performed KKR calculations with LDA-1/2 band gap corrections on coherently strained supercells. We report values for the band offset parameters and explore the microscopic electronic structure at the interface. Our calculations demonstrate the importance of band corrections for calculating electronic structure parameters, such as band offsets, and provide a basis for further investigations into the (Ga,In)N alloy system using the CPA.

HL 48.3 Thu 15:30 POT/0251

GaPN growth on As-Modified Si(100) for defect-reduced heteroepitaxy — •Hitha Haridas[1], Kai Daniel Hanke[1], Agnieszka Paszuk[1,2], and Thomas Hannappel[1] — [1]Technische Universität Ilmenau, Fundamentals of Energy Materials, Ilmenau,Germany — [2]BMFTR Junior Research Group PARASOL, Technische Universität Ilmenau, Germany

The Monolithic integration of III-V semiconductors with Si(100) offers a promising route toward high-efficiency,low-cost optoelectronic devices. Among these materials, GaPN is a promising candidate for III-V/Si integration because it can be grown lattice-matched to silicon, thereby minimizing strain and reducing the formation of misfit dislocations. However, structural defects generated during the earliest stages of growth can propagate into subsequent epitaxial layers, ultimately limiting device performance. In this study, we investigate the nucleation and early-stage growth behavior of GaPN on As-modified Si(100) surfaces by combining ex situ surface morphology analysis,electron channeling contrast imaging, and in situ optical spectroscopy.This integrated approach allows us to systematically evaluate how variations in the initial growth conditions influence defect formation. The insights gained provide broader guidance for improving interface quality and advancing III-V/Si heteroepitaxy through more precise control over the initial growth phases.

HL 48.4 Thu 15:45 POT/0251

Acoustoelectric effect in organic-inorganic semiconductor systems — •Paromita Bhattacharjee[1], Patrick Ganswindt[2], Alexander S. Urban[2], and Hubert Krenner[1] — [1]Institute of Physics, University of Münster, Germany — [2]Faculty of Physics, Ludwig-Maximilians-Universität München, Germany

Surface acoustic waves (SAWs) are elastic waves propagating on the surface of a piezoelectric solid and while interacting with a semiconductor, its strain and piezoelectric fields modulate the band-gap. Strain-induced field imposes an acoustoelectric (AE) drag on the charges in the direction of SAW propaga-tion, and in a photoconductive semiconductor, excitons get ionized by piezoelectric field into separate elec-trons and holes, captured and transported by SAW [1]. Utilizing these effects, we present first study of SAW-induced charge transport in hybrid organic-inorganic semiconductor system of organic polymer, poly(3-hexylthiophene) (P3HT) and halide perovskite (CsPbBr3 and CsPb(IxBr1-x)3) nanowires (HPNWs). In samples with only HPNWs the total AE current nearly vanishes due to comparable electron-hole mobilities in these materials [2]. However, in hybrid layers, weak AE effect is observed with CsPb(IxBr1-x)3 NWs and a hole dominated AE transport with CsPbBr3 NWs. The band realignment at the heterojunction explains that while for CsPb(IxBr1-x)3 -P3HT ambipolar electron-hole transport occurs via the NWs, for CsPbBr3-P3HT, electrons are limited by low electron mobility in P3HT. HL 48.5 Thu 16:15 POT/0251

Ultra-high vacuum exfoliation method for the preparation of large-area single layer TMDC films — •Zhiying Dan[1], Ronak Sarmasti Emami[1], Antonija Antonija Grubisic-Cabo[1], Petra Rudolf[1], Deepnarayan Biswas[2], and Tien-Lin Lee[2] — [1]Zernike Institute for Advanced Materials, University of Groningen, 9747 AG Groningen, The Netherlands — [2]Diamond Light Source Ltd., Harwell Science and Innovation Campus, Didcot, Oxfordshire, OX11 0DE, UK

Two-dimensional transition metal dichalcogenides (2D TMDCs) are promising candidates for next-generation electronic, optical, and spintronic devices. While mechanical exfoliation yields high-quality 2D flakes, their lateral size is typically limited to tens of micrometers. Here, we report the preparation of 2D WS2 and WSe2 using a recently developed kinetic in situ single-layer synthesis (KISS) method, performed in ultra-high vacuum and tailored for surface science studies. We examine how substrate choice and chalcogen species affect film size and quality using X-ray photoelectron spectroscopy, low-energy electron diffraction, atomic force microscopy, and X-ray standing waves (XSW). Our results show that the quality of the bulk TMDC crystal is crucial for successful KISS exfoliation. Moreover, preliminary XSW data suggest that KISS does not degrade the underlying substrate, highlighting its potential as a non-destructive approach for 2D material synthesis.

HL 48.6 Thu 16:30 POT/0251

Electrical conduction and sensing properties of contacted CNTs after MOF synthesis — •Marvin J. Dzinnik[1], Adrian Hannebauer[2], Feriel Friha[1], Andreas Schaate[2], and Rolf J. Haug[1,3] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hanover, Germany — [2]Institut für Anorganische Chemie, Leibniz Universität Hannover, 30167 Hanover, Germany — [3]Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, 30167 Hanover, Germany

Metal-organic frameworks (MOFs) are a versatile sensor material: they are tunable, highly porous, and can be precisely grown on carbon nanotubes (CNTs).[1]

Here, we investigate how UiO-66 MOF growth affects single nanotubes. We performed DC measurements on contacted multi-walled carbon nanotubes (MWCNTs) before and after UiO-66 synthesis. We observe pronounced changes in both magnitude and character of the electrical response, indicating a strong interaction between MWCNT and MOF. AC measurements show a linear response to ethanol vapor up to 40 000 ppm, suggesting that single MWCNT-MOF hybrids are promising, tunable gas-sensing elements.

HL 48.7 Thu 16:45 POT/0251

Nucleation behavior for remote epitaxy of GaAs and AlAs on carbon-covered GaAs substrates — •Binamra Shrestha, Tobias Henksmeier, and Dirk Reuter — Paderborn University, Paderborn, Germany

Recently, remote epitaxy was proposed as a method that enables the growth of free-standing single-crystal layers and substrate reuse by using atomically thin 2D materials as release layers. In this work, we investigate the epitaxial growth behavior of GaAs and AlAs on ultrathin amorphous carbon layers deposited by PECVD on GaAs substrates. The amorphous carbon exhibits a graphene-like structure consisting predominantly of in-plane sp^2 bonding, thereby serving as a quasi-2D template capable of transmitting the substrate's electrostatic potential for remote epitaxial growth.

We performed controlled nucleation studies using molecular beam epitaxy (MBE). First, a GaAs buffer layer is grown on the bare GaAs to planarize the substrate surface, then the sample is covered with amorphous carbon. Subsequently, ultrathin GaAs layers ranging from 0.25 nm to 2 nm are deposited on the graphene/GaAs template at 300 °C, and the resulting nuclei are examined via atomic force microscopy (AFM). Nucleation is first observed at approximately 0.37 nm deposition thickness, with nuclei predominantly aligned along atomic

steps. This strong step-edge preference indicates that remote epitaxy is the dominant mechanism, compared to pinhole-initiated nucleation. These results highlight the suitability of PECVD-deposited amorphous carbon as an effective 2D interlayer for remote epitaxy.

HL 48.8 Thu 17:00 POT/0251

Quantum confinement in semiconductor random alloys: a case study on Si/SiGe/Si — •Daniel Dick[1,2,3,4], Florian Fuchs[1,2,3], Sibylle Gemming[2,4], and Jörg Schuster[1,2,3] — [1]Center for Micro- and Nanotechnology, TU Chemnitz, Germany — [2]Center for Materials, Architecture and Integration of Nanomembranes, TU Chemnitz, Germany — [3]Fraunhofer Institute for Electronic Nanosystems (ENAS), Chemnitz, Germany — [4]Institute of Physics, TU Chemnitz, Germany

When the size of random alloys is reduced, local fluctuations of alloy composition become more influential. Using extended Hückel theory, we study the semiconductor alloy SiGe sandwiched between Si due to its relevance in semiconductor devices. We evaluate the effects of the alloy composition, layer thickness, and local fluctuations of the Ge concentration on band alignment and the band gap. Results are compared to the finite quantum well model. This model captures the essenial physics and can act as a computationally faster surrogate model.

Phonon-mediated nonlinearity and defects in hexagonal boron nitride — •Nahid Talebi — Institute of Experimental and Applied Physics, Kiel University, Germany

Hexagonal boron nitride (hBN) hosts a rich phonon landscape whose strong oscillator strengths in the first and second Reststrahlen bands give rise to negative permittivity and support the propagation of hyperbolic phonon polaritons. In this work, we show that these phonon modes can mediate highly efficient down-conversion of optical excitation, enabling strong coupling to point defects and facilitating the coherent excitation of their electronic states. We further demonstrate that such defect states in hBN can couple efficiently to excitons in hybrid hBN*perovskite structures, establishing a robust exciton*defect interaction channel. Remarkably, we find that excitonic energy can be transported over distances up to 150 micrometers through incoherent hopping across a defect network within hBN. By combining spatially and spectrally resolved photoluminescence and cathodoluminescence spectroscopy, we identify the mechanisms governing coherent and incoherent defect excitation and reveal the interplay and strong coupling among excitons, defects, and phonons in hBN. These insights establish hBN as a versatile platform for phonon-assisted light*matter interactions and long-range energy transport in hybrid quantum nanophotonic systems.

HL 49.2 Thu 16:45 POT/0081

Spin Dynamics of Quantum Sensors Based on Hexagonal Boron Nitride — •Paul Konrad[1], Andreas Sperlich[1], Igor Aharonovich[2], and Vladimir Dyakonov[1] — [1]Experimental Physics 6, Julius-Maximilians-Universität Würzburg, 97074 Würzburg — [2]School of Mathematics and Physical Sciences, University of Technology Sydney, Ultimo, NSW 2007, Australia

Colour centres in solid-state materials show great potential in quantum information technology and sensing applications. The spin triplet system of the lately discovered negatively charged boron vacancy (V_B^-) in hexagonal boron nitride (hBN) can be exploited in terms of its application as temperature, magnetic field, and pressure sensor.[1] Increasing the sensitivity of these nano-scale sensors is a crucial step towards application and requires not only controlled generation[2] but deep knowledge about the dynamics of the system. This includes predicted but experimentally hardly accessible intermediate states.

In this study, we achieve a direct measurement of a 24.0(3) ns relaxation time from the dark intermediate state to the ground state at room temperature, which approximately doubles at low temperatures. These findings are corroborated by detailed simulations of populations. Accounting for this relaxation considerably enhances spin manipulation efficiency, allowing substantial optimization of the quantum sensor's sensitivity based on boron vacancies.[3]

Exciton-enhanced light emission in pristine and doped MoS_2 from ab initio calculations — •Adriana Bocchini[1], Djennane Khaoula[2], Henry Hübschmann[1], Nikita Siverin[3], Andreas Farenbruch[3], Maja Groll[1], Klaus Jöns[1], Gerhard Berth[1], Dmitri Yakovlev[3], Wolf Gero Schmidt[1], and Uwe Gerstmann[1] — [1]Universität Paderborn, Germany — [2]Yahia Fares University of Medea, Algeria — [3]Technische Universität Dortmund, Germany

Two-dimensional transition metal dichalcogenides (2D-TMDs) are emerging as a suitable alternative in a variety of electronic and optoelectronic devices [1,2]. The properties of this family, in fact, can be systematically customized upon structural modification, e.g., via exfoliation or dopants. Notably, most of these properties are strongly determined by excitons, the formation of which is strongly facilitated by defects [3]. In this study, we use DFT routines to systematically investigate the influence of excitons on the optical properties of MoS_2 films. Thereby, we do not only analyze the dependency of the optical response on the layer thickness, but also their evolution upon the application of external electric fields or by twisting the layers relative to each other. In addition, we model MoS_2-based Janus structures by selectively substituting some of the S atoms with heavier chalcogens and analyze the suitability of these configurations as possible light-emitting solid-state quantum dots.

Thermodynamic properties of quantum defects in boron nitride using machine-learned force fields — •Ariel Moises Cabrera Aguilar and Carla Verdi — The University of Queensland, Brisbane, Australia

Hexagonal boron nitride (hBN) has emerged as an excellent host material for bright single-photon emitters. Experimental and computational studies associate these single-photon emitters (SPEs) in hBN predominantly with carbon-related defects. However, the lack of first-principles calculations at finite temperatures and with sufficiently large supercells hinders the establishment of a consensus on the most likely defect candidates for quantum-technology applications. Machine-learned force fields (MLFFs) provide highly accurate finite-temperature simulations because they can be trained to reproduce first-principles energies and forces across diverse configurations. We trained a MLFF capable of describing various carbon cluster defects (C_B, C_N, C_BC_N, C_BV_N, C_BC_i, and C_NC_i) at temperatures up to approximately 2000 K. To evaluate the accuracy of the force field in reproducing atomic positions, interatomic energies, and forces across these structures, we compute formation energies, phonon dispersions, and photoluminescence spectra, and compare these quantities with available experimental data. The force field successfully reproduces the line shape of several defects in multilayered systems of different supercell sizes. The MLFF is used to investigate multiple defects in large supercells over long molecular dynamics simulation times, allowing us to capture metastable structures that emerge at finite temperature.

Probing Terahertz Emission and Structural Dynamics in Quasi-two-dimensional $NbOI_2$ — •Daniel Geyer[1], Rieke von Seggern[1], Soufiane El-Kabil[1], Zouchen Fu[3], and Sascha Schäfer[1,2] — [1]Department of Physics, University of Regensburg, Germany — [2]Regensburg Center for Ultrafast Nanoscopy (RUN), Germany — [3]Nankai University, Tianjin, China

Optically induced processes in matter, captured via time-resolved imaging methodologies, uncover a variety of transient phenomena evolving on ultrafast time scales. Layered ferroelectric niobium oxide dihalides $NbOX_2$ (X=I, Cl, Br) have garnered significant interest in this context, as they combine pronounced optical nonlinearities [1,2] with a ferroelectric order parameter that can be controlled via optical stimuli [3]. In this work, we investigate the $NbOI_2$ compound as a material platform in which both regimes of ultrafast light-matter interaction can be accessed within different experimental approaches.

At first, we explore thin $NbOI_2$ flakes as promising stackable terahertz (THz) emitters. We demonstrate broadband THz generation via nonlinear optical rectification, characterized using a time-domain THz emission spectroscopy setup.

Secondly, we discuss the photoinduced evolution of the material's ferroelectric polarization, employing time-resolved electron diffraction in an ultrafast transmission electron microscope (UTEM).

HL 52.2 Fri 9:45 POT/0006

AlGaN/GaN-based grating-gate plasmonic crystals for nonlinear THz applications — Pavlo Sai[1], Vadym V. Korotyeyev[2], Serhii Kukhtaruk[2], Dmytro B. But[1], Maksym Dub[1], Alexej Pashkin[3], Stephan Winnerl[3], Wojciech Knap[1], and •Martin Mittendorff[4] — [1]Institute of High Pressure Physics PAS ul. Sokołowska 29/37, Warsaw 01-142, Poland — [2]V. Ye. Lashkaryov Institute of Semiconductor Physics (ISP) NASU prospect Nauky 41, Kyiv 03028, Ukraine — [3]Helmholtz-Zentrum Dresden-Rossendorf 01328 Dresden, Germany — [4]Universität Duisburg-Essen Fakultät für Physik 47057 Duisburg, Germany

We present time-resolved THz measurements on grating-gate plasmonic crystals, based on the two-dimensional interface electron gas in epitaxial GaN/AlGaN heterostructures. The free-electron laser FELBE at Helmholtz-Zentrum Dresden-Rossendorf served as tunable source for intense, narrowband THz pulses at about 1.8 THz, the plasmon frequency was tuned via the grating-gate. The strongest pump-probe signals are observed at resonance, where a rather low pump fluence of about 200 nJ/cm^2 leads to a pump-induced change in transmission of more than 40% [1]. The signal decays within about 50 ps. The experimental results are complemented by a finite-difference time-domain electrodynamic simulation, allowing to identify the main driving mechanisms for the observed strong nonlinearity, e.g. near-field effects and hot charge carriers.

HL 52.3 Fri 10:00 POT/0006

Plasmonic nonlinearity in AlGaN/GaN-based rectangular patches — •Nandita Bajpai[1], Pavlo Sai[2,4], Maksym Dub[2,4], Alexej Pashkin[3], Stephan Winnerl[3], Wojciech Knap[2,4], and Martin Mittendorff[1] — [1]Department of Physics, University of Duisbur-Essen,Duisburg,Germany — [2]Institute of HighPressurePhysics,Warsaw,Poland — [3]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [4]Center for Terahertz Sciences and Applications CENTERA -CEZAMAT Warsaw University of Technology, Warsaw, Poland

Recent observation of enhanced nonlinear THz absorption by resonant excitation of 2D plasmons in the AlGaN/GaN based plasmonic crystal has revealed a strong pump-induced transparency of probe upto 45%[1].Here, we investigate the nonlinear coupling between the perpendicular plasmonic modes in AlGaN/GaN-based rectangular patches. To this end, we performed a two colour pump probe experiment at the free-electron laser facility at the Helmholtz-Zentrum Dresden-Rossendorf. The spectrally narrow pump pulse was used to drive the plasmonic resonance at 1.95 THz whereas a broadband THz pulse from a synchronized table-top time domain spectroscopy setup was exploited to probe the plasmonic mode at 1.38 THz. We observed a relative pump - induced change in transmission of probe upto 12%, which is attributed to the excitation of hot carriers that decays within 25ps.

HL 52.4 Fri 10:15 POT/0006

Elucidating carrier dynamics in bismuth thin film with time-resolved terahertz spectroscopy — •Guriviredy Yettapu, Fabian Thiemann, Michael Horn-von Hoegen, and Martin Mittendorff — University of Duisburg-Essen, Duisburg, Germany

Bismuth (Bi) is a Peierls distorted semimetal in its bulk state that transforms into a semiconductor for thicknesses below ~30 nm [1]. Time-resolved terahertz spectroscopy is an ideal tool to investigate the charge carrier dynamics by following the pump-induced change in electric field with pump-probe delay. Herein, we employed optical-pump terahertz-probe spectroscopy to elucidate the carrier dynamics in single crystalline Bi film with a thickness ~36 nm, including spectrally resolved measurements to determine the frequency dependent complex conductivity. At a pump fluence of 30 uJ/cm2, we observe a pump-induced change of the electric field of about 20 %, followed by an exponential decay with a relaxation time of ~7 ps. Our results reveal that carrier relaxation times are hardly affected by the pump fluence, the complex conductivity can be well described by the Drude model. Our future studies include thickness- and temperature-dependent measurements to gain insights about the carrier-lattice interactions in the semiconductor and semimetal phase. [1] C. A. Hoffman et al., Phys. Rev. B. 48, 11431-11434 (1993).

HL 52.5 Fri 10:30 POT/0006

Identifying the semiconductor doping range addressable by terahertz time-domain spectroscopy — •Joshua Hennig[1,2], Jens Klier[1], Stefan Duran[1], Mirco Kutas[1,2], Georg von Freymann[1,2], and Daniel Molter[1] — [1]Department for Materials Characterization and Testing, Fraunhofer Institute for Industrial Mathematics ITWM, 67663 Kaiserslautern, Germany — [2]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

Semiconductors are essential materials for the technological advancements of the 21st century. With the growing demand for semiconductor devices going along with this, the need for fast and non-destructive characterization techniques is growing quickly, too. Terahertz time-domain spectroscopy (THz-TDS) has proven to be capable of measuring the desired properties of various semiconductors over the last decades. Yet, it is still not widely established for this purpose. One reason is that for each combination of material, doping concentration and thickness the possibility to characterize the sample has to be evaluated individually. Therefore, we are developing a simulation-based tool that can help identify the accessible doping ranges. Based on simulations of the interaction between a terahertz pulse and an arbitrary layer stack of doped semiconductor materials, a well-founded estimate of the characterizability with reflection THz-TDS is retrieved. These simulations allow for a better understanding of the suitability of a THz-TDS characterization for specific semiconductor samples and hence to establish THz-TDS further in the semiconductor industry.

HL 53: Organic Semiconductors: Carrier Dynamics

Time: Friday 9:30–11:15 Location: POT/0051

Invited Talk HL 53.1 Fri 9:30 POT/0051

Organic semiconductors: Opening new perspectives in sustainable electronics — •Karl Leo — IAPP, TU Dresden

Organic semiconductors enable a variety of novel applications for flexible, lightweight, and environmentally friendly electronics. One unique advantage of these carbon-based materials is their compatibility with body tissue, thus opening perspetives for completely new medical applications on and even in the human body. Furthermore, the materials set available in this technology allows biodegradability and thus sustainable electronics without the serious environmental issue of conventional electronics. In the first part of my talk, I will show examples how organic electronic devices can be used in postsurgical monitoring, avoiding life-threatening complications. In the second part of the talk, I will address lignocellulose leaf skeleton structures (Leaftronics) as basis for a variety of novel applications, such as semitransparent electrodes.

HL 53.2 Fri 10:00 POT/0051

Unveiling the role of disorder on carrier concentration transients in electrochemical transistors — •Tobias Krebs and Martijn Kemerink — IMSEAM, Heidelberg University, Germany

Already the drain current transients in organic electrochemical transistors hint for not yet fully understood underlaying device physics, as they show a generally slower turn on compared to turn off, with the difference between these on- and off- switching times varying over orders of magnitude between materials and driving voltages. Tracking the charge carrier concentration during switching then completes this asymmetric picture: A sharp doping front entering the device during turn on, followed by gradual bulk de-doping during turn off. We measure these concentration transients optically, using the red-shifted absorption in the doped state of the redox active polymers we investigated. Comparison of this data with drift-diffusion simulations revealed a strong dependence of this asymmetry on the broadness of the density of states, which in our simulations both modulates the carrier density dependence of hole mobilities and influences the maximum charge carrier concentration for a set gate voltage. Our simulation framework also allowed us to study the surprisingly small effect of ionic mobilities in the semiconductor on switching times, above a device specific mobility threshold. The results can be used to guide the rational design of improved devices.

HL 53.3 Fri 10:15 POT/0051

Simulation of Coulomb Glass Behavior in Organic Semiconductor Devices at high carrier densities — •Magdalena Dörfler[1], Heinz Bässler[2], Anna Köhler[1,2], and Harald Oberhofer[3] — [1]Soft Matter Optoelectronics and Bayerisches Polymerinstitut (BPI), Experimental physics II, University of Bayreuth, Universitätsstr. 30, Bayreuth, Germany — [2]Bayreuth Institute of Macromolecular Research (BIMF), University of Bayreuth, Universitätsstr. 30, Bayreuth, Germany — [3]Chair for Theoretical Physics VII and Bavarian Center for Battery Technologies, University of Bayreuth, Universitätsstr. 30, Bayreuth, Germany

Recent advances in organic transistors (OFETs, EGOFETs, OECTs) enable device operation at high charge carrier densities where Coulomb interactions between carriers become significant.

Using Kinetic Monte Carlo simulations, we investigate carrier-carrier Coulomb interactions in OFET-like structures. Comparing simulations with and without these interactions reveals reduced carrier mobility and increased activation energy when interactions are included, with effects increasing for higher carrier densities.

Our results indicate a transition to correlated transport with a Coulomb gap in a dynamic density of states. The system exhibits Coulomb glass behavior, where the activation energy reflects structural reorganization of the carrier ensemble.

Notably, the Coulomb gap appears at ambient temperature and does not require variable-range hopping, unlike to the situation in electron liquids and inorganic semiconductors.

HL 53.4 Fri 10:30 POT/0051

Dual Ferroelectric and Semiconducting behaviour in supramolecular organics — •Tara Vollus[1], Sophia Klubertz[1], Shyamkumar Vadakket Haridas[2], Oleksandr Shysho[2], Max von Delius[2], and Martijn Kemerink[1] — [1]IMSEAM, Heidelberg University, Germany — [2]Institute of Organic Chemistry, Ulm University, Germany

The combination of interacting conductive and ferroelectric properties, resulting in a multifunctional material, has the potential to simplify the structure of memory devices. It has been demonstrated that the organic ferroelectric material C6H6F5O-C3-amide (M3) exhibits both these properties, showing ferroelectricity and an unexpected DC conductivity.[1][2] It has been shown that the latter is related to the presence of interfacial dipoles that allow efficient charge injection from (oxidation and/or reduction by) metal contacts and is enhanced by a supramolecular arrangement formed at higher temperatures and under an applied electric field. Here, we demonstrate the effects of alignment and, especially, the presence of both n- and p-type doping-like processes, suggesting that M3 is a wide-bandgap organic semiconductor that reversibly can be reduced and oxidized. Kelvin probe force microscopy measurements revealed filament-like potential structures that may act as pathways for bipolar charge transport, and suggest the formation of dynamic pn-junctions.[3]

[1] Mager et al., arXiv:2507.11309 [cond-mat.mtrl-sci] [2] Mager et al., arXiv:2506.02673 [cond-mat.mtrl-sci] [3] Matyba et al., DOI:10.1038/nmat2478

HL 53.5 Fri 10:45 POT/0051

Backbone Alignment and Morphology Formation in PBTTT Thin Films: Insights from In-Situ GIWAXS — •Robin M. Teichgreber[1], Christopher R. McNeill[2], and Eva M. Herzig[1] — [1]Dynamics and Structure Formation - Herzig Group, University of Bayreuth, Universitätsstr. 30, Bayreuth — [2]Material Science and Engineering, Monash University, 20 Research Way, Clayton

The performance of organic electronic devices strongly depends on the morphology of the organic semiconductor thin film [1]. Enhancing the understanding on fundamental structure-function relationships is therefore crucial to improve the performance of such devices in the future. Highly aligned films can furthermore be used to study fundamental charge separation processes. Controlling the alignment of polymer backbones is a challenge in the first place, demanding further research on the processes of structure formation resulting in aligned films. Using PBTTT as a model system, the influence of different coating parameters on the kinetics of film formation during the deposition thin films via blade-coating is investigated by employing time-resolved in-situ GIWAXS measurements. Furthermore, the formation of high degrees of alignment during the post-deposition annealing process was studied with temperature-resolved GIWAXS. [1] Herrmann, N.J., von Coelln, N., Teichgreber, R.M., Höfener, S., Huck, C., Ghalami, F. et al. (2023) J. Mater. Chem. C, 11, 10185-10197.

HL 53.6 Fri 11:00 POT/0051

Multiscale Modelling of the Density of States in PEDOT:Tosylate Films — •Melissa Kim Meinel and Igor Zozoulenko — Laboratory of Organic Electronics, Linköping University, Norrköping, Sweden

A key descriptor of the electronic structure is the density of states (DOS), which directly affects properties such as charge mobility, intrinsic capacitance, and optical absorption. Structural disorder and the local electrostatic environment strongly influence the DOS but are rarely captured in full detail in computational studies that often rely on small model systems or simplified methods. We present a multiscale modelling approach for computing the DOS of realistic PEDOT:Tosylate films. Molecular dynamics simulations generate film structures that capture the complex packing and disorder of PEDOT chains and counterions. These configurations are analysed within a quantum mechanical/molecular mechanical (QM/MM) framework, where molecular mechanics accounts for large-scale heterogeneity while quantum calculations resolve local electronic states under explicit electrostatic embedding of the environment. Steric effects are treated at the MM level, while the QM region can be limited to a single chain. Accurate results require optimally tuned range-separated hybrid functionals, geometry optimisation of the QM chain, and iterative adaptation of charge distributions to capture realistic environmental effects. This framework enables quantitatively realistic, morphology-sensitive predictions of the electronic structure and has been applied to systems at different oxidation levels.

HL 54: 2D Materials IX – Photonic properties and devices

Time: Friday 9:30–12:45 Location: POT/0081

HL 54.1 Fri 9:30 POT/0081

Signature of interference between second and fourth order nonlinearities in atomically thin crystals — •Paul Herrmann[1], Jonas Margraf[1], Sebastian Klimmer[1], Sebastian Piehler[2], Maximilian Graml[2], Muhammad Sufyan Ramzan[3], Caterina Cocchi[3], Jan Wilhelm[2], and Giancarlo Soavi[1,4] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Germany — [2]Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, Germany — [3]Institute of Condensed Matter Theory and Optics, Friedrich Schiller University Jena, Germany — [4]Abbe Center of Photonics, Friedrich Schiller University Jena, Germany

Transition metal dichalcogenides (TMDs) are a well studied class of two-dimensional materials, whose opto-electronic properties are dominated by excitons and exhibit strong light-matter interaction. The relaxed phase matching in TMD monolayers facilitates the emission of many orders of nonlinearities with approximately equal efficiency. Thus, one can in principle observe interference effects between nonlinearities of different orders N (N=2,3,4,...). Here, we observe a previously unseen modulation of the generated second harmonic upon rotation of the input fundamental polarization. By combining wavelength and power dependent measurements with macroscopic, symmetry-based calculations and microscopic density functional theory simulations, we can assign this modulation to an interference between second and fourth order terms of the nonlinear polarization.

HL 54.2 Fri 9:45 POT/0081

Measurement of optically induced broken time-reversal symmetry in atomically thin crystals — •Florentine Friedrich[1], Paul Herrmann[1], Shridhar Shanbhag[2], Sebastian Klimmer[1], Jan Wilhelm[2], and Giancarlo Soavi[1] — [1]Institute of Solid State Physics, University of Jena, Germany — [2]Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, Germany

Time-reversal symmetry (TRS) and space-inversion symmetry (SIS) are fundamental properties underlying phenomena like magnetism and non-trivial spin

textures in crystals. Transition Metal Dichalcogenides (TMDs) offer a tunable platform to study the interplay of these symmetries, which can be engineered by tuning the number of layers and via all-optical bandgap modulation. We propose a powerful, all-optical approach using third harmonic (TH) Faraday rotation to probe broken TRS, regardless of the SIS [1]. By exciting mono- and bilayer TMDs with elliptically polarized light, we achieve spin-selective bandgap modulation, consequently breaking TRS. This symmetry reduction modifies the nonlinear susceptibility tensor, causing a measurable rotation of the emitted TH polarization. Our experimental results are supported by analytical theory for both mono- and bilayer TMDs and provide a unique tool to investigate spin, valley, and layer coupling in atomically thin semiconductors, thereby contributing to the understanding of the relation between crystal symmetries and the nonlinear optical response of a material.

HL 54.3 Fri 10:00 POT/0081

Analytical Theory Of Third Harmonic Generation In Two-Dimensional Materials — •Shridhar Sanjay Shanbhag[1], Florentine Friedrich[2], Paul Herrmann[2], Sebastian Klimmer[2], Giancarlo Soavi[2], and Jan Wilhelm[1] — [1]Institute of Theoretical Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, 93053 Regensburg, Germany — [2]Institute of Solid State Physics, Friedrich Schiller University Jena, 07743 Jena, Germany

Valleytronics explores the valley degree of freedom in materials like transition metal dichalcogenides (TMDs), using electrons in ±K valleys as binary states for information encoding. In valleytronics applications, efficient valley readout is crucial. We show that third harmonic generation (THG) provides an ultrafast solution to valley readout for both centrosymmetric and non-centrosymmetric materials [1].

We solved the semiconductor Bloch equations perturbatively to derive an analytical expression for the polarization state of the emitted third harmonic signal. Our analysis shows how material parameters influence the polarization and attributes polarization rotation to spin and valley dependent optical Stark and Bloch-Siegert shifts in TMDs. Our theoretical predictions closely align with experiments, providing the microscopic mechanism and thus helping advance valleytronic readout mechanisms.

[1] Friedrich, F., Herrmann, P., Shanbhag, S.S. et al. Nat. Photon. (2025). https://doi.org/10.1038/s41566-025-01801-2

HL 54.4 Fri 10:15 POT/0081

Nonlinear optical characterization of oxidized thin layered MoS2 — •Henry Hübschmann[1], Gerhard Berth[1], Klaus Jöns[1], Katharina Burgholzer[2], and Alberta Bonanni[2] — [1]Paderborn University, Paderborn, Germany — [2]Johannes Kepler University Linz, Linz, Austria

In the field of two-dimensional structures the class of transition metal dichalcogenides (TMDs) has sparked great interest in the last decades. Semiconductor materials like molybdenum disulfide (MoS2) have found many applications in photonic and optoelectronic devices [1,2]. An important characteristic is the tunability of the band structure and therefore consequently the possibility for modification of electronic and optical properties [3]. Within this work we conduct comprehensive second order nonlinear optical analysis on thermally oxidized mechanically exfoliated MoS2. In this context a layer number dependent investigation of the nonlinear response up to seven-layer configurations of AB-stacked 2H-MoS2 is performed. Here we found fingerprints of induced structural modifications identified which manifest themselves in the strength of the nonlinear response and a resulting symmetry break of centrosymmetric media.

HL 54.5 Fri 10:30 POT/0081

quantum electrodynamics of excitons in bilayer graphene — •abraham nava mireles — the institut of photonic sciences, castelldefels, spain.

Cavity quantum electrodynamics has been a cornerstone in understanding light-matter interactions. In the so-called strong-coupling regime, these interactions cannot be described as a simple combination of their light and matter components. Instead, light and matter form new hybrid states. This project aims to push beyond into the ultrastrong coupling (USC) regime, where the interaction strength becomes comparable to the system's transition frequencies. In this regime, quantum vacuum fluctuations and elementary excitations become significant. This enables not only the control of quantum effects but also the modification of a material's ground state, even in the absence of external light. To that end, we explore the coupling between confined hyperbolic phonon polaritons (HPhPs) in hexagonal boron nitride (hBN) and excitons in bilayer graphene (BLG). The hyperbolic nature enables deep subwavelength confinement, enhancing the photonic density of states. In BLG, extended dipole transitions exhibit a nonlocal optical response, in which propagating HPhPs allow momentum-dependent transitions and access to a continuum of electronic final states. This leads to enhanced emission rates and to each exciton effectively coupling to multiple polaritonic modes, ultimately reaching a regime where the coupling strength compares to the transition frequency. This platform opens new possibilities for quantum technologies and non-perturbative light-matter engineering.

HL 54.6 Fri 10:45 POT/0081

All-TMDC nanobeam cavities with embedded $MoSe_2$ monolayers for enhanced light-matter interaction — •Aris Koulas-Simos[1], Pietro Metuh[2], Athanasios Paralikis[2], Kartik Gaur[1], Maximilian Klonz[1], Imad Limame[1], Chirag Palekar[1], Battulga Munkhbat[2], and Stephan Reitzenstein[1] — [1]Institut für Physik und Astronomie, Technische Universität Berlin, Berlin, Germany — [2]Department of Electrical and Photonics Engineering, Technical University of Denmark, Kongens Lyngby, Denmark

All-TMDC photonic structures enable enhanced light-matter interaction by combining high index contrast with atomically thin excitonic materials in a homogeneous platform [1]. Recent theoretical work [2] shows that all-TMDC nanostructures can support very large Purcell factors, highlighting their potential for nanoscale lasing. We realize WS_2 nanobeam cavities with a $MoSe_2$ monolayer embedded inside the dielectric cavity for improved field-exciton coupling compared to the conventional evanescent coupling schemes. Simulations predict a cavity mode at 766 nm with $Q \approx 4 \cdot 10^3$, a mode volume of approximately 2.6 $(\lambda/n)^3$, and a confinement factor $\Gamma \approx 0.8\%$. Cross-polarized reflectivity at room temperature reveals resonances between 725 and 760 nm with Q-factor values of 100-300, and low-temperature photoluminescence confirms coupling of the $MoSe_2$ monolayer to the cavity mode. These results establish a monolithic TMDC platform for future all-TMDC nanolasers and quantum emitters.

HL 54.7 Fri 11:15 POT/0081

Temperature-Dependent Moiré Polariton Formation in Bilayer MoSe2 Integrated in DBR based Microcavities — •Chirag Palekar[1], Aris Koulas-Simos[1], Imad Limame[1], Stephan Reitzenstein[1], and Bárbara Rosa[1,2] — [1]Institut für Physik und Astronomie, Technische Universität Berlin, Hardenbergstrasse 36, 10623 Berlin, Germany — [2]University of Campinas, R. Sérgio Buarque de Holanda, 777, 13085-636, Brazil

Twisted bilayer (tBL) MoSe2, which hosts moiré polaritons, when integrated into microcavities, provides a versatile platform for exploring light-matter interactions in moiré-engineered quantum materials. In the absence of the cavity, we observed the PL spectrum of the tBL exhibits multiple resonances corresponding to distinct moiré excitons. When embedded within a DBR cavity, such moiré excitons enter the strong coupling regime with the confined cavity photon mode, leading to the formation of moiré exciton-polaritons. Temperature-induced resonance tuning enables systematic control over the exciton-photon detuning, allowing modulation of the coupling strength. Remarkably, these moiré polaritons remain observable even at temperatures exceeding 150 K, underscoring the robustness of the hybridized light-matter states. Modeling the system using a coupled oscillator approach reveals a Rabi splitting as large as 11 meV. Our results demonstrate that temperature serves as an efficient external control parameter for engineering and tuning moiré exciton polaritons in twisted, atomically thin semiconductors, opening pathways toward reconfigurable polaritonic devices based on van der Waals heterostructures.

HL 54.8 Fri 11:30 POT/0081

Cavity polaritons in a hybrid van-der-Waals superconductor-semiconductor structure — •Seyma Esra Atalay, Hangyong Shan, Martin Esmann, and Christian Schneider — Carl von Ossietzky Universität Oldenburg, Germany

Monolayers of transition metal dichalcogenides (TMDs) offer new possibilities to study superconductivity. In this project, we investigate hybrid heterostructures of $NbSe_2/MoSe_2$ van der Waals layers, in the framework of cavity experiments. $NbSe_2$ and $MoSe_2$ are TMDs; superconductivity occurs in $NbSe_2$ [1], and the monolayer $MoSe_2$ is a direct band gap semiconductor that hosts excitons with high oscillator strength. By embedding the $NbSe_2/MoSe_2$ heterostructure in an open cavity [2], we achieve strong coupling between the $MoSe_2$ excitons and the cavity photons, forming exciton-polaritons, as evidenced by the pronounced Rabi gap seen in subsequent longitudinal and transversal cavity modes in where we tuned the open cavity length. This implementation of a hybrid superconductor-semiconductor monolayer polariton cavity forms the foundation of experiments to gain insight into how exciton-polariton coupling can influence the superconductive phase of $NbSe_2$ and allow us to further investigate optically tunable superconducting hybrid systems.

HL 54.9 Fri 11:45 POT/0081

Room temperature hybrid exciton-polaritons in a Perovskite-TMD heterostructrue — •Marti Struve[1], Hamid Pashaei Adl[1], Oliwia Janikwska[2], Sven Stephan[3], Jamie Fitzgerald[4], Paulina Plochocka[2,5], Christian Schneider[1], and Martin Esmann[1] — [1]Carl von Ossietzky Universität, Oldenburg, Germany — [2]Wrocław University of Science and Technology, Wrocław, Poland — [3]University of Applied Sciences Emden, Emden, Germany —

[4]Philipps-University Marburg, Marburg, Germany — [5]Laboratoire National des Champs Magnetiques Intenses, Toulouse, France

Chemically synthesized quasi-2D halide perovskites (HaP) exhibit strong excitonic resonances with large oscillator strength, high binding energy and tunable emission, making them an interesting platform for polariton physics at room temperature. Transition metal dichalcogenide (TMD), while showing lower oscillator strength, offer access to K-valley selective rules, opening the access to polarized excitonic states. In this work, we demonstrate the formation of hybrid exciton-polaritons in a quasi-2D HaP-TMD heterostructure embedded in a planar open cavity at room temperature. Using the tunability of our open cavity we first confirm strong coupling of our materials separately. When combined the system exhibits three polaritonic branches, showing a hybridization of the polariton modes that is reproduced using a three-oscillator Hamiltonian, revealing a state where both excitonic fractions become comparable. Our results lay the foundation to imprint the accessibility of the K-valley selection rules to HaP-polaritons devices leading to additional degrees of freedom.

HL 54.10 Fri 12:00 POT/0081

Tunable Room-Temperature Polaritons Achieving the Very Strong Coupling Regime in Quasi-2D Layered Perovskites — •Hamid Pashaei Adl[1], C. Bennenhei[1], M. Struve[1], P. Peksa[2], M. Dyksik[2], M. Baranowski[2], K. W. Song[3], M. Gittinger[1], C. Lienau[1], J. K. König[4], J. M. Fitzgerald[4], N. P. Jasti[5], F. Eilenberger[6], P. Plochocka[2], E. Malic[4], O. Kyriienko[7], M. Esmann[1], and C. Schneider[1] — [1]Carl von Ossietzky Universität Oldenburg, Germany. — [2]Wroclaw University of Science and Technology, Wroclaw, Poland. — [3]Xiamen University Malaysia, Sepang, Malaysia. — [4]Philipps-Universität, Marburg, Germany. — [5]JNCASR, Bangalore, India. — [6]Max Planck School of Photonics, Jena, Germany. — [7]University of Sheffield, UK.

Layered halide perovskites are organic and inorganic 2D or quasi-2D layers, which self-assemble in solution realizations of quantum well stacks with giant exciton oscillator strengths, tunable emission spectra and very large exciton binding energies. In this contribution, we discuss widely tunable room-temperature cavity exciton polaritons at the cross-over from the strong coupling to the very strong coupling regime, in mechanically exfoliated quasi-2D Ruddlesden-Popper iodide perovskite integrated into an open microcavity. We gradually increased the cavity length and observed a pronounced anti-crossing behavior associated with successive longitudinal cavity modes. The Rabi splitting exhibited a systematic reduction with increasing cavity length; however, the scaling behavior deviated from the conventional square root dependence typically observed in the strong coupling regime.

HL 54.11 Fri 12:15 POT/0081

Optical Gain in Lasers Based on Two-Dimensional TMD Semiconductors — Tommy Schulz[1], •Daniel Erben[1], Alexander Steinhoff[2], Weng Chow[3], and Frank Jahnke[1] — [1]Institute for Theoretical Physics and Bremen Center for Computational Materials Science, University of Bremen, P.O. Box 330 440, 28334 Bremen, Germany — [2]Institute for Physics, Faculty V, Carl von Ossietzky University Oldenburg, 26129 Oldenburg, Germany — [3]Sandia National Laboratories, Albuquerque, New Mexico 87185, USA

We present a direct comparison of the optical gain in InGaAs quantum wells (QWs) and transition-metal dichalcogenide (TMD) monolayers on SiO_2 and encapsulated in hBN. A central objective of this work is to theoretically quantify the gain and to identify its microscopic origin. As a result, we find a substantially larger magnitude of the gain in TMDs - especially in WS_2 - and comparable transparency carrier densities in both systems. The enhanced interband Coulomb interaction in TMDs provides this superior gain performance, although the valley-rich conduction band makes sustaining population inversion more challenging than in InGaAs/GaAs QWs. Encapsulating WS_2 in hBN - a common approach to improve optical quality - proves advantageous, as it reduces carrier drain into side valleys, which lowers the transparency carrier density compared with WS_2/SiO_2. Lastly, we investigate the Henry factor (α), which governs key laser properties such as linewidth behaviour. InGaAs QWs exhibit large α values near transparency, hBN-encapsulated WS_2 shows weakly negative values - an indication towards more favourable lasing performance.

HL 54.12 Fri 12:30 POT/0081

Room-temperature polariton condensate in a quasi-2D hybrid perovskite — M. Struve[1], C. Bennenhei[1], H. Pashaei Adl[1], K.W. Song[2], H. Shan[1], N. Matukhno[1], J.-C. Drawer[1], S. Stephan[1], F. Eilenberger[3], N.P. Jasti[4], D. Cahen[4], O. Kyriienko[5], C. Schneider[1], and •M. Esmann[1] — [1]Carl von Ossietzky Universität Oldenburg — [2]Xiamen University, Sepang, Malaysia — [3]Frauenhofer IOF, Jena — [4]Weizmann Institute of Science, Rehovot, Israel — [5]University of Sheffield, UK

Quasi-2D halide perovskites are chemically synthesized quantum well stacks with large exciton oscillator strength and binding energy. Although promising for polaritonics, bosonic condensation and polariton lasing have so far remained elusive in quasi-2D perovskites at ambient conditions. Here, we demonstrate room-temperature cavity exciton-polariton condensation in mechanically exfoliated crystals of $(BA)_2(MA)_2Pb_3I_{10}$ in an in-situ tunable optical microcavity [1]. We observe a polariton condensation threshold of 0.41 μJcm^{-2} per pulse and detect a strong non-linear response. Interferometric measurements confirm the spontaneous emergence of spatial coherence across the polariton condensate. Our results lay the foundation for a new class of room-temperature polariton lasers based on quasi-2D halide perovskites with great potential for heterointegration with other van-der-Waals materials, photonic crystals and waveguides.

HL 55: Quantum Dots and Wires: (Single) Photonics

Time: Friday 9:30–12:30 Location: POT/0251

HL 55.1 Fri 9:30 POT/0251

Fabrication of a III/V SiO2/SiN hybrid cavity incorporating a single Stark tunable (In,Ga)As quantum dot for high rate single photon generation — •Imad Limame, Kartik Gaur, Sarthak Tripathi, Setthanat Wijitpatima, Aris Koulas-Simos, Chirag Chandrakant Palekar, and Stephan Reitzenstein — Institute for Physics and astronomy, Technical University of Berlin, Berlin, Germany

The advancement of quantum photonic technologies, particularly secure communication based on semiconductor quantum dots (QDs), relies on the on-demand generation of high-quality quantum light. Emission of single photons with high brightness, purity, and indistinguishability is essential for scalable quantum networks. However, the photon emission rate of QDs is fundamentally limited by their nanosecond-scale radiative lifetime. To overcome this, QDs are integrated into photonic nanostructures that enhance light-matter interaction via the Purcell effect, accelerating emission dynamics. Yet, such approaches often require complex bonding and alignment, hindering scalability.

We demonstrate a scalable hybrid cavity platform integrating a Stark-tunable QD within a p-i-n diode into a resonator composed of an epitaxially grown III-V bottom mirror and a PECVD-deposited dielectric top DBR. Deterministic QD positioning using marker-based EBL ensures precise spatial and spectral alignment, improving photon extraction and reducing the radiative lifetime. This approach enables scalable, high-brightness, coherent quantum light sources, providing a solid foundation for next-generation integrated quantum photonics.

HL 55.2 Fri 9:45 POT/0251

Deterministic single-photon source with on-chip GHz acoustic clock — •Alexander Kuznetsov[1], Meysam Saeedi[1], Zixuan Wang[2], Kevin Silverman[2], and Klaus Biermann[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e. V., Hausvogteiplatz 5-7, 10117 Berlin, Germany — [2]National Institute of Standards and Technology, Boulder, Colorado 80305, USA

Solid state single-photon sources are a key component in quantum communication. Their efficiency depends strongly on the single-photon (SP) emission rates. Typically, the latter can be enhanced via Purcell effect by embedding quantum dots (QDs) in optical microcavities (MC), which requires the energy matching between MC optical mode and QD energies. Here, we demonstrate triggering of QD SP emission using dynamic Purcell effect induced by acoustic strain at a frequency of several GHz. To this end, InAs QDs are integrated in a hybrid photon-phonon AlGaAs microcavity, where the density of optical states is tailored by the lateral confinement of photons in um-sized traps defined lithographical patterning of the microcavity spacer. We demonstrate modulation of QD energy up to 14 GHz using quasi-monochromatic strain of a piezoelectrically excited bulk acoustic wave. The modulation periodically shifts the QD transition in resonance with a spectrally narrow confined optical mode, leading to an enhancement of emission, i.e., the dynamic Purcell effect. In combination with high-Q MCs this approach is promising for SP rates above 10 GHz under continuous wave optical excitation. [arXiv:2510.22826]

HL 55.3 Fri 10:00 POT/0251

Beyond-Dipole Radiative Lifetimes of Excitons and Biexcitons in GaAs/AlGaAs Quantum Dots — •Petr Klenovský — Masaryk University, Brno, Czech Republic — Czech Metrology Institute, Brno, Czech Republic

Semiconductor quantum dots are promising sources of on-demand single and entangled photons, but a quantitative microscopic description of their radiative lifetimes remains challenging. We theoretically investigate Coulomb-correlated multi-particle states (X^0, $X^{\pm}$, XX) in weakly confining GaAs/AlGaAs quantum dots using an 8-band $\mathbf{k}\cdot\mathbf{p}$ model combined with continuum elasticity and configuration interaction (CI). Polarization-resolved oscillator strengths and radiative rates are computed both in the dipole approximation and in a quasi-electrostatic beyond-dipole formulation based on a Poisson reformulation of the dyadic Green tensor. For the dots studied, the beyond-dipole treatment yields exciton and biexciton lifetimes in quantitative agreement with experiment. We further analyze electric-field tuning of the multi-particle spectrum and the resulting indistinguishability, characterized by $P = \tau^X/(\tau^X + \tau^{XX})$, and discuss the sensitivity to CI-basis size and to electron-electron and hole-hole exchange.

HL 55.4 Fri 10:15 POT/0251

High-quality single photons from cavity-enhanced biexciton-to-exciton transition — •Nils Heinisch[1], Francesco Salusti[1], Timon L. Baltisberger[2], Mark R. Hogg[2], Malwina A. Marczak[2], Rüdiger Schott[3], Sascha R. Valentin[3], Andreas D. Wieck[3], Arne Ludwig[3], Klaus D. Jöns[1], Richard J. Warburton[2], and Stefan Schumacher[1] — [1]Department of Physics, CeOPP, and PhoQS, Paderborn University, Germany — [2]Department of Physics, University of Basel, Switzerland — [3]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, Germany

Generating high-quality photons using the biexciton-exciton cascade benefits from the separability of the photons from the two-photon excitation laser pulse. However, the intrinsic lifetime ratio between biexciton (XX) and exciton (X) states leads to a fundamental limit for the achievable indistinguishability of the single photons [1]. Therefore, the XX must decay much faster than the X. We achieve this with an optical resonator that resonantly enhances the XX-X transition. By optimizing the cavity parameters and avoiding phonon-mediated cavity feeding, we show that high-quality cavity photons originating from XX can be generated. Furthermore, we show that spectral filtering restores single-photon quality in regimes of XX binding energies, where X emission into the cavity is not initially excluded. Our theoretical investigations are joined by key results from the experimental demonstration, which make this approach a major advance in the realization of practical quantum light sources. [1] E. Schöll et al., PRL 125, 233605 (2020). D. Bauch et al., Adv. Quantum Technol. 7, 2300142 (2024).

HL 55.5 Fri 10:30 POT/0251

Photon-mediated electron capture into a single quantum emitter — •Daniel Oppers[1], Hendrik Mannel[1], Luca Henrichs[1], Fabio Rimek[1], Arne Ludwig[2], Axel Lorke[1], and Martin Geller[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, Duisburg, Germany — [2]Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

Single-photon emitters are one of the key components of quantum information technology. Especially single self-assembled quantum dots in a p-i-n diode structure for charge control are still a promising candidate. We use an InAs/GaAs quantum dot in a bias regime, where the dot is uncharged and drive the exciton transition optically resonant with a cw diode laser. A second off-resonant cw laser with a lower energy than any optical transition is used to induce an internal photoeffect [1], exiting electrons from the electron reservoir in the diode, that are captured into the quantum dot. Consequently, we observe a quenching of the exciton transition, which can no longer be driven resonantly. This electron capture by photo-excitation of electrons from the reservoir (see also [2]) is measured here in real-time, observing every quantum jump from an uncharged to a charged quantum dot in a random telegraph signal. Evaluating the telegraph signal using waiting time distributions we observe a linear increase in the electron capture rate scaling up with increasing excitation power of the off-resonant laser. Our findings reveal that photo-induced quenching is a possible source of exciton dephasing.

[1] P. Lochner et. al., Phys. Rev. B **103**, 075426 (2021)
[2] A. Kurzmann Appl. Phys. Lett. **108**, 263108 (2016)

HL 55.6 Fri 10:45 POT/0251

Influence of the internal photoelectric effect on the indistinguishability of single quantum dot photons — •Luca Henrichs[1], Fabio Rimek[1], Hendrik Mannel[1], Daniel Oppers[1], Arne Ludwig[2], Martin Geller[1], and Axel Lorke[1] — [1]Universität Duisburg-Essen, Lotharstr. 1, 47048 Duisburg — [2]Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

A single self-assembled quantum dot (QD) is one of the promising candidates as a bright (high photon rate) and stable (Fourier-limited) linewidth single photon source [1]. For applications in photonic devices or in quantum communication networks the dephasing process is an important property, where besides spin- and charge noise, the Auger-Meitner [2] and the photoeffect [3] could play an important role.

Here, we investigate the impact of the internal photoelectric effect on the indistinguishability of single QD photons. We used pulsed Hong-Ou-Mandel measurements at different excitation intensities of the exciton transition to determine the photon indistinguishability in various driving regimes, ranging from coherent scattering (the Heitler regime) to the incoherent regime above the saturation intensity. Above saturation, we observe the influence of the photoeffect, which reduces the indistinguishability. Our findings represent an important step toward understanding the decoherence of single photons in this important quantum system.

15 min. break

HL 55.7 Fri 11:15 POT/0251

An ultra-compact deterministic source of maximally entangled photon pairs — Moritz Langer[1], Pavel Ruchka[2], Ahmad Rahimi[1], Sara Jakovljevic[2], Yared G. Zena[1], Sai Abhishikth Dhurjati[1], Alexey Danilov[1], Mandira Pal[1], Riccardo Bassoli[3], Frank H. P. Fitzek[3], Oliver G. Schmidt[4], Harald Giessen[2], and •Caspar Hopfmann[1,2] — [1]Institute for Emerging Electronic Technologies, IFW Dresden, Helmholtzstraße 20, 01069 Dresden, Germany — [2]4th Physics Institute and Research Center SCoPE, University of Stuttgart, 70569 Stuttgart, Germany — [3]Deutsche Telekom Chair of Communication Networks, Technische Universität Dresden, Dresden, Germany — [4]Research Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, Chemnitz, Germany

We demonstrate an ultra-compact source of on-demand, maximally entangled photon pairs using single GaAs quantum dots in monolithic microlenses, efficiently fiber-coupled in a cryogenic environment. A 3D-printed micro-objective facilitates near-diffraction-limited performance at 3.8 K. The system achieves high single-photon emission rates (392(20) kHz) and purities (0.992(5)) via two-photon resonant excitation. Leveraging the exciton-biexciton cascade, it produces near-maximally entangled photon pairs (peak entanglement negativities of 2n=0.96(2)). This quantum light source combines state-of-the-art performance and stability with a dramatically reduced footprint, well-suited for seamless industrial integration.

HL 55.8 Fri 11:30 POT/0251

Spectral shadows of a single GaAs quantum dot — •Jens Hübner[1], Kai Hühn[1], Lena Klar[1], Fei Ding[1], Arne Ludwig[2], Andreas D. Wieck[2], and Michael Oestreich[1] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover, Germany — [2]Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, 44780 Bochum, Germany

Semiconductor quantum dots are today's leading candidates for generating single and entangled photons. However, even the most advanced devices face performance limitations due to charge state fluctuations within the quantum dot and its surrounding environment. We have carried out detailed time-resolved resonance fluorescence measurements on an individual charge-tunable GaAs quantum dot, providing new insight into the spectral signatures generated by the complex landscape of unintentional impurities. For the neutral exciton and the negatively charged trion transitions, we uncover multiple Stark-shifted resonances, linked to rare spectral jumps smaller than the homogeneous linewidth. In other experiments, these jumps are typically obscured by measurement noise. In contrast, the positively charged and doubly negatively charged trions exhibit distinctly different behaviors. We quantify the underlying impurity charge dynamics over timescales ranging from sub-milliseconds to several seconds, and demonstrate that the hole population of the positively charged trion is limited in our state-of-the-art pin-structure by fast hole loss combined with slow hole recapture.

[Hühn et al., arXiv:507.20290 (2025)]

HL 55.9 Fri 11:45 POT/0251

Adhesive bonding of In(Ga)As - QD membrane on Silicon for evanescent light coupling — •J. Unfried[1], R. Vijayan[1], U. Pfister[1], D. Wendland[2], S. Oberle[1], M. Weiss[1], M. Jetter[1], S. Portalupi[1], and P. Michler[1] — [1]IHFG, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — [2]AG Pernice, Universität Münster, Heisenbergstraße 11, 48149 Münster, Germany

Hybrid integration of III-V materials with silicon photonics involves combining efficient III-V light emitters with low-loss, CMOS-compatible Si platforms. This allows high-performance PICs to be realised. Adhesive bonding is a scalable and flexible method for achieving this integration. It provides and enables lithography-defined alignment. However, this approach also presents significant challenges. Efficient coupling between the III-V active membrane and Si waveguides (WG) requires an extremely thin, optically transparent bonding layer to enable strong evanescent coupling. Such thin layers restrict the thermal budget available for post-bonding processes, and may result in delamination during subsequent fabrication steps. Reliable integration therefore necessitates an optimised bonding process and carefully controlled fabrication conditions. This work focuses on integrating an InGaAs membrane with C-band InAs QDs

onto a Si photonic platform using an optimised adhesive bonding scheme. A simulation-guided design approach is employed to identify suitable waveguide and taper geometries, and a reproducible bonding process is used to fabricate uniform, thin bonding layers and tapered InGaAs waveguides that efficiently couple QD emission into Si waveguides.

HL 55.10 Fri 12:00 POT/0251

Revisiting Quantum Well Thickness Fluctuation Quantum Dots as a Source of Single Photons — •Tom Fandrich[1], Frederik Benthin[1], Yiteng Zhang[1], Benjamin Bohn[1], Maximilian Heller[1], Johan Hilbig[1], Tom Rakow[1], Arijit Chakraborty[1], Doaa Abdelbarey[1], Eddy P. Rugeramigabo[1], Michael Zopf[1,2], and Fei Ding[1,2] — [1]Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover — [2]Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, Schneiderberg 39, 30167 Hannover

Semiconductor-based quantum dots (QDs) are promising candidates for quantum network applications due to their ability to generate single, entangled, and indistinguishable photons on demand. Modern epitaxial III-V quantum emitters based on local droplet etching with nanohole infilling or Stranski-Krastanov growth exhibit excellent properties from the near-infrared to the telecom bands. An alternative from the early days of QD research involved QDs formed by thickness fluctuations in quantum well (QW) heterostructures. These QW thickness fluctuation (QWTF) QDs can naturally display strong light-matter interaction due to giant oscillator strengths, yet have not been the focus of recent research as quantum emitters for single-photon applications. In this work, we investigate the optical properties of naturally formed QWTF QDs in GaAs QWs emitting near 780 nm. Our results demonstrate that their distinctive properties justify revisiting QWTF QDs with today's standard for single-photon sources competing against state-of-the-art epitaxial approaches.

HL 55.11 Fri 12:15 POT/0251

Single-Photon Emission with High Spectral Purity from Site-Controlled InGaN Quantum Dots — •Nima Hajizadeh[1,2], Nils Bernhardt[2], Richard Zimmermann[2], Felix Nippert[2], Luca Sung-Min Choi[2], Benjamin Damilano[3], Jean-michel Chauveau[4], and Markus Wagner[1,2] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V. — [2]Technische Universität Berlin, Institute of Solid State Physics — [3]Université Côte d'Azur, CNRS, CRHEA — [4]Université Paris Saclay, Université Versailles Saint Quentin, CNRS, GEMaC

The development of high-quality Single-Photon Emitters (SPEs) based on Indium Gallium Nitride (InGaN) Quantum Dots (QDs) is essential for advancing quantum technologies. We present a comprehensive investigation of SPEs based on novel top-down fabricated, site- and size-controlled InGaN QDs. In this work, the optical and quantum optical properties of these isolated QDs are comprehensively investigated using high-resolution, time-correlated micro-photoluminescence (μ-PL) spectroscopy, including temperature-, power- and polarization-dependent measurements, as well as hyperspectral PL mapping of their excitonic emission. The purity of the single-photon emission is evaluated by measuring the second-order intensity autocorrelation function $g^{(2)}(\tau)$ in a Hanbury-Brown and Twiss (HBT) setup. We show that the emitter exhibits an exceptionally sharp emission bandwidth below 0.02 nm and pronounced anti-bunching with $g^{(2)}(0) < 0.36$. These results confirm the potential of our site-controlled growth methodology to deliver high-purity SPEs with narrow spectral lines.

HL 56: Quantum Emitters in 3D Semiconductors

Time: Friday 11:15–12:30 Location: POT/0006

HL 56.1 Fri 11:15 POT/0006

Electrically driven single-photon sources for scalable quantum photonics operating at the telecommunication wavelengths — •Alessandro Puddu[1,2], Junchun Yang[2], Shengqiang Zhou[1], Artur Erbe[1,2], Ahmad Echresh[1], Kambiz Jamshidi[2], and Yonder Berencén[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstrasse 400, Dresden, 01328, Germany — [2]Technische Universität Dresden, Dresden, 01069, Germany

Silicon-based quantum technologies provide a scalable platform for photonics due to their CMOS compatibility and ease of integration. Single-photon sources operating at telecom wavelengths are key components for low-loss quantum communication networks and the emerging quantum internet. Integrating these emitters with reconfigurable photonic elements such as multiplexers, modulators, filters, etc. and on-chip single-photon detectors is essential for realizing scalable quantum hardware. Optical excitation methods, however, rely on complex and alignment-sensitive laser systems, limiting their integration potential. Electrically driven color centers offer a compact and fully integrable alternative. This paper is focused on achieving electrically driven single-photon emission from individual color centers embedded in a silicon PIN diode. Emission in the telecom O- and L-bands is particularly advantageous, as it aligns with low-loss and low-dispersion regions in standard optical fibers. To improve emission efficiency and on-demand single photon generation, a single-color center will be coupled to a CMOS-compatible optical cavity, enabling Purcell-enhanced emission and efficient integration into silicon photonic circuits.

HL 56.2 Fri 11:30 POT/0006

Liquid Metal Alloy Ion Sources for Quantum Emitters — •Nico Klingner[1], Lukas Prager[1], Gregor Hlawacek[1], Stefan Findeisen[1], Wolfgang Pilz[2], and Paul Mazarov[2] — [1]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden - Rossendorf (HZDR), Bautzner Landstr. 400, 01328 Dresden, Germany — [2]Raith GmbH, Konrad-Adenauer-Allee 8, 44263 Dortmund, Germany

Liquid metal alloy ion sources (LMAIS) have evolved into powerful emitters for generating focused ion beams (FIBs) of a wide range of elemental species. In recent years, they have become a key enabling tools for quantum technologies, supporting applications such as deterministic single-ion implantation, the controlled creation of defect centers acting as single-photon sources, or for local isotopic purification of silicon for quantum-grade materials.

In this contribution, we present an overview of the LMAIS fabrication process, inluding eutectic alloy phase diagrams in selecting suitable compositions, the microfabrication and sharpening of emitter needles, and the challenges of alloy wetting and reservoir filling. As the alloy chemistry and emitter surface are highly susceptible to contamination, all steps are recently carried out under ultra-high-vacuum conditions to prevent oxidation and ensure reproducible operating characteristics.

Finaly we will show a summary and an outlook on single photon emitter production that benefit from the unique versatility of LMAIS-based ion beams.

HL 56.3 Fri 11:45 POT/0006

Defect-based quantum emitters in aluminum nitride — •Annkathrin Köhler, Jan Böhmer, and Carsten Ronning — Friedrich Schiller Universität, Jena, Deutschland

Aluminum nitride (AlN) has recently gained attention as a promising platform for integrated quantum photonic applications, where single-photon emitters (SPEs) play a key role in quantum communication and on-chip information processing. Its wide bandgap, CMOS compatibility, and established role in optoelectronic technologies make AlN an attractive host for stable, room-temperature SPEs. However, the microscopic origin and controllability of its defect-based emission remain insufficiently understood, challenging the implementation in scalable quantum photonic devices. Here, we investigated the defect-related luminescence in commercially available PVD-grown AlN thin films using micro-photoluminescence spectroscopy and second-order correlation measurements. By characterizing both intrinsic defects and extrinsic impurities introduced through controlled ion irradiation, we aim to identify routes toward reproducible and deterministic creation of optically active defect centers. Ion irradiation provides a tunable method for introducing specific defect types and spatially localized emitters, potentially enabling on-demand SPE fabrication. This study supports the development of AlN as a viable wide-bandgap host for quantum light sources and outlines directions for integrating AlN-based SPEs into future photonic architectures.

HL 56.4 Fri 12:00 POT/0006

Atomic force lithography positioned circular Bragg cavities for high performance quantum dot based quantum light sources. — •Abhishikth Dhurjati[1], Moritz Langer[1], Yared Zena[1], Ahmad Rahimi[1], Liesa Raith[1], Martin Bauer[1], Riccardo Bassoli[2], Frank Fitzek[3], and Caspar Hopfmann[2] — [1]Institute for Emerging Electronic Technologies, IFW Dresden, Helmholtzstraße 20, 01069 Dresden, Germany — [2]Quantum Communication Networks research group, Deutsche Telekom Chair of Communication Networks, Dresden University of Technology, Germany — [3]Deutsche Telekom Chair of Communication Networks, Dresden University of Technology, Germany

Semiconductor quantum dots (QDs) are excellent quantum emitters, but their random spatial distribution hinders deterministic cavity integration. We present a room-temperature atomic force microscopy (AFM) assisted nano-oxidation technique enabling deterministic QD positioning with a radial displacement of 51(28) nm. Free-standing circular Bragg gratings fabricated around positioned GaAs QDs exhibit a 245-fold photoluminescence enhancement and fine-structure splitting comparable to bulk QDs. Polarization-resolved measurements and simulations show robust cavity-coupled emission for in-plane displacements up to 50 nm and devices with Stokes imbalance below 5 percent, confirming precise alignment and a scalable route toward high-performance quantum light sources.

HL 56.5 Fri 12:15 POT/0006

Bright quantum dot light sources using monolithic microlenses on gold back-reflectors — •Moritz Langer[1,2,3], Sai A Dhurjati[1], Yared Zena[1], Ahmad Rahimi[1], Mandira Pal[1], Liesa Raith[1], Sandra Nestler[1], Riccardo Bassoli[2,3], Frank H P Fitzek[3], Oliver G Schmidt[4], and Caspar Hopfmann[1,2,3] — [1]Institute for Emerging Electronic Technologies - IFW Dresden, Dresden, Germany — [2]Quantum Communication Networks Research Group, Dresden University of Technology, Germany — [3]Deutsche Telekom Chair of Communication Networks, Dresden University of Technology, Germany — [4]Research Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, Germany

We present a scalable approach for fabricating bright GaAs quantum-dot photon sources by integrating QDs into broadband monolithic AlGaAs microlens arrays on gold-coated GaAs substrates. Thermally reflowed photoresist templates are transferred into AlGaAs thin films using an optimized 3D reactive-ion etching process, enabling large-area arrays with highly uniform lens geometries. Photoluminescence statistics reveal brightness enhancements of up to *200, occurring in roughly 1 out of 200 lenses, in good agreement with our developed fabrication-yield model. Finite-difference time-domain simulations predict extraction efficiencies of up to 62% for free-space collection and 37% for fiber-coupling. These results highlight the strong potential of this platform for compact, scalable entangled-photon sources in future quantum networks.

HL 57: Nitrides IV – Optical properties

Time: Friday 11:30–12:45 Location: POT/0051

HL 57.1 Fri 11:30 POT/0051

Optical Properties of Sn-doped n-type GaN — •Hannah Bendin[1], Elias Kluth[1], Kazuki Ohnishi[2], Kansuke Hamasaki[2], Shugo Nitta[2], Naoki Fujimoto[2], Hirotaka Watanabe[2], Yoshio Honda[2], Hiroshi Amano[2], Rüdiger Goldhahn[1], and Martin Feneberg[1] — [1]Otto-von-Guericke-Universität Magdeburg, Germany — [2]Nagoya University, Japan

GaN is at the heart of many contemporary electronic and optoelectronic applications. To increase the efficiency of high-power devices, the preparation of degenerately doped n-type GaN of high quality is required. Generally, Si and Ge are introduced as dopants, each giving rise to their own challenges. For example, high Si-doping is counteracted by carrier compensation and an increase in tensile stress. Recently, Sn has also gained interest as a dopant in GaN. Initial theoretical and experimental studies show promising results, introducing Sn as a candidate for strain control in n-type GaN via co-doping with Si or Ge, as the radius mismatch between Ga and Sn causes compressive strain, unlike Si or Ge. Here, we investigate Sn-doped samples with different carrier concentrations grown by halide vapor phase epitaxy by employing a variety of optical techniques. To determine the influence of the carrier concentration in GaN:Sn on the optical properties, we apply spectroscopic ellipsometry, Raman spectroscopy, and photoluminescence. Two sets of samples have been investigated: (I) GaN:Sn on a GaN/sapphire template and (II) GaN:Sn on a freestanding GaN substrate.

HL 57.2 Fri 11:45 POT/0051

Optical properties of ScAlN: investigation by spectroscopic ellipsometry — •Christina Harms[1], Jona Grümbel[1], Duc V. Dinh[2], Zhuohui Chen[3], Oliver Brandt[2], Martin Feneberg[1], and Rüdiger Goldhahn[1] — [1]Otto-von-Guericke-Universität, Institut für Physik, Magdeburg, Germany — [2]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — [3]Huawei Technologies Canada Co., Ltd., Kanata, Canada

$Sc_xAl_{1-x}N$ alloys are of increasing interest due to their unique ferroelectric and optoelectronic properties. In this work, we investigate the dielectric function of this material using spectroscopic ellipsometry. A series of $Sc_xAl_{1-x}N$ samples with $0 \leq x \leq 0.35$, grown on AlN/Si by plasma-assisted molecular beam epitaxy, were measured in the infrared (IR) and ultraviolet (UV) spectral range. In the IR range, the E_1(TO) phonon mode is characterized in terms of its resonance frequency ω and broadening γ, which are analyzed as a function of Sc content. Additionally, the dielectric limit ε_∞ is derived. With increasing Sc content, ω decreases, while both γ and ε_∞ increase. In the UV range, we determine the optical bandgap E_g as well as the corresponding ε_∞ and describe the observed trends across the composition range. Here, E_g decreases systematically with increasing Sc content and ε_∞ increases accordingly. The results are compared with recent results from literature, showing consistent trends in the optical properties throughout the investigated composition range.

HL 57.3 Fri 12:00 POT/0051

Near-lattice-matched AlScN/GaN heterostructures studied by spectroscopic ellipsometry and photoluminescence — •Alwin Wüthrich[1], Rajendra Kumar[2], Oana Malis[2], Rüdiger Goldhahn[1], and Martin Feneberg[1] — [1]Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Germany — [2]Department of Physics and Astronomy, Purdue University, USA

Understanding the fundamental properties of the novel ferroelectric material AlScN, such as ferroelectricity, tunable lattice constants, a wide and tunable band gap, and high piezoelectric coefficients, is crucial for its correct implementation in modern applications. Examples include processing units based on non-volatile memory and the design of infrared devices that utilize transitions between strongly confined electronic states, i.e., intersubband transitions. Here, near-lattice-matched AlScN layers (with 4–25% Sc) were grown by molecular beam epitaxy (MBE) on MBE-grown GaN layers. The samples were investigated by spectroscopic ellipsometry from the near-infrared to the far-ultraviolet range, probing infrared-active phonons and interband transitions. Additionally, the samples were studied by temperature-dependent photoluminescence, revealing luminescence from a two-dimensional electron gas.

HL 57.4 Fri 12:15 POT/0051

Near-Infrared Photocurrent Spectroscopy of InN Two-Terminal Devices — •Alexandra V. Nemmaier[1,2], Maximilian A. Gruber[1,2], Abhilash Ulhe[1,2], Gregor Koblmüller[1,2], and Alexander W. Holleitner[1,2] — [1]Walter Schottky Institute, TU Munich, Germany — [2]Exzellenzcluster e-conversion, Munich, Germany

The semiconductor InN, with its narrow bandgap, high electron mobility, and specific carrier cooling mechanisms, is a promising platform for optoelectronics and hot carrier solar cells. We investigate epitaxial InN layers grown on GaN by near-infrared photocurrent spectroscopy. We measure the spatially resolved photocurrent to characterize the photoresponse in gated two-terminal devices. This approach offers a new perspective on hot carrier generation, charge carrier transport, and relaxation mechanisms close to the bandgap of the material.

HL 57.5 Fri 12:30 POT/0051

Structural and vibrational properties of strain-free $Al_{1-x}Sc_xN$ nanowires — Adriano Notarangelo[1], Ileana Florea[2], Philippe Vennéguès[2], Aidan Campbell[1], Hans Tornatzky[1], Jonas Lähnemann[1], Thomas Auzelle[1], Lutz Geelhaar[1], Oliver Brandt[1], and •Philipp John[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V. 10117 Berlin, Germany — [2]Université Côte d'Azur, CRHEA, CNRS, 06905 Sophia-Antipolis Cedex, France

The incorporation of Sc into the wurtzite crystal lattice of AlN enhances its piezoelectricity and induces ferroelectricity, making $Al_{1-x}Sc_xN$ an attractive material for novel types of group-III nitride based devices. Yet, the lattice distortions giving rise to these functionalities are superimposed to distortions arising from residual strain introduced during the heteroepitaxy on lattice-mismatched substrates.

In this work, self-assembled wurtzite $Al_{1-x}Sc_xN$ nanowires are grown by molecular beam epitaxy, varying the Sc content x from 0 to 0.38. The nanowire geometry allows elastic relaxation to occur, resulting in strain-free, bulk-like $Al_{1-x}Sc_xN$. A non-linear evolution of lattice parameters and a continuous redshift of the E_2^{high} and A_1(TO) phonon modes as a function of Sc content are found, confirming its incorporation into the wurtzite lattice and revealing modifications of anion-cation bond strength and coordination environment.

Our results highlight the advantages of bulk-like $Al_{1-x}Sc_xN$ for probing its fundamental properties, laying the ground work for further device applications.

Overview of Invited Talks and Sessions

(Lecture halls HSZ/0002, HSZ/0004, POT/0112, POT/0151, POT/351, and POT/361; Poster P2 and P4)

Invited Talks

MA 1.1	Sun	16:00–16:30	TRE/PHYS	**Recent advances and challenges in magnetic structure determination** — •Dmytro Inosov
MA 4.1	Mon	9:30–10:00	POT/0151	**From ML to Kinetics: Modeling the Switching in Ferroelectric Wurtzites** — •Andrew Rappe, Drew Behrendt, Atanu Samanta, Von Braun Nascimento
MA 4.2	Mon	10:00–10:30	POT/0151	**Topological order parameter switching** — •Sergey Artyukhin
MA 4.3	Mon	10:30–11:00	POT/0151	**Optical Control of Ferroaxial Order via Circular Phonon Excitation** — •Zhiyang Zeng, Michael Först, Michael Fechner, Dharmalingam Prabhakaran, Paolo Radaelli, Andrea Cavalleri
MA 10.1	Mon	15:00–15:20	POT/0112	**Multi-field analysis of magnetic materials: Phase-field based simulations of magnetic domains and phase transition** — •Mobina Alaeddini, Jörg Schröder, Maximilian Vorwerk
MA 10.2	Mon	15:20–15:40	POT/0112	**Realistic Modelling of Finite Temperature Electron Transport Properties in Ferromagnets** — •Fabian Engelke, Christian Heiliger
MA 10.3	Mon	15:55–16:20	POT/0112	**Exploring magneto- and multicaloric materials for room and cryogenic temperature applications** — •Benedikt Beckmann
MA 10.4	Mon	16:20–16:45	POT/0112	**Nonlinear magnon dynamics: From the discovery of Floquet magnons to CMOS-compatible magnon computing** — •Christopher Heins
MA 10.5	Mon	16:45–17:10	POT/0112	**The geometric memory of quantum wave functions** — •Niclas Heinsdorf
MA 10.6	Mon	17:10–17:35	POT/0112	**Altermagnets and Odd-parity-wave Magnets** — •Anna Birk Hellenes
MA 14.1	Tue	9:35–10:20	HSZ/0002	**Femtophonomagnetism** — •Sangeeta Sharma, John Dewhurst
MA 14.2	Tue	10:20–10:50	HSZ/0002	**THz-driven dynamical ferroicity in paraelectric and diamagnetic perovskites** — •Martina Basini
MA 14.3	Tue	10:50–11:20	HSZ/0002	**Angular momentum transfer and chiral phonons from first principles** — •Markus Weissenhofer, Philipp Rieger, MS Mrudul, Luca Mikadze, Sergiy Mankovsky, Svitlana Polesya, Hubert Ebert, Ulrich Nowak, Peter M. Oppeneer
MA 14.4	Tue	11:35–12:05	HSZ/0002	**Inertial Spin Dynamics: A Signature of Non-Markovian Interactions in Ferromagnets** — •Vivek Unikandanunni, Felix Hartmann, Matias Bargheer, Eric Fullerton, Stefano Bonetti, Janet Anders
MA 14.5	Tue	12:05–12:35	HSZ/0002	**Atomistic simulations of ultrafast spin-lattice dynamics** — •Richard Evans, Mara Strungaru
MA 18.1	Tue	9:30–10:00	POT/0151	**Magnetic Cooling: From applications at room temperature to hydrogen liquefaction** — •T. Gottschall, E. Bykov, M. Strassheim, T. Platte, C. Fujta, D. Benke, M. Fries, W. Liu, A. Döring, K. Skokov, O. Gutfleisch, J. Wosnitza
MA 25.1	Wed	9:30–10:00	HSZ/0002	**Coherent phononic control of chirality** — •Michael Först
MA 25.2	Wed	10:00–10:30	HSZ/0002	**Towards a modern theory of chiralization (and can chiral phonons help us get there?)** — •Nicola Spaldin
MA 25.5	Wed	11:15–11:45	HSZ/0002	**Observation and control of chiral phonons in non-centrosymmetric materials** — •Hiroki Ueda
MA 27.1	Wed	9:30–10:00	HSZ/0004	**Towards sub-10fs magnetization switching** — Reza Rouzegar, Oliver Franke, Gal Lemut, Oliver Gueckstock, Junwei Tong, Dieter Engel, Xianmin Zhang, Georg Woltersdorf, Piet W. Brouwer, Tobias Kampfrath, •Quentin Remy
MA 29.1	Wed	9:30–10:00	POT/0112	**Exploring the interplay between spin and chirality** — •Angela Wittmann

MA 35.1	Wed	15:00–15:30	POT/0112	**Magneto-optic Kerr effects of higher order in magnetization in thin films of different crystal orientations** — •Timo Kuschel
MA 40.1	Thu	9:30–10:00	HSZ/0002	**Magnetic order induced chiral phonons in a ferromagnetic Weyl semimetal** — •Luyi Yang
MA 40.6	Thu	11:15–11:45	HSZ/0002	**Thermal Hall Effects of Magnons and Phonons** — •Alexander Mook
MA 43.1	Thu	9:30–10:00	POT/0112	**Defect-Induced Phase Transitions in the 2D Magnetic Semiconductor CrSBr** — •Shengqiang Zhou
MA 44.1	Thu	9:30–10:00	POT/0151	**2D and 3D racetracks: Interplay of geometric and magnetic chiralities** — •Stuart Parkin
MA 44.2	Thu	10:00–10:30	POT/0151	**Combined MFM/KPFM at the Ultimate Sensitivity Limit for Probing Curvature-Engineered Micromagnetic States** — •Emily Darwin, Reshma Peremadathil Pradeep, Luca Berchialla, Daniel Rotthardt, Ales Hrabec, Hans Hug
MA 44.3	Thu	10:30–11:00	POT/0151	**Curvilinear magnetism in superconducting spintronics** — •Sol Jacobsen
MA 44.4	Thu	11:15–11:45	POT/0151	**Advanced Control of Magnetic Nanostructures via Metasurface Engineering and Voltage-Driven Functionalities** — •Anna Palau
MA 44.5	Thu	11:45–12:15	POT/0151	**Magnetic tomography of noncollinear spin textures in curvilinear geometries** — •Sandra Ruiz-Gomez

Invited Talks of the joint Symposium SKM Dissertation Prize 2026 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	HSZ/0002	**Stochastic-Calculus Approach to Non-equilibrium Statistical Physics** — •Cai Dieball
SYSD 1.2	Mon	10:00–10:30	HSZ/0002	**Nonuniform magnetic spin textures for sensing, storage and computing applications** — •Sabri Koraltan
SYSD 1.3	Mon	10:30–11:00	HSZ/0002	**Anomalous Quantum Oscillations beyond Onsager's Fermi Surface Paradigm** — •Valentin Leeb
SYSD 1.4	Mon	11:00–11:30	HSZ/0002	**Coherent Control Schemes for Semiconductor Quantum Systems** — •Eva Schöll
SYSD 1.5	Mon	11:30–12:00	HSZ/0002	**On stochastic thermodynamics under incomplete information: Thermodynamic inference from Markovian events** — •Jann van der Meer

Invited Talks of the joint Symposium Fluids with Broken Time-Reversal Symmetry: Odd/Hall Viscosity between Active Matter and Electron Flows (SYBS)

See SYBS for the full program of the symposium.

SYBS 1.1	Tue	9:30–10:00	HSZ/AUDI	**Odd viscosity in three-dimensional fluids: flows, wakes, and eddies** — •Tali Khain
SYBS 1.2	Tue	10:00–10:30	HSZ/AUDI	**Odd viscosity in two-dimensional hydrodynamic electron transport** — •Igor Gornyi, Dmitry Polyakov
SYBS 1.3	Tue	10:30–11:00	HSZ/AUDI	**Odd slip on chiral active surfaces** — •Andrej Vilfan, Yuto Hosaka
SYBS 1.4	Tue	11:15–11:30	HSZ/AUDI	**Parity-odd transport in electron fluids** — •Johanna Erdmenger
SYBS 1.5	Tue	11:30–11:45	HSZ/AUDI	**Curved Odd Elasticity** — Lazaros Tsaloukidis, Yuan Zhou, Jack Binysh, Nikta Fakhri, Corentin Coulais, •Piotr Surówka

Invited Talks of the joint Symposium Beyond Transistors: Material-Based Edge Computing Paradigms (SYBT)

See SYBT for the full program of the symposium.

SYBT 1.1	Wed	9:30–10:00	HSZ/AUDI	**Finding Neuromorphic Advantage with Magnetism** — •Johan Mentink
SYBT 1.2	Wed	10:00–10:30	HSZ/AUDI	**Accelerating Neural Networks Computation with Ferroelectric Oxides** — •Laura Bégon-Lours, Nikhil Garg, Alexandre Baigol, Anwesha Panda, Nathan Savoia, Alexander Flasby
SYBT 1.3	Wed	10:30–11:00	HSZ/AUDI	**a photonic approach to probabilistic computing** — •Wolfram Pernice
SYBT 1.4	Wed	11:15–11:45	HSZ/AUDI	**Tackling Reliability and Scalability in Neuromorphic Computing via Noise-aware Learning** — •Eleni Vasilaki
SYBT 1.5	Wed	11:45–12:15	HSZ/AUDI	**Bayesian nanodevices for trustworthy artificial intelligence** — •Damien Querlioz

Invited Talks of the joint Symposium Interacting Degrees of Freedom in Ultrathin Quantum Films (SYQF)

See SYQF for the full program of the symposium.

SYQF 1.1	Fri	9:30–10:00	HSZ/AUDI	**Exciton dressing by extreme nonlinear magnons in a layered semiconductor** — •Geoffrey M. Diederich
SYQF 1.2	Fri	10:00–10:30	HSZ/AUDI	**A tale of demons and decay in two-dimensional (alter)magnets** — •Alexander Mook
SYQF 1.3	Fri	10:30–11:00	HSZ/AUDI	**Magnetism, light and matter - Role of excitons in two-dimensional magnets** — •Florian Dirnberger
SYQF 1.4	Fri	11:15–11:45	HSZ/AUDI	**Advantages and challanges of resonance Raman scattering with infrared excitation energy** — •Leonetta Baldassarre
SYQF 1.5	Fri	11:45–12:15	HSZ/AUDI	**Shining light on 2D antiferromagnets** — •Dmytro Afanasiev

Sessions

MA 1.1–1.2	Sun	16:00–18:15	TRE/PHYS	**Hands-On Tutorial: Magnetic Structure Determination Using Fullprof and SARAh Representation Analysis (joint session MA/TUT)**
MA 2.1–2.12	Mon	9:30–12:45	HSZ/0004	**Altermagnets I**
MA 3.1–3.12	Mon	9:30–12:45	POT/0112	**Complex Magnetic Oxides**
MA 4.1–4.6	Mon	9:30–12:00	POT/0151	**Focus Session: Novel mechanisms of ferroic switching (joint session MA/FM)**
MA 5.1–5.9	Mon	9:30–12:00	POT/0351	**Surface Magnetism and Topological Insulators (joint session MA/TT)**
MA 6.1–6.12	Mon	9:30–12:45	POT/0361	**Magnetic Imaging Techniques I**
MA 7.1–7.86	Mon	9:30–12:30	P2	**Poster Magnetism I**
MA 8.1–8.13	Mon	15:00–18:30	HSZ/0002	**Altermagnets II**
MA 9.1–9.13	Mon	15:00–18:30	HSZ/0004	**Magnonics I**
MA 10.1–10.6	Mon	15:00–18:05	POT/0112	**INNOMAG e.V. Prizes 2026 (Diplom-/Master and Ph.D. Thesis)**

Sessions

– Invited Talks, Topical Talks, Tutorials, Contributed Talks, and Posters –

MA 1: Hands-On Tutorial: Magnetic Structure Determination Using Fullprof and SARAh Representation Analysis (joint session MA/TUT)

The functionalities of many materials of contemporary interest are related to complex types of magnetic ordering. Accurate magnetic structure determination is thus crucial for understanding and optimizing such materials.

After an introduction into the subject, participants of the tutorial will gain hands-on experience on the methods for magnetic structure determination.

Time: Sunday 16:00–18:15 Location: TRE/PHYS

Invited Talk MA 1.1 Sun 16:00 TRE/PHYS

Recent advances and challenges in magnetic structure determination — •Dmytro Inosov — Institut für Festkörper- und Materialphysik, TU Dresden, Germany

In this introductory tutorial talk, I will provide an overview of magnetic structure determination in the context of recent advances in magnetic materials. I will focus on the limitations and challenges of magnetic structure refinement, and explain why it is important to use the full range of complementary experimental methods alongside conventional diffraction in order to develop a consistent understanding of magnetic structures. This is particularly important when dealing with complex types of magnetic order, such as noncollinear and multi-Q spin textures, altermagnets, and systems with multiple magnetic sublattices or very weak and/or fluctuating magnetic moments.

Tutorial MA 1.2 Sun 16:30 TRE/PHYS

Hands-On Tutorial: Magnetic Structure Determination Using Fullprof and SARAh Representation Analysis — •Matthias Frontzek — Oak Ridge National Laboratory, Neutron Scattering Division, One Bethel Valley Road, 37831 Oak Ridge, TN, USA

The determination of magnetic structures is a crucial aspect of materials science, particularly for understanding the magnetic properties of novel materials. Given the limited availability of neutrons with the closure of smaller sources, competitive access to beam time, and the high hurdles associated with software usage, there is an increasing need for training in the analysis of magnetic structures. This tutorial aims to provide participants with practical skills in magnetic structure determination using SARAh and Fullprof, two powerful tools frequently utilized in this field.

Participants will:

-Gain hands-on experience with the tools and techniques necessary for magnetic structure determination.

-Refine nuclear and magnetic structures using real data sets.

-Understand key concepts in diffraction techniques and steps involved in the magnetic structure determination process.

Important: for Hands-on participation, please bring a laptop with a working installation of Fullprof (https://www.ill.eu/sites/fullprof/).

For links to Fullprof, SARAh stand-alone and tutorial data visit: https://neutrons.ornl.gov/wand/users

MA 2: Altermagnets I

Time: Monday 9:30–12:45 Location: HSZ/0004

MA 2.1 Mon 9:30 HSZ/0004

Electric Control of Spin and Valley Polarization in the XMoTeO6 Family of Two-dimensional Altermagnets — •Avijeet Ray[1], Fatemeh Haddadi[2], Antimo Marrazzo[3], and Marco Gibertini[1,4] — [1]University of Modena and Reggio Emilia, Italy — [2]EPFL, Switzerland — [3]SISSA, Italy — [4]Istituto Nanoscienze-CNR, Italy

Altermagnets are a special class of antiferromagnets with zero net magnetization but spin-split bands, even in the absence of spin-orbit-coupling. In semiconducting altermagnets, this spin-splitting can give rise to spin-valley locking, where valleys located at specific k-points have a well-defined spin. Still, symmetries connecting the spin sublattices impose an overall degeneracy between valleys of opposite spins. An external electric field can break these symmetries, enabling controllable spin (and valley) polarization. This is particularly promising in two-dimensional (2D) materials where it is easy to apply a vertical electric field in a double-gate field-effect setup, provided that 2D altermagnets with suitable crystal symmetries are found. Here, by using first-principles simulations, not only we put forward an interesting family of 2D altermagnets that display the correct symmetries, but we also show that the electric field effect is sizable in these materials and reaches the requirements needed for applications in spin-valleytronics.

MA 2.2 Mon 9:45 HSZ/0004

Zeeman Quantum Geometry as a Probe of Unconventional Magnetism — •Snehasish Nandy[1], Neelanjan Chakraborti[2], and Sudeep Kumar Ghosh[2] — [1]National Institute of Technology Silchar, Silchar, India — [2]Indian Institute of Technology Kanpur, Kanpur, India

Unconventional magnets with momentum-dependent spin-splitting but zero net magnetization form a recently identified class of collinear magnets that are challenging to probe via conventional means. We show that these systems can be distinguished through intrinsic gyrotropic magnetic (IGM) currents, enabled by the Zeeman quantum geometry, which captures the coupled response of electronic states to momentum translation and spin rotation. Examining two prototypical two-dimensional unconventional magnets with Rashba spin-orbit coupling, a time-reversal-broken d-wave altermagnet and a time-reversal-symmetric p-wave magnet, we uncover a direct link between crystalline symmetry, spin-split band structures, and transport signatures. The d-wave altermagnet exhibits both transverse conduction and longitudinal displacement IGM currents, whereas p-wave magnet supports only transverse conduction IGM current. Remarkably, the mixed d-wave altermagnet supports all four types of IGM currents, including a longitudinal conduction current enabled by symmetric (Zeeman) Berry curvature that is forbidden in conventional quantum geometry. These responses, measurable via Hall transport and optical probes, persist even when conventional quantum geometry-driven linear responses vanish, offering unique access to hidden spin-split band structures.

MA 2.3 Mon 10:00 HSZ/0004

Spin demons in d-wave altermagnets — •Pieter Gunnink[1], Jairo Sinova[1], and Alexander Mook[2] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, Mainz 55128, Germany — [2]University of Münster, Institute of Solid State Theory, 48149 Münster, Germany

Demons are a type of plasmons, which consist of out-of-phase oscillations of electrons in different bands. Here, we show that d-wave altermagnets, a recently discovered class of collinear magnetism, naturally realize a spin demon, which consists of out-of-phase movement of the two spin species [1]. The spin demon lives outside of the particle-hole continuum of one of the spin species, and is therefore significantly underdamped, reaching quality factors of > 10. We show that the spin demon carries a magnetic moment, which inherits the d-wave symmetry. Finally, we consider both three and two dimensional d-wave altermagnets, and show that spin demons exists in both.

[1] Gunnink, Sinova, Mook, Phys. Rev. Lett. 135, 126701 (2025)

MA 2.4 Mon 10:15 HSZ/0004

Altermagnetism in magnetic nanoisland arrays — •Rhea Hoyer[1], Lukas Körber[2], Tobias Wagner[3], and Alexander Mook[1] — [1]Institut für Festkörpertheorie, Universität Münster, Münster, Germany — [2]Institute of Molecules and Materials, Radboud University, Nijmegen, The Netherlands — [3]Department of Physics, Johannes Gutenberg University Mainz, Mainz, Germany

We present a macrospin model for magnetic island arrays engineered with altermagnetic symmetries. The islands interact purely via dipole-dipole coupling, which makes the strict spin-orbit-free limit of altermagnetism inaccessible. Although the magnon dispersion is split by spin-orbit coupling, the magnon bands

remain spin-polarized, exhibiting a characteristic d-wave-like pattern of the spin expectation value across the Brillouin zone. This residual altermagnetic character gives rise to direction-dependent spin dynamics and suggests the possibility of anisotropic spin-transport phenomena in mesoscopic artificial magnets.

MA 2.5 Mon 10:30 HSZ/0004

Magnons in Antialtermagnets — •Robin R. Neumann[1,2,3], Rodrigo Jaeschke-Ubiergo[2], Ricardo Zarzuela[2], Jairo Sinova[2,4], and Alexander Mook[1,2] — [1]University of Münster, Münster, Germany — [2]Johannes Gutenberg University Mainz, Mainz, Germany — [3]Martin Luther University Halle-Wittenberg, Halle, Germany — [4]Texas A&M University, College Station, USA

Altermagnets and antialtermagnets are unconventional magnetic phases with compensated magnetization and nonrelativistic spin splitting in their electronic band structures. In altermagnets, this spin splitting has even parity, whereas in antialtermagnets it has odd parity. In this talk we go beyond electrons and demonstrate that magnons, the collective spin excitations of magnetically long-range ordered systems, inherently feature an odd-parity spin polarization in antialtermagnets without spin-orbit or dipolar coupling. We present minimal model spin Hamiltonians free of spin-orbit coupling that stabilize antialtermagnetic ground states, discuss their symmetries, and characterize the spin-polarized magnon band structures.

MA 2.6 Mon 10:45 HSZ/0004

Magnetization processes and spin-lattice coupling in the hexagonal easy-plane altermagnet α-MnTe — •Sahana Rössler[1], Victoria Ginga[1], Ece Uykur[2], Yurii Skourski[3], Jeremy Sourd[3], Sergei Zherlitsyn[3], Marcus Schmidt[4], Yurii Prots[4], Helge Rosner[4], Ulrich Burkhardt[4], Ulrich K. Rössler[5], and Alexander A. Tsirlin[1] — [1]Felix Bloch Institute for Solid State Physics, Leipzig University, Leipzig, Germany — [2]HZDR, IBP and Materials Research, Dresden, Germany — [3]HLD, HZDR, Dresden, Germany — [4]MPI CPfS, Dresden, Germany — [5]Institute for Theoretical Solid-State Physics, Leibniz IFW Dresden, Germany

We investigated the magnetization dynamics associated with domain behavior in α-MnTe using magnetization, magnetostriction, sound velocity, and attenuation measurements. Angle- and field-dependent magnetization data reveal complex magnetic responses with a distinct anomaly around 1 T, reflecting domain-related processes. Magnetostriction and elastic constant measurements indicate strong lattice effects at the field-induced reorientation transition. These features were analysed using a phenomenological micromagnetic model incorporating higher-order anisotropic exchange interactions that couple the weak ferromagnetic component to the antiferromagnetic order parameter. The model successfully reproduces the generic behaviour of the magnetic states and demonstrates that the observed uniaxial and unidirectional anisotropies arise from metastable domain configurations and irreversible magnetization processes [1].

Emergent Altermagnetism in Antiferromagnetic Surfaces — •Colin Lange[1], Rodrigo Jaeschke Ubiergo[1], Alexander Mook[2], and Jairo Sinova[1] — [1]Institut für Physik, Johannes Gutenberg Universität Mainz, Germany — [2]Institut für Festkörpertheorie, Universität Münster, Germany

Three-dimensional altermagnets with collinear compensated order and nonrelativistic spin splitting have recently been realized, but experimental access to their 2D counterparts remains limited. We show that surfaces of the most abundant class of collinear magnets – conventional 3D antiferromagnets – provide a general route to 2D altermagnetism through surface-induced symmetry breaking. We implement this in a semi-infinite stack geometry, effectively modeling a thin film to establish a direct connection to experimental systems. This way, the symmetry analysis made here has direct implications for readily available experiments and materials. Using our novel definition of "surface spin groups", which lies between the 3D and 2D cases due to the semi-infinite geometry, we provide a full symmetry classification of all possible cases of altermagnetic surface termination. We scan available databases of magnetic materials, and conclude that almost half of the collinear antiferromagnets can host an altermagnetic surfaces. We present calculations of spin-split surface states in realistic candidates, that can serve for future experimental verification of surface induced altermagnetism. Our work positions the broadly accessible landscape of antiferromagnets as a promising foundation for 2D altermagnetism, whose experimental realization remains limited.

MA 2.8 Mon 11:30 HSZ/0004

Angle-dependent magnetoresistance induced by interface-generated spin current in RuO_2/permalloy heterostructures — Akashdeep Akashdeep[1], Ewiese Mohammad Ababneh[2], Christin Schmitt[1], Edgar Galíndez-Ruales[1], Felix Fuhrmann[1], Timo Kuschel[1], Mathias Kläui[1], Vivek Amin[2], and •Gerhard Jakob[1] — [1]Johannes Gutenberg University, Mainz, Germany — [2]Indiana University, Indianapolis, USA

Ruthenium dioxide (RuO_2) is a promising altermagnetic candidate. In our PLD grown films clear signs of altermagnetism were found by photoemission [1] and optically induced spin polarization with d-wave symmetry [2]. However, recent reports suggest that RuO_2 may be nonmagnetic in its ground state. (100)-oriented RuO_2 films are expected to generate spin currents with transverse spin polarization parallel to the Neel vector. We investigated magnetotransport in epitaxial RuO_2/permalloy (Py) heterostructures to examine spin Hall magnetoresistance and interfacial effects. Our measurements revealed a pronounced negative angular-dependent magnetoresistance that we attribute to interface-generated spin current (IGSC) at the RuO_2/Py interface supported by drift-diffusion calculations. The interface effects predominate over possible altermagnetic contributions [3]. This finding is in accord with recent muon spin resonance on our films [4].

X-ray magnetic circular dichroism of altermagnet α-Fe2O3 based on multiplet ligand-field theory using Wannier orbitals — Ruiwen Xie, Hamza Zerdoumi, and •Hongbin Zhang — TU Darmstadt, Darmstadt, Germany

Hematite α-Fe2O3 is a g-wave altermagnet, possessing an easy-axis and easy-plane weak ferromagnetic phase below and above Morin temperature, respectively. The presence of these phases renders it a good candidate to study the characteristic spin splitting in altermagnets under the impacts of relativistic effect and finite temperature. We have calculated the band structure of α-Fe2O3 based on density functional theory (DFT) considering the Coulomb correction and spin-orbit coupling effects. Additionally, the DFT + dynamical mean-field theory calculations have been performed at finite temperatures. It is found that the spin splitting in α-Fe2O3 preserves with either SOC or temperature effect included. Furthermore, we present a numerical simulation of the x-ray magnetic circular dichroism (XMCD) of the L2,3 edge of Fe using a combination of DFT with multiplet ligand-field theory. In terms of the different Néel vectors present in α-Fe2O3, we calculate the x-ray absorption spectroscopy of the L2,3 edge of Fe in the form of conductivity tensor and analyze the XMCD response from a perspective of symmetry. A characteristic XMCD line shape is expected when the Néel vector is along [010] direction and the light propagation vector is perpendicular to the Néel vector, which can be further distinguished from the XMCD response originated from weak ferromagnetism with the light propagation vector parallel to the Néel vector.

MA 2.10 Mon 12:00 HSZ/0004

Magnetic circular dichroism in resonant Auger electron diffraction from altermagnets — •Peter Krüger — Chiba University, Chiba, Japan

Recently we demonstrated that in altermagnets, there exists a large magnetic circular dichroism (MCD) in resonant photoelectron diffraction (RPED) [1]. The MCD-RPED signal is time-reversal odd and characteristic of the altermagnetic state. It is proportional to the local XMCD signal from a single magnetic sublattice and thus provides a direct probe of the sublattice magnetization. Here we show that MCD-RPED occurs in all altermagnets independently of the orientation of the Néel vector. This is a major difference to the weak XMCD observed in some altermagnets [2]. We also extend the theory to resonant Auger electron diffraction, whose MCD gives similar information as that of RPED, while being conceptually simpler. We discuss the symmetry properties of the MCD signal and explain its physical origin with a simple model. [1] P. Krüger, Phys. Rev. Lett. 135, 196703 (2025). [2] A. Hariki et al, Phys. Rev. Lett. 132, 176701 (2024).

MA 2.11 Mon 12:15 HSZ/0004

Heisenberg models of altermagnets — •Volodymyr Kravchuk[1,2], Kostiantyn Yershov[1,2], and Jeroen van den Brink[1] — [1]Leibniz Institute for Solid State and Materials Research, 01069 Dresden, Germany — [2]Bogolyubov Institute for Theoretical Physics of the National Academy of Sciences of Ukraine, 03143 Kyiv, Ukraine

Being collinear-compensated magnets, altermagnets differ from conventional antiferromagnets by a more complex symmetry transformation that connects two sublattices. Due to the specific local nonmagnetic surroundings of the magnetic atoms, the symmetry transformation also involves rotation or mirror reflection, in addition to translation and time reversal. Here we propose Heisenberg models for a number of materials, including d-wave (rutiles), bulk g-wave (CrSb, MnTe), and planar g-wave (FeS2) alternagnets. The models capture the altermagnetic properties due to the additional superexchange interactions whose bonds orientations respect the symmetry of the local nonmagnetic surrounding of the magnetic atoms. Using our models, we reproduce the altermagnetic splitting in the magnon spectra, and predict a number of new effects induced by altermagnetism, namely fluctuation-induced piezomagnetism and thermal spin conductivity for d-wave altermagnets, and emergent magnetization of domain walls for both d- and g-wave altermagnets. For planar g-wave altermagnets, we demonstrate that mechanical stress can induce the effective g-wave – d-wave

transition for low-energy magnons. As a result, the stress-induced thermal spin conductivity appears.

MA 2.12 Mon 12:30 HSZ/0004

Multiferroic altermagnet $BiFeO_3$ investigated by DFT+DMFT and XMCD — •Hamza Zerdoumi, Ruiwen Xie, Fu Li, and Hongbin Zhang — Institute of Materials Science, TU Darmstadt, 64287 Darmstadt, Germany

As an emergent magnetic ordering, altermagnets with finite non-relativistic spin splitting exhibit a wide spectrum of fascinating properties. In this work, combining density functional theory (DFT) and dynamical mean-field theory (DMFT), we investigate how such splitting evolves as a function of temperature in $BiFeO_3$. Moreover, by solving the DFT-derived atomic Hamiltonian, we evaluated x-ray magnetic circular dichoism (XMCD) with detailed symmetry analysis, which can be considered as a characteristic feature for altermagnetic ordering. Furthermore, as $BiFeO_3$ is a well-established multiferroic compound, we evaluate the nonlinear transport properties such as shift current originated from the quantum geometry, and further explore how such altermagnetic properties can be tailored by external electric fields.

Twisted planar freestanding La0.7Sr0.3MnO3 junctions — •Alejandro Martín Merodio, Victor Rouco, Fernando Gallego, David Sanchez-Manzano, Carlos León, and Jacobo Santamaria — GFMC, Dpto. de Física de Materiales, Facultad de Ciencias Físicas, Universidad Complutense de Madrid, 28040 Madrid, Spain

The recent realization of membranes of transition metal oxides has enabled their mechanical assembly in twisted bilayers opening avenues to wards oxide twistronics. The ferroic orders hosted by transition metal oxides, many of which are stable at room temperature, offer exciting opportunities for the search of chiral ferroic properties in twisted ox ide membranes. In this work we present the growth, fabrication and characterization of twisted stacks made of La0.7Sr0.3MnO3 (LSMO), a half-metallic ferromagnetic perovskite with highly tunable properties. We have studied the temperature dependent magnetotransport across the interface of two twisted LSMO membranes for different twisting angles. These samples exhibit a large low temperature magnetoresistance MR up to 32% which switches abruptly at small (10 mT) magnetic fields. These MR values are well above the 0,01% AMR typically observed in single LSMO flakes. This approach allows exploring material combinations which are not possible in epitaxial heterostructures and opens promising avenues towards oxide based CMOS compatible spintronic devices.

MA 3.2 Mon 9:45 POT/0112

Controlling Magnetic Anisotropy in Barium Hexaferrite by Cation Doping — •Jakob Baumsteiger[1,2] and Cesare Franchini[1,2] — [1]Faculty of Physics and Center for Computational Materials Science, University of Vienna, Vienna, Austria — [2]Department of Physics and Astronomy "Augusto Righi", Alma Mater Studiorum - Università di Bologna, Bologna, Italy

Circulators are essential components in many radio-frequency systems, including 5G base stations. Their operating frequency is primarily determined by the magnetic properties of the ferrite core - specifically the anisotropy field and the saturation magnetization. Experimental studies suggest that both quantities can be actively modified in barium hexaferrite - one of the ferrites commonly used in circulators - through cation doping. However, the relationship between doping and the resulting magnetic properties is highly complex and not yet fully understood. We investigate the electronic structure of pristine and cobalt-doped barium hexaferrite using density functional theory. Our calculations show that the additional electron introduced by cobalt plays a key role in modifying the material's magnetocrystalline anisotropy. By occupying a localized orbital at the cobalt site, it locally activates spin-orbit interactions, leading to substantial changes in the magnetocrystalline anisotropy energy even at low doping concentrations. The insights gained from our results support the design of miniaturized circulators capable of operating over broad frequency bands.

MA 3.3 Mon 10:00 POT/0112

Emergent magnetic ordering in high-entropy oxides — •Laura T. Corredor[1,2], Augustè Stanionytė[3], Richard Matyšek[3], Anja U. B. Wolter[4], Carlos F. Eugenio[2,5], Andrea Kirsch[2,5], Giuditta Perversi[6], and Anna Isaeva[1,2,3] — [1]TU Dortmund University, Germany — [2]Research Center Future Energy Materials and Systems, Germany — [3]University of Amsterdam, The Netherlands — [4]Leibniz IFW Dresden, Germany — [5]Ruhr University Bochum, Germany — [6]Maastricht University, The Netherlands

Magnetism in high-entropy oxides (HEOs) has emerged as a compelling topic due to the unique behavior arising from extreme cationic disorder. HEOs offer a rich platform for fundamental studies and are promising for applications like energy-efficient magnetic devices and catalysts. Recently, long-range magnetic order was reported in some HEOs, e.g. the AFM rocksalt $(Co_{0.2}Ni_{0.2}Cu_{0.2}Mg_{0.2}Zn_{0.2})O$[1] and cubic perovskite $La(Cr_{0.2}Mn_{0.2}Fe_{0.2}Co_{0.2}Ni_{0.2})O$[2], demonstrating that HEOs can host long-range magnetic order despite substantial chemical disorder. We present the exploration of magnetism across three HEO families: (1) cubic perovskites $BaIn_{1-x}M_xO_{3-\delta}$[3], (2) spinel M_3O_4 and (3) rocksalt MO. The M site is shared by up to five (post-)transition metals. Some members of the M_3O_4 family exhibit remarkably high T_N up to 618 K, highlighting its potential for stabilizing robust magnetic interactions. In contrast, $BaIn_{1-x}M_xO_{3-\delta}$ display glassy behavior. We examine how chemical complexity shapes magnetic properties across these families. [1] Chem. Mat. 2019 31 (10), 3705-3711. [2] Adv. Sci. 2022, 9, 2200391. [3] Solid State Ionics (2024) 427, 116901.

Exploring the electronic structure of (111)-oriented $La_{0.7}Sr_{0.3}MnO_3$ through soft X-ray ARPES and DFT — •Øyvind Finnseth, Sverre M. Selbach, Hendrik Bentmann, and Ingrid Hallsteinsen — NTNU, Trondheim, Norway

While $La_{0.7}Sr_{0.3}MnO_3$ (LSMO) has been widely studied due to its room-temperature ferromagnetism and half-metallicity, the majority of work has been focused on thin films in the (001)-orientation. The less conventional (111)-orientation has received far less attention despite its distinct intriguing properties, including sixfold in-plane magnetic anisotropy and enhanced interfacial coupling in heterostructures. As such, a full description of the electronic structure of LSMO in this orientation is lacking. Here, we consider epitaxial thin films of LSMO grown by pulsed laser deposition on (111)-oriented $SrTiO_3$ substrates. We first develop an in-vacuum methodology for surface preparation of the films by annealing in an oxygen atmosphere. The electronic band structure of the films is probed by soft X-ray angle-resolved photoemission spectroscopy (ARPES) using a synchrotron lightsource. The tunability of the photon energy allows for precise control of the probed out-of-plane momentum, yielding a full description of the LSMO electronic band structure. Density functional theory (DFT) calculations are performed to obtain the theoretical band structure of bulk LSMO modeled through the use of the special quasirandom structures approach. By comparing the calculated band structure to the experimental results, we find that the DFT calculations are able to accurately predict the LSMO electronic band structure.

MA 3.5 Mon 10:30 POT/0112

Unveiling the Origins of Strong Magnetostriction in Cobalt Ferrite using neutron scattering. — •Guratinder Kaur — School of Physics and Astronomy, The University of Edinburgh, UK

Cobalt ferrite (CoFe2O4, CFO) stands out among advanced functional materials due to its exceptional magnetostrictive behaviour. This property allows its shape to be influenced by its magnetic state, making it desirable for various technological applications such as electronic devices, ferrofluids, magnetic drug delivery, microwave devices, and high-density information storage1-3. The present study provides a comprehensive investigation using neutron diffraction to explore the interplay between CFO's nuclear and magnetic structures4 across varying temperatures. This study complements our recent inelastic neutron scattering (INS) experiments on single crystal and powder samples. The combined data, along with our INS findings and developed excitonic theory, will provide a deeper understanding of the underlying mechanism responsible for CFO's strong magnetostrictive effect5. This knowledge will be valuable for designing novel materials with precisely controlled magnetostrictive properties for applications in areas like sensors and actuators6. Polarized Neutron Scattering Studies on SDW Order in $Sr_{1.5}Ca_{0.5}RuO_4$ and $Sr_2Ru_{0.95}Co_{0.05}O_4$ — •Felix Wirth[1], Yvan Sidis[2], Paul Steffens[3], Kevin Jenni[1], Agustinus Agung Nugroho[4], Karin Schmalzl[5], Mechthild Enderle[3], and Markus Braden[1] — [1]II. Physic. Inst., Univ. Cologne, Germany — [2]LLB, CEA Saclay, France — [3]ILL, Grenoble, France — [4]Inst. Teknologi, Bandung, Indonesia — [5]JCNS Outst. ILL, Grenoble, France

Superconductivity in Sr_2RuO_4 emerges close to magnetic instabilities from Fermi-surface nesting at incommensurate $Q^{\alpha\beta}$ ≈(0.3,0.3,L) and Q^{γ} ≈(0.15,0.15,L)[1]. In $Sr_{1.5}Ca_{0.5}RuO_4$ the anisotropic fluctuations at $Q^{\alpha\beta}$

condense into a c-axis polarized spin-density-wave[2]. Polarized inelastic neutron scattering reveals an unusual hierarchy of excitations with enhanced longitudinal modes. In contrast, transverse modes are suppressed, although their energy dependence remains similar to that of the parent compound. Above the SDW transition, longitudinal and transverse contributions show a split response, incompatible with tetragonal symmetry and suggestive of electronic nematicity. Ti^{4+} and Mn^{3+} substitution stabilise the same static order at $Q^{\alpha\beta}$[3]. By contrast, 5% Co doping does not yield the expected ferromagnetic cluster glass but a new magnetic order at Q≈(0.2,0.2,0) with intensity following the Ru^{4+} form factor that cannot be attributed to the known nesting vectors in this system. [1] Jenni, K. et al., Phys. Rev. B 103, 104511 (2021), [2] Kunkemöller, S. et al., Phys. Rev. B 89, 045119 (2014), [3] Braden, M. et al., Phys. Rev. Lett. 88, 197002 (2002)

Magnetic structure and magnetic excitations of the triple layer $Sr_4Ru_3O_{10}$ — •Lara Kiefer[1], Zahrasadat Ghazinezhad[1], Felix Wirth[1], Jens Mettler[1], Ursula Bengaard Hansen[2], Paul Steffens[2], Oksana Zaharko[3], Vladimir Pomjakushin[3], Karin Schmalzl[4], Devashibhai Adroja[5], Augustinus Agung Nugroho[6], and Markus Braden[1] — [1]Inst. Phys. 2, Cologne, Germany — [2]ILL, Grenoble, France — [3]PSI, Villingen, Switzerland — [4]JCNS Out. ILL, Grenoble, France — [5]ISIS, Didcot, UK — [6]FMIPA ITB, Badung, Indonesia

The triple-layer transition-metal oxide $Sr_4Ru_3O_{10}$ is a member of the Ruddlesden-Popper series with a layered orthorhombic structure. It is a ferromagnetic metal (T_C=105 K) with an additional metamagnetic transition below 60 K. The nature of the intermediate phase is still under debate. Using multiple neutron diffraction techniques, we were able to determine its magnetic structure. Our inelastic neutron experiments revealed a parabolic, isotropic dispersion with a stiffness constant comparable to that of $SrRuO_3$ [1,2]. However, the spin-wave scattering at low constant energy transfer deviates from the expected isotropic ring, and the stiffness increases upon heating, mirroring $SrRuO_3$ [1,2]. Polarized neutron measurements reveal longitudinal spin excitations inside the ferromagnetic phase. These amplitude-type fluctuations are unexpected in a standard Heisenberg ferromagnet, suggesting the emergence of a new class of magnetic excitations beyond conventional transverse magnons. [1] K. Jenni et al., Phys. Rev. B 107, 174429 (2023). [2] K. Jenni et al., Phys. Rev. Lett. 123, 017202 (2019).

MA 3.8 Mon 11:30 POT/0112

Multi-length scale investigation of the Perovskite-Brownmillerite topotactic phase transition in $La_{0.7}Sr_{0.3}MnO_{3-\delta}$ thin films — •C. Yin[1,2], X. Bai[3], Z. Xu[4], V. Lauter[5], S. Zhou[6], F. Gunkel[7], L. Cao[2,8], G. Puebla Hellmann[4], R.E. Dunin-Borkowski[3], and O. Petracic[2,1] — [1]Faculty of Mathematics and Natural Sciences, Heinrich Heine University Düsseldorf — [2]Jülich Centre for Neutron Science (JCNS-2), JARA-FIT, Forschungszentrum Jülich GmbH — [3]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons (ER-C), JARA-FIT, Forschungszentrum Jülich GmbH — [4]QZabre LLC, Zürich, 8050, Switzerland — [5]Neutron Scattering Division, Neutron Sciences Directorate, Oak Ridge National Laboratory, Oak Ridge, TN, 37831, USA — [6]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf (HZDR) — [7]Peter Grünberg Institut (PGI-7), JARA-FIT, Forschungszentrum Jülich GmbH — [8]School of Advanced Materials, Peking University, Shenzhen Graduate School, Shenzhen, 518055, China

In $La_{0.7}Sr_{0.3}MnO_{3-\delta}$, the introduction of oxygen vacancies induces a topotactic phase transition from the perovskite phase to an oxygen-vacancy ordered Brownmillerite phase. The influence of oxygen vacancies on near-surface magnetic domains is probed via Nitrogen-Vacancy (NV) magnetometry. Polarized Neutron Reflectometry (PNR) provide depth-resolved magnetization profiles and oxygen stoichiometry. Scanning Transmission Electron Microscopy (STEM) elucidates the atomic structure and depth-dependent oxidation states.

Probing Spin-Waves and Spin-Phonon Coupling in a Double Perovskite Oxide: A Raman Study — •Akriti Singh and Surajit Saha — Indian Institute of Science Education and Research Bhopal, Bhopal, India

Double perovskites have emerged as a promising class of materials to explore the novel magnetic phenomena. This includes high-TC magnetic orderings, spin-reorientation, magnetostriction, and multiferroicity due to the presence of complex spin arrangements, competing exchange pathways or magneto-elastic couplings. Here, we report the evolution of magnetic excitations in Ca2NiWO6 using inelastic light scattering and explore the complex interplay between the lattice and spin degrees of freedom. To get insights into the underlying magnetic dynamics, we performed temperature-dependent magnetization, x-ray diffraction, and Raman spectroscopic measurements. Our results indicate an antiferromagnetic ground state below 50 K along with signatures of magnetostriction and spin-phonon coupling. Additionally, we employ magneto-Raman spectroscopy to probe the low-energy spin-waves (magnons), providing evidence of the nature and origin of magnetism in the system. Taken together, our findings on Ca2NiWO6 highlight its potential as a fertile ground to study the complex magnetic phenomena arising due to its exchange interactions, suggesting that it may be a possible candidate for applications in spintronics, magnonics, and other advanced spin-based technologies.

MA 3.10 Mon 12:00 POT/0112

resonant inelastic x-ray scattering spectra of the dynamic jahn-teller Cu^{2+} center in $CuAl_2O_4$ — •Takumi Gengo[1], Kenta Touge[2], Ara Go[3], and Naoya Iwahara[1] — [1]Graduate School of Engineering, Chiba University, Chiba, Japan — [2]Department of Materials Science, Faculty of Engineering, Chiba University, Chiba, Japan — [3]Department of Physics, Chonnam National University, Gwangju, South Korea

Cu spinel compounds such as $CuAl_2O_4$ and $CuGa_2O_4$ attract attention as spin-orbit entangled magnets. The density mean-field theory calculations show that the spin-orbit coupling on the Cu site suppresses the Jahn-Teller deformation in the ground state, which is consistent with the x-ray diffraction data. On the contrary, recent resonant inelastic x-ray scattering (RIXS) measurement of $CuAl_2O_4$ suggests the possibility that the Jahn-Teller deformation develops. Such a contradictory situation could occur due to the development of the dynamic Jahn-Teller effect .

This study aims to theoretically elucidate the nature of quantum states on Cu sites induced by the competition between spin-orbit and electron-phonon (vibronic) couplings. We successfully reproduced the Cu L_2- and L_3-edge RIXS spectra based on our model with the quantum mechanical treatment of the lattice degrees of freedom (i.e., dynamic Jahn-Teller effect), which is consistent with the structural data. This study supports the former theoretical prediction that $CuAl_2O_4$ is a 3d spin-orbit coupled magnet.

MA 3.11 Mon 12:15 POT/0112

EMCD analysis of ferrimagnetic moments changes in Ti-doped barium hexaferrite — •Hitoshi Makino[1], Rolf Erni[2], Devendra Singh Negi[3], Ján Rusz[4], Bernd Rellinghaus[1], and Darius Pohl[1] — [1]DCN, TU Dresden, Dresden, Germany — [2]Empa, Swiss Federal Laboratories for Materials Science and Technology, Dübendorf, Switzerland — [3]Indian Institute of Technology Jodhpur, Jodhpur, India — [4]Uppsala University, Uppsala, Sweden

Barium hexaferrite ($BaFe_{12}O_{19}$) is a robust permanent magnet material with good thermal and environmental stability. Small substitutions of Fe by Ti are known to enhance the coercivity at elevated temperatures. Our goal is to reveal changes of the ferrimagnetic arrangement of the moments by the Ti doping using electron energy-loss magnetic chiral dichroism (EMCD), an element- and site-specific probe of magnetic moments via electron energy-loss spectroscopy (EELS). We modified a highly accurate classical EMCD methodology with an improved signal-to-noise ratio, enabling the quantitative deconvolution of the Fe-$L_{2,3}$ edges into oxidation- and site-resolved magnetic contributions. The results suggest that the magnetic structure changes primarily at the tetrahedral site. Using the recently established atomic-resolution electron vortex beam EMCD, we verified these results from an alternative perspective. These measurements reveal a threefold supersymmetry in the magnetic-moments, consistent with the symmetry of the site occupied by Ti substitution identified in the STEM-EELS elemental map. These observations deepen our understanding of magnetic structure changes induced by Ti doping in barium hexaferrite.

MA 3.12 Mon 12:30 POT/0112

Long-range spin density wave order in bilayer nickelates revealed by neutron diffraction — •Igor Plokhikh — TU Dortmund University, Department of Physics, 44227 Dortmund, Germany — Research Center Future Energy Materials and Systems, 44227 Dortmund, Germany

The observation of pressure-induced superconductivity in Ruddlesden Popper nickelates has triggered renewed interest in their magnetic ground states as potential precursors to unconventional superconductivity [1]. Using high-intensity neutron powder diffraction (NPD) complemented by muon-spin rotation/relaxation (μSR), we directly resolve long-range spin-density-wave (SDW) order in bilayer $La_3Ni_2O_7$ and $La_2PrNi_2O_7$ below 150 K [2].

Magnetic Bragg reflections appear at propagation vectors $q_1 = (0, \frac{1}{2}, 0)$ for both compounds and an additional vector $q_2 = (\frac{1}{2}, \frac{1}{2}, 0)$ exclusively in undoped $La_3Ni_2O_7$. Representation analysis reveals amplitude-modulated SDW structures composed of alternating low- (≈ 0.05 μ_B) and high-moment (≈ 0.7 μ_B) Ni sites forming antiferromagnetically stacked bilayers along the c-axis. The coexistence of two distinct stacking polymorphs corresponding to q_1 and q_2 reflects quasi-two-dimensional magnetic order intrinsic to this system.

These findings provide the first direct neutron evidence for SDW order in bilayer nickelates and offer crucial insights into their ground state.

MA 4: Focus Session: Novel mechanisms of ferroic switching (joint session MA/FM)

This focus session highlights recent advances in ferroic switching across ferroelectric, multiferroic, ferroaxial and magnetic systems. Topics include topologically protected order-parameter dynamics, ultrafast non-thermal switching, and complex domain-wall phenomena revealed by atomistic modeling, ultrafast optics and advanced imaging. Contributions span machine-learning-based simulations of domain kinetics, optical control of ferroaxial and structural orders, multiferroic multi-cell memory concepts, and theoretically predicted unidirectional domain-wall motion with time-crystal behavior. Together, these works uncover new switching pathways and robust functional mechanisms, offering promising routes toward energy-efficient memory and quantum devices.

From ML to Kinetics: Modeling the Switching in Ferroelectric Wurtzites — •Andrew Rappe, Drew Behrendt, Atanu Samanta, and Von Braun Nascimento — Department of Chemistry, University of Pennsylvania, Philadelphia, PA 19104-6323 USA

We present a series of works, from the development of a new force field (MLFF) for multi-scale simulations of bulk AlN, through application of MLFF to understand the atomistic switching mechanism, to the development of a new kinetic model to uncover how switching changes as a function of experimental conditions.

We train our MLFF to 1000s of DFT calculations, so the underlying calculations are as accurate as DFT with the flexibility in simulation size of classical MD. Powered by the MLFF, we can predict the energies, forces, and phonon dispersions of AlN at dramatically lower cost, thus enabling the study of emergent and long-range effects, such as the frequency-dependent dielectric functions and multiple FE domains.

Applying the AlN MLFF, we uncover the atomistic mechanism of domain wall (DW) migration and domain growth in wurtzites. We find that the critical nucleus is a single broken Al-N bond along the polar axis; this creates a cascade of bond breaking in a single column of atoms due to the stability of the 180° DW in wurtzites. We reveal the switching mechanism of 1D atomic columns propagating from a slow-moving 2D fractal-like DW in the basal plane.

Finally, we develop an analytical extension to the KAI model that accounts for fractal FE domains. To do this, we take the traditional model of circles that can nucleate and grow and add a budding term.

Invited Talk MA 4.2 Mon 10:00 POT/0151

Topological order parameter switching — •Sergey Artyukhin — Quantum Materials Theory, Genova, Italy

Ferroic orders are widely used to encode information in data storage devices and may provide a beneficial way to circumvent Boltzmann tyranny affecting conventional MOSFET memory [1]. However, information writing involves order parameter switching, facilitated by domain nucleation and motion of domain walls across a disordered material, which leads to energy dissipation. Recently, an alternative order parameter switching paradigm has been introduced, where the ordered state tracking the free energy minimum continuously rotates the order parameter direction as the free energy surface is deformed by an external driving [2]. The process is analogous to Thouless pumping and is topologically protected. A related mechanism allows pumping of topological spin textures in space [3].

Invited Talk MA 4.3 Mon 10:30 POT/0151

Optical Control of Ferroaxial Order via Circular Phonon Excitation — •Zhiyang Zeng[1,2], Michael Först[1], Michael Fechner[1], Dharmalingam Prabhakaran[2], Paolo Radaelli[2], and Andrea Cavalleri[1,2] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Department of Physics, Clarendon Laboratory, University of Oxford, Oxford, United Kingdom

Ferroaxial order is a distinct ferroic order in crystal systems characterized by a rotational texture of electric dipoles. Its unique symmetry prohibits direct coupling to static fields or stress, making conventional control approaches ineffective.

Based on symmetry analysis, we identify a coupling between the ferroaxial order and circularly driven optical phonons, which can be resonantly excited with circularly polarized mid-infrared light. Exploiting this coupling, we experimentally achieve reversible, deterministic switching of the ferroaxial order in the prototype material RbFe(MoO4)2 using single-shot excitation.

This work establishes a new mechanism for manipulating ferroaxial order via light-driven phonons, enabling dynamic control of ferroic properties in complex materials.

MA 4.4 Mon 11:15 POT/0151

Coherent Control of Competing Structural Orders in SrTiO3 — •M. Fechner[1], H. Wang[2], M. Foerst[1], G. Orenstein[2], A. Disa[3], M. Trigo[2], and A. Cavalleri[1] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Stanford Pulse Institute, SLAC National Accelerator Laboratory, Menlo Park, CA, USA — [3]School of Applied & Engineering Physics, Cornell University, Ithaca, NY USA

The interplay between antiferrodistortive (AFD) rotation and polar instability prevents the formation of ferroelectric order in SrTiO3 yet keeps the paraelectric-to-ferroelectric transition on the verge of emerging. Light excitation has been shown to induce metastable ferroelectricity[1], but the response of the AFD order to such optical driving remains unclear. Here we use time-resolved X-ray scattering to track AFD-order dynamics, launched by mid-infrared excitation of the Ti-O stretching vibration, from 10 K to 135 K above the cubic transition. In the tetragonal phase below 110 K, the AFD order transiently increases before the AFD angle is reduced, whereas in the cubic phase rotational fluctuations initially grow before being strongly suppressed[2]. A unified lattice model, incorporating nonlinear coupling of the excited infrared phonon to the AFD mode and to strain, captures both regimes. With a single set of coupling parameters, we reproduce behaviors for both phases, indicating a common underlying mechanism that also constrains explanations for the light-induced ferroelectric state.

MA 4.5 Mon 11:30 POT/0151

Multi-cell unit storage based on a multiferroic — •Maksim Ryzhkov[1], Alexey Shuvaev[1], Maxim Mostovoy[2], Andrei Pimenov[1], Anna Pimenov[1], and Sergey Artyukhin[3] — [1]Institute of Solid State Physics, Vienna University of Technology, Vienna, Austria — [2]Zernike Institute for Advanced Materials, University of Groningen, Groningen, The Netherlands — [3]Quantum Materials Theory, Istituto Italiano di Tecnologia, Genova, Italy

Recent advances in multiferroic materials offer promising prospects for next-generation memory and data-processing devices. Previous studies [1,2] have shown that rare-earth manganates RMn_2O_5, particularly with R = Gd, are strong candidates for storage applications due to their topologically protected four-state magnetoelectric switching and the efficient electric-field control of this switching.

In this work, we demonstrate that this system enables the realization of a multi-cell storage unit capable of encoding and decoding at least five bits. We show that only two key ingredients are required:

(i) the four-state magnetoelectric switching observed during magnetic-field sweeps, and

(ii) a ferroelectric domain structure in the bulk together with local inhomogeneities (e.g., internal mechanical stresses) that produce a distribution of the spin-flop critical field H_c across different domains.

Thus, the magnetoelectric domains in $GdMn_2O_5$ are not an unwanted bug but an essential feature enabling multi-cell functionality.

MA 4.6 Mon 11:45 POT/0151

E-field induced unidirectional motion of domain wall in a ferromagnet and time crystals — •Margherita Parodi[1,2], Sergey Artyukhin[1], and Maxim Mostovoy[3] — [1]Quantum Materials Theory, Italian Institute of Technology, Genova, Italy — [2]Physics Department, University of Genova, Italy — [3]Theory of Condensed Matter, Zernike Institute for Advanced Materials, Groningen, The Netherlands

Noncollinear spin textures may break inversion symmetry and induce ferroelectric polarization, giving rise to multiferroicity. Here we study the most basic non-collinear spin texture: a domain wall in a collinear (anti)ferromagnet. The spin chirality of the domain wall is analogous to that in spiral multiferroics and like-

wise leads to ferroelectric polarization. Here we find that oscillating magnetic and electric fields can drive a unidirectional motion of the magnetic texture, similar to how electrons are transported by the Thouless pump. Furthermore, for certain periods of a driving field, the domain wall demonstrates complex behaviour akin to a time crystal, with the period equal to an integer multiple of the driving periods. The phenomenon arises due to a mismatch between the natural timescale of the domain wall motion and the driving field period.

MA 5.1 Mon 9:30 POT/0351

Impact of keV He-ion bombardment on the magnetic proximity effect in Pt/Fe bilayers — •Mika Ossenschmidt[1], Arne Vereijken[1], Yahya Shubbak[1], Varun Vanakalapu[1], Maik Gaerner[2], Arno Ehresmann[1], and Timo Kuschel[2] — [1]University of Kassel, Germany — [2]Bielefeld University, Germany

The static magnetic proximity effect (MPE) describes the occurrence of spin polarization at the interface of nominally paramagnetic materials caused by its adjacency to a ferromagnetic material. KeV-He light ion bombardment (IB) of thin-film interfaces offers the opportunity to modify the interface properties of thin-film systems without destroying the thin films, e.g., as shown for exchange-bias systems [1].

Samples of Pt 4 nm/Fe 10 nm//MgO(001) were fabricated by sputter deposition and the subsequent IB was performed with 10 keV He^+ ions with a varying ion dose from 10^{15} to 10^{17} ions/cm^2 in a few steps. To analyze the strength of the MPE in Pt, x-ray resonant magnetic reflectivity measurements were performed at the Pt L_3 absorption edge (11.567 keV) at DESY beamline P09 [2].

The fits of the x-ray reflectivity measurements provide a significant difference for the roughness σ of the Pt-Fe interface due to IB while substrate and surface roughnesses as well as layer thicknesses remained nearly unchanged. The resulting maximum Pt moment at the interface for the sample with IB is higher than without IB, due to the increasing intermixing of Pt and Fe atoms at the Pt-Fe interface.

Exchange splitting at surfaces: a new paradigm for spin-polarization in antiferromagnets — •William Schaarman and Sophie Weber — Chalmers University of Technology, Göteborg, Sweden

There has been recent interest in combining the robustness and ultrafast dynamics of antiferromagnets with the transport properties of spin-polarized band structures. While antiferromagnetic bands are typically spin-degenerate, exceptions to this rule such as the altermagnets have demonstrated the possibility to obtain spin polarization in bulk antiferromagnets via selective symmetry lowering. Here, we use symmetry analysis and density functional theory to examine a ferromagnetic-like exchange splitting at certain surfaces. Such spin polarization of the surface-projected band structure can occur for surface orientations with a net two-dimensional magnetization which can emerge via symmetry-lowering at the antiferromagnet's surface. By analyzing the band structure of a slab geometry projected onto a single surface, we confirm surface spin polarization in two representative materials, magnetoelectric Cr2O3 and altermagnetic FeF2. We rationalize the magnitudes of exchange splitting on distance surface orientations in these two materials as a complex interplay between the exchange and crystal field splittings of individual magnetic atoms making up the surface. Notably, our analysis shows the effect of surface exchange splitting can in some cases be of the order of eV which has important implications for spintronic devices.

MA 5.3 Mon 10:00 POT/0351

Image-potential states on a 2D Gr-ferromagnet hybrid: enhancing spin and stacking sensing — Maciej Bazarnik[1,2] and •Anika Schlenhoff[1,2] — [1]Institute of Physics, University of Münster, Germany — [2]Department of Physics, University of Hamburg, Germany

With the increasing research interest in 2D materials, image-potential states (IPSs) have regained attention as sensitive probes, e.g. for a charge transfer at buried graphene(Gr)-metal interfaces. For a Gr-ferromagnet hybrid, the question arises how IPSs sense a respective spin transfer laterally varying within the moiré heterostructure.

Here, we present spin-resolved scanning tunneling microscopy and spectroscopy studies on Fe intercalated Gr/Ir(111), that show the IPSs' sensitivity to the spatial variation of the Gr-Fe distance, and of the interfacial charge and spin transfer within the moiré unit cell [1]. A stacking contrast between fcc and hcp sites, indistinguishable in the direct tunneling mode, is provided by the IPSs. We observe a moiré-site- and energy-dependent spin-polarization of the IPSs that can be mapped across the entire moiré unit cell. Unlike the electronic states around the Fermi energy, the lowest IPSs are found to exhibit a high spin-polarization on the on-top sites attributed to their interfacial character at the respective Gr-Fe distance. Since the physisorbed Gr is only weakly spin-polarized on these sites, our work demonstrates that the lowest order IPSs can be used to locally sense the spin density at magnetic interfaces buried by a nonmagnetic passivation layer.

MA 5.4 Mon 10:15 POT/0351

Theoretical Investigation of Intrinsically Patterned 2D Transition Metal Halides: Defects, Structure, and Magnetic Phenomena — •Neeta Bisht[1], Andreas Görling[1], Feifei Xiang[2], Binbin Da[2], Mohammad Sajjan[2], Sabine Maier[2], and Christian Neiss[1] — [1]Lehrstuhl für Theoretische Chemie, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstraße 3, 91058 Erlangen

— [2]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen

In the quest for complex structured functional materials, defect engineering and patterning in two-dimensional (2D) systems are critical for tuning material properties and enabling new functionalities. Herein, we report on intrinsically patterned 2D transition metal dihalides (TMDs) on a gold surface, featuring periodic halogen vacancies in the upper and bottom halide layers that result in alternating coordination of the transition metal atoms throughout the film.

We explore the formation pathways leading to periodic halogen vacancies and their role in modifying the electronic and magnetic structure of TMDs. Our calculations also explores the possibility of non-collinear magnetic textures through the magnetic anisotropy calculations. The excellent match between the experimental findings and the DFT calculations, confirms the intrinsic vacancy lattice. By coupling our theoretical results with experimental observations, we provide a comprehensive framework for understanding the structure formation and magnetic properties of 2D materials.

MA 5.5 Mon 10:30 POT/0351

Magnetic domain structure of holmium films at low temperatures — •Patrick Härtl[1], Vijayalaxmi Sankeshwar[2], and Matthias Bode[1] — [1]Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — [2]Indian Institute of Science Education and Research(IISER), Pune, Maharashtra 411008, India

Rare-earth metals play a central role in modern magnetism, with their behavior largely governed by the element-specific sign and oscillation period of the RKKY interaction. However, real-space investigations of their complex magnetic domain structures remain scarce. Here, we present a systematic study of the structural and magnetic properties of epitaxial holmium (Ho) films grown on W(110), using low-temperature spin-polarized scanning tunneling microscopy (SP-STM).

Bulk Ho crystallizes in a hexagonal close-packed structure and exhibits an exceptionally large magnetic moment of approximately 10 μ_B, forming a helical spin spiral below T_C = 20 K. In our films, we find predominantly ferromagnetic in-plane domains for thicknesses up to about 50 atomic layers (AL), with domain walls strongly pinned to crystalline defects. For coverages above 50 AL, additional out-of-plane stripe domains emerge, which we attribute to the uncompensated c-axis magnetization of the helical cone state. Domain wall analysis reveals Néel-capped Bloch-type walls with characteristic widths of roughly ≈ 1.2 nm (60°), ≈ 3 nm (120°), and ≈ 4 nm (180°). The stripe domains are suppressed by out-of-plane magnetic fields of $\mu_0 H = \pm 300$ mT.

MA 5.6 Mon 10:45 POT/0351

Electronic bounds in magnetic crystals — •Daniel Passos[1] and Ivo Souza[1,2] — [1]Centro de Física de Materiales, Universidad del País Vasco, 20018 San Sebastián, Spain — [2]Ikerbasque Foundation, 48013 Bilbao, Spain

A quantum system in its ground-state must display non-negative optical absorption. This simple statement forms the basis for a string of inequalities between moments of the absorptive conductivity. Through the use of sum rules, these inequalities provide bounds on quantities of physical interest. Recent discoveries include new constraints on the electronic localization length in insulators, and an upper bound on the bandgap of topological insulators. Current research focuses on finding inequalities relating ground-state properties such as the quantum metric to more directly measurable quantities.

We present a systematic study of bound relations between different electronic properties of magnetic crystals: electron density, effective mass, orbital magne-

tization, localization length, Chern invariant, and electric susceptibility. New results include a lower bound on the electric susceptibility of Chern insulators, and an upper bound on the sum-rule part of the orbital magnetization. In addition, bounds involving the Chern invariant are generalized from two dimensions (Chern number) to three (Chern vector). Bound relations are established for metals as well as insulators, and are illustrated for model systems. The manner in which they approach saturation in a model Chern insulator with tunable flat bands is analyzed in terms of the optical absorption spectrum.

Hidden Dirac-Like Crossings in a Prototypical Topological Insulator — •Wei-Sheng Chiu[1,2], Ina Marie Verzola[3], Ying-Jiun Chen[1], Rovi Angelo Beloya Villaos[3], Claus Michael Schneider[1,2], Feng-Chuan Chuang[3], and Christian Tusche[1,2] — [1]Forschungszentrum Jülich, Germany — [2]Universität Duisburg-Essen, Germany — [3]National Sun Yat-sen University, Taiwan

The prototypical topological insulator Bi_2Se_3 has been extensively studied for its topological surface state characterized by a $\mathbb{Z}_2$ topological invariant. By using spin-resolving momentum microscopy with an Au passivated Ir(100) imaging spin filter, we simultaneously recorded the spin-resolved momentum maps (k_x, k_y) over entire surface Brillouin zone of Bi_2Se_3. In addition to the well-known Dirac cone near Fermi energy, we observe a sequence of several Dirac-like spin textures and crossings spanning binding energies down to 4 eV at the $\overline{\Gamma}$ point. Moreover, a Dirac-like crossing is also found at a binding energy 2.3 eV at the $\overline{M}$ point. Our first-principles calculations indicate that those overlooked bands are attributed to surface states. The Dirac-like crossing at the $\overline{M}$ point arises from crystalline-symmetry-enforced degeneracy at the high symmetry point, showing that Bi_2Se_3 has a more complex surface electronic structure than previously expected.

MA 5.8 Mon 11:30 POT/0351

Single domain spectroscopic signatures of a magnetic Kagome metal — •Lukasz Plucinski[1], Gustav Bihlmayer[1], Yuriy Mokrousov[1], Yishui Zhou[2], Yixi Su[2], Jonathan Denlinger[3], Aaron Bostwick[3], Christopher Jozwiak[3], Eli Rotenberg[3], Dmitriy Usachov[4], and Claus M. Schneider[1] — [1]FZ Jülich — [2]JCNS/MLZ Garching — [3]ALS/LBNL Berkeley — [4]DIPC San Sebastian

We investigate the magnetic Kagome metal $DyMn_6Sn_6$ using high-resolution micro-focused circular-dichroic angle-resolved photoemission (μ-CD-ARPES) to probe its magnetic and electronic properties. By tuning the kinetic energy to various features of the Dy $4f$ multiplet, we resolve magnetic domains in samples cryo-cooled down to 20 K. Smaller, but clear signatures are detected in the Mn $3p$ levels. The behavior of both Dy $4f$ and Mn $3p$ features are in remarkable agreement with our modeling based on the Hartree-Fock method, revealing ferrimagnetic alignment of Dy and Mn local moments, and further strengthening our interpretation. Adjusting the energy to the Mn $3d$-dominated valence bands reveals signatures which we relate to the orbital magnetization through a comparison to *ab initio* electronic structure calculations. Our study establishes the spectroscopic access to a single magnetic domain in a Kagome metal, paving the way for further research into imaging magnetic phases of novel magnetic materials using μ-CD-ARPES. Preprint is available at https://arxiv.org/abs/2507.12085.

Topologically non-trivial Kondo insulating state in graphene nanoribbons — •Amogh Kinikar[1,2], Guangze Chen[3], Yanwei Gu[4], David Jacob[5,6], Joaquín Fernández-Rossier[7], Gonçalo Catarina[2], António T. Costa[7], Oliver Gröning[2], Carlo Antonio Pignedoli[2], Klaus Müllen[4], Pascal Ruffieux[2], Jose L. Lado[8], Akimitsu Narita[4], and Roman Fasel[2,9] — [1]KIT, Karlsruhe, Germany — [2]Empa, Dübendorf, Switzerland — [3]Chalmers University of Technology, Gothenburg, Sweden — [4]MPIP, Mainz, Germany — [5]UPV/EHU, San Sebastián, Spain — [6]Basque Foundation for Science,Bilbao, Spain — [7]INL, Braga, Portugal — [8]Aalto University, Espoo, Finland — [9]University of Bern, Bern, Switzerland

Metallic rare-earth alloys display characteristic correlated electron phenomena due to interactions between electrons which give rise to a narrow heavy-fermion band near the Fermi level that hybridizes with the metallic band and opens a hybridization gap. When the Fermi level falls within this gap the system forms a Kondo insulator, which can also acquire a topologically non-trivial character. Here we provide evidence for a topological Kondo insulating state in a specific atomically precise graphene nanoribbon synthesized on Au(111) by on surface methods and characterized by scanning probe microscopy. We observe a sharp resonance near the Fermi level and a pronounced zero-bias peak at the ribbon termini. We show that these spectroscopic signatures are a fingerprint of a topological Kondo insulating state in this graphene nanoribbon.

Nanoscale Dipolar Fields in Artificial Spin Ice Probed by Scanning NV Magnetometry — •Ephraim Spindler[1], Vinayak Shantaram Bhat[2], Elke Neu[1], Mathias Weiler[1], and M. Benjamin Jungfleisch[2] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU in Kaiserslautern, Germany — [2]Department of Physics & Astronomy, University of Delaware, Newark, USA

Artificial spin ices (ASI) offer a versatile platform to study frustration and collective spin dynamics in engineered magnetic lattices. We employ scanning probe microscopy based on a single nitrogen-vacancy (NV) center in diamond - a non-invasive, nanoscale quantum sensing technique - to study two square-lattice ASI systems with varied inter-element coupling strengths.

We use NV fluorescence quenching for rapid state determination and continuous-wave optically detected magnetic resonance to quantitatively map magnetic stray fields and extract vectorial dipolar field information. We fit the experimentally determined field components to micromagnetic simulations to infer local magnetic configurations in an iterative procedure.

These micromagnetic modeling results demonstrate that our method successfully quantifies the deviation between the expected and detected dipolar coupling field strengths, which we describe using an effective saturation magnetization. We show that the subtle magnetization tilt induced by small external fields is detectable and quantifiable through its impact on the local dipolar stray fields in the ASI.

MA 6.2 Mon 9:45 POT/0361

Probing nanoscale magnetic phenomena with cryogenic scanning NV magnetometry — •Mirko Bacani[1], Clemens Schäfermeier[1], Ankit Sharma[1], Christopher Kelvin von Grundherr[1], Dieter Andres[1], Khaled Karrai[1], Gabriel Puebla-Hellmann[2], Jan Rhensius[2], Andrea Morales[2], and Florian Otto[1] — [1]attocube systems GmbH , Haar, Germany — [2]QZabre AG, Zurich, Switzerland

Emerging technologies increasingly rely on precise control and understanding of magnetic phenomena at the nanoscale and cryogenic temperatures. NV magnetometry offers a unique approach, combining quantum sensing with scanning probe precision to achieve magnetic field mapping at resolutions and sensitivities beyond conventional limits. We present cw-ODMR imaging of materials hosting emergent quantum and topological magnetic phenomena, including Abrikosov vortices in BSCCO and YBCO, interlayer domain textures in twisted bilayer CrSBr, magnetic domains in skyrmions-hosting Ir/Fe/Co/Pt multilayers, and meronic spin textures in synthetic antiferromagnets.

The imaging was performed by the cryogenic scanning NV magnetometer integrated into a closed-cycle cryostat with turnkey operation from 2-300 K. The system reaches the sensitivity of 3 uT/sqrt(Hz) with automated ODMR for quantitative stray-field mapping. These results exemplify the versatility of cryogenic NV magnetometry as a tool for probing superconductivity, correlated magnetism, and emergent spin textures in quantum materials.

Switchable magnetic nanowire probes for differential magnetic force microscopy — Florian Sandbaumhüter[1,2], •Aniruddha Sathyadharma Prasad[1,2], Rachappa Ravishankar[1,2], Volker Neu[1], Bernd Büchner[1,2], and Thomas Mühl[1] — [1]IFW Dresden — [2]TU Dresden

Recent work on magnetic force microscopy (MFM) has highlighted the need to implement a differential MFM technique to better eliminate interfering electrostatic and topographical crosstalk from MFM images. In addition, the use of specialized MFM probes containing iron-filled carbon nanotubes (FeCNTs) as the sensing element has enabled easy quantitative imaging of magnetic fields and field gradients [1]. In this talk, we demonstrate in-situ differential MFM in a reversed tip-sample arrangement. This is based on our switchable magnetic probes which consist of FeCNTs attached to micron-sized electromagnets, i.e. planar microcoils [2]. The large field gradients of these microcoils make sure that there is only a minimal effect on the sample being measured. Furthermore, the highly inhomogeneous fields produced by our microcoils also provide a new playground for studies of domain wall motion in ferromagnetic nanowires.

MA 6.4 Mon 10:15 POT/0361

Magnetic Vector Tomography of Thick Chiral Magnets — •Polly Mitchell[1], Claire Donnelly[1,3], Luke Turnbull[2], Jeffrey Neethirajan[1], Rikako Yamamoto[1,3], Marina Raboni Ferreira[1], Burkhard Kaulich[2], and Luke Higgins[2] — [1]MPI CPfS, Dresden, Germany — [2]Diamond Light Source, Harwell Campus, Didcot, UK — [3]SKCM[2] Hiroshima University, Hiroshima, Japan

Complex three-dimensional (3D) textures such as Bloch points, chiral bobbers and hopfions form in chiral magnets through the interplay between Dzyaloshinskii-Moriya and exchange interactions. The 3D nature of such structures provides advantages such as higher degrees of freedom, and the potential for volume-based information encoding. However, the investigation of thick samples presents a number of challenges: first, whether the cancellation of opposing magnetic vectors through the sample will hinder the 3D reconstruction, and second, the high absorption of soft x-ray and electron microscopies. Here we address both challenges, obtaining experimental insight into the 3D configuration of thick chiral magnets. By performing numerical simulations of magnetic vector tomography, we find that increased angular sampling mitigates vector cancellation, allowing accurate high-resolution 3D mapping of samples up to 3μm thick. Following this insight, we harness pre-edge phase soft X-ray ptychography to perform magnetic tomography of a 700nm thick $Co_8Zn_9Mn_3$ sample. In this way, we are able to recover the 3D magnetisation vector field of a thick chiral sample, demonstrating magnetic tomography as a robust technique to recover complex configurations in thick magnetic systems.

MA 6.5 Mon 10:30 POT/0361

Self-Consistent Magnetic Force Microscopy Simulator Framework — •Dominik Schramm[1], Claas Abert[2], Jakub Jurczyk[1], and Amalio Fernández-Pacheco[1] — [1]Tu Wien — [2]Universität Wien

With the advancement in 3D nanofabrication techniques such as Focused Electron Beam Induced Deposition (FEBID), manufacturing of complex magnetic nanostructures emanating more complex stray fields becomes feasible. [1] To quantify these fields, the development of a modified Vector- Magnetic Force Microscope (MFM), resolving all three spatial components of the stray field while still maintaining industrial feasibility, is targeted.

To design an optimized MFM tip, the micromagnetic simulation framework Neuralmag is leveraged to simulate an MFM signal. The simulator allows us to self-consistently study the impact of tip geometry, inclination angle, magnetic state as well as additional oscillatory modes not only on the output, but also on the magnetic states of tip and sample themselves. Furthermore, the simulator is employed to simulate MFM along a topographically non-trivial sample surface.

MA 6.6 Mon 10:45 POT/0361

Toward 3D magnetic force microscopy: Simultaneous torsional cantilever excitation to access a second, orthogonal stray field component — •Jori F. Schmidt[1], Lukas M. Eng[1,2], and Samuel D. Seddon[1] — [1]TU Dresden, Institute of Applied Physics, Nöthnitzer Strasse 61, 01187 Dresden, Germany — [2]ct.qmat: Dresden-Würzburg Cluster of Excellence EXC 2147, TU Dresden, 01062 Dresden, Germany

Magnetic Force Microscopy (MFM) is a technique for recording maps of the magnetic stray field above a sample, as is for instance well documented for skyrmions. The magnetized tip usually couples to the out-of-plane magnetic sample stray field through cantilever oscillations perpendicular to the sample surface. Nevertheless, the stray field has a 3-dimensional distribution, the reconstruction of which has not been widely performed so far due to the uniaxial sensitivity of standard MFM.

Here, we introduce a novel way towards experimentally mapping the full 3D sample stray field, by simultaneously oscillating the MFM cantilever at its vertical (out-of-plane) and lateral (in-plane) fundamental resonance frequencies, thus making it possible to directly compare and quantify the vertical MFM (V-MFM) and the lateral MFM (L-MFM) signals. We have tested this novel setup for its overall performance and signal-to-noise ratio, using a hard disk with known magnetization, where a good agreement was found between experimental results.[1]

Hamiltonian reverse engineering from magnetic skyrmion images via deep learning surrogates — •Moritz Winterott[1,2] and Samir Lounis[3] — [1]Peter Grünberg Institut, Forschungszentrum Jülich & JARA, Germany — [2]Faculty of Physics, University of Duisburg-Essen, Germany — [3]Institut für Physik and Halle-Berlin-Regensburg Cluster of Excellence CCE, Martin-Luther Universität Halle-Wittenberg, Germany

The extraction of physical parameters from experimental observations is a central inverse problem in condensed matter physics. Complex magnetic textures such as skyrmions are imaged via Scanning Tunneling Microscopy (STM), which probes the local density of states (LDOS). Inferring the underlying interactions by matching theoretical models to experimental LDOS is often computationally expensive. In this work, we introduce a deep-learning framework that serves as a fast and accurate surrogate for this modeling process. Our approach employs a novel neural network architecture that integrates modern Transformers[1,2] with Convolutional Neural Networks (CNNs) to extract spatial features from energy-resolved LDOS images and to learn the highly nonlinear mapping to the parameters of an effective tight-binding Hamiltonian. These parameters encode the skyrmion texture, hopping amplitudes, and spin-orbit coupling strengths. Also, on-the-fly noise augmentation during training enhances robustness, enabling the model to maintain high accuracy even for noisy experimental data.

Can a Quantum Computer Simulate Nuclear Magnetic Resonance Spectra Better than a Classical One? — •Keith R. Fratus, Nicklas Enenkel, Sebastian Zanker, Jan-Michael Reiner, Michael Marthaler, and Peter Schmitteckert — HQS Quantum Simulations GmbH, Karlsruhe, Germany

The simulation of the spectra measured in nuclear magnetic resonance (NMR) spectroscopy experiments is a computationally non-trivial problem, and as such, it represents a problem for which a quantum computer may provide some practical advantage over traditional computing methods. In order to understand the extent to which such problems may provide examples of useful quantum advantage, it is important to understand the limitations of existing classical simulation methods. In this talk, we present our classical solver designed to solve such problems, and benchmark its performance. We find that it performs well, even outside of the more typical experimental regimes, and discuss what implications this may have for future efforts to demonstrate quantum advantage in the context of NMR.

MA 6.9 Mon 11:45 POT/0361

From imaging static magnetic fields to characterization of GHz magnetic noise - multi-method magnetometer comprising NV, MFM and MOKE — •Nele Harnack, Björn Josteinsson, Andrea Morales, Simon Josephy, and Gabriel Puebla-Hellmann — QZabre Ltd., Zürich (Switzerland)

Nanoscale imaging of static and GHz magnetic fields allows the in-depth study of phenomena like skyrmions, spin-waves and antiferromagnets. Experimental techniques include nitrogen-vacancy (NV) magnetometry, magnetic force microscopy (MFM) and magneto-optic Kerr effect (MOKE) [1,2]. In NV magnetometry, a spin defect in diamond serves as an atomic-scale sensor, delivering quantitative results and high resolution [3]. Here, we show how NV centers yield information complementary to MFM and MOKE - stray field and reconstructed magnetization - in a comparative study of BiYIG using the three techniques. The study is performed on a commercial microscope (QSM), enabling fast localization of the sample region when switching between modes. NV imaging provides insight beyond static field imaging [4]. Here we use scanning relaxometry (T1) to image the GHz magnetic noise present in the sample. The combination of methods enables an in-depth study of magnetic textures in BiYIG, with NV extending the capabilities of well-established techniques by measuring the coupling of the NV spin state to spin fluctuations in the material. Comm., 2021, 12, 767.

MA 6.10 Mon 12:00 POT/0361

Nanoscale mapping of magnetic orientations with complex x-ray magnetic linear dichroism — •Marina Raboni-Ferreira[1,2], Benedikt J. Daurer[3], Jeffrey Neethirajan[1], Andreas Apseros[4,5], Sandra Ruiz-Gómez[1,6], Burkhard Kaulich[3], Majid Kazemian[3], and Claire Donnelly[1,7] — [1]MPI CPfS, Dresden, Germany — [2]UNICAMP, Campinas, Brazil — [3]DLS, Didcot, UK — [4]ETH, Zurich, Switzerland — [5]PSI, Villigen, Switzerland — [6]ALBA, Barcelona, Spain — [7]WPI-SKCM2, Hiroshima, Japan

Compensated magnets are of increasing interest for both fundamental research and applications, as their net-zero magnetization enables ultrafast dynamics and robust order. To understand and control this order, nanoscale mapping of local domain structures is essential. Here, we combine X-ray magnetic linear dichroism (XMLD), a spectroscopic technique sensitive to the local Néel-vector orientation, with ptychography, a coherent X-ray imaging technique, to obtain high-resolution images of in-plane magnetic orientations in a model sample exhibiting a Landau pattern. By combining these techniques with an unsupervised machine learning approach, we retrieve the full complex XMLD spectrum of the sample, and map its magnetic domains with sub-100-nm resolution. Our results show that phase contrast is significantly stronger than the corresponding absorption contrast, offering higher spatial resolution imaging. This establishes phase contrast as a high-resolution mechanism for mapping magnetic orientations and paves the way toward higher-dimensional X-ray imaging, including Néel-vector orientation tomography of antiferromagnets.

MA 6.11 Mon 12:15 POT/0361

Development of in-house high-yield in-situ TEM chip production with magnetic thin-films — •Sindre Vie Jørgensen[1], Patrick R. B. Thomassen[1], Trond Hauklien[1], Marthe Linnerud[1], Asle Sudbø[1], David Barriet[1,2], and Magnus Nord[1] — [1]IFY, NTNU, Norway — [2]NYB Partner DA

Transmission Electron Microscopy (TEM) is a powerful tool for studying materials at the nanoscale. For future device materials, being able to apply a biasing voltage during TEM imaging is highly advantageous for observing magnetic domain responses at the nanoscale. We have developed a 'frontside-then-backside' method to create in-situ biasing TEM chips for as-deposited thin-film samples. This creates 100+ chips from a 4" Si wafer per production batch, which is highly customisable, allowing for multiple designs, TEM window dimensions, and circuit layouts simultaneously, with little variation in production time. This method has been tested with 20 nm thick, 5 um wide permalloy thin films with two narrow sections, 2,5 um wide, for a local increase in current density. Bias has been applied during magnetic Lorentz TEM (LTEM) to verify in-situ capabilities by shifting magnetic domain walls within the film via thermal excitation. This greatly expands the utility of the TEM for studying device-relevant magnetic materials, as simultaneous in-situ studies of the magnetics, structure and composition become possible.

MA 6.12 Mon 12:30 POT/0361

Scanning Magnetometry of van der Waals magnets under in-situ controlled strain — •Yuchen Zhao[1], José Claudio Corsaletti Filho[1], Chenhui Zhang[2], Yejin Lee[1], Young-Gwan Choi[1], Elina Zhakina[1], Hyunsoo Yang[2], Elena Gati[1], Claire Donnelly[1], and Uri Vool[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]National University of Singapore, Singapore, Singapore

In recent years, van der Waals (vdW) magnets have emerged as one of the promising research directions in the field of condensed matter physics. Due to their thin nature, vdW magnets are mechanically more flexible than their bulk counterparts, allowing them to withstand greater strain. Because strain distorts the lattice, it is expected to modify magnetic properties and may even stabilize new magnetic states. While magnetic imaging of vdW materials has so far been limited to small applied strains, achieving and visualizing magnetic textures under large strain remains a significant challenge. Here, we report a technique that enables large in-situ controlled strain engineering of vdW magnets under scanning probe microscopy at room temperature. We use a piezoelectric actuator-based uniaxial strain cell to strain Fe_3GaTe_2 flakes as a proof-of-principle example of our method. By incorporating this setup into the Magnetic Force Microscope (MFM), we can locally probe the influence of strain on magnetic textures, revealing strain modulation of the magnetic configuration. In the future, this setup will open the investigations of strain-induced magnetic effects in a broad class of vdW systems.

MA 7: Poster Magnetism I

Time: Monday 9:30–12:30 Location: P2

MA 7.1 Mon 9:30 P2

Gapped ground state in a new V(IV) based sawtooth chain — •Ralf Feyerherm[1], Tim Müller[2], and Gündog Yücesan[2] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie, 14109 Berlin — [2]Heinrich-Heine-Universität Düsseldorf, 40225 Düsseldorf

The sawtooth chain (or delta chain) consists of edge-sharing triangles of magnetic ions carrying Heisenberg spins. Assuming antiferromagnetic interactions between the spins, it is a relatively simple model system for studying the effect of magnetic frustration. Despite extensive theoretical literature, experimental realizations of antiferromagnetic sawtooth chains are very rare. Recently, we (TM and GY) synthesized $[VO(2,2'\text{-bpy})(H_2O)][V(\mu\text{-}O)(C_6H_5PO_3)_2]2H_2O$, a new Vanadyl complex, in which V(IV) ions with $S = 1/2$ form a sawtooth chain. The T dependence of the magnetic susceptibility χ suggests a dimerized state with $J = 18$ K and a gap of 36 K, consistent with heat capacity data. Notably, $\chi(T)$ cannot be well described by the Bleaney-Bowers equation, suggesting that a simple dimer model does not work. The magnetization $M(H)$ at 2 K starts to increase steeply above ≈ 80 kOe and reaches a value of $0.065\mu_B$ per f.u. at 140 kOe. High-field magnetization measurements are under way to search for a possible $M_{sat}/2$ plateau predicted theoretically for a specific range of parameters.

MA 7.2 Mon 9:30 P2

Disorder-driven magnetic duality in ktenasite — •Anton Kulbakov[1], Kaushick Parui[1], Roman Gumeniuk[2], Eduardo Carrillo-Aravena[3,4], María Teresa Fernández-díaz[5], Stanislav Savvin[5,6], Artem Korshunov[7], Sergey Granovsky[1], Thomas Doert[3], Dmytro Inosov[1], and Darren Peets[1] — [1]IFMP, TUD, Dresden, Germany — [2]Institut für Experimentelle Physik, TU Bergakademie Freiberg, 09596 Freiberg, Germany — [3]Fakultät für Chemie und Lebensmittelchemie, TUD — [4]Würzburg-Dresden ct.qmat, TUD, Dresden, Germany — [5]ILL, 71 avenue des Martyrs, CS 20156, 38042 Grenoble CEDEX 9, France — [6]ICMA, Facultad de Ciencias, CSIC Universidad de Zaragoza, 50009 Zaragoza, Spain — [7]DIPC, Paseo Manuel de Lardizábal, 20018 San Sebastián, Spain

Ktenasite is a rare platform where structural disorder tunes the effective dimensionality and stabilizes coexisting ordered and glassy magnetic phases, offering a unique opportunity to explore the interplay of frustration, disorder, and dimensional crossover in quantum magnets. Neutron diffraction reveals significant Cu/Zn mixing at the Cu2 site, which tunes the Cu^{2+} sublattice from a two-dimensional scalene-distorted triangular lattice into a one-dimensional spin-chain network. Magnetic susceptibility, neutron diffraction, ac susceptibility, and specific heat measurements collectively indicate magnetic duality.

MA 7.3 Mon 9:30 P2

Using applied magnetic fields to induce unconventional magnetic order in the frustrated quantum magnet, clinoatacamite, Cu2Cl(OH)3 — •Juliana Avtarovski[1], Kirrily Rule[1,2], Leonie Heinze[3,4], Stefan Sullow[3], Michael Lerch[1], Moeava Tehei[1], and Siobhan Tobin[2] — [1]School of Physics, University of Wollongong, NSW 2522, Australia — [2]Australian Centre for Neutron Scattering, Australian Nuclear Science and Technology Organisation, Lucas Heights, NSW 2234, Australia — [3]Institut für Physik der Kondensierten Materie, Technische Universität Braunschweig, D- 38106 Braunschweig, Germany — [4]Jülich Centre for Neutron Science (JCNS) at Heinz Maier-Leibnitz Zentrum (MLZ), Forschungszentrum Jülich GmbH, 85748 Garching, Germany

The natural mineral clinoatacamite, [Cu2Cl(OH)3], exhibits low-temperature, frustrated magnetic behaviour where competing interactions are responsible for novel magnetic properties. Attempts to establish the magnetic phases in this material have been undertaken and an unconventional applied field (H||b) phase diagram has been revealed. Two critical transition temperatures at zero field have been identified with long range antiferromagnetic (AFM) order for T1 < 6K, and paramagnetic behaviour for T2 >18K. In-field magnetisation data collected between 6-18K reveal three distinct phases for H||b which are not completely understood. Until now, the phase diagram of clinoatacamite has not been probed for H||a* or H||c*. We present neutron scattering of single crystal clinoatacamite in applied fields to map out the phase diagram for H||a*.

MA 7.4 Mon 9:30 P2

Optimization of Neural Quantum States for Frustrated and Chiral Spin Hamiltonians — Andreas Haller, •Stefan Liscak, Vladislav Kuchkin, Andreas Michels, and Thomas Schmidt — University of Luxembourg

Neural quantum states (NQS) offer a versatile variational Ansatz for the study of strongly correlated quantum systems, especially when dimensionality or frustration restricts the use of traditional tensor-network techniques. In order to facilitate effective ground-state searches for such Hamiltonians, we introduce a custom optimization code base. We evaluate the performance of our framework's implementations of the stochastic reconfiguration (SR) and the minimal-step SR (minSR) scheme against well-known NQS optimizers like those available in NetKet. For standard test cases, our results achieve accuracy similar to matrix product state methods (DMRG), demonstrating the competitiveness and robustness of the optimization protocols. Based on these validations, we have investigated an extension of the variational Ansatz that incorporates parameter-dependent local rotations of the computational basis directly into the optimization process. This concept is inspired by earlier findings that, following appropriate local spin rotations, skyrmionic matrix-product states show significant overlap with the simple product states. We studied the effect of adaptive basis rotations in chiral and frustrated systems on sampling requirements and convergence.

MA 7.5 Mon 9:30 P2

Single-crystal growth of intermetallic compounds using the optical floating-zone method — •Moritz Scheffer[1], Florian Kübelbäck[1], Leo Maximov[1], Andreas Bauer[1], and Christian Pfleiderer[1,2,3] — [1]School of Natural Sciences, Technical University of Munich, Garching, Germany — [2]Heinz Maier-Leibnitz-Zentrum (MLZ), Technische Universität München,Garching,Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Technical University of Munich, Garching, Germany

High-quality single crystals are an important prerequisite for major advances in experimental solid-state research. To ensure high degree of structural order with a small crystalline mosaicity, low concentrations of defects and impurities, and the absence of parasitic phases, it is crucial to avoid contaminations in every step

of the preparation process [1]. The central part of our preparation process is the optical floating zone technique. After moving to a new laboratory, we have re-established our ultra-high vacuum compatible preparation chain for intermetallic compounds and demonstrated its potential by preparing samples from several compound, such as the potentially frustrated paramagnet Fe_2Al_5 [2].

MA 7.6 Mon 9:30 P2

Rare-earth substitution tuning of a proximate quantum spin-ice pyrochlore — •Yinghao Zhu, Jonathan Gustavo Acosta Ramon, and Yixi Su — JCNS-MLZ, Forschungszentrum Jülich GmbH, Garching, Germany

Pyrochlore-structure frustrated magnets with the general formula R2B2O7 (where R represents magnetic 4f rare-earth ions and B is a non-magnetic cation) consist of a three-dimensional network of corner-sharing tetrahedra. This 3D geometry gives rise to a richer landscape of magnetic interactions and spin configurations compared to their 2D counterparts, such as triangular or kagome latices. The nature of the magnetic anisotropy depends on the specific rare-earth ion: for instance, in Nd2Zr2O7, the Nd3+ ions exhibit local (111) Ising anisotropy, leading to an all-in-all-out antiferromagnetic ground state. In contrast, Yb2Ti2O7 hosts XY-like spins with moments confined to planes perpendicular to the local (111) axes. In this work, we introduce partial substitution of Nd3+ into Yb2Ti2O7, aiming to perturb the pure XY anisotropy of Yb3+ with Ising-like contributions from Nd3+. This allows us to explore the interplay between different types of magnetic anisotropy within the geometrically frustrated pyrochlore framework. Building on the high-quality single crystal obtained, future neutron scattering studies on YbNdTi2O7 are expected to provide valuable insights into the anisotropic spin correlations and potential emergent quantum phenomena arising from the interplay of Ising and XY interactions.

MA 7.7 Mon 9:30 P2

Echo pulses of ultrafast terahertz spintronic emitters — •Krishna Rani Sahoo[1], David Stein[2], Jannis Bensmann[1], Robert Schmidt[1], Steffen Michaelis de Vasconcellos[1], Manfred Albrecht[2], and Rudolf Bratschitsch[1] — [1]University of Münster, Institute of Physics, 48149 Münster, Germany — [2]University of Augsburg, Institute of Physics, 86159 Augsburg, Germany

In its simplest form, an ultrafast terahertz (THz) spintronic emitter consists of a ferromagnetic layer (e.g. Fe) and a nonmagnetic layer (e.g. Pt), grown on an insulating substrate (e.g. sapphire). THz time-domain spectroscopy is a powerful tool for investigating the ultrafast dynamics in THz spintronic emitters. The measured THz waveform provides not only access to the amplitude but also to the phase. Interestingly, additional echo pulses are found in the THz emission of spintronic emitters. We show that these delayed THz pulses are due to reflections of either the optical pump pulse or the THz pulse at different interfaces of the spintronic emitter. Our study provides design strategies for novel spintronic THz emitters with tailored pulse sequences.

MA 7.8 Mon 9:30 P2

Narrow Band THz Emission from micropatterned STEs — •Nikos Kanistras[1], Bikash Das-Mohapatra[1], Seth Kurfman[1], Quentin Remy[2], Reza Rouzegar[2], Tobias Kampfrath[2], and Georg Schmidt[1] — [1]Institut für Physik, Martin-Luther Universität Halle Wittenberg, Von-Danckelmann-Platz 3, 06120 Halle, Germany — [2]Department of Physics, Freie Universität Berlin, 14195 Berlin, Germany

It has recently been demonstrated that Spintronic THz Emitters (STEs) made of metallic multilayers can be used to create ultrashort and broad band THz emission. Such STEs show great potential to complement or even replace conventional semi conducting THz sources due to their straightforward and cost-effective fabrication techniques resulting in seamless on-chip integration with modern device technologies[1, 2]. While quite often the broad band emission is highly desirable, in some cases narrow band or even single frequency emission is preferred, for example for spectroscopy applications.

In this work we present devices for narrow band emission of THz radiation in the range of 1-20THz, based on CoFeB/Pt STE. The samples use a striped emitter on a wedge of a material with an index of refraction >1 (e.g. glass). Our results demonstrate a viable and straightforward method to produce controlled emission in a deterministic THz frequency band, supported by a simple model.

Switching the magnetization of quantum antiferromagnets: Schwinger boson mean-field approximation gauged with exact diagonalization — Florian Johannesmann, •Asliddin Khudoyberdiev, and Götz S. Uhrig — Condensed Matter Theory, TU Dortmund University, Otto-Hahn-Straße 4, 44227 Dortmund, Germany

For operation on the THz scale, antiferromagnets (AFM) are preferable to commonly used ferromagnets. Also, the lack of stray fields allows for much higher densities of bits. Still, efficient switching of the AFM order and the control of its orientation remain one of the main challenges for applications. Recently, we developed a time-dependent Schwinger boson mean-field theory, to study the sublattice magnetization in anisotropic quantum AFMs [1,2]. To corroborate the obtained results, we compare the short-time dynamics of the mean-field approach to exact numerical calculations for small clusters. We obtained a good agreement: The numerical approach corroborates our mean-field findings, with only about 6 % deviations.

Ultrafast Magnetization Dynamics of the self-intercalated vdW ferromagnet Cr_xTe_y — •Maximilian Staabs[1], Tim Titze[1], Pia Henning[2], G.S.Matthijs Jansen[1], Stefan Mathias[1], Jasnamol Palakkal[2], and Daniel Steil[1] — [1]I. Physikalisches Institut, University of Goettingen — [2]Institute for materials physics, University of Goettingen

The groundbreaking discovery of ferromagnetic ordering in layered two-dimensional $CrTe_2$ at ambient temperature [1] has sparked the research interest in chromium-tellurides over the last several years, establishing Cr_xTe_y as a premier platform for next generation spintronics or skyrmionic devices [2].

While the role of intercalation on the magnetic ordering in a static setting is well understood, its impact on ultrafast dynamics remains unclear. Here we use time-resolved MOKE and transient reflectivity measurements to identify the role of intercalation on the ultrafast dynamics in thin films of $CrTe_2$ and Cr_2Te_3 fabricated by hybrid pulsed laser deposition [3]. The pump-probe experiments reveal several significant differences in the ultrafast magnetization dynamics, including the appearance of heavily damped magnon modes at lower temperatures of Cr_2Te_3, as well as significantly stronger coherent phonon modes in $CrTe_2$.

Coupled Magnon-Phonon Dynamics: From Ab Initio Boltzmann Transport to the Three-Temperature Model — •Philipp Rieger, Markus Weissenhofer, and Peter M. Oppeneer — Uppsala University, Uppsala, Sweden

The ultrafast transfer of angular momentum and heat between spin and lattice subsystems is key to spintronics, recently demonstrated to occur on sub-picosecond timescales [1]. While the Three-Temperature Model (3TM) remains a cornerstone for describing this ultrafast demagnetization, its crucial spin-lattice coupling parameter, G_{sl}, typically relies on empirical fitting [2]. To address this, we developed an atomistic framework [3,4] that solves the coupled magnon-phonon Boltzmann transport equation based solely on ab initio inputs. Applied to bcc Fe and fcc Ni, we resolve real-time mode-level dynamics, transport properties, and quasiparticle lifetimes. Crucially, we demonstrate for the first time that the macroscopic 3TM spin-lattice coupling emerges as a valid linear approximation of the underlying non-thermal microscopic dynamics. Consequently, we derive a first-principles G_{sl} that reproduces the seminal results of Beaurepaire et al. [2], unifying the microscopic and phenomenological descriptions of ultrafast spin-lattice dynamics.

Fluence dependency of ultrafast-demagnetization in Gadolinium and Terbium — •Timo Dully, Christian Strüber, and Martin Weinelt — Freie Universität Berlin

The magnetic moment in rare-earth metals is primarily determined by the 4f orbitals. Upon optical pumping, the 4f spin polarization decays on markedly different timescales in Gd and Tb of 14 ps and 0.4 ps, respectively. Earlier studies attributed this difference to the stronger magnetocrystalline anisotropy of Tb relative to Gd [1].

Optical excitation of the 5d6s electrons transfers energy to the phonon system; the 4f orbitals are strongly localized and tightly coupled to the lattice. Recent measurements, however, have revealed direct 5d - 4f electron scattering upon optical excitation of Tb, offering an alternative explanation for the differing response times. The first 4f multiplet excitation in Tb requires 0.26 eV, whereas the corresponding excitation energy in Gd is 4.1 eV. Thus hot electrons in the 5d6s valence bands excite 4f electrons via inelastic electron-electron scattering in Tb but not in Gd [2] This should lead to an ultrafast equilibration of 5d and 4f electron temperatures in Tb.

Motivated by these findings, we investigate the fluence dependence of the valence-electron temperature. Using a tr-ARPES setup with 1300 nm pump and XUV probe pulses, we determine the electron-temperature dependence on pump fluence.

Magnetic properties of Mn_3Sn layer systems — •Paul Marschall[1], Wolfgang Hoppe[1], Prajwal Rigvedi[2], Banabir Pal[2], Georg Woltersdorf[1], and Stuart Parkin[2] — [1]Martin Luther University Halle-Wittenberg, Institute of Physics, Halle (Saale), Germany — [2]Max Planck Institute of Microstructure Physics, Halle (Saale), Germany

Illuminating a nanometer thin metallic bilayer consisting of a ferromagnetic (FM) and a non-magnetic layer (NM) with an intense femtosecond laser pulse launches an ultrafast spin current from the FM into the NM layer where it is subsequently converted into a charge current pulse via the inverse spin Hall effect. This system is established as a so called spintronic terahertz emitter (STE) usable either as a source for THz radiation [1] or for on-chip ultrafast current pulses [2]. The polarity of radiation or current can be fully inverted by switching the magnetization of the FM layer. In this study we focus on the magnetic cluster moment of the non-collinear antiferromagnet Mn_3Sn [3] replacing the FM layer of the canonical STE. The on-chip ultrafast current pulses generated by single Mn_3Sn layers or Mn_3Sn|Pt layer systems are measured with the help of a fast sampling oscilloscope and coplanar microwave probe tip [2]. The conducted experiments allow to analyze the reorietation of the in-plane magnetic cluster moment due to external magnetic fields.

MA 7.14 Mon 9:30 P2

Femtosecond spin dynamics in Ni and Fe probed by transient x-ray magnetic circular dichroism — •L. Endler[1], M. Elhanoty[2], T. Lojewski[3], L. Le Guyader[4], G. Mercurio[4], B. van Kuiken[4], J. Tasto[5], L. Kämmerer[5], A. Delin[6], O. Eriksson[2], O. Granas[2], U. Bovensiepen[5], H. Wende[5], K. Ollefs[1], and A. Eschenlohr[5] — [1]Univ. Heidelberg — [2]Uppsala Univ. — [3]Univ. of Tokyo — [4]European XFEL — [5]Univ. Duisburg-Essen — [6]KTH Sweden

Despite their simple compositions, elemental Fe, Ni and their alloys still spark questions with regard to ultrafast demagnetization dynamics after photoexcitation. By combining ultrafast X-ray absorption, circular dichroism spectroscopy (XMCD) and *ab intio* theory we aim to entangle the underlying processes in elemental Fe and Ni. Electronic correlations have been found to influence the dynamics at ultrafast timescales in elemental Ni [1]. We observed XMCD peak shifts toward lower photon energies at <1 ps timescales, followed by a shift towards higher energies at a few ps. Fe XMCD spectra showed an increase in L_3 and decrease in L_2 edge spectral area at ≈ 100 fs.

We acknowledge the financial support through the DFG within the framework of the CRC1242.

MA 7.15 Mon 9:30 P2

Development of a Laboratory Soft X-Ray Reflectometer for Ultrafast Magnetisation Studies — •Pierre Gautier[1], Clemens von Korff Schmising[1], and Stefan Eisebitt[1,2] — [1]Max Born Institut für Nichtlineare Optik und Kurzzeitspektroskopie, Berlin, Germany — [2]Technische Universität Berlin, Institut für Optik und Atomare Physik, Berlin, Germany

Ultrafast spectroscopy in the extreme ultraviolet (XUV) range is a powerful experimental tool for investigating ultrafast magnetisation dynamics, providing element-specific information and access to the non-equilibrium electronic density of states. Using reflection geometry, experimental observables also allow direct access to depth-dependent dynamics. In this study, we present the initial findings from a recently developed experimental setup optimised for broadband reflectometry of magnetic materials. Soft X-ray radiation is generated through highharmonic generation using 100 kHz, sub-10 femtosecond laser pulses produced by a fibre laser with a two-stage pulse compression scheme. A high-resolution spectrometer optimised for photon energies between 45 eV and 180 eV is mounted on a goniometer arm, allowing access to angles of incidence ranging from $\theta = 0^{\circ}$ to 80°. The goal of this research is to resolve the ultrafast dynamics of spatial magnetisation profiles, spin currents, and spin accumulation within functional heterostructures.

MA 7.16 Mon 9:30 P2

Ultrafast Rearrangement of Antiferromagnetic Spin order Probed with Femtosecond X-ray Diffraction — •Yoav William Windsor[1,2], Sang-Eun Lee[1], Daniela Zahn[1], Kristin Kliemt[3], Christian Schüssler-Langeheine[4], Niko Pontius[4], Denis Vyalikh[5], Urs Staub[6], Cornelius Krellner[3], and Laurenz Rettig[1] — [1]Fritz Haber Institute der MPG, DE — [2]TU Berlin, DE — [3]Goethe-Universität Frankfurt, DE — [4]Helmholtz-Zentrum Berlin, DE — [5]DIPC, San Sebastián, ES — [6]Paul Scherrer Institut, Villigen, CH

Ultrafast spin manipulation carries great potential for future information technology. In particular, antiferromagnets offer the prospect of faster and more efficient spin dynamics, as well as exploitable magnetic properties that are unavailable in ferromagnets. One example is the internal arrangement of spins. Controlling this can alter how the antiferromagnet stores data, interacts with neighboring materials, etc.

Here we demonstrate manipulation of the spin structure in $LnRh_2Si_2$ (Ln = Ho, Dy; see also [1-3]) by means of femtosecond optical excitation. We probe the transient spin arrangement using femtosecond resonant X-ray diffraction tuned to the Ln ions' $M_{4,5}$ edges ("soft X-rays"). By probing the azimuthal dependence of the transient magnetic Bragg intensity, we disentangle the ultrafast rearrangement of the spin order from ultrafast demagnetization.

Miniaturized Multipoles for Ultrafast Electron Microscopy — •Johannes Schultz[1], Max Herzog[1], and Axel Lubk[1,2] — [1]IFF, IFW Dresden, Helmholtzstraße 20, 01069 Dresden — [2]IFMP, TU Dresden, Haeckelstraße 3, 01069 Dresden

Ultrafast Electron Microscopy (UEM) is an emerging technique developed in the last decades. By combining the high spatial resolution of EMs with a temporal resolution down to fs, it provides insights into dynamic processes in the field of nanophotonics, magnetodynamics, and lattice motion among others. Most UEM setups use pumped electron sources, which provide the highest time resolution but suffer from a limited repetition rate (≈10 MHz), are expensive and technically complex and hence difficult to (retro)fit into EMs. We therefore propose an alternative technique based on easy-to-retrofit, miniaturized (for fast switching) magnetic multipoles chopping the beam to short pulses. They consist of planar copper electrodes with permalloy pole pieces on top (≈ 50 μm size), which are structured by lithography on a silicon wafer. The devices are supplied with radio-frequency electrical signals via a custom made holder compatible with standard ports of our EM (FEI Titan^3), which allows for easy device integration into the central part (C2 aperture plane) of the condenser system. In the lower part of the EM, the beam is chopped by a small aperture (C3 aperture). Considering the magnification of the condenser system, the optical power of the devices (100 μrad deflection at 3 GHz and 300 keV electron energy) and the diameter of the chopping aperture (150 nm), a time resolution of ≈ 1 ps at repetition rates ≫ 10 MHz can be achieved.

MA 7.18 Mon 9:30 P2

Magnetization-dependent electronic structure and ultrafast electron dynamics in CrGeTe3 — •Tulio de Castro[1], Samuel Beaulieu[1], Shuo Dong[1], Maciej Dendzik[1], Tommaso Pincelli[2], Lawson Lloyd Lloyd[2], Ralph Ernstorfer[2], Martin Wolf[1], and Laurenz Rettig[1] — [1]Fritz-Harber-Institut der Max-Planck-Gesellschaft, Berlin — [2]I0AP, Technische Universität Berlin, Berlin.

Magnetic 2D van-der-Waals materials offer novel opportunities for spin-based nanodevices, with advantages over charge-based technologies. One promising material is the semiconductor CrGeTe3 (CGT), which exhibits ferromagnetic order below the Curie temperature(TC=63 K). Here, we investigate bulk CGT using femtosecond time and angle-resolved photoemission spectroscopy(trARPES), to elucidate how magnetic order modifies the electronic structure, and to directly measure the ultrafast dynamics of exchange splitting and demagnetization. We observe a temperature-dependent shift in band energies below TC, associated with magnetic order. Upon femtosecond optical excitation, we observe an ultrafast renormalization of band energies, which we discuss in terms of transiently modified exchange splitting and superexchange pathways. Our results provide a direct ultrafast timescale for electron redistribution in magnetically ordered CGT, and give insight into the pathways of spin-electron interactions in CGT.

MA 7.19 Mon 9:30 P2

Time-resolved resonant magnetic small-angle scattering with a laser-driven soft-X-ray plasma source — •Pascal Wernicke[1], Maximilian Mattern[1], Johannes Tümmler[1], Stefan Eisebitt[1,2], and Daniel Schick[1] — [1]Max-Born-Institut für Nichtlineare Optik und Kurzzeitspektroskopie, Berlin, Germany — [2]Institut für Physik & Astronomie, TU Berlin, Germany

Resonant soft-X-ray scattering methods provide unique possibilities to study nanometer-scale magnetization states with element selectivity. Employing ultrashort pulsed X-ray sources accesses the laser-induced dynamics on ultrafast timescales beyond a spatially-averaged insight. Based on a laser-driven plasma X-ray source, we have developed a novel instrument to carry out time-resolved magnetic small-angle X-ray scattering (SAXS) experiments in the soft-X-ray range between 500 and 1500 eV with sub-10 ps temporal resolution. Due to the flexibility of our laboratory-scale setup, we can further vary the sample environment, e.g., by applying external magnetic fields as well as cryogenic temperatures, and hence investigate ground-state-dependent dynamics of emergent textures such as magnetic domains. Specifically, we aim at following laser-driven dynamics of spatially heterogenous phase transitions, e.g. during the prototypical magneto-structural antiferromagnetic (AFM) to ferromagnetic (FM) transition in FeRh. Here, resonant magnetic SAXS can resolve the relevant time and length scales on which FM domains emerge during this first-order transition.

MA 7.20 Mon 9:30 P2

Impact of crystallographic cuts on the magnetoelectric switching of Cr_2O_3. — •Anuvrat Tripathi, Igor Veremchuk, Oleksandr V. Pylypovskyi, Pavlo Makushko, and Denys Makarov — Helmholtz-Zentrum Dresden-Rossendorf e.V., Bautzner Landstrasse 400, 01328 Dresden, Germany

The phenomenon of magnetoelectric (ME) switching in Cr_2O_3 has been demonstrated to facilitate the control of magnetism by an electric field, a property that renders it a subject of considerable interest for applications in low-power spintronics and memory devices [1]. However, the dependence of switching efficiency on crystallographic orientation remains poorly understood [2]. A systematic study of magnetic switching in bulk Cr_2O_3 single crystals with different crystallographic cuts and epitaxial Cr_2O_3 thin films grown on Al_2O_3 substrates with varying orientations has been conducted. By applying fields over a transition from the paramagnetic to the magnetically ordered state, we are able to modify the distribution of the antiferromagnetic (AFM) domains in Cr_2O_3 and identify this change via magnetotransport. A comparison between single crystals and thin films reveal the role of crystal-cut symmetry and epitaxial grown in governing the switching process. The results of this study make it possible to optimize controlled magnetism in spintronic devices based on Cr_2O_3.

MA 7.21 Mon 9:30 P2

Ferromagnetic Cellulose Nanocomposite for Coating and Filament Production toward Flexible Electronic Materials — •Andrei Chumakov[1], K. Gordeyeva[2], C.J. Brett[1,2], D. Menzel[3], A.V. Riazanova[2], M. Schwartzkopf[1], and D. Soederberg[2] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]KTH Royal Institute of Technology, Stockholm, Sweden — [3]Technische Universität Braunschweig, Braunschweig, Germany

Nanocellulose is a renewable, lightweight, and robust platform for sustainable flexible electronics. Imparting stable ferromagnetism enables thin, patternable, biodegradable components for sensing, tagging, and memory. We report a ferromagnetic nanocomposite via electrostatic co-assembly of negatively charged cellulose nanofibrils (-1360 μmol g^{-1}) with positively charged strontium hexaferrite nanoplatelets. Opposite charges ensure homogeneous dispersion and high coercivity retention of the final composite. Spray-coated films (10-100 nm) on silicon show uniform loading, in-plane nanoplatelet alignment (SEM/SAXS/WAXS), and coercive fields matching hard-magnetic particles. In parallel, we produce magnetic filaments by (i) co-extruding aligned CNFs with ferrites via gelation and (ii) coating CNF yarns with ferrite sheaths. These fibers retain nanocellulose's high specific modulus (60 GPa·cm^3/g) and >1000 MPa strength while gaining magnetic functionality. Together, these coatings and fibers offer a scalable, water-based techniques to magnetically active, biodegradable media.

MA 7.22 Mon 9:30 P2

Copper- and zinc-substituted nanocrystalline ferrites for biomedical applications — •Todor R. Karadimov, Milena T. Georgieva, and Petar A. Georgiev — Faculty of Physics, Sofia University St. Kliment Ohridski, Department of Condensed Matter Physics and Microelectronics, Sofia, 1164, Bulgaria

Worlwide concern of antibiotic resistance has prompted the research of novel, inorganic nanomaterials, effective against pathogens. Nanocrystalline copper- and copper/zinc-substituted ferrites were prepared under solvothermal synthesis conditions at temperatures up to 200°C. The samples' crystalline phases, particle shape and size, and magnetic properties at ambient temperatures, were determined by powder x-ray diffraction, electron microscopies, and vibrating sample magnetometry, respectively. These revealed that the resultant Cu-modified ferrites consisted of agglomerates of nanocrystalline iron ferrite, Fe_3O_4, with metallic copper inclusions. In the zinc-substituted samples the resultant precipitate consisted of agglomerates of a superparamagnetic spinel phase, e.g. $Zn_{0.6}Fe_{0.4}Fe_2O_4$, with nano-crystalline copper particles spread within them. The zinc-substituted samples showed a maximum magnetization of 30 emu/g, which is significant for practical applications. Antimicrobial agar well tests against Gram-positive and Gram-negative bacteria Escherichia coli ATCC 25922 and Staphylococcus aureus ATCC 25923 showed moderate activity of all investigated materials, correlating with the copper content and particle size. However, *Daphnia magna* toxicity tests indicated strong ecotoxicity, suggesting uncontrolled release in the environment should be avoided.

MA 7.23 Mon 9:30 P2

Machine Learning assisted 3D Tracking, Evaluation and Analysis of near-substrate transported Superparamagnetic Microparticles for Intelligent Experimentation and Sensing Applications — •Nikolai Weidt[1,2], Nikita Popkov[2,3], Yahya Shubbak[1,2], Rico Huhnstock[1,2], Kristina Dingel[2,3], Bernhard Sick[2,3], and Arno Ehresmann[1,2] — [1]Institute for Physics and CINSaT, University of Kassel, Heinrich-Plett-Str. 40, 34132 Kassel, Germany — [2]AIM-ED, Joint Lab of Helmholtzzentrum für Materialien und Energie, Berlin (HZB) and University of Kassel, Hahn-Meitner-Platz 1, 14109, Berlin, Germany — [3]Intelligent Embedded Systems, University of Kassel, Wilhelmshöher Allee 71-73, 34121, Kassel, Germany

We present a framework for intelligent control and analysis of superparamagnetic microparticles transported above magnetic domain-patterned samples. Particles are actuated by tailored magnetic stray field landscapes and external field pulse sequences, enabling remote-controlled, near-surface motion. Implementing the open-source TANGO Controls system, the setup supports modular hardware integration, synchronized operation and live data evaluation. Real-time 3D particle trajectory reconstruction can be achieved by combining deep-learning-based tracking with an automated focus-sweep calibration. This closed-loop approach paves the way for rapid evaluation of particle interaction events and supports adaptive experiments, advancing lab-on-a-chip biosensing and machine-learning-assisted diagnostics.

MA 7.24 Mon 9:30 P2

Enhancement of Magnetic and Photocatalytic properties of MnZn/CdZn core/shell structures via lattice matching. — •Ahmed Faramawy, Hesham El-Sayed, Adel Abdel-Sattar, and Romany Nessem — Ain Shams University, Cairo, Egypt

Core/shell nanostructures of ferrite as shell (Mn0.7Zn0.3Fe2O4/CdxZn1-xFe2O4 (x = 0-0.)) were successfully synthesized via a hydrothermal route to explore the role of lattice matching on their structural, magnetic, optical, and photodegradation properties. X-ray diffraction and Rietveld refinement confirmed the formation of single-phase spinel structures with coherent core/shell interfaces. TEM and EDX mapping verified uniform shell growth and compositional gradients, indicating true core/shell formation. Moreover, the saturation magnetization showed a 14% enhancement at x = 0.3 due to optimal lattice coherence and minimal interfacial strain. Optical analysis showed that the direct bandgap decreased. The observed bandgap narrowing and high Urbach energy at moderate Cd2+ levels indicate improved electronic mobility and reduced activation energy for charge transport. Furthermore, Photocatalytic activity studies confirm that the synthesized Mn0.7Zn0.3Fe2O4/CdxZn1-xFe2O4 core-shell nanocomposites have excellent photodegradation behaviour to methylene blue (MB) compared to the bare core.

MA 7.25 Mon 9:30 P2

Magnetic relaxation and structural characterization of single-core FeOx nanoparticle dispersions in solvents of varying viscosity — •Amala Thuruthiyil Jose[1,2], Sascha Ehlert[3], Artem Feoktystov[4], Andreas Stadler[3,2], Martin Dulle[3], and Oleg Petracic[1,5] — [1]Jülich Centre for Neutron Science JCNS-2, Forschungszentrum Jülich GmbH, Germany — [2]RWTH Aachen University, Landoltweg 2, 52056 Aachen, Germany — [3]Jülich Centre for Neutron Science JCNS-1, Forschungszentrum Jülich GmbH, Germany — [4]Forschungszentrum Jülich GmbH, Jülich Centre for Neutron Science (JCNS) at MLZ, Lichtenbergstrasse 1, Garching, Germany — [5]Heinrich Heine University Düsseldorf, Faculty of Mathematics and Natural Sciences, Düsseldorf

We have investigated the structural and magnetic properties of monodisperse single-core iron-oxide nanoparticles dispersed in solvents of systematically varied viscosity. The particles were synthesized via thermal decomposition. Magnetic measurements were performed using SQUID magnetometry, employing zero-field-cooled (ZFC) and field-cooled (FC) curves to probe changes in blocking behavior and relaxation dynamics. To examine the influence of the solvent environment on particle stability, SAXS measurements were carried out. We observe clear viscosity-dependent shifts in the nanoparticle solvent system, reflecting the gradual emergence of Brownian relaxation as solvent mobility increases. The observed viscosity and phase-dependent magnetic signatures demonstrate how solvent dynamics can be used to tune and separate Néel and Brownian relaxation.

MA 7.26 Mon 9:30 P2

Coexistence of ferromagnetism and spin-glass behaviour in CeNiSb3 — •Haribrahma Singh[1], Prabuddha Kant Mishra[1], Gaurav Kumar[2], Aarti Gautam[1], Rie Y. Umetsu[3], Ratnamala Chatterjee[2], and Ashok Kumar Ganguli[1,4] — [1]Department of Chemistry, Indian Institute of Technology Delhi, 110016, India — [2]Department of Physics, Indian Institute of Technology Delhi, New Delhi 110016, India — [3]Institute for Materials Research, Tohoku University, 2-1-1 Katahira, Aoba-ku, Sendai 980-8577, Japan — [4]Department of Chemical Sciences, Indian Institute of Science Education and Research, Berhampur, Odisha 760003, India

We present a comprehensive investigation of the structural and magnetic properties of of CeNiSb3. DC magnetization measurements confirm long-range ferromagnetic ordering below the Curie temperature TC = 7.2 K accompanied by marked magnetic irreversibility. In the ordered phase, CeNiSb3 exhibits strong magnetic anisotropy. Additionally, a field-induced spin-reorientation transition is observed along the b-axis at TC = 6.8 K. Non-equilibrium spin-dynamics measurements reveal a clear memory effect, and thermoremanent magnetization relaxations follow a stretched-exponential form with β=0.30, indicative of spin-glass like behaviour. This is corroborated by AC susceptibility, Power-law analysis yields a characteristic relaxation time of 10^-10s. Under an applied DC magnetic field, the AC susceptibility evolves from a single cusp to a double-peak structure, providing strong evidence for the coexistence of reentrant spin-glass and ferromagnetic ordering below TC in CeNiSb3.

MA 7.27 Mon 9:30 P2

Magnetic phase transitions in Z-type magneto-electric hexaferrites — •Borislava Georgieva[1], Petya Peneva[1], Svetoslav Kolev[1,2], Kiril Krezhov[1], Chavdar Ghelev[1], Lan Maria Tran[3], Michał Babij[3], Benedicte Vertruyen[4], Peter Tzvetkov[5], Daniela Kovacheva[5], and Tatyana Koutzarova[1] — [1]Institute of Electronics, Bulgarian Academy of Sciences, Sofia, Bulgaria — [2]Neofit Rilski South-Western University, Blagoevgrad, Bulgaria — [3]Institute of Low Temperature and Structure Research, Polish Academy of Sciences, Wroclaw, Poland — [4]CESAM, GREENMAT, Chemistry Institute, University of Liège, Liège, Belgium — [5]Institute of General and Inorganic Chemistry, Bulgarian Academy of Sciences, Sofia, Bulgaria

The difference is well known in the occurrence of strong magnetoelectric effects in single magnetoelectric materials (ferrites), depending on their physical state. The single-crystal Z-type hexaferrite Sr3Co2Fe24O41 exhibits a magnetoelectric effect at room temperature. We report studies on the structural and magnetic properties of Sr3Co2Fe24O41 in powder and bulk samples, focusing on the influence of the synthesis conditions. The precursor powders were prepared by sol-gel auto combustion and synthesized at 1200-1250 °C. XRD spectra showed characteristic peaks corresponding to the Z-type hexaferrite structure as a main phase. SEM images of the powder sample showed agglomerated particles forming clusters of different sizes and shapes, while in the bulk sample we observed large regions of hexagonal particles. Magnetic phase transitions between 4.2 and 300 K were observed.

MA 7.28 Mon 9:30 P2

Investigating magnetoelastic effects in multiferroic $CoCr_2O_4$ — •Abdelrahman Elsaid[1], Ryan Morrow[1], Robert Kluge[1], Sabine Wurmehl[1], Bernd Büchner[1,2], and Vilmos Kocsis[1] — [1]IFW-Dresden — [2]TU-Dresden

In a previous study based on optical spectroscopy, chromium-based spinels were found to exhibit significant magnetoelasticity if the magnetic A-site ion was occupied by a Jahn-Teller active ion. While the sentiment of this finding is true, optical spectroscopy is mostly sensitive to symmetry lowerings, and magnetoelasticity - meaning any sort of lattice deformation - may remain unnoticed in optics. Moreover, one of the chromium spinels with orbital singlet ions, $CoCr_2O_4$ is a known multiferroic, where the magnetoelectric interactions are originating from the conical spin order. It is an interesting question whether the polar distortion accompanying the spin order has a noticeable effect on the size of the unit cell, namely: can a piezo-magnetoelectric effect appear in $CoCr_2O_4$?

This motivated us to investigate $CoCr_2O_4$ using high-sensitivity capacitance dilatometry, a method not just sensitive to symmetry lowerings, but also to delicate changes in the size of the unit cell. We have found that, in line with the optical spectroscopy measurements, the unit cell shows zero change in size upon the appearance of the magnetic order. However, the application of magnetic field still reveals a significant magnetostriction in the magnetoelectric conical phase, which suggests the presence of piezo-magnetoelectric interactions.

MA 7.29 Mon 9:30 P2

Equilibrium control of quantum magnets via cavity magneto-electric coupling — •Nicolas Schmölz[1], Beatriz Pérez González[2], Mónica Benito[2], Marcus Kollar[1], and Francesco Piazza[1] — [1]Theoretische Physik III, University of Augsburg — [2]Quanteninformation und Quantencomputing, University of Augsburg

We investigate the possibility of exploiting a cavity magneto-electric coupling mechanism, whereby spin excitations carry an electric dipole moment, in order to enhance the interactions between photons and correlated (quantum) magnets.

The free-energy of the material is modified by the hybridization between collective spin excitations and cavity photons. We provide estimates for the change in free energy for specific materials which are solely based on experimental input via the measurement of the optical conductivity and the magnetoelectric response.

Our results should guide future experimental realizations by identifying optimal magnetic materials and cavity designs, aiming at a non-invasive equilibrium control of material's phases and functionalities.

MA 7.30 Mon 9:30 P2

Magnetic phase transitions and spin-driven multiferroicity in BaHoFeO4 — •Filip Kadlec[1], Christelle Kadlec[1], Toan Dang[2], Denis Kozlenko[3], T.P. Hoang[2], Sergei Kichanov[3], LTP Thao[4], TL Phan[5], N Tran[2], Tomáš Kmječ[6], Jaroslav Kohout[6], Vojtěch Chlan[6], and Manh-Huong Phan[7] — [1]Institute of Physics CAS, Prague, Czechia — [2]Duy Tan Univ., Danang, Vietnam — [3]Dubna, Russia — [4]Univ. of Danang, Vietnam — [5]VNU Hanoi, Vietnam — [6]Fac.of Mathematics and Physics, Charles Univ., Prague — [7]Univ.of South Florida, Tampa, USA

Magnetic and multiferroic properties of $BaHoFeO_4$ originate in geometrical frustration and in interactions between Fe and Ho sublattices. The magnetic phase transitions remind of the parent compound $BaYFeO_4$ which exhibits an AFM order below the Néel temperature of 48 K. Below 3K, in magnetic field above 1.5 T, specific changes in the magnetic configuration lead to a spin- and H-induced ferroelectric polarization. As magnetic field increases, the ferroelectric polarization peaks, and it disappears above 5 T. Such an unusual ferroelectric behavior is likely related to H-induced metamagnetic phase transitions. We studied polycrystalline BaHoFeO4 using THz time-domain spectroscopy, X-ray diffraction, neutron powder diffraction, Mössbauer spectroscopy and magnetization measurements. Three different AFM structures were observed on cooling, as well as two metamagnetic phase transitions induced by magnetic field of up to 7 T. In view of the proven robustness of the sublattice of Fe spins, these changes of magnetic configurations are attributed to the frustrated Ho-spin sublattice.

MA 7.31 Mon 9:30 P2

Ab initio approaches to the dynamical magnetoelectric effect — •Torsten Geirsson[1], Davide Sangalli[2], and Alejandro Molina-Sánchez[1] — [1]ICMUV, University of Valencia, Spain — [2]ISM-CNR, Rome, Italy

The magnetoelectric (ME) tensor quantifies how an electric field induces magnetization and is key to understanding the coupling between electric and magnetic degrees of freedom. While most studies address the static ME response, its finite-frequency generalization reveals how electric fields drive magnetic excitations on ultrafast timescales. At optical frequencies, the ME effect can be resonantly enhanced by interband or excitonic transitions, giving rise to measurable nonreciprocal magneto-optical signals, as observed for Cr2O3.

We present a first-principles framework to compute the dynamical ME tensor in magnetic insulators, separating spin and orbital contributions and focusing on the electronic response. Approaches based on linear-response theory and real-time simulations are combined to access both equilibrium and transient ME dynamics. Using Cr_2O_3 as a prototypical example, we show how real-time propagation captures non-equilibrium ME effects induced by ultrafast electric-field pulses. Our work establishes a route for connecting ab initio ME response calculations with emerging ultrafast magneto-optical experiments.

MA 7.32 Mon 9:30 P2

High-resolution optical imaging of multiferroic domain topology in $ErMnO_3$ — •Andy Disheng An[1], Andrin Caviezel[1], Erik de Vos[1], Thomas Lottermoser[1], Jan Gerrit Horstmann[1,2], and Manfred Fiebig[1] — [1]Department of Materials, ETH Zürich, Switzerland — [2]Institute of Physical and Theoretical Chemistry, University of Würzburg, Germany

We present a study of the multiferroic domain structure in $ErMnO_3$ using scanning second-harmonic generation (SHG) microscopy. As SHG can couple to both magnetic and ferroelectric orders simultaneously, this confocal technique allows for artefact-free, high-resolution imaging of multiferroic order. In the ferroelectric phase of the type-I multiferroic $ErMnO_3$, topological defects arise as vortices at the meeting point of their six domain states, giving rise to their characteristic six-fold cloverleaf domain pattern. Below the Néel temperature, new topological defects form at the intersection between the cloverleaf domain structure and the antiferromagnetic domain walls. We show for the first time that the SHG intensity is strongly suppressed at the vortex cores. Furthermore, recent theoretical calculations predict attractive interactions between the magnetic domain walls in hexagonal manganites [1], whereby our low-temperature scanning SHG setup is a capable and practical method for the experimental verification of these predictions.

MA 7.33 Mon 9:30 P2

Magnetic Phases in ErFeO3 — •Leo Maximov[1,3], Thomas Reyher[1], Florian Kübelbäck[1,3], Johanna Jochum[2], Andreas Bauer[1,3], and Christian Pfleiderer[1,2,3] — [1]School of Natural Science, Physik-Department, Technical University of Munich, Garching, Germany — [2]Heinz Maier-Leibnitz Zentrum (MLZ), Technical University of Munich, Garching, Germany — [3]Zentrum für QuantumEngineering (ZQE), Technical University of Munich, Garching, Germany

Rare-earth orthoferrites (RFeO3) have been extensively studied for their multiferroic properties [1,2]. Most recently, in ErFeO3, a central motivation has been the observation of Dicke cooperativity in magnetic interactions [3], suggesting that collective coupling between localized moments and excitations can strongly alter spin dynamics. Such cooperative effects may influence magnon dispersion near crystal-field levels. Neutron studies provided Fe3+ spin-wave dispersions [4], and revealed hybrid spin-wave and crystal-field excitations [5]. However, a systematic mapping of the full spin-wave dispersion, as well as possible cooperative effects, remains lacking. We report single-crystal growth of ErFeO3 using the optical floating-zone method. Structural quality was verified by single-crystal Laue and powder X-ray diffraction. Measurements of the magnetization and the heat capacity allow us to establish the anisotropic magnetic phase diagram as a prerequisite for further studies. [1] Y.Ke, et al., Sci. Rep. 6, 19775 (2016). [2] R.L. White, JAP 40, 1061 (1969). [3] Li, Xinwei, et al. Science 361.6404 (2018). [4] Shapiro Physical Review B 10.5 (1974). [5] Zic, et al., J. Appl. Phys. 130, 014102 (2021).

MA 7.34 Mon 9:30 P2

Exploring Quantum Geometry in the Dual Topological Insulator BiTe — •Maksim Povolotskiy[1], Renjith Mathew Roy[1], Ji Eun Lee[1], Yanpeng Qi[2], and Martin Dressel[1] — [1]1. Physikalisches Institut, Universität Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany — [2]School of Physical Science and Technology, Shanghai Tech University, Shanghai 201210, China

We present an optical spectroscopy study of the dual topological insulator bismuth telluride (BiTe) over a broad infrared range (from 5 meV to 2.5 eV), supported by transport measurements and ab initio calculations. BiTe, a member of the $(Bi_2)_m(Bi_2Te_3)_n$ homologous series, hosts both weak topological insulator (WTI) and topological crystalline insulator (TCI) surface states [1]. High pressure, low temperatures, and directional magnetic fields are applied to access and probe distinct electronic states located on different crystal facets. By systematically varying the measurement geometry and external conditions, the optical response aims to distinguish bulk contributions from surface states protected by different symmetries: time-reversal symmetry in the WTI and crystalline symmetry in the TCI [2]. Additionally, the analysis focuses on signatures of quantum geometric effects on electron-phonon coupling, which are expected to manifest as anomalies in the infrared-active phonon modes and reflect nontrivial Berry curvature in the electronic bands [3]. The results offer perspectives on the interplay between topology, lattice vibrations, and quantum geometry in BiTe. [1] Nat Commun 8, 14976 (2017) [2] Nat. Mater. 19, 610 (2020) [3] arXiv:2410.09677 (2024)

MA 7.35 Mon 9:30 P2

Design and Implementation of Voltage Gating in Weyl Semimetals — •Kamila Szczurek[1], Dola Chakrabartty[1], Lilian Prodan[1], István Kézsmárki[1], Kai Litzius[1], and Felix Büttner[1,2] — [1]Center for Electronic Correlations and Magnetism, University of Augsburg, Augsburg, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

Weyl semimetals are promising candidates for next generation spintronic devices due to their exotic electronic properties, expected to lead to low power magnetic switching. These promising properties were predicted by theoretical work but have yet to be verified. This research presents the design and implementation of an experimental setup aimed at enabling voltage gating studies of Weyl semimetals using magneto-optical Kerr effect (MOKE) techniques. A polar laser MOKE system in combination with a full-field Kerr microscope was developed and tested, with particular focus on the alignment of the components during operation in a shared setup. A small lamella of the ferromagnetic Weyl semimetal Fe_3Sn_2 was used as the initial sample due to the material's large anomalous Hall response and tunable Berry curvature effect, making it particularly attractive for voltage-control studies using MOKE. However, the limited size and geometry of a lamella introduced challenges in obtaining a clear MOKE signal, highlighting the neccessity for combined full-field and laser MOKE measurements. Despite practical challenges, the setup was successfully commissioned, laying the groundwork for future measurements under applied gate voltages.

MA 7.36 Mon 9:30 P2

Imaging Magnetic Orders in Topological Kagome Ferro- and Antiferromagnets using Single-Spin Magnetometry — •Anusree Vannada Puleri, Yuchen Zhao, Claire Donnelly, Uri Vool, Claudia Felser, and Edouard Lesne — Max-Planck-Institute für Chemische Physik fester Stoffe, Dresden, Germany

Kagome magnets are promising candidates for next-generation memory applications due to their high ordering temperatures and untapped unconventional magnetic ground states and topological properties. These include large anomalous Hall and spin Hall responses arising from sizeable accumulations of Berry curvature in momentum space.

In this study, we focus on the Kagome ferromagnet (FM) Fe_3Sn_2 which exhibits massive Dirac fermions and noncollinear FM order [1], and the Kagome antiferromagnet Mn_3Sn, which displays non-collinear anti-ferromagnetism and Weyl fermions [2]. We present how high-quality epitaxial thin films of Fe_3Sn_2 and Mn_3Sn, can be grown using magnetron sputtering, with controlled tuning of thicknesses and strain. We perform detailed structural characterizations, and resort to a combination of magnetic force microscopy, and nitrogen vacancy (NV)-based magnetometry to image FM and AF domains in these intriguing Kagome magnets.

MA 7.37 Mon 9:30 P2

Synthesis, characterization and magnetic properties of selected Shandites compounds — •Mervenur Keles, Ahmad Omar, Christian G. F. Blum, Dmitriy Efremov, Bernd Büchner, and Sabine Wurmehl — Leibniz Institute for Solid State and Materials Research, Helmholtzstraße 20, Dresden, 01069, Germany

Shandite-type Co3M2X2 (M: In, Sn, Pb, Tl; X: S, Se), with a unique Kagome lattice structure, serves as a model system for studying the interaction between structure, magnetism, topology, and electronic correlation. Some shandite compounds are magnetic Weyl semimetals that exhibit unconventional transport phenomena. However, the physical properties are strongly dependent on the stoichiometry and sample quality, which are rather difficult to achieve as-desired along with high reproducibility. To address this, we investigate multiple synthesis and crystal-growth routes for selected Co3M2X2 compounds, performing comprehensive structural, chemical, transport, and magnetic characterization. We present correlations between the synthesis route, resulting structure/stoichiometry, and observed physical properties. Through DFT calculations and ARPES measurements done in collaboration, we further investigate the band structure of these potential Co3M2X2 Kagome semimetals, with the aim to establish key parameters for topological band formation and magnetic order, and thus validate a Weyl Type III semimetal.

MA 7.38 Mon 9:30 P2

Investigating Magnetic Material Parameters — •Kübra Kalkan[1], Ross Knapman[1,2], Atreya Majumdar[1], and Karin Everschor-Sitte[1] — [1]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany — [2]Institute of Mechanics, University of Duisburg-Essen, Germany

Ideal magnetic materials would significantly enhance the performance and energy efficiency of modern technological devices [1]. In practice, however, real magnetic samples inevitably contain spatial inhomogeneities that weaken magnetic properties and thus, limit device capabilities. Understanding how these imperfections influence magnetization dynamics is therefore essential for both fundamental insight and material optimization. In this study, we investigate how spatial variations in exchange stiffness and uniaxial anisotropy affect high-temperature magnetization dynamics in thin films. Using physically inspired latent-inference methods [2, 3] applied to micromagnetic simulations, we develop a physics-informed, data-driven framework for quantifying the role of inhomogeneities. This approach enables the inference of material parameters directly from highly fluctuating magnetization behavior, offering a route toward deeper understanding and the design of more energy-efficient magnetic materials.

MA 7.39 Mon 9:30 P2

Atomistic spin dynamics with quantum coloured noise — •Fried-Conrad Weber[1,2], Felix Hartman[2], Matias Bargheer[1,2], Janet Anders[2,3], and Richard Evans[4] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH — [2]University of Potsdam, Institute of Physics and Astronomy — [3]Department of Physics and Astronomy, University of Exeter — [4]School of Physics, Engineering and Technology, University of York

Predicting temperature-dependent magnetisation is a challenge to classical atomistic spin dynamics (ASD) due to the absence of quantum statistics. Here, we present a novel implementation of an open-system Landau-Lifshitz-Gilbert equation within the VAMPIRE package that incorporates quantum coloured noise and non-Markovian memory effects. This approach models the quantum nature of the thermal bath and its self-consistent interaction with magnetic moments. Our results show excellent quantitative agreement with experimental magnetisation curves for nickel and gadolinium across the full temperature range, significantly enhancing the predictive capabilities of ASD beyond standard classical methods.

MA 7.40 Mon 9:30 P2

Differentiable Micromagnetics for Inverse Parameter Extraction — •Moritz Kamm[1,2], Kai Litzius[2], and Felix Büttner[1,2] — [1]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [2]Center for Electronic Correlations and Magnetism, University of Augsburg

Extracting intrinsic micromagnetic parameters from imaging data usually involves extensive trial-and-error and often remains ambiguous. We address this challenge with a differentiable inversion method that recovers material parameters directly from a single magnetic domain image. Unlike recent neural-network approaches, the method is fully analytical and physics-driven. Because the entire pipeline is differentiable, it integrates naturally with modern optimization and gradient-based design workflows. From an experimentally accessible magnetization image, we perform a deterministic Néel-type reconstruction of the full vector field and infer material constants by enforcing fixed-point consistency under the Landau-Lifshitz-Gilbert relaxation operator. The recovery of the wall-width-determining ratio $\rho = A/K_u$ is enabled by our autograd-compatible micromagnetic solver and consistently achieves relative errors below 1%, providing physically meaningful parameters for downstream micromagnetic modeling or the identification of candidate exotic spin textures. While demonstrated here for Néel walls, the framework is general and extensible to richer energy models, alternative lifting strategies, and other magnetic imaging modalities, establishing a foundation for differentiable inverse micromagnetics.

MA 7.41 Mon 9:30 P2

jaxFMM: Fast and Accurate Stray Field Evaluation for FEM Micromagnetics — •Robert Kraft[1,2], Florian Bruckner[3], Dieter Suess[1,3], and Claas Abert[1,3] — [1]Research Platform MMM Mathematics-Magnetism-Materials, University of Vienna, Vienna, Austria — [2]Vienna Doctoral School in Physics, University of Vienna, Vienna, Austria — [3]Physics of Functional Materials, University of Vienna, Vienna, Austria

Micromagnetic simulations provide invaluable insight for the design of novel magnetic devices and materials. The size and complexity of simulated geometries is ever-increasing, quickly reaching limits in terms of computational cost. Here, the long-ranged stray or demagnetizing field proves to be particularly challenging since its complexity scales quadratically with the system size. Therefore, highly efficient and parallel routines for the evaluation of the stray field are a crucial component in any micromagnetic simulation code. We introduce jaxFMM, an open-source Fast Multipole Method (FMM) implementation written in JAX with a focus on stray field evaluation for Finite-Element simulation codes. Linear complexity scaling, efficient parallel execution on GPUs and precise control over the approximation error enable dynamic simulations of very large and complicated geometries. Additionally, the code is easy to use, extremely concise and ready for machine-learning or inverse-design tasks with automatic differentiation.

MA 7.42 Mon 9:30 P2

Theoretical study of the electronic and magnetic properties of Cd1-xMnxTe quantum wire under the combined effects of the applied magnetic field, spin orbit coupling and exchange effects — •Diana dahliah, Mohammad Elsaid, and Asaad Shandi — physics department, An Najah National University

This poster presents a study for the electronic and magnetic properties of Cd1-xMnxTe quantum wire (QW). The Hamiltonian for an electron confined in a quantum wire, in the presence of an external magnetic field and Rashba spin orbit interaction, had been solved. The obtained energy dispersion relation had been used to calculate the electronic structure and display the Landau levels and density of states for different physical Hamiltonian s parameters. The density of states function shows a significant dependence on spin, Rashba, exchange effect and magnetic field. The dependence of the magnetic properties like magnetization and magnetic susceptibility on the magnetic field strength, quantum wire radius, and exchange and Rashba strength parameters have been examined. The computed results show that the material can display a phase transition between Paramagnetic and Diamagnetic types. In addition, an oscillatory behavior in the magnetic susceptibility as a function of magnetic field has been observed. This oscillating behavior is a result of Landau levels crossing in the quantum wire energy spectra.

MA 7.43 Mon 9:30 P2

Workflow for Robust Code and Data Management exemplified for the numerical calculation of the Hopf index — •Jonas Nothhelfer, Ross Knapman, and Karin Everschor-Sitte — Universität Duisburg-Essen

Structured workflows for code and data management are essential in scientific projects to ensure reproducibility, transparency, and high-quality results. In this work, we examine such workflows from the perspective of a system administrator, focusing on the infrastructure and tools required to support scientific computing. Using a recent project as a case study, we illustrate a workflow designed to make the projects numerical methods for calculating the three-dimensional topological Hopf index accessible to the research community [1]. The workflow not only provides Python scripts but also includes extensions for the established micromagnetic simulation software Mumax3 [2]. Code development and version control are managed via GitLab, ensuring that the most up-to-date source code is available [3], while Zenodo is employed to assign persistent identifiers to released versions, thereby facilitating long-term accessibility and citation [4].

Overcoming quadratic complexity in time for fast-moving textures in micromagnetics: A moving window approach — •Michael Karl Steinbauer[1,2,3], Florian Bruckner[1,2], and Claas Abert[1,2] — [1]University of Vienna — [2]Research Platform MMM — [3]Vienna Doctoral School in Physics

From domain walls and skyrmion race track memory to magnon wave guides: A lot of recent interest in the field of magnetism has focused on fast-moving magnetic textures in otherwise homogeneously magnetized media. Micromagnetic modeling of these phenomena presents a significant computational challenge however, as the displacement of the texture typically requires the simulation volume to increase proportional to time t, leading to an overall simulation complexity of $O(t^2)$.

We introduce a general-purpose simulation methodology that achieves linear scaling $O(t)$ instead. This is accomplished by employing a moving simulation window that encompasses only a small region around the magnetic feature and is continuously re-centered as the feature moves, leveraging that the magnetization ahead of and behind the feature is often highly uniform. To mitigate finite-size effects, we implement a compensation of surface charges. Furthermore, this approach readily accommodates the introduction of location-dependent material parameters, such as material defects or grain structures. The method was implemented for the python library magnum.np [1], where it was successfully used to reduce computational times of a domain wall simulation from multiple weeks to less than a day.

MA 7.45 Mon 9:30 P2

Ferroelectric-controllable spin-orbit torque in two-dimensional magnetic heterostructures — •Weiyi Pan, Gusthavo Brizolla, and Jaroslav Fabian — Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany

The spin-orbit torque (SOT) in two-dimensional (2D) van der Waals magnets plays a crucial role in next-generation spintronic devices. However, achieving nonvolatile control of SOT in 2D systems remains challenging. In this work, we theoretically demonstrate that placing Fe_3GeTe_2, a promising 2D magnet exhibiting experimentally observable SOT effects, on a ferroelectric In_2Se_3 substrate, enables nonvolatile manipulation of the SOT through ferroelectric polarization reversal. Further analysis reveals that the polarization switching mainly affect the intra-band contribution to the SOT. Our results provide an effective strategy for controlling SOT in realistic 2D heterostructures, paving the way for tunable and energy-efficient spintronic devices in the future. This research has been supported by 2D SPIN-TECH.

MA 7.46 Mon 9:30 P2

Unidirectional Rashba-Edelstein Magnetoresistance in Topological Insulator-based magnetic Heterostructures — •Steffen Kober[1], Ruslan Salikhov[2], Jan Deinert[2], Igor Ilyakov[2], Alexey Ponomaryov[2], Atiqa Arshad[2], Thales Oliveira[2], Kang Jin[2], Gulloo Prajapati[2], Patrik Pilch[1], Anneke Reinold[1], Sergio Valenzuela[3], Carmen Gómez Carbonell[3], Zhe Wang[1], and Sergey Kovalev[1] — [1]TU Dortmund, Department of Physics, Dortmund, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [3]Catalan Institute of Nanoscience and Nanotechnology

Our recent experimental study of transition metal-based heterostructures has demonstrated that the unidirectional spin-Hall magnetoresistance remains active even at picosecond timescales. Here, we report on experimental investigations of the unidirectional Rashba-Edelstein magnetoresistance in topological insulator (TI)-based magnetic heterostructures, in particular, on the nonlinear terahertz (THz) responses in TI/Al/NiFe/Al thin films. The Rashba-Edelstein effect lifts the spin degeneracy due to inversion symmetry breaking at the interface of the TI, enhancing spin-dependency in the momentum space. We use anisotropic THz second harmonic generation to characterize the Rashba-Edelstein magnetoresistance. To separate this from other possible contributions, such as the thermally driven spin-Seebeck effect, we study samples with varying aluminum layer thicknesses between the TI and the ferromagnetic NiFe, which modifies spin propagation and proximity effects between the ferromagnet and the TI's spin texture.

MA 7.47 Mon 9:30 P2

X-ray Absorption Spectroscopy and X-ray Magnetic Circular Dichroism investigation of magnetic properties in monolayer van-der-Waals 3d transition metal diiodides — •Lorenzo Grilli[1], Amina Kimouche[2], Awsaf Chowdhury[1], Jendrik Gördes[1], Chen Luo[3], Florin Radu[3], Sangeeta Thakur[1], Marcel Walter[1], and Wolfgang Kuch[1] — [1]Freie Universität Berlin, Germany — [2]Universität Potsdam, Germany — [3]Helmholtz-Zentrum Berlin for Materials and Energy, Germany

Numerous theoretical works [e.g. A. S. Botana, Phys. Rev. Materials 3, 044001 (2019)] predict that robust magnetic order can persist down to the monolayer limit in 3d transition-metal dihalides. Here we investigate the epitaxial growth and electronic properties of ultrathin MnI_2 and CoI_2 films on heavy-metal and van-der-Waals substrates, using thermal evaporation from stoichiometric sources. Structural properties are characterized in-situ by LEED and XPS. Motivated by STM results [Daniel Rothhardt et al., ACS Nano 19, 2261 (2025)] showing that iodine reacts with Ag before forming MnI_2 islands, we use XPS to quantify stoichiometry and interface chemistry for MnI_2 grown on Ag(111) and on graphene, directly comparing a reactive metal substrate with an inert van-der-Waals one. In parallel, we explore growth of CoI_2 on similar substrates. The magnetic response of these epitaxial films is probed by XAS and XMCD at the VEKMAG end station of BESSY II, providing element-specific sensitivity to spin and orbital moments in the ultrathin limit. We discuss how the substrate influences the magnetic behaviour of MnI_2 and CoI_2 monolayers.

MA 7.48 Mon 9:30 P2

Strong Magnetic Anisotropy in CrSBr Revealed by Magnetotransport Measurements — •Paul Nufer[1,2], Monika Scheufele[1,2], Matthias Grammer[1,2], Julian Herrschmann[2,4], Florian Dirnberger[2,3,4], Matthias Althammer[1,2], and Stephan Geprägs[1] — [1]Walther-Meißner-Institut, BAdW, Garching, Germany — [2]TUM School of Natural Sciences, Physics Department, TUM, Garching, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany — [4]Zentrum für Quantum Engineering (ZQE), TUM, Garching, Germany

The antiferromagnetic two-dimensional van-der-Waals material CrSBr exhibits unique electronic properties, as its conductivity is strongly dependent on the direction of the current flow with respect to its orthorhombic crystalline symmetry as well as on the anisotropic magnetic properties. In our work, we investigate the interplay of the magnetic and electronic anisotropies by magnetotransport measurements. Therefore, exfoliated CrSBr multilayers are patterned into Hall-bar structures via lift-off processes using electron-beam lithography and sputter deposition. The magnetotransport measurements are conducted in cryogenic conditions between 10 K and 200 K. By measuring the field- and angle-dependent magnetoresistance in different rotation planes of the magnetic field, we characterize the temperature- and field-dependent magnetic phase transitions of CrSBr and find an anisotropic magnetoresistance of up to 40%. We extract the anisotropy and critical magnetic fields by using free-energy simulations and demonstrate the good agreement between simulation and experimental data.

MA 7.49 Mon 9:30 P2

High-frequency spin eigenstates of an altermagnetic domain wall — •Oksana Peschanska[1] and Volodymyr Kravchuk[1,2] — [1]Bogolyubov Institute for Theoretical Physics of the National Academy of Sciences of Ukraine, 03143 Kyiv, Ukraine — [2]Leibniz-Institut für Festkörper- und Werkstoffforschung, Helmholtzstraße 20, D-01069 Dresden, Germany

We have considered the scattering of spin waves by a domain wall (DW) in an easy-axis d-wave altermagnet (e.g. CoF2, MnF2). Similar to the conventional antiferromagnet, the scattering problem is reduced to the Schröedinger equation with $sech^2$ potential. However, due to altermagnetism, the amplitude of the scattering potential depends on the energy of the magnons. The latter has a number of physical consequences: (i) the scattering process is different for the clockwise and counterclockwise polarized magnons; (ii) the transmission coefficient is a nonmeromorphic function of the complex-valued wave vector, so a modification of Levinson's theorem is required; (iii) new high-frequency bound (localized) eigenstates appear and propagate along DW. The number of new eigenstates, their eigenfrequencies, and eigenfunctions depend on the altermagnetic strength, wave vector q along DW, and orientation of the DW relative to the crystallographic axes. With the increase of q, the size of the localization region of the bound state can increase as well as decrease, depending on the eigenstate polarization, the sign of the altermagnetic parameter, and the DW orientation.

MA 7.50 Mon 9:30 P2

Mössbauer Spectroscopy on the Candidate Altermagnet Material $FeNb_4S_8$ — •Jan Friedrichsen[1], Felix Seewald[1], Lilian Prodan[2], Joachim Deisenhofer[2], István Kézsmárki[2], and Hans-Henning Klauss[1] — [1]Institut für Festkörper- und Materialphysik, TU Dresden, Germany — [2]Experimental Physics V, Institute of Physics, University of Augsburg, Augsburg, Germany

$FeNb_4S_8$ is a proposed altermagnet and a member of the layered intercalated transition metal dichalcogenides. The crystal structure consists of stacked layers of $NbSe_2$, with sandwich layers of intercalated Fe atoms in hexagonal order[1]. Magnetic order is reported below the transition temperature $T_C = 150$ K.[2] Mössbauer spectra at room temperature show the presence of a finite electric field gradient (EFG) of $V_{zz} = -6.50(74)$ V/Å^2. At 4.2 K however the absolute value of the electric field gradient is considerably larger with a value of $V_{zz} = -66.45(13)$ V/Å^2. Mössbauer data proof predominantly colinear arrangement of the local iron spins along the c-axis and is consistend with the proposed altermagnetic state. First measurements indicate a strong magnetostriction as a likely source of the strong temperature dependence of V_{zz}. The hyperfine field that is reached at 4.2K is 15.52(14) T. We will discuss the implications of the mössbauer results on the electronic and magnetic structure and dynamics.

MA 7.51 Mon 9:30 P2

Altermagnetism on hyperbolic lattices — •Eric Petermann[1,2], Kristian Maeland[1,2], Haye Hinrichsen[1,2], and Björn Trauzettel[1,2] — [1]Institute for Theoretical Physics and Astrophysics, University of Würzburg, D-97074 Würzburg, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, D-97074 Würzburg, Germany

Altermagnets are a novel class of magnetic systems characterized by their momentum-dependent spin splitting without net magnetization. In this work, we extend established Euclidean tight-binding models of altermagnets to hyperbolic lattices defined on a discretized Poincaré disk. Using hyperbolic crystallography and hyperbolic band theory, we derive and analyze the band structure in these lattices. We discover particular properties of altermagnetism in hyperbolic space, for instance, higher angular momentum spin splitting in two-dimensional real space models. We find that orbital ordering or nonmagnetic sites are not essential to see spin-splitting in hyperbolic lattices, unlike Euclidean space.

MA 7.52 Mon 9:30 P2

Magnetic aftereffect and Barkhausen steps in thin Mn_5Si_3 films — •Gregor Skobjin[1], Javier Rial[2], Sebastian Beckert[3,4], Helena Reichlová[3,5], Vincent Baltz[2], Lisa Michez[6], Richard Schlitz[1], Michaela Lammel[1], and Sebastian Goennenwein[1] — [1]Department of Physics, University of Konstanz, Germany — [2]Univ. Grenoble Alpes, CNRS, CEA, Gren. INP, IRIG-SPINTEC, France — [3]IFMP and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, Germany — [4]DCN, TU Dresden, Germany — [5]Institute of Physics ASCR, Czech Republic — [6]Aix Marseille Université, CNRS, CINAM, AMUTECH, France

Altermagnets are an intriguing novel class of magnetic materials. We exploit the anomalous Hall effect response of micropatterned Mn_5Si_3 thin films to investigate their magnetization relaxation behavior. In experiments at T < 200 K i.e., in the altermagnetic phase, and for magnetic fields for which the samples exhibit large magnetic susceptibility, we observe a strong magnetic aftereffect as well as Barkhausen-like steps in the time-dependent Hall voltage evolution. More specifically, we recorded the evolution of the Hall voltage in micropatterned Hall bars with widths of 10 μm down to 0.1 μm at a series of different magnetic field magnitudes to gain insights into potential domain effects in the altermagnetic phase of Mn_5Si_3 at micron and submicron length scales. We critically analyze our experimental results and discuss implications for the micromagnetic structures in altermagnetic thin films.

MA 7.53 Mon 9:30 P2

Magnon-Driven Propulsion of Domain Walls in Altermagnets — •Nils Keller, Ricardo Zarzuela, Rodrigo Jaeschke-Ubiergo, and Jairo Sinova — Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany

Altermagnets form a recently identified class of collinear magnets whose compensated order coexists with time-reversal symmetry breaking and a spin-split electronic band structure with characteristic d-, g- and i-wave symmetry. Domain-wall propulsion by magnons is a central mechanism for spin-based information processing, but in antiferromagnets it relies on angular-momentum transfer because the domain-wall potential itself is reflectionless. In contrast, we show that altermagnetic domain walls can be propelled directly by magnons through linear-momentum transfer, without requiring the wall to acquire internal angular momentum first. This arises from the characteristic symmetry of the altermagnet, which generates a direction-dependent modification of the spin-wave scattering potential. As a result, both redshift and partial reflection of magnons become possible, lowering the energy cost for domain-wall motion and enabling direction-selective propulsion. These anisotropies suggest new strategies for logic and memory concepts based on steering domain walls along symmetry-selected channels. We identify the low-velocity regime and clarify the distinct scattering mechanisms responsible for the propulsion.

MA 7.54 Mon 9:30 P2

Current-induced Spin-Orbit Torque effects in RuO_2 thin films — •Niklas Schmolka, Florian Knossalla, Maik Gärner, Karsten Rott, and Günter Reiss — Bielefeld University, Germany

Current-induced manipulation of the antiferromagnetic order offers a promising route toward ultrafast and energy-efficient spintronic memory devices [1]. Results that are consistent with Néel vector switching could be a hint for antiferromagnetism in RuO_2 [2].

Here, we use eight-terminal devices to investigate Spin-Orbit Torque effects in RuO_2 thin films. We study bilayers consisting of RuO_2|Pt and RuO_2|W where Pt and W act as heavy-metal layers generating Spin-Orbit Torques. We observe signatures of reversible Néel vector reorientation through Hall measurements, with the two sample systems showing opposite responses consistent with the opposite Spin Hall Angles of Pt and W [3].

Additionally we measure pure RuO_2 films and examine the temperature dependence of the switching mechanism to further identify magnetic contributions and disentangle possible non-magnetic effects [4].

MA 7.55 Mon 9:30 P2

Tuning Anomalous Hall Effect in a d-wave Altermagnet — •Sergio Rodríguez Fernández, Rodrigo Jaeschke Ubiergo, and Jairo Sinova — Johannes Gutenberg-Universität Mainz, Deutschland

Altermagnets are a novel class of collinear magnets that, despite being magnetically compensated, break time-reversal symmetry. Their electronic band struc-

ture shows spin splitting with characteristic d-, g-, or i-wave symmetry. Owing to their broken time-reversal symmetry, they have been shown, both theoretically and experimentally, to exhibit an Anomalous Hall Effect (AHE) that depends strongly on the orientation of the Néel order.

In this poster, we discuss the AHE in d-wave altermagnets. Using minimal models, symmetry analysis, and the Kubo response formalism, we show how the AHE emerges from different orientations of the Néel vector. We build our minimal models with focus on the tunnability of these responses, and we apply our approach to realistic candidate materials. Our work deepens the understanding of transport properties in altermagnets, contributing to their growing relevance in spintronics research.

MA 7.56 Mon 9:30 P2

Growth of $MnSe_2$ Single Crystals as a Candidate for Supercell Altermagnets — •Mayra Handel, Franziska Walther, Sarah Krebber, Cornelius Krellner, and Kristin Kliemt — Physikalisches Institut, Goethe Universität Frankfurt, 60438 Frankfurt am Main

$MnSe_2$ is predicted to be a supercell altermagnet with d-wave order [1] at a temperature below T_N=49K [2]. $MnSe_2$ crystallizes in a cubic structure and shows a commensurate magnetic structure. Supercell altermagnets are characterized by a magnetic unit cell that is an integer multiple of the crystallographic unit cell. The enlarged magnetic unit cell introduces additional degrees of freedom in supercell altermagnets, enabling control over the spatial orientation of the order parameter. We report on the current progress in the growth of $MnSe_2$ single crystals by means of chemical vapor transport, employing various stoichiometries and transport agents. In addition, we present the chemical and structural characterization of polycrystalline samples of $MnSe_2$.

Possibility for altermagnetic to antiferromagnetic phase transition in $LaTiO_3$ — •Igor Maznichenko and Samir Lounis — Institute of Physics, Martin Luther University Halle-Wittenberg, D-06099 Halle, Germany

Here we investigate and compare the electronic band structure of altermagnetic and antiferromagnetic phases in Mott insulator $LaTiO_3$ [1]. Using *abinitio* calculations, we have found a stable altermagnetic phase with the *G*-type arrangement. In $LaTiO_3$, triple-degenerated cubic Ti t_{2g} orbitals are occupied by only one electron, the semiconducting band gap separates the occupied Ti $t_{2g}^1 e_g^0$ subband from the unoccupied conduction band edge, while the *f* states of La appear at much higher energies. The key structural factor of *Pbnm*-$LaTiO_3$, which determines its band gap and zero magnetization, is optimally rotated TiO_6. Using simulations of disorder for these Ti t_{2g} orbitals, we demonstrate the fragility of the altermagnetic phase with multiorbital effects.

MA 7.58 Mon 9:30 P2

Electrical control of the exchange bias effect at model ferromagnet-altermagnet junctions — •Gaspar De la Barrera and Alvaro Nunez — Universidad de Chile, Santiago, Chile

This work analyzes the behavior of the interface between a ferromagnetic material and an altermagnet. We use a well-established line of arguments based on electronic mean-field calculations to show that new surface phenomena that lead to altermagnetic materials induce an exchange bias effect on the nearby ferromagnet. We reveal the physical mechanisms behind this phenomenon that lead to quantitative control over its strength. Interestingly, we predict exotic electric-field-induced phenomena. This is an analogy to the relationship between exchange bias and the injection of spin currents in spin-transfer-dominated scenarios, which has been reported earlier in the traditional antiferromagnetic/ferromagnetic junction.

MA 7.59 Mon 9:30 P2

NEGF Quantum Transport Simulations in Altermagnetic Systems — •Tim Kalsberger[1], Erik Schroedter[1], Nicola Lo Gullo[2], Jan-Philip Joost[1], and Michael Bonitz[1] — [1]CAU Kiel, Germany — [2]Università della Calabria, Italy

Altermagnets have the potential to open a broad landscape of new applications. Promising examples include the fields of spintronics and ultrafast photomagnetism, which combine the special properties of altermagnets with ultrafast dynamics and quantum transport. One of these properties is the emergence of spin-polarized currents under an applied bias due to the spin-anisotropic Fermi surface, despite having zero net magnetization [1]. Accurate simulations of spin-resolved dynamics in large, strongly correlated systems are challenging and, with most methods, often impossible for long time scales due to the large basis size and complexity, even for simple lattice models. In this work, we use the quantum fluctuations approach based on non-equilibrium Green functions (NEGF) [2, 3] to simulate correlated, time-resolved, large altermagnetic systems out of equilibrium in scenarios aligned with realistic experimental setups.

Chirality dependent orbital magnetism and anomalous transport in twisted antiferromagnetic bilayers — •Zhiyuan He — Weinberg 2, 06120 Halle (Saale), Germany

Twisted magnetic van der Waals heterostructures have emerged as a fertile ground for exploring the interplay between lattice geometry and magnetism. While the twist angle magnitude governs the moiré potential scale, the physical consequences of the twist angle sign (chirality) remain unexplored due to the inherent mirror symmetry in conventional bilayer systems. In largely this work, we theoretically investigate the electronic structure and orbital transport properties of twisted A-type antiferromagnetic bilayers using a tight-binding model that incorporates lattice anisotropy and interface-induced symmetry breaking. We researched that the interference between the rotating lattice anisotropy and a fixed symmetry-breaking field lifts texture the degeneracy between positive ($+\theta$) and negative ($-\theta$) twist configurations. This symmetry breaking manifests significantly in the momentum-space distribution of the Orbital Magnetic Moment (OMM). on the twist chirality, leading to non-reciprocal Berry curvature distributions. These findings suggest that the twist sign can serve as a switchable degree of freedom to manipulate orbital-driven transport phenomena, such as the topological Hall effect and magneto-optical responses, in altermagnetic moiré systems.

MA 7.61 Mon 9:30 P2

EMCD on Altermagnets — Hitoshi Makino[1], Sebastian Schneider[1], Sebastian Beckert[1], Rikako Yamamoto[2,3], Claire Donnelly[2,3], and •Pohl Darius[1] — [1]DCN, TUD Dresden University of Technology, Dresden, Germany — [2]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [3]WPI-SKCM Hiroshima University, Hiroshima, Japan

Altermagnets represent a recently discovered class of magnetic materials featuring unique symmetry properties and compensated magnetic structures, which set them apart from conventional ferromagnets and antiferromagnets. Their novel electronic and magnetic characteristics are interesting for both fundamental research and advanced technological applications, particularly in spintronics. It has recently been shown that X-ray Magnetic Circular Dichroism is sensitive to time-reversal symmetry breaking in altermagnets. A similar behavior is expected for electron energy loss magnetic chiral dichroism (EMCD), the electron wave analogue to XMCD, a method providing element-specific sensitivity and high spatial resolution spectroscopic and imaging capabilities in an electron microscope. We will present first proof-of-principle EMCD experiments on MnTe and Fe_2O_3 and its comparison to structural TEM investigations and XMCD measurements to demonstrate the versatility of our approach and its application to probe altermagnetic materials at the nanoscale.

MA 7.62 Mon 9:30 P2

Growth and properties of altermagnetic MnTe thin films — •Lukas Stroh, Maik Gaerner, Judith Bünte, Karsten Rott, Jan Schmalhorst, Andreas Hütten, and Günter Reiss — Bielefeld University, Germany

In recent years, a new unconventional magnetic phase, named altermagnetism, has emerged [1]. Such altermagnetic materials combine anisotropic time-reversal symmetry breaking with the vanishing net-magnetization of antiferromagnets. One of the materials in which altermagnetism has been observed in is manganese telluride (MnTe) [2,3]. Here, we systematically investigate the growth of MnTe thin films on SrF_2(111) via magnetron co-sputtering. We analyze how the growth-conditions influence structural and electronic properties, including the spontaneous anomalous Hall effect.

Seed-layer assisted epitaxial growth of Mn_5Si_3 thin films on Al_2O_3 — •Maximilian Koll[1], Maik Gaerner[1], Judith Bünte[1], Finn Peters[1], Andreas Hütten[1], Karsten Rott[1], Jan Schmalhorst[1], Martin Wortmann[2], and Günter Reiss[1] — [1]Bielefeld University, Faculty of Physics, 33615 Bielefeld, Germany — [2]Bielefeld University of Applied Sciences and Arts, Faculty of Engineering and Mathematics, 33619 Bielefeld, Germany

Mn_5Si_3 thin films are a prominent platform in which signatures of altermagnetism, such as the anomalous Hall effect [1] or the anomalous Nernst effect [2,3], have been observed. These responses are consistent with a theoretically predicted d-wave altermagnetic state that breaks time-reversal symmetry while exhibiting zero net magnetization as well as THz spin-current dynamics [4].

Here, we report on the growth of epitaxial Mn_5Si_3(0001) on Al_2O_3(0001) via magnetron sputtering and molecular beam epitaxy. We demonstrate that a high-temperature Mn_5Si_3 seed layer significantly enhances the crystallinity of the thin

films while maintaining a smooth surface morphology. Finally, we show that the emergence of a spontaneous anomalous Hall effect in the Mn_5Si_3 thin films is highly sensitive to the Mn content as well as the annealing procedure.

Ab-initio investigation of altermagnetic splitting in the NiAs-type solid solutions (Cr,Mn)-(Sb,Te) — •Karel Knížek and Kyohoon Ahn — Institute of Physics, Czech Academy of Sciences, Prague, Czechia

CrSb is a layered collinear antiferromagnet with perpendicular magnetic anisotropy in the hexagonal structure of NiAs-type, which holds particular interest for AFM spintronics since it belongs to a few compounds which have both high ordering temperature (T_N = 705 K) and substantial altermagnetic spin splitting. Phase diagrams of solid solutions between antiferromagnetic CrSb and ferromagnetic MnSb and CrTe are rich in many various magnetic arrangements [1,2,3]. The observed evolution of the magnetic order as a function of composition for both phase diagrams is consistent with the assumption of the dominance of the M-X-M (M=Cr,Mn, X=Sb,Te) superexchange interaction. The strength of this interaction depends on the M-X-M angle, which is correlated with trigonal distortion of the MX_6 octahedra. Within these phase diagrams, we have performed electronic structure calculation to investigate the evolution of magnetic ordering, with focus on the altermagnetic spin splitting in case of antiferromagnetic ordering, as a function of structural parameters, namely the trigonal distortion and cell volume. In particular we have studied the effect of uniaxial pressure.

Correlation of in-situ Hall measurements with LTEM on Fe/Gd multilayers — •Sebastian Beckert[1], Sebastian Schneider[1], Joe Sunny[2], Manfred Albrecht[2], Bernd Rellinghaus[1], and Darius Pohl[1] — [1]DCN, cfaed, TU Dresden, Dresden, Germany — [2]Institute of Physics, University of Augsburg, Augsburg, Germany

Topologically protected skyrmions are promising information carriers for next generation memory devices, because they can be electrically manipulated and detected, e.g., through their Hall signatures. Sputtered Fe/Gd multilayers host skyrmions at room temperature, making them an ideal model system for exploring the correlation between skyrmion formation and the topological Hall effect (THE) [1].

Building on prior in-situ correlations of Hall responses and Lorentz transmission electron microscopy (LTEM) imaging in antiskyrmion hosting materials [2], we combine simultaneous Hall-voltage measurements with LTEM imaging of the magnetic state of sputtered Fe/Gd multilayers. These experiments aim to disentangle the relationship between skyrmion presence and the Hall signal, which are typically probed independently.

Effects of chiral polypeptides on skyrmion stability and skyrmion diffusion — Fabian Kammerbauer[1], Yael Kapon[2], •Theo Balland[1], Shira Yochelis[2], Yossi Paltiel[2], and Mathias Kläui[1] — [1]Institut für Physik, Johannes Gutenberg Universität Mainz, 55099 Mainz, Germany — [2]Institute of Applied Physics, Faculty of Sciences, The Hebrew university of Jerusalem, Jerusalem 9190401, Israel

CISS, chirality-induced spin selectivity is a phenomenon that has raised significant interest due to the large spin polarizations generated by organic molecules and other effects such as magnetic switching of ferromagnets impacted by chiral molecules [1]. In hybrid systems, these chiral molecules have been observed to influence magnetic properties such as changes in the magnetization [2]. In this study, we investigate how chiral molecules of α-helix polyalanine interact with chiral spin structures, namely magnetic skyrmions, which are stabilized in ferromagnetic/heavy metal multilayers due to Dzyaloshinskii-Moriya interaction [3]. Using magneto-optic Kerr effect imaging, we show that chiral polypeptides can influence the stability of skyrmions by modifying the ranges of temperature and applied magnetic field in which they are stable. We also show that the chiral molecules affect the skyrmion dynamics, in particular the thermal diffusion of the skyrmions [4].

Coupled and decoupled topological textures in van der Waals heterostructure — •Sourav Chowdhury[1], Daniel Metternich[2], Simon Gaebel[2], Chithra Sharma[3], Jayjit Dey[1], Victor Deinhart[2], Tim Butcher[2], Michael Schneider[2], Josefin Fuchs[2], Bastian Pfau[2], and Moritz Hoesch[1] — [1]Deutsches Elektronen-Synchrotron (DESY), Hamburg, Germany — [2]Max-Born-Institut (MBI), Berlin, Germany — [3]University of Hamburg, Hamburg, Germany

Topological nanodomain spin textures in two-dimensional (2D) van der Waals (vdW) magnets are attracting increasing interest for next-generation spintronic technologies, offering pathways to ultradense data storage, energy-efficient operation, and unconventional data processing architectures [1]. Using element-specific X-ray imaging, we visualize a variety of topological spin textures in an Fe3GeTe2/CrGeTe3 heterostructure and directly resolve their interlayer behavior. We find that nanodomains in the two layers are strongly coupled under certain conditions, while within a specific magnetic-field window, the domains become decoupled and evolve independently. This transition from coupled to decoupled topological textures can be understood in terms of distinct magnetic anisotropy contributions in the two layers, arising from interlayer interactions rather than solely from the properties of the individual materials. [1] K. Chang et al., Science 2016, 353, 274.

MA 7.68 Mon 9:30 P2

Anisotropic skyrmion liquid phase — •Daniel Schick[1], Tim Matthies[2], Thomas Mutschler[1], Levente Rózsa[3,4], and Ulrich Nowak[1] — [1]University of Konstanz, Konstanz, Germany — [2]University of Hamburg, Hamburg, Germany — [3]Wigner Research Centre for Physics, Budapest, Hungary — [4]Budapest University of Technology and Economics, Budapest, Hungary

Melting transitions in two-dimensional systems of particles have attracted much attention in research since the development of the Kosterlitz-Thouless-Harperlin-Nelson-Young theory, particularly because of an intermediate phase with long-ranged orientational but short-ranged translational order, called the hexatic phase.

Magnetic skyrmions are topological quasiparticles in thin magnetic films and, due to their two-dimensional nature, are subject to KTHNY theory. Recently, the hexatic phase was identified experimentally in skyrmion lattices [1]. Here, we use a molecular dynamics simulation to study the phase transitions in skyrmion ensembles. Taking into account the anisotropic interaction of skyrmions in the $(Pt_{0.95}Ir_{0.05})$/Fe/Pd(111) system, we show how this anisotropy influences the phase of the skyrmion system. Instead of an intermediate hexatic phase between solid and liquid phase, one observes a direct solid-liquid transition, with a global orientational order even in the liquid phase.

Rotating Skyrmion Lattice by Circularly Polarized Light — •Reza Doostani and Achim Rosch — University of Cologne, Cologne, Germany

Previously, it has been studied that shining a circularly polarized light on a skyrmion crystal (SkX) induces rotation in the lattice. This is due to Inverse Faraday Effect where spins experience local magnetic field. The magnitude of rotation depends on the fluence of light and its polarization. There exist a fluence threahold under which the SkX does not rotate. Further, one can start and stop the rotation by doing double pulse laser experiment and changing the separation time between two pulses. These results has been theoretically described where coherent oscillation of rotation amplitude as a function of pulse separation matches the experimental observation. However the theoretical value for rotation amplitude (for clean system) is orders of magnitude smaller than experimental value. Previously, the only source of rotation was due to Gilbert damping, however this cannot describe the rotation alone. In this work, we investigate other source of rotation in this system, namely we induce disorder and analyze its effect.

MA 7.70 Mon 9:30 P2

Noise measurements on magnetic skyrmions in magnetic multilayers — •Arthur Schmidt[1], Bereket Ghebretinsae[1], Joe Sunny[2], Manfred Albrecht[2], and Jens Müller[1] — [1]Institute of Physics, Goethe University Frankfurt, 60438 Frankfurt am Main, Germany — [2]Institute of Physics, University of Augsburg, Universitätsstraße 1, 86135 Augsburg, Germany

Magnetic skyrmions are topologically protected spin textures which usually appear in materials with broken inversion symmetry and strong spin-orbit coupling due to emergent Dzyaloshinskii-Moriya interaction (DMI). While in bulk materials skyrmions exist mostly at low temperatures, in magnetic multilayers (MM) they can be stabilized at room temperature [1], which, in combination with their small size, stability and fast and energy efficient movement, make them promising for spintronics applications e.g. in unconventional computing and high-density magnetic storage. Here we present first results on low-frequency resistance noise spectroscopy measurements on Pt-Co-Ta-based MM systems which host Néel-type skyrmions at room temperature. The intention is to utilize low-frequency noise as an effective probe for the electrical characterization of

fundamental skyrmion properties such as the skyrmion lattice constant or their mean velocity and to investigate their current-induced dynamics [2-4].

Parameter-Dependent Stability of Magnetic Hopfions — •Niklas Oettgen, Sandra C. Shaju, Maria Azhar, and Karin Everschor-Sitte — Faculty of Physics, University of Duisburg-Essen, Duisburg, Germany

Hopfions are three-dimensional topologically protected magnetic textures that can be considered as closed loops of twisted skyrmion strings. We implement a model of spatially varying Dzyaloshinskii-Moriya interactions in micromagnetic simulations to explore Hopfion stability across a range of external magnetic fields and uniaxial anisotropies. Our simulations identify a clear regime in which the Hopfion remains metastable, and give insight into the conditions required for their formation and robustness.

MA 7.72 Mon 9:30 P2

Stability and Internal Structure of Skyrmioniums — •Finn Feldkamp[1,2], Alessandro Pignedoli[1], Ross Knapman[1], Maria Azhar[1], and Karin Everschor-Sitte[1] — [1]Faculty of Physics and Center for Nanointegration Duisburg-Essen, Duisburg, Germany — [2]Faculty of Physics and Earth System Sciences Leipzig University, Leipzig, Germany

Skyrmioniums are magnetic textures that can emerge in thin-film magnets under suitable conditions, potentially coexisting with other configurations such as domain walls and skyrmions. They can be understood as two nested skyrmions with opposite topological charge, giving rise to a ring-like, non-topological structure rather than the single-core profile characteristic of skyrmions. In this work, we investigate the stability and internal structure of skyrmioniums in thin films, examining the influence of crystalline anisotropy, external magnetic fields, and the demagnetization field. We present a comparative analysis with skyrmions, highlighting key similarities and differences in their stability regimes and structural responses to material and field parameters.

MA 7.73 Mon 9:30 P2

Investigation of the hyperfine coupling constants of the endohedral fullerene N@C_{60} — •Rebecca Löffler, Marco Sommer, and Johann Klare — Inst. of Physics, Univ. Osnabrück, Barbarastr. 7, 49076 Osnabrück, Germany

Endohedral fullerenes such as N@C_{60} are considered promising systems for spin-based quantum bits and quantum sensors on a nanoscale due to their exceptional spin stability and long coherence times, even at room temperature. In this work, the temperature-dependent hyperfine coupling constant of N@C_{60} in various solvents was investigated using EPR spectroscopy. To understand the influence of the chemical environment, crystalline N@C_{60} was introduced into organic solvents (toluene, CS_2) and into an aqueous host*guest complex with two γ-cyclodextrin molecules and then compared. The results show that a vibration model to Waiblinger (PhD thesis, Univ. Konstanz, 2001) reliably describes the behavior of N@C_{60} in crystalline form and in organic solvents, but cannot be applied to the γ-cyclodextrin complex. For crystalline N@C_{60}, a vibrational energy of E = (14,7 ± 0,2) meV was determined. Phase transitions could be detected in toluene and in the γ-cyclodextrin complex by changes in the hyperfine coupling constants. The results show that the hyperfine coupling constant has great potential for use in quantum sensor technology, especially for precise measurements of phase transitions, such as the freezing of water.

MA 7.74 Mon 9:30 P2

Electron paramagnetic resonance and magnetization studies on tetrahedral Co^{II} complexes — •Matthias Heinrich[1], Jan Arneth[1], Amit Gharu[2], Kuduva Vignesh[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Department of Chemical Sciences, IISER Mohali, India

We report the static and dynamic magnetic properties of a series of five cobalt complexes of the type $Co^{II}_4Co^{II}$ with four octahedrally coordinated Co^{III} centers in the low-spin $S = 0$ state and a magnetically isolated Co^{II} ion ($S = 3/2$) in distorted tetrahedral coordination. The tetrahedral distortion differs across the series due to variations in bond lengths and bond angles. Our static and dynamic magnetization measurements of all compounds reveal field-induced magnetic relaxation as well as pronounced magnetic anisotropy. For one representative complex, high-field EPR-studies are presented which allow to determine the anisotropic g-factor as well as the easy-plane anisotropy. The effect of tetrahedral distortion on the magnetic anisotropy is quantitatively evaluated and discussed.

MA 7.75 Mon 9:30 P2

Investigating the Magnetic 3d-3d and 3d-4f Interaction in Triangular $Cr^{III}_3Ln^{III}$ Complexes — •Rui Yang[1], Jan Arneth[1], Muthu Thangavel[2], Christopher Anson[2], Annie Powell[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Institute for Inorganic Chemistry, Karlsruhe Institute of Technology, Germany

The interplay between the highly localized 4f electrons of the lanthanide ions and the more diffuse transition-metal 3d electrons leads to complex and often weak coupling mechanisms that are difficult to predict and quantify. Here, we report the static and dynamic magnetic properties of a series of isostrucural triangular $Cr^{III}_3Ln^{III}$ (Ln^{III} = Y, Gd, Tb, Dy, Ho, Er, Yb) complexes studied by means of dc/ac magnetization and high-field EPR. In particular, we investigate the bare 3d-magnetism of the Cr^{III}-triangle which is realized for diamagnetic Ln=Y and systematically study the 3d-4f interaction in the series of paramagnetic Ln.

MA 7.76 Mon 9:30 P2

Optimization of metal-doped M0.2Fe2.8O4/PEG nanocomposite for enhanced magnetic and relaxometric performance in MRI applications — •Mennatallah Abouhasswa[1], Ahmed Al Shahawy[2], Samaa El Dek[2], Messaoud Harfouche[3], Nagwa Okasha[1], Giuliana Aquilanti[4], Neama Imam[5], and Jan Ingo Flege[5] — [1]Physics Department, Ain Shams University, Egypt — [2]Faculty of Postgraduate Studies for Advanced Sciences, BeniSuef University, Egypt — [3]SESAME Synchrotron, Jordan — [4]Elettra,Sincrotrone Trieste, Italy — [5]Brandenburg University of Technology Cottbus, Senftenberg, Germany

Magnetic spinel ferrites are promising magnetic resonance imaging (MRI) contrast agents owing to their tunable structure, magnetic anisotropy, and biocompatibility. M0.2Fe2.8O4 nanoparticles (M = Fe2+, Mn2+, Cu2+) coated Polyethylene glycol (30%PEG-6000) were synthesized to correlate cation substitution with structural, magnetic, and relaxometric behavior. XRD, HRTEM, FTIR, XPS, synchrotron-based XAFS spectroscopy, and Vibrating Sample Magnetometer (VSM) confirmed single-phase nanocrystals (8-13 nm) with mixed Fe2+/Fe3+ states and preserved spinel geometry upon PEG coating. Mn-doping enhanced saturation magnetization and transverse relaxivity, providing the strongest T2 weighted MRI contrast. The results demonstrate that combining controlled B-site substitution with hydrophilic PEG capping enables concurrent optimization of magnetic response and colloidal stability, highlighting Mn0.2Fe2.8O4/PEG as a high-performance and biocompatible MRI nanocontrast agent.

MA 7.77 Mon 9:30 P2

Height Calibration of Nitrogen Vacancy Diamond Tips Using Current-Carrying Wires — Robin Abram, •Ricarda Reuter, Alexander Fernández Scarioni, Sibylle Sievers, and Hans Werner Schumacher — Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany

Scanning Nitrogen Vacancy Microscopy (SNVM) is a measurement technique capable of resolving the spatial distribution of magnetic stray fields with nanometer and microtesla resolution, respectively. It combines optical field detection with a scanning probe-like approach, where the key component is a diamond scanning tip containing a single NV center. While magnetic field measurements are quantum-calibrated with respect to the position of the NV center, precise knowledge of the distance to the sample is required to also consider the height dependence. The latter can currently only be estimated with an uncertainty of up to several nanometers, most commonly by calibration with a known stray field, e.g. using ferromagnetic microstructures. We established an improved height calibration based on SNVM studies of the current-induced Oersted field in Pt wires by Lee et al.. The out of plane field component is extracted from the raw data taken along the NV spin axis, following the approach first introduced by Schendel et al. and later applied to SNVM by Dovzhenko et al., and fitted to an analytical model. Using this approach, we realized a height calibration with an uncertainty of 10 nanometers for both 100 and 111 cut diamond tips. We also found that the nominally expected NV height underestimates the calibration result by about 30 nanometers.

MA 7.78 Mon 9:30 P2

Influence of Reference Sample and Scan Parameters on Magnetic Force Microscopy Calibrations — •Christopher Habenschaden[1], Baha Sakar[2], Sibylle Sievers[1], and Hans Werner Schumacher[1] — [1]Physikalisch-Technische Bundesanstalt (PTB), 38116 Braunschweig, Germany — [2]Felix Bloch Institute for Solid State Physics, University of Leipzig, Linnéstraße 5, 04103 Leipzig

Magnetic force microscopy (MFM) is a technique that enables the precise characterization of magnetic stray field distributions with high sensitivity and spatial resolution. By employing an appropriate calibration procedure, MFM can also provide quantitative values for magnetic fields. This calibration typically involves measuring a reference sample to identify the stray field or stray field gradient of the tip at the sample's surface. This distribution is known as the tip transfer function (TTF), which is obtained through regularized deconvolution in Fourier space. The performance of this process is heavily influenced by the reference sample's properties, scan parameters, and the detection system's noise characteristics, which can restrict its applicability. Our findings indicate that achieving a strong overlap of frequency components between the reference sample and the sample under test is more crucial for accurately reconstructing the stray field than simply obtaining a precise real-space representation of the tip's stray field distribution.

MA 7.79 Mon 9:30 P2

Accessing in-plane stray field components with torsional resonance mode magnetic force microscopy — •Jorge Marqués-Marchán[1], José Claudio Corsaletti Filho[1], Pamela Morales-Fernández[1], and Claire Donnelly[1,2] — [1]MPI CPfS, Dresden, Germany — [2]WPI-SKCM2, Hiroshima, Japan

In recent years, the emergence of 3D nanomagnetism and topological configurations has highlighted the importance of mapping the 3D vector field components in these systems. A lab-based technique that could provide such contrast is torsional resonance mode magnetic force microscopy (TR-MFM), where the MFM probe oscillates laterally with respect to the sample surface. Although MFM is a well-established technique, the use of TR-MFM has only been validated on standard samples [1,2]. Here, we use TR-MFM in combination with standard MFM to map both the in-plane and out-of-plane stray field components of different samples, aiding the understanding of different 3D magnetic configurations.

MA 7.80 Mon 9:30 P2

Lensless magneto-optical imaging — •Volker Neu[1], Giancarlo Pedrini[2], Ivan Soldatov[1], Stephan Reichelt[2], and Rudolf Schäfer[1] — [1]IFW Dresden, Helmholtzstr. 20, 01069 Dresden — [2]Institut für Technische Optik (ITO), Univ. Stuttgart, Pfaffenwaldring 9, 70569 Stuttgart

Magneto-optical methods, which utilize the interaction of polarized light with the magnetization state of the sample in reflection (magneto-optical Kerr effect) or in transmission (Faraday effect) present the most prominent classical microscopy techniques to investigate magnetic microstructures down to a few hundred nanometers.

In a first proof-of-principle study [1] we verified the feasibility of lensless magnetic imaging in the optical regime and explored the various contrast mechanisms that can be applied in such an approach. We demonstrate that the reconstructed intensity is in full qualitative agreement with the intensity contrast expected from conventional lens-based Faraday microscopy. This holds for the usual application of linearly polarized light with an almost crossed analyzer, but also for the less common combination of linearly polarized light with fully crossed analyzer. The additional phase information, not accessible with conventional microscopy, offers direct access to domain information in the latter case. This initial verification of lensless magneto-optical imaging will enable the various established advantages of lensless microscopy to be utilized for the examination of magnetic materials in the future.

MA 7.81 Mon 9:30 P2

Soft X-ray ptychography with SOPHIE — Tim A Butcher[1,2], Simone Finizio[1], Lars Heller[1], Nicholas W Phillips[1,3], Blagoj Sarafimov[1], Carlos A F Vaz[1], Armin Kleibert[1], Benjamin Watts[1], Mirko Holler[1], and •Jörg Raabe[1] — [1]Paul Scherrer Institut, 5232 Villigen PSI, Switzerland — [2]Max Born Institut, 12489 Berlin, Germany — [3]CSIRO, 3168 Clayton, Australia

Soft X-ray ptychography is rapidly becoming one of the key synchrotron-based magnetic imaging techniques, thanks to the possibility of combining high spatial resolutions over large scan areas with strong contrast mechanisms such as X-ray circular and linear dichroisms. To meet the demands of the user community for ptychography imaging, the SOft X-ray Ptychography Highly Integrated Endstation (SOPHIE) was developed at the Swiss Light Source. In this presentation, we give an overview of the design and performance of the endstation during its commissioning at the SoftiMAX beamline of MaxIV, together with an example of its imaging capabilites, where sub 10nm resolution at the Fe L_3 edge was demonstrated in routine conditions.

MA 7.82 Mon 9:30 P2

High resolution imaging of ultrathin PMA films for racetrack applications — •Anindit Das[1], Sebastian Schneider[1], Jae-Chun Jeon[2], and Bernd Rellinghaus[1] — [1]DCN, cfaed, TU Dresden, Dresden, Germany — [2]Max Planck Institute for Microstructure Physics, D-06120 Halle (Saale), Germany

The realization of domain wall (DW)-based racetrack memory requires Perpendicular Magnetic Anisotropy (PMA) thin films with finely tuned magnetic properties. This work combines direct imaging via Lorentz Transmission Electron Microscopy (LTEM) with micromagnetic simulations to establish design principles for such materials. Our simulations systematically vary key parameters—including saturation magnetization (M_s), uniaxial anisotropy (K_u), exchange stiffness (A_{ex}), and the Dzyaloshinskii-Moriya interaction (DMI)—to understand their impact on DW structure and dynamics. We identify that an optimal balance is critical: a high K_u ensures thermal stability, while a moderate M_s and tailored DMI are essential for efficient, fast DW motion. However, significant challenges arise from conflicting requirements; for instance, a high A_{ex} is necessary for robust DWs but can also increase the depinning field, and excessive DMI can compromise DW integrity. This study provides a crucial map of the material parameter space, highlighting the trade-offs between stability, speed, and fabricability to guide the development of viable PMA films for racetrack memory.

Financial support by the DFG through TRR 404, project no. 528378584, is gratefully acknowledged.

Theory of transport properties of coplanar spin spirals — •Ilja Turek — Institute of Physics of Materials, Czech Acad. Sci., Brno, Czech Rep.

Coplanar spin spirals are compensated magnetic systems related closely to the recently introduced p-wave magnets [1]. Their special magnetic order leads to the absence of space-inversion symmetry, which is a necessary prerequisite for a nonzero Edelstein effect (change of magnetization due to an external electric field). Here, we consider simple tight-binding models of nonrelativistic coplanar spin spirals and study their transport properties within the Kubo linear response theory and the conserving selfconsistent Born approximation [2]. We reveal that depending on the model details, both the electric conductivity and the coefficient of the Edelstein effect contain not only a coherent (quadratic in the averaged one-particle propagators) term, but also a nonnegligible incoherent term due to the disorder-induced vertex corrections. Consequences for reliable evaluation of the transport properties of real spin-spiral systems are discussed briefly as well. [1] A. Chakraborty et al., Nat. Commun. 16 (2025) 7270. [2] I. Turek, Phys. Rev. B 93 (2016) 245114.

MA 7.84 Mon 9:30 P2

Emergent non-coplanar magnetism and colossal transverse magnetoresponse in strongly correlated nodal-line half-metal — •Jyotirmoy Sau[1,2], Sourav Chakraborty[1], and Manoranjan Kumar[1] — [1]S. N. Bose National Centre for Basic Sciences, Kolkata 700106, India — [2]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

Understanding the interplay of strong correlation and temperature in nodal-line semimetals can unlock new pathways for spin current control. Here, we consider the $3d$-$5d$ double-perovskite Ba_2CoWO_6, which features mirror-symmetry-protected nodal lines, strong Co-site interactions, and spin-orbit coupling at W sites. Our first-principles and exact diagonalization results reveal a half-metallic ground state with high-spin Co and topologically non-trivial bands. Finite spin-orbit coupling gaps out nodal points and induces band inversion. The ensuing non-trivial Berry curvature generates an anomalous Hall response and stabilizes a non-coplanar magnetic order. Our semi-classical Monte Carlo finite-temperature simulation of the five-orbital Hubbard model confirms the non-coplanar magnetic order and uncovers colossal transverse magnetoresponse. We predict the temperature and magnetic field scales for the tunability of the magnetoresponse.

MA 7.85 Mon 9:30 P2

Exploring the tunability of magnetism and charge density waves states in VSe2 — •Javier Corral Sertal[1,2], Adolfo O. Fumega[3], S. Blanco-Canosa[4], and Victor Pardo[2,5] — [1]CiQUS, Centro Singular de Investigacion en Quimica Biolóxica e Materiais Moleculares, Universidade de Santiago de Compostela, Santiago de Compostela, Spain — [2]Departamento de Física Aplicada, Universidade de Santiago de Compostela, Santiago de Compostela, Spain — [3]Department of Applied Physics, Aalto University, 02150 Espoo, Finland — [4]Donostia International Physics Center (DIPC), San Sebastián, Spain — [5]Instituto de Materiais iMATUS, Universidade de Santiago de Compostela, Santiago de Compostela, Spain

Transition metal dichalcogenides (TMDs, MX_2 : M = Nb, Ti, V..., X = S, Se, Te...) are a familiy of two-dimensional (2D) layered materials that attract great attention because of their large landscape of collective phenomena that differ from the bulk ones. Among them, magnetism in low dimensions has been argued for decades, being rejected by the Mermin-Wagner theorem but found as Ising-type ferromagnets in purely 2D-materials VSe_2 is a TMDs where ferromagnetism is present in its normal state (NS) bulk phase, but becomes supressed when the charge density wave (CDW) phase $4 \times 4 \times 3$ appears or it is reduced to the monolayer limit. Here, we present a computational study of several heterostructure packaging of VSe_2 with other TMDs materials in order to elucidate if the formation of the CDW can be supressed by different stacking arrangements, and if with these stackings we are able to retain magnetism in the system.

MA 7.86 Mon 9:30 P2

Temperature dependence of the spin-wave dispersion in the spin-polarized homogeneous electron gas — •Michael Neugum, Noah Spiegelberg, and Arno Schindlmayr — Universität Paderborn, Department Physik, 33095 Paderborn, Germany

Spin waves are an important class of elementary excitations in magnetically ordered materials. Due to the absence of an energy gap, they are easily thermally excited and, consequently, influence technological applications like spintronics or magnetic data storage. The impact of temperature is twofold: First, the occupation numbers of the bosonic spin-wave modes increase with the temperature. Second, the dispersion itself changes, leading to lowered spin-wave energies and hence to an accelerated population. The latter effect is largely ignored in cur-

rent ab initio calculations, which are typically performed at 0 K and often lack proper temperature-dependent functional expressions. Here we calculate the spin-wave dispersion of the spin-polarized homogeneous electron gas at finite temperature within time-dependent density-functional theory, taking only the exchange functional into account. The temperature dependence of the exchange kernel is fully included. Our results demonstrate that the spin-wave energies are indeed systematically lowered as the temperature increases. As an important observation, the spin-wave stiffness also decreases, so that there is a nonnegligible effect on long-wavelength modes and on thermodynamic quantities, such as the specific heat capacity, even at low temperature.

Odd-parity spin splitting and anomalous Hall effect in spiral magnets — •Shun Okumura[1,2], Moritz M. Hirschmann[2], and Yukitoshi Motome[3] — [1]Quantum-Phase Electronics Center, The University of Tokyo, Tokyo, Japan — [2]RIKEN Center for Emergent Matter Science, Wako, Japan — [3]Department of Applied Physics, The University of Tokyo, Tokyo, Japan

Altermagnetism with collinear antiferromagnetic order has recently attracted considerable interest for a spontaneous anomalous Hall effect (AHE) mediated by spin-orbit coupling (SOC). In contrast, non-coplanar magnetic textures such as skyrmions exhibit a topological Hall effect by imprinting a Berry phase on itinerant electrons even in the absence of SOC. However, in the case of spiral magnetism, a prototypical example of a non-collinear and coplanar magnetic structure, the conditions required to realize AHE have yet to be thoroughly explored.

In this study, we investigate the AHE in metallic systems coupled to commensurate spiral magnetic textures. The electronic bands exhibit odd-parity spin splitting with spin polarization perpendicular to the helical plane. In the presence of SOC and finite magnetization, the Berry curvature concentrated along the spin-nodal lines leads to a characteristic AHE in the spin spiral state. This spiral-induced AHE depends sensitively on the SOC type, helical plane, and magnetization direction. We also demonstrate that a "p-wave" magnet with a commensurate spin spiral, recently identified in an f-electron material, can host this enormous AHE.

Pines' Demons in d-Wave Altermagnets: From Hidden Modes to Fano-Demon States — •Habib Rostami[1] and Johannes Hofmann[2] — [1]Department of Physics, University of Bath, United Kingdom — [2]Department of Physics, Gothenburg University, Sweden

We develop a Fermi-liquid description of d-wave altermagnets and analyze their charge and spin collective excitations [1]. In addition to the conventional undamped plasmon, where both spin components oscillate in phase, we find an acoustic plasmon (demon) mode with out-of-phase spin dynamics. Using the dynamical structure factor, we show that the demon frequency and spectral weight depend sensitively on the Landau parameters and on the propagation direction. As a function of angle, the acoustic mode evolves from a hidden state with vanishing spectral weight in the density response, to a weakly damped propagating demon, and, below a critical interaction parameter, to a Fano-demon mixed state that strongly hybridizes with particle-hole excitations and exhibits an asymmetric line shape. We briefly discuss possible implications for probing and exploiting collective electron spin oscillations in altermagnetic materials.

MA 8.3 Mon 15:30 HSZ/0002

Studying altermagnetism with muon-spin spectroscopy — •Thomas Hicken[1], Jonas Kreiger[1], Jennifer Graham[1], Zurab Guguchia[1], Franziska Walther[2], Kristin Kliemt[2], Cornelius Krellner[2], Helena Reichlova[3], Klára Uhlířová[4], Juraj Krempaský[1], Nirmal Ghimire[5], and Hubertus Luetkens[1] — [1]PSI, Switzerland — [2]Goethe-Universität Frankfurt, Germany — [3]Czech Academy of Science, Czech Republic — [4]École Polytechnique Fédérale de Lausanne, Switzerland — [5]University of Notre Dame, USA

With properties of both ferro- and antiferro-magnets, altermagnetism is of interest for fundamental physics and spintronic applications. Understanding the magnetic structure, and hence magnetic symmetries, is of utmost importance. Further, it has been suggested that altermagnets may have unique dynamic fluctuations. To answer these questions, muon spin spectroscopy (μSR) measurements provide information that is complementary to, and unique from, other probes. I will discuss how we are using μSR to probe a number of materials, including $Co_{1/4}NbSe_2$ [1], a proposed g-wave altermagnet, Ce_4Sb_3, which shows promise as an altermagnet with $4f$ moments, and MnTe [2], which is perhaps the best studied altermagnet so far. Our measurements, combined with muon stopping site calculations, reveal the sometimes unexpected magnetic structure of candidate altermagnetic materials, and test some of the key predictions of altermagnetism.

Broadband nonlinear Hall response and multiple wave mixing in a room temperature altermagnet — •Berthold Jaeck — HKUST, Department of Physics, Clear Water Bay, Kowloong, Hong Kong

Altermagnets are characterized by magnetic crystal order that manifests in a non-relativistic spin-splitting of the electronic bands. Their electric material properties should thus be determined by the underlying symmetries. We report the discovery of a broadband third-order nonlinear anomalous Hall effect in altermagnetic CrSb at room temperature that exhibits a distinct spatial anisotropy [1]. The comparison of our experimental observations with symmetry analyses and model calculations shows that this nonlinear Hall response is induced by the nonlinear electric susceptibility of a Berry curvature quadrupole. This quadrupole precisely reflects the magnetic and crystalline symmetries encoded in the altermagnetic g-wave order parameter. We then utilize the nonlinear electric susceptibility of CrSb to realize a multiple wave mixing device with pronounced four wave mixing output. Our study provides a generalized understanding of the impact of magnetic crystal order on the electric material properties of altermagnets and significantly expands their technological scope to include high-frequency applications up to the THz regime.

We acknowledge funding by the Hong Kong RGC (Grant Nos.26304221, 16302422, 16302624, and C6033-22G) and the Croucher Foundation (Grant No.CIA22SC02).

MA 8.5 Mon 16:00 HSZ/0002

Ce_4Sb_3: A Kondo metal as candidate for d-wave altermagnetism — •Franziska Walther[1], Thomas J. Hicken[2], Venkata Krishna Bharadwaj[3], Julian Kaiser[4], Bin Shen[4], Jan Priessnitz[5], Rahel Ohlendorf[6], Michelle Ocker[1], Alexander Fedorov[7], Anton Jesche[4], Hubertus Luetkens[2], Philipp Gegenwart[4], Elena Gati[7], Denis Vyalikh[8], Libor Šmejkal[5], Jairo Sinova[3], Cornelius Krellner[1], and Kristin Kliemt[1] — [1]Uni Frankfurt, Germany — [2]PSI, Switzerland — [3]Uni Mainz, Germany — [4]Uni Augsburg, Germany — [5]MPI PKS Dresden, Germany — [6]MPI CPfS Dresden, Germany — [7]HZB Berlin, Germany — [8]DIPC Donostia, Spain

The study of altermagnetic materials has been focused so far on magnetic d-systems. Here, we present Ce_4Sb_3 as a lanthanoid-based altermagnetic candidate to study the altermagnetism arising from local $4f$ moments, where magnetism is mediated indirectly by the RKKY interaction. Below 4 K, the cubic compound Ce_4Sb_3 orders magnetically and d-wave altermagnetism is theoretically predicted. Furthermore, the material shows Kondo behaviour, enabling it to be a promising candidate to study pressure-induced quantum critical phenomena in systems with altermagnetic spin fluctuations. Here, we report on the single crystal growth by the Czochralski method in a quasi-crucible free high pressure setup, the physical characterization of the magnetic ground state and a first study by angle-resolved photoemission and muon spin spectroscopy.

MA 8.6 Mon 16:15 HSZ/0002

Optical Kerr Signatures in d-wave and g-wave Altermagnets — •Luca Felipe Haag[1], Paul Herrgen[1], Jairo Sinova[2], Benjamin Stadtmüller[3], Martin Aeschlimann[1], and Hans Christian Schneider[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, Germany — [2]Institut für Physik, Johannes Gutenberg University, Mainz — [3]Experimentalphysik II, Institute of Physics, University of Augsburg, Germany

The non-relativistic spin splitting in the electronic states of altermagnets makes them promising candidates for next-generation spintronic materials [1,2], but the identification and characterization of these materials is difficult. In a previous study, we demonstrated that altermagnets show intriguing time-dependent magneto-optical properties when probed by ultrashort pulses, which are linked to their particular spin symmetries [3]. In this contribution we analyze the pump-induced Kerr response of different candidate materials in detail. To this end, we theoretically investigate the probe response due to the pump induced birefringence and explain how to distinguish between anisotropic charge carrier distributions and magnetic signatures. Our results suggest that pump-probe Kerr microscopy is a viable tool to image the domain structure of specific altermagnets.

MA 8.7 Mon 16:30 HSZ/0002

Ferroelectricity-driven altermagnetism in two-dimensional van der Waals multiferroics — •Bo Zhao[1], Fu Li[1], Wei Ren[2], Hao Wang[1], and Hongbin Zhang[1] — [1]Theory of Magnetic Materials, Institute of Materials Science, Technical University of Darmstadt, 64287 Darmstadt, Germany — [2]Institute for Quantum Science and Technology, State Key Laboratory of Advanced Refractories, Materials Genome Institute, Physics Department, Shanghai University, Shanghai 200444, China

Altermagnets (AMs) are an unconventional class of collinear compensated antiferromagnets that exhibit momentum-dependent spin splitting despite zero net magnetization. Using spin space group (SSG) symmetry analysis and first-principles calculations, we show that altermagnetism in two-dimensional multiferroics can be efficiently controlled by ferroelectric polarization and interlayer sliding. As a material platform, monolayer and bilayer $FeCuP_2S_6$ display finite spin splitting when ferroelectric sublattices are linked by nonsymmorphic screw-axis operations instead of pure translation or inversion. Interlayer sliding allows reversible switching or suppression of this spin splitting through SSG modifications. We further find that the anomalous Hall response directly probes these spin-split states. These results highlight 2D van der Waals multiferroics as promising systems for electrically tunable altermagnetism and next-generation spintronic applications.

Elastocaloric probing and tuning of multipolar order in the altermagnet MnF_2 — •Rahel Ohlendorf[1,2], Luca Buiarelli[3], Hilary M. L. Noad[1], Andrew P. Mackenzie[1,4], Rafael M. Fernandes[5], Turan Birol[3], Jörg Schmalian[6], and Elena Gati[1,2,7] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]Technische Universität, Dresden, Germany — [3]University of Minnesota, Minneapolis, USA — [4]University of St Andrews, UK — [5]University of Illinois Urbana-Champain, Urbana, USA — [6]Karlsruhe Institute of Technology, Karlsruhe, Germany — [7]Goethe Universität, Frankfurt, Germany

Altermagnets break time-reversal symmetry without net magnetization [1], with the order parameter described by the ferroic ordering of multipoles rather than dipoles. In *d*-wave altermagnets, the predicted ferrooctupolar order couples to magnetic field and strain. In this talk, we demonstrate that elastocaloric experiments under strain and magnetic field are a powerful thermodynamic and symmetry-sensitive probe of the finite-temperature ferrooctupolar critical point. We resolve elastocaloric signatures of altermagnetic crossover lines and entropy accumulation. By combining our experiments with DFT calculations, we provide a microsopic explanation for the size of the observed thermodynamic effects. As a result, we outline the route to stronger thermodynamic responses in insulating and metallic altermagnets (both *d*-wave and *g*-wave), establishing elastocaloric measurements as a key probe of altermagnetic criticality.

MA 8.9 Mon 17:15 HSZ/0002

Optical phonons as a testing ground for spin group symmetries — Felix Schilberth[1], Mark Kondákor[4], Denis Ukulov[2], Lilian Prodan[1], Alexander Tsirlin[3], Peter Lemmens[2], Karlo Penc[4], Istvan Kézsmárki[1], and •Joachim Deisenhofer[1] — [1]Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute for Physics, University of Augsburg, D-86159 Augsburg, Germany — [2]Institute of Condensed Matter Physics, TU Braunschweig, Mendelssohnstr. 3, 38106 Braunschweig, Germany — [3]Felix Bloch Institute for Solid-State Physics, Leipzig University, 04103 Leipzig, Germany — [4]Institute for Solid State Physics and Optics, HUN-REN Wigner Research Centre for Physics, H-1525 Budapest, P.O.B. 49, Hungary

We present a detailed study of the infrared- and Raman-active modes in the collinear antiferromagnet and altermagnet candidate $Co_2Mo_3O_8$. Comparing to *ab initio* calculations accurately capturing the eigenfrequencies, we identify all expected phonon modes at room temperature and deduce their selection rules with the magnetic point group and the spin group. We observe the change of selection rules upon antiferromagnetic ordering, agreeing with the relativistic symmetry approach, while the spin group formalism predicts no changes. Therefore, optical phonons sensing the symmetry of the magnetic order can reveal if relevant magnon-phonon coupling is compatible with the spin-group approach or not.

MA 8.10 Mon 17:30 HSZ/0002

Optical properties of altermagnetic candidate MnTe — •Ece Uykur[1], Marcus Schmidt[2], Stephan Winnerl[1], and Alexander A. Tsirlin[3] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, 01328 Dresden, Germany — [2]Max Planck Institute for Chemical Physics of Solids, 01067 Dresden, Germany — [3]Felix Bloch Institute for Solid-State Physics, University of Leipzig, 04103 Leipzig, Germany

MnTe is one of the promising altermagnetic candidates, where the band splitting, which is a key feature of altermagnetic materials, are confirmed via angle-resolved photoemission spectroscopy (ARPES) [1] and inelastic neutron scattering [2] experiments. In the next step, control of this unique property is desired. Given that in the spin configuration level the compound is antiferromagnetic, light control is a promising route in this regard.

Here, we present optical characterization of MnTe. Broadband infrared spectroscopy (down to the THz regime) and Raman spectroscopy of the compound are reported. Relevant phonon and magnon responses are identified. Results suggest that unusual optical activity is present in MnTe and provide a promising route for light-matter interactions.

First-principles study on piezomagnetism in altermagnet CoF_2 — •Hiroshi Katsumoto[1,2], Kunihiko Yamauchi[2], and Tamio Oguchi[2] — [1]Division of Materials and Manufacturing Science, Graduate School of Engineering, The University of Osaka, Suita, Japan — [2]Center for Spintronics Research Network, The University of Osaka, Toyonaka, Japan

Altermagnetic materials have recently attracted considerable interest due to their characteristic spin splitting in the absence of spin–orbit coupling (SOC). Among them, CoF_2 is notable not only for its altermagnetic band structure but also for its longstanding classification as a piezomagnetic material with large piezomagnetic coefficients [1]. Nevertheless, the microscopic link between its electronic structure and mechanical response has not been fully clarified. In this study, we investigate the origin of piezomagnetism in CoF_2 by means of first-principles calculations. We identify two distinct mechanisms: one driven by SOC-induced anisotropic spin–lattice coupling, and the other emerging from the SOC-independent spin splitting inherent to altermagnetism. By examining how strain influences the electronic states through these mechanisms, we gain new microscopic insights into piezomagnetism in CoF_2 and discuss implications for designing functional antiferromagnets with tailored magnetoelastic properties. This presentation was supported by JSPS KAKENHI Grand Number JP23H05457.

Influencing altermagnetic transitions by strain and layering — •Marnin Di Nunzio, Frank Lechermann, and Ilya Eremin — Institut für Theoretische Physik III, Ruhr-Universität Bochum, D-44780 Bochum, Germany

Altermagnets are collinearly ordered magnets, that break time-reversal symmetry, with a zero magnetization, and a spin-split band structure. By employing the minimal tight-binding Hubbard-like model within mean-field and rotationally invariant slave boson (RISB) approximation we explore the effect of uniaxial strain and electronic correlations on altermagnetism in mono- and bilayer systems. We single out two configurations of bilayer stackings and examine the altermagnetic transition and the effect of doping respectively. Following the application of uniaxial strain and doping in the monolayer, we uncover a fully spin-polarized Fermi surface. In the bilayer system doping itself is sufficient to achieve a complete metallic spin-polarization.

MA 8.13 Mon 18:15 HSZ/0002

Relativistically Distinct Altermagnetic States in α-Fe_2O_3 by X-ray Spectromicroscopy — •Rikako Yamamoto[1,2], Sina Mayr[3,4], Atsushi Hariki[5], Simone Finizio[3], Eugen Weschke[6], Markus Weigand[6], Libor Šmejkal[7], Jan Kuneš[8], Claire Donnelly[1,2], and Sebastian Wintz[6] — [1]MPI-CPfS, Dresden Germany — [2]WPI-SKCM[2] Hiroshima University, Hiroshima, Japan — [3]PSI, Villigen, Switzerland — [4]ETH, Zürich, Switzerland — [5]Osaka Metropolitan University, Osaka, Japan — [6]HZB, Berlin, Germany — [7]MPI-PKS, Dresden, Germany — [8]Masaryk University, Kotlářská, Czech Republic

In this study, we demonstrate the altermagnetic nature of α-Fe_2O_3 using x-ray magnetic linear and circular dichroism (XMLD and XMCD) spectroscopy and imaging. We observed an oscillatory XMCD signal for the x-ray beam along the *c*-axis, perpendicular to the net magnetization due to canting, which originates purely from altermagnetism.

Although the XMCD signal vanishes below the Morin reorientation transition as dictated by symmetry, we show that the x-ray absorption (XAS) alone provides sufficient contrast allowing to distinguish in- and out-of-plane orientations of the Néel vector. By combining the XMCD, XMLD and XAS contrast, we map out the continuous three-dimensional variation of the Néel vector in our samples. This approach can be broadly applied to a wide range of other materials.

Non-reciprocal phonon propagation along skyrmion strings — •Riccardo Ciola[1], Naofumi Matsuyama[2], Markus Garst[1], Lars Franke[1], Yoshimitsu Kohama[2], Toshihiro Nomura[3], Sergei Zherlitsyn[4], and Shinichiro Seki[2] — [1]Karlsruhe Institute of Technology (KIT), Germany — [2]University of Tokyo, Japan — [3]Shizuoka University, Japan — [4]Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Germany

Non-centrosymmetric cubic chiral magnets host two-dimensional skyrmion textures that extend in the third direction, forming strings. In this work, we investigate the influence of magneto-elastic coupling on the collective excitations of the incommensurate skyrmion lattice phase. Within a microscopic theoretical framework that combines a Ginzburg-Landau description of the chiral magnet with a coupling to the underlying atomic crystal, we predict that magneto-elastic interactions give rise to a pronounced nonreciprocity in the propagation of acoustic phonons along the skyrmion strings. This directional asymmetry stems from the hybridisation between skyrmion lattice magnon modes and acoustic phonons, resulting in hybridized quasiparticles with strongly modified dispersions. Furthermore, our theory predicts the emergence of a phason gap, i.e., a gap of the translational Goldstone mode of the skyrmion lattice induced by a distortion of the atomic crystal. Altogether, our findings establish skyrmion-based topological superlattices as a theoretical platform for engineering chimeric magnon-phonon excitations, opening new directions in quasiparticle design and emergent material functionalities.

Magnetically controllable phononic crystals experimentally investigated by combined μSNS-MOKE and μBLS — •Philipp Knaus, Maximilian Alexander Thiel, and Mathias Weiler — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern, Germany

Phononic crystals (PnCs) enable tailored elastic wave propagation and bandgap formation in the GHz range [1]. We present a pillar-type PnC made of gold on a $LiNbO_3$ substrate for controlling Rayleigh surface acoustic waves (SAWs). Using broadband interdigital transducers and nanoscale patterning, we demonstrate a phononic bandgap of 50 MHz at 1.6 GHz. The dispersion relation and spatially resolved SAW fields are measured with a combined micro-focused Super-Nyquist-Sampling Magneto-Optic Kerr Effect (μSNS-MOKE) [2,3] and micro-focused Brillouin Light Scattering (μBLS) setup, providing frequency-, phase-, time-, and space-resolved detection. Measurements reveal clear suppression of SAW propagation within the bandgap and allow direct reconstruction of the dispersion relation. We additionally study the impact of magnetic field on the bandstructrue of PnCs fabricated from CoFe pillars. Paving the way for reconfigurable SAW waveguides, tunable filters, and active phononic devices.

Coherent Magnetoelastic Phonon Generation in CMOS-Compatible Ni/Si Microstructures — •Mohammad Javad Kamali Ashtiani[1], Johan Sebastian Ramirez Amado[2], Abbas Koujok[1], Hanadi Mortada[1,2], Björn Heinz[1], Asma Mouhoub[2], Thibaut Devolder[2], Philipp Pirro[1], and Alexandre Abbass Hamadeh[2] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Center de Nanosciences et de Nanotechnologies, CNRS, Universite Paris-Saclay, 91120, Palaiseau, France

We investigate coherent phonon generation in a CMOS-compatible device using Ni micro-striplines fabricated on Si. Due to the coherent precession of the magnetization in Ni and its significant magnetostriction, the free energy oscillates at the drive frequency. Under appropriate conditions, this leads to oscillation of elastic forces on the Si substrate, which launches a propagating surface acoustic wave (SAW). By sweeping the excitation frequency and external magnetic field, we identify resonant conditions for magnon excitation in Ni stripes, which leads to coherent phonon generation.

Under this resonant excitation (e.g., 2.35 GHz, 10 mT), we observe strong phonon emission by micro-focused Brillouin light scattering. These results demonstrate that Ni/Si microstructures provide an efficient platform for studying field-tunable magnon-phonon interactions and magnetoelastic phonon generation in non-piezoelectric media. This research was supported by ANR-25-CE24-6700-01 (SAWSiX) and the DFG through TRR-173/3-268565370 Spin+X (Project-B01).

MA 9.4 Mon 15:45 HSZ/0004

Phase-resolved imaging of coherent phonon-magnon coupling — •Yannik Kunz[1], Florian Kraft[1], Kevin Künstle[1], Matthias Küss[2], Stephan Glamsch[2], Manfred Albrecht[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU in Kaiserslautern, Germany — [2]Institute of Physics, University of Augsburg, Augsburg, Germany

The interaction between surface acoustic waves (SAWs) and spin waves (SWs) has become a major focus in magnetoacoustic research, as numerous studies have demonstrated the efficiency of SAW-driven SW excitation [1,2]. However, the coherence of the underlying magnetoelastic driving mechanism has so far only been inferred indirectly from microfocused Brillouin light scattering measurements [3].

We employ spatially resolved polarization-modulating optical detection [4] to directly visualize the resonant SAW-to-SW conversion with phase sensitivity. Hereby, $LiTaO_3$ provides a platform to excite shear-horizontal SAW modes in a magnetostrictive $Co_{40}Fe_{40}B_{20}$(5 nm) layer. Our technique enables direct imaging of the coherent driving of spin waves by surface acoustic waves, providing advanced insights into the dynamics of phonon-magnon coupling.

Magnon-polaron control in a surface magnetoacoustic wave resonator — •Kevin Künstle[1], Yannik Kunz[1], Tarek Moussa[1], Katharina Lasinger[1,2], Kei Yamamoto[3], Philipp Pirro[1], John F. Gregg[2], Akashdeep Kamra[1], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, Kaiserslautern, 67663, Germany — [2]Clarendon Laboratory, Department of Physics, University of Oxford, Parks Road, Oxford, OX1 3PU, United Kingdom — [3]Advanced Science Research Center, Japan Atomic Energy Agency, Tokai, 319-1195, Japan

We demonstrate strong coupling between confined phonons and finite-wavelength magnons, forming a magnon-polaron cavity with field-tunable coupling strength [1]. Our platform combines a low-loss YIG film with a ZnO-based surface acoustic wave (SAW) resonator, enabling exceptionally low magnon-polaron dissipation rates below $\kappa/2\pi < 1.5$ MHz. The observed hybridization is accurately captured by a phenomenological model including the spatial mode profiles of SAWs and spin waves. We further observe Rabi-like oscillations in the coupled SAW spin-wave system, revealing time-domain magnon-polaron formation and establishing a platform for engineered hybrid spin-acoustic excitations.

Understanding change in the sound wave frequency in a ferromagnet under magnetic field influence (Simon effect) in the low-field regime — •Ievgeniia Korniienko[1], Pablo Nieves[2], and Dominik Legut[1] — [1]IT4Innovations, VSB-TU Ostrava, Ostrava, Czech Republic — [2]University of Oviedo, Oviedo, Spain

The Simon effect exhibits itself as the dependence of the ultrasonic wave velocity in a ferromagnetic crystal under applied magnetic field and it was explained using linear theory of magnetoelasticity in 1958. However, the recent research in the interaction of surface acoustic waves with spin waves in ferromagnetic films, as well as widespread use of the pulse echo technique for the study of various materials, has renewed interest in better understanding of the Simon effect. In our work, based on the example of bcc Fe, we propose a refined formula to describe the Simon effect, which contains terms related to dispersion effects associated with the exchange stiffness. We compare our analytical solutions with other alternative computational approaches and show that dispersion effects can be significant and cannot be neglected in the low field regime. As a result, we propose a more accurate analytical formula [1], which, due to its relative simplicity, can become a convenient tool to estimate the magnitude of the magnetic field effect on the sound wave speed propagation in a cubic ferromagnetic crystal, as well as it explains observed deviations from analytically expected results in Simon effect at low magnetic field.

All-YIG based functional magnonic crystals — •Rouven Dreyer, Bikash Das Mohapatra, Seth Kurfman, Georg Schmidt, and Georg Woltersdorf — Martin Luther University Halle-Wittenberg, Institute of Physics, 06120 Halle, Germany

For novel magnon-based applications, such as neuromorphic or reservoir computing, so far metallic ferromagnets with large saturation magnetization and high magnonic damping are the material of choice in order to locally manipulate the amplitude and phase of a propagating spin wave in an Yttrium-Iron-Garnet (YIG) layer underneath. Such YIG-metal heterostructures allow for sufficient control of band gaps in spin-wave dispersion in magnon-based Fabry-Perot-resonators or magnonic crystals [1]. In this work, we demonstrate an all-YIG based heterostructure, which imprints phase shifts and amplitude suppression on propagating waves due to the coupling of the device to the chiral spin wave. Thus, the YIG structure acts as a chiral magnonic resonator (CMR). These CMRs can be combined to realize magnonic crystals and allow for active control of individual gaps. To achieve this, the micron-sized YIG CMRs may be initialized in a different field state with respect to the YIG layer. In particular, an antiparallel magnetization alignment allows for sufficient suppression of a propagating Damon-Eshbach spin wave, as demonstrated by using spatially- and frequency-resolved SNS-MOKE [2].

MA 9.9 Mon 17:15 HSZ/0004

Exchange-dominated spin waves in Ga:YIG nanowaveguides — •Andrey Voronov[1], Khrystyna Levchenko[1], Roman Verba[2], Kristyna Davidkova[1,3], Carsten Dubs[4], Michal Urbanek[5], Qi Wang[6], Dieter Suess[1], Claas Abert[1], and Andrii Chumak[1] — [1]Faculty of Physics, University of Vienna, Vienna, Austria — [2]V.G. Baryakhtar Institute of Magnetism of the NAS of Ukraine, Kyiv, Ukraine — [3]Vienna Doctoral School of Physics, University of Vienna, Vienna, Austria — [4]INNOVENT e.V. Technologieentwicklung, Jena, Germany — [5]CEITEC BUT, Brno University of Technology, Brno, Czech Republic — [6]Huazhong University of Science and Technology, Wuhan, China

Spin-wave computing offers a path beyond CMOS scaling, but miniaturization to the 100 nm regime limits long-distance spin-wave transport. Gallium-substituted YIG (Ga:YIG) addresses this challenge through its reduced saturation magnetization, enabling excitation of exchange-dominated spin waves with superior transport properties. We report a combined experimental and theoretical study of spin-wave propagation in Ga:YIG waveguides down to 145 nm width and 73 nm thickness. Using micro-focused Brillouin light scattering, TetraX sim- ulations, and analytical dispersion modeling, we show that Ga:YIG supports spin waves with group velocities up to 600 m/s, largely independent of waveguide width, resulting in enhanced propagation lengths compared to pure YIG. These results demonstrate that gallium substitution enables faster and longer-lived spin waves, establishing Ga:YIG as a promising platform for nanoscale magnonic devices.

MA 9.10 Mon 17:30 HSZ/0004

Spin Hall micro-bars: Near zero effective magnetization for low oscillation-onset thresholds — •Abbas Koujok[1], Hidekazu Kurebayashi[2], kei Yamamoto[3], Björn Heinz[1], Abbass Hamadeh[4], Takeshi Seki[5], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, Kaiserslautern, Germany — [2]London Centre for Nanotechnology, University College London, London, United Kingdom — [3]Advanced Science Research Center, Japan Atomic Energy Agency, Tokai, Japan — [4]Centre de Nanosciences et de Nanotechnologies, CNRS, Université Paris-Saclay, Palaiseau, France — [5]Institute for Materials Research, Tohoku University, Sendai, Japan

Spin Hall devices, being promising building blocks in magnonic circuitry, are progressively being researched in the context of lowering required driving charge currents. Here, the impact of near zero effective magnetization on reducing oscillation-onset threshold in magnetic spin Hall micro-bars is studied using micro-focused Brillouin light scattering spectroscopy. We show that a threshold current density reduction of more than two orders of magnitude can be achieved in comparison to the lowest reported values from other studies in this regard. This reduction shows that controlling the effective magnetization can pave the way to employ spin Hall based devices as energy efficient elements in magnonic circuitry.

MA 9.11 Mon 17:45 HSZ/0004

Pinch points in the dynamical spin structure factor of dipolar ferromagnets — Michal Stekiel[1], Christoph Resch[2], •Konrad Scharff[3], Markus Garst[3], and Christian Pfleiderer[2] — [1]Jülich Center for Neutron Science at MLZ, Jülich, Germany — [2]School of Natural Sciences, Technical University Munich, Garching, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany

The long-range dipolar interaction gives rise to a pinch-point non-analyticity in the dynamical spin structure factor of a ferromagnet [1]. Its experimental observation is challenging because the strength of the pinch-point singularity at zero magnetic field scales both with the magnetic moment and the size of the easy-plane anisotropy. We demonstrate that suitable materials for its detection are the rare-earth diborides, ErB2 and HoB2, as they possess a large magnetic moment on the order of 10 Bohr magneton and a pronounced easy-plane anisotropy two orders of magnitude larger than their direct exchange. In both materials, we were able to resolve pinch-point singularities in energy-momentum space using inelastic neutron scattering. The experimental signatures are quantitatively reproduced by a Heisenberg model with exchange, anisotropy and dipolar interaction.

MA 9.12 Mon 18:00 HSZ/0004

Spin-wave emission with current-controlled frequency by a PMA-based spin-Hall oscillator — •Moritz Bechberger[1], David Breitbach[1], Abbas Koujok[1], Björn Heinz[1], Carsten Dubs[2], Abbass Hamadeh[3], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, D-67663 Kaiserslautern, Germany — [2]INNOVENT e.V. Technologieentwicklung, D-07745 Jena, Germany — [3]Université Paris-Saclay, Centre de Nanosciences et de Nanotechnologies, CNRS, 91120, Palaiseau, France

Spin-Hall oscillators (SHOs) are of particular interest for neuromorphic computing, as they are able to synchronize via spin waves. We demonstrate a SHO based on low-damping gallium-substituted yttrium-iron-garnet (Ga:YIG) with perpendicular magnetic anisotropy (PMA). In-plane magnetized Ga:YIG allows for the operation at a high efficiency level while also enabling resonant spin-wave emission by exploiting the positive nonlinear frequency shift. Via micro-focused Brillouin light scattering spectroscopy, we investigate the properties of auto-oscillation and emission. Multiple modes are excited and compete internally, with two emitted modes detected up to distances larger than 10 μm. Their frequencies combine to an extended bandwidth of approximately 1.6 GHz. The observed two-mode system and its transition to a single mode at higher currents are reproduced via micromagnetic simulations, which account for spatial variation of the PMA arising due to the microstructures on Ga:YIG. Our results propose a promising platform for SHOs with long-range coupling via spin waves.

MA 9.13 Mon 18:15 HSZ/0004

Dispersion-tunable low-loss implanted spin-wave waveguides — •Jannis Bensmann[1], Robert Schmidt[1], Kirill O. Nikolaev[3], Dmitrii Raskhodchikov[1,2], Shraddha Choudhary[1], Richa Bhardwaj[1], Shabnam Teheriniya[1,2,4], Akhil Varri[1,2], Sven Niehues[1], Ahmad El Kadri[1], Johannes Kern[1], Wolfram H. P. Pernice[1,2,4], Sergej O. Demokritov[3], Vladislav E. Demidov[3], Steffen Michaelis de Vasconcellos[1], and Rudolf Bratschitsch[1] — [1]University of Münster, Institute of Physics and Center for Nanotechnology, Münster, Germany — [2]University of Münster, Center for Soft Nanoscience, Münster, Germany — [3]University of Münster, Institute of Applied Physics, Münster, Germany — [4]Heidelberg University, Kirchhoff-Institute for Physics, Heidelberg, Germany

Spin waves offer a promising pathway toward energy-efficient information processing. Here, we present an etchless fabrication method for low-loss spin-wave waveguides in thin yttrium iron garnet (YIG) films using maskless silicon ion implantation. Focused Si-ion irradiation locally amorphizes YIG to create a low-magnetization cladding, effectively confining spin waves while preserving the pristine magnetic properties of the waveguide core. Spin-wave propagation is directly imaged via Faraday rotation microscopy, revealing decay lengths exceeding 100 μm even for submicron waveguides. By tuning the implantation dose and waveguide width, we achieve precise dispersion control. Our approach enables large spin-wave networks, offering a promising route toward magnonic integrated circuits.

MA 10: INNOMAG e.V. Prizes 2026 (Diplom-/Master and Ph.D. Thesis)

Die Arbeitsgemeinschaft Magnetismus der DPG hat einen Dissertationspreis und einen Diplom-/Masterpreis ausgeschrieben, welche auf der Tagung der DPG 2026 in Dresden vergeben werden. Ziel der Preise ist die Anerkennung herausragender Forschung im Rahmen einer Diplom-/Masterarbeit beziehungsweise einer Promotion und deren exzellente Vermittlung in Wort und Schrift. Im Rahmen dieser Sitzung tragen die besten der für ihre an der Hochschule eines Mitgliedslands der European Physical Society durchgeführten Diplom-/Masterarbeit beziehungsweise Dissertation Nominierten vor. Im direkten Anschluss entscheidet das Preiskomitee über den Gewinner bzw. die Gewinnerin des INNOMAG e.V. Diplom/Master-Preises und des Dissertationspreises 2026. Talks will be given in English!

Time: Monday 15:00–18:05 Location: POT/0112

Invited Talk MA 10.1 Mon 15:00 POT/0112

Multi-field analysis of magnetic materials: Phase-field based simulations of magnetic domains and phase transition — •Mobina Alaeddini, Jörg Schröder, and Maximilian Vorwerk — Institut für Mechanik, Universität Duisburg-Essen, Essen, Deutschland

Rising global temperatures have triggered research into novel, efficient, and sustainable alternatives to conventional cooling technologies to tackle the rapidly increasing demand for air conditioning and the resulting strain on energy resources. Among these, novel cooling technologies exploit the magnetocaloric effect, in which the application of magnetic fields induces reversible thermal responses suitable for cooling. Despite its technological relevance, a comprehensive description of the coupled magnetocaloric behavior requires advanced modeling approaches. Current research focuses on understanding and optimizing the magnetocaloric response of materials such as Heusler alloys, which are among the most promising candidates for solid-state cooling. To investigate these effects in a controlled and quantitative manner, a multi-field variational phase-field framework based on finite elements is employed. The formulation relies on the time-dependent Ginzburg-Landau equation and incorporates magnetic, mechanical, and thermal contributions within a unified free-energy description governing the transformation from paramagnetic austenite to ferromagnetic martensite. This approach enables a detailed analysis of the coupled magnetic and structural evolution and provides a predictive framework for magnetocaloric material design.

Invited Talk MA 10.2 Mon 15:20 POT/0112

Realistic Modelling of Finite Temperature Electron Transport Properties in Ferromagnets — •Fabian Engelke and Christian Heiliger — Justus Liebig University Giessen, Germany

The quantitative description of the electrical resistivity of a magnetic material remains challenging to this day. While prior publications reached good agreement with experiment in the so-called supercell or direct approach for non-magnetic materials where the spin-disorder contribution to the resistivity is negligible, an accurate, purely theoretical description of magnetic materials remains elusive. This shortcoming can be attributed to the missing accuracy in the description of the temperature-dependent spin-disorder itself. Considering the example of bcc-Fe, we demonstrate that the inclusion of quantum mechanical effects by semiclassical local quantization of the Heisenberg model significantly improves the description of the spin-disorder component to the electrical resistivity. Compared to previous approaches, this model includes the description of magnetic short-range order effects, enabling us to study temperature effects around and above the Curie temperature, where prior mean-field theory-based approaches inevitably predicted a constant contribution. Furthermore, by analyzing the spin-resolved conductivity tensor, we extend our investigation beyond resistivity to determine the spin-flip diffusion length in bcc-iron.

Exploring magneto- and multicaloric materials for room and cryogenic temperature applications — •Benedikt Beckmann — Institute of Materials Science, Technical University of Darmstadt, Darmstadt, Germany

A sustainable future requires energy-efficient and environmentally friendly cooling technologies. This thesis investigates Ni(-Co)-Mn-Ti Heusler alloys [1,2,3], Fe_2AlB_2-type MAB phases [4], $La(Fe,Si)_{13}$-type compounds [5], and $Co_4(OH)_6(SO_4)_2[enH_2]$ [6] for magneto- and multicaloric cooling at room and cryogenic temperatures. At room temperature, optimized Ni(-Co)-Mn-Ti Heusler alloys show large isothermal entropy and adiabatic temperature changes but are limited by hysteresis [1,2], motivating the work on hysteresis-free, low-cost MAB phases [4]. At cryogenic temperatures, universal hysteresis limitations of first-order phase transition materials are revealed for caloric hydrogen liquefaction [3,5], driving follow-up studies [7]. Following these discoveries, the novel second-order material $Co_4(OH)_6(SO_4)_2[enH_2]$ shows record performance among rare-earth-free materials [6], highlighting the potential of transition-metal-based hydrogen liquefaction.

Nonlinear magnon dynamics: From the discovery of Floquet magnons to CMOS-compatible magnon computing — •Christopher Heins — Helmholtz-Zentrum Dresden-Rossendorf, Institute for Ion Beam Physics and Materials Research, Dresden, Germany

Magnetic vortices are prominent examples for topology in magnetism with a rich set of dynamic properties. They exhibit an intricate magnon spectrum and show a special eigen-resonance of the vortex texture itself, the gyroscopic motion of the vortex core. While there has been studies about magnon assisted reversal of the vortex core polarity, the impact of the vortex core motion on the magnon spectrum wasn't addressed so far. Both excitation types are clearly separated by one order of magnitude in their resonance frequencies, where magnons are in the lower GHz range and the vortex typically gyrates at a few hundred MHz. This clear separation allows for experiments studying the temporal evolution of the magnon spectrum when the motion of the vortex core is driven by an external stimulus. We present experimental and numerical studies on how the magnon eigenstates are transformed into Floquet bands, when the vortex ground state is periodically modulated in time by the gyroscopic motion of the vortex core [1]. The existence of the Floquet bands is evidenced by the appearance of magnon frequency combs, where the comb spacing is determined by the frequency of the gyroscopic motion. References: [1] C. Heins, et al., arXiv:2409.02583, accepted with Science

Invited Talk MA 10.5 Mon 16:45 POT/0112

The geometric memory of quantum wave functions — •Niclas Heinsdorf — Max Planck Institut für Festkörperforschung

Altermagnets are a newly identified type of collinear antiferromagnetism with vanishing net magnetic moment, characterized by lifted Kramers degeneracy in parts of the Brillouin zone. Their time-reversal symmetry-broken band structure has been observed experimentally and is theoretically well understood. On the contrary, altermagnetic fluctuations and the formation of the corresponding instabilities remain largely unexplored. We establish a correspondence between the quantum metric of normal and the altermagnetic spin-splitting of ordered phases. We analytically derive a criterion for the formation of instabilities and show that the quantum metric favors altermagnetism. We recover the expression for conventional q=0 instabilities where the spin-splitting terms of the normal-state model are locally absent. As an example, we construct an effective model of MnTe and illustrate the relationship between quantum geometry and altermagnetic fluctuations by explicitly computing the quantum metric and the generalized magnetic susceptibility.

Invited Talk MA 10.6 Mon 17:10 POT/0112

Altermagnets and Odd-parity-wave Magnets — •Anna Birk Hellenes — Institute of Physics of the Czech Academy of Sciences

The discovery of altermagnets was enabled by an unorthodox symmetry framework, spin groups, allowing to classify all collinear magnetic orders [1]. This raises the questions of whether (i) altermagnetism can be verified experimentally, (ii) new magnets with unknown symmetries can be realized, and (iii) whether they can be useful for spintronics.

In my thesis, I have contributed to answering these questions affirmatively. In this talk, I will review altermagnetic symmetries [1], present our theory-experiment verification of altermagnetism [2-4], and show that it enables spintronics phenomena such as giant magnetoresistance effects [5]. I will then discuss our theoretical prediction that odd-parity-wave magnetism arises in noncentrosymmetric, noncollinear magnets with a combined translation and time-reversal symmetry [6]. Contrary to common assumptions, they host non-relativistic spin-split electronic bands while preserving time-reversal symmetry:

unlike ferromagnets and altermagnets, which break it. Our work opens broad opportunities for exploring altermagnets and odd-parity-wave magnets with potential applications including giant magnetoresistance [5], transport anisotropy [6], and Edelstein [7] effects.

MA 11: Electron Theory of Magnetism and Correlations (joint session MA/TT)

Time: Monday 15:00–18:00 Location: POT/0151

MA 11.1 Mon 15:00 POT/0151

Origin of pressure-induced anomalies in the nodal-line ferrimagnet $Mn_3Si_2Te_6$ — Varun Venkatasubramanian[1], Makoto Shimizu[2], •Daniel Guterding[3], and Harald O. Jeschke[1] — [1]Research Institute for Interdisciplinary Science, Okayama University, Okayama, Japan — [2]Department of Physics, Graduate School of Science, Kyoto University, Kyoto, Japan — [3]Technische Hochschule Brandenburg, Brandenburg an der Havel, Germany

The nodal-line ferrimagnet $Mn_3Si_2Te_6$ exhibits a pressure-induced insulator-to-metal transition (IMT), which coincides with pronounced anomalies in its magnetic ordering temperature and anomalous Hall conductivity. We employ density functional theory (DFT) in combination with classical Monte Carlo simulations to elucidate the origin of these effects. Pressure-dependent Heisenberg Hamiltonians extracted from DFT reveal a strong evolution of exchange couplings across the structural transition from the trigonal to the monoclinic phase, producing a dome-shaped variation of the ferrimagnetic ordering temperature in quantitative agreement with experiment. While our simulations capture the pressure-driven IMT and magnetic evolution, the anomalous Hall response cannot be fully explained by intrinsic Berry curvature effects, indicating additional extrinsic contributions.

[1] V. Venkatasubramanian, M. Shimizu, D. Guterding, and H. O. Jeschke, *Origin of pressure-induced anomalies in the nodal-line ferrimagnet $Mn_3Si_2Te_6$*, arXiv:2509.18238

Near Room-Temperature Ferromagnetism and Insulator-Metal Transition in van der Waals Material $CrGeTe_3$ — Daniel Guterding[1], Jihaan Ebad-Allah[2], Gili Scharf[3], Han-Xiang Xu[4], Makoto Shimizu[5], Junya Otsuki[6], Alon Ron[3], Christine Kuntscher[2], and •Harald O. Jeschke[6] — [1]Technische Hochschule Brandenburg, Brandenburg an der Havel, Germany — [2]Augsburg University, Augsburg, Germany — [3]Tel Aviv University, Tel Aviv, Israel — [4]Chinese Academy of Sciences, Beijing, China — [5]Kyoto University, Kyoto, Japan — [6]Research Institute for Interdisciplinary Science, Okayama University, Okayama, Japan

We investigate how pressure tunes the electronic and magnetic properties of the van der Waals ferromagnet $CrGeTe_3$, a promising material for near room-temperature applications. Using DFT+DMFT, we trace the transition from semiconducting to metallic ferromagnet [1]. Optical conductivity reveals a mid-infrared feature, signalling orbital-selective correlations, while a double-exchange mechanism stabilizes high-temperature ferromagnetism [2]. The anomalous Hall effect shows extrinsic behaviour beyond pure Berry curvature effects [3]. These results highlight the interplay of magnetism and electronic correlations in achieving tunable ferromagnetism in $CrGeTe_3$, suggesting that pressure and charge carrier doping offer promising routes to control magnetism and transport in layered materials.

MA 11.3 Mon 15:30 POT/0151

Ground State of the Topological Insulator Candidate Eu_2AuGe_3 — •Vinicius Estevo Silva Frehse[1], Aleksandr Sukhanov[1], Artem Korshunov[2], Eugen Weschke[3], Aly Abdeldaim[4], Priscila Rosa[5], and Marein Rahn[1] — [1]Universität Augsburg, Augsburg, Germany — [2]Donostia International Physics Center, San Sebastián, Spain — [3]Helmholz Zentrum Berlin, Berlin, Germany — [4]Diamond Light Source, Didcot, UK — [5]Los Alamos National Laboratory, Los Alamos, USA

Eu_2AuGe_3 is an unusual rare earth germanide in which quasi-trigonal europium sheets are interleaved with Au-Ge honeycomb layers, where high-throughput calculations indicate potential for topological band inversions. Bulk and transport data have revealed a series of (re-)ordering transitions upon cooling, as well as metamagnetic transitions at low temperature. Recently, we identified a broad transition around T_{CDW} = 130 K as the continuous freezing-out of a buckling mode of the honeycomb layers.

Here, we present preliminary evidence from neutron and resonant elastic X-ray scattering, which hints at helical magnetic order below T_N = 11 K. Unexpectedly for the nominally spin-only divalent europium, the magnetic order also appears to be accompanied by a modulated orbital order parameter. This phase is preceded by a transition at 23 K, where we observe a subtle doubling of the *ab*-plane, possibly related to the charge density wave formed during T_{CDW}.

MA 11.4 Mon 15:45 POT/0151

Electronic structure, magnetic and optical properties of antiferromagnetic 3*d*-oxides from a Wannier-localized optimally-tuned screened range-separated hybrid functional — •Alexander Shick[1,2], Guy Ohad[2], Jeffrey Neaton[3,4], and Leeor Kronik[2] — [1]FZU-Institute of Physics, Czech Academy of Sciences, Prague, Czech Republic — [2]Weizmann Institute of Science, Rehovoth, Israel — [3]University of California, Berkeley, USA — [4]Lawrence Berkeley National Laboratory, Berkeley, USA

We apply the recently developed Wannier-localized, optimally tuned, screened range-separated hybrid (WOT-SRSH) functional to prototypical bulk antiferromagnetic insulators — MnO, NiO, and hematite (Fe_2O_3). Comparison to calculations based on well-established functionals, namely PBE0, and HSE06, as well as to self-consistent quasiparticle GW and dynamic mean field theory calculations, and to experiment, shows that the WOT-SRSH functional provides a good quantitative description of band gaps, spin magnetic moments, photoemission, and optical absorption spectra. This establishes WOT-SRSH as a uniform, non-empirical framework for band theory of electronic, magnetic, and optical properties of magnetic insulators.

MA 11.5 Mon 16:00 POT/0151

Spectroscopic evidence of Kondo resonance in 3*d* van der Waals ferromagnets — •Deepali Sharma[1,2], Neeraj Bhatt[1], Asif Ali[1], Rajeswari Roy Chowdhury[1], Chandan Patra[1], Ravi Prakash Singh[1], and Ravi Shankar Singh[1] — [1]IISER Bhopal, Bhopal, India — [2]TU Dortmund, Dortmund, Germany

Two-dimensional van der Waals (vdW) ferromagnets drive the advancement in spintronic applications and enable the exploration of exotic magnetism in low-dimensional systems. The entanglement of the dual–localized and itinerant–nature of electrons lies at the heart of the correlated electron systems giving rise to exotic ground state properties such as complex magnetism, heavy fermionic behavior, Kondo lattice formation, etc. Through temperature-dependent electronic structure of vdW ferromagnets, Co substituted Fe_3GeTe_2, probed using high-resolution photoemission spectroscopy and density functional theory combined with dynamical mean field theory (DFT + DMFT), we provide direct evidence of the emergence of Kondo resonance peak driven by complex interplay between localized and itinerant electrons. Further, in overall agreement with the experimental electronic structure and magnetic properties, DFT + DMFT also reveals non-Stoner magnetism. The findings provide a way forward to the understanding of complex interplay between electronic structure, exotic magnetism, and heavy fermionic behavior leading to the Kondo scenario in 3*d* vdW ferromagnets.

MA 11.6 Mon 16:15 POT/0151

T-linear and quadratic transport across the Cuprate and Nickelate phase diagram : pseudogap, strange-metal and Fermi-liquid — •Dongwook Kim[1], Motoharu Kitatani[2], Juraj Krsnik[3], and Karsten Held[4] — [1]Wiedner Hauptstraße 8-10, 1040 Wien — [2]3-2-1 Koto, Kamigori-cho, Ako-gun, Hyogo 678-1297, Japan — [3]Trg Republike Hrvatske 14. HR-10000 Zagreb Croatia — [4]Wiedner Hauptstraße 8-10, 1040 Wien

We investigate DC resistivity and nodal quasiparticle (QP) scattering in hole-doped cuprates-nickelate type superconductors by ladder dynamical vertex approximation (LDΓA). In the pseudogap regime of doping δ = 0.1-0.175, we observe a crossover from T-linear to T^2 resistivity at low T. For dopings δ = 0.2-0.25, the resistivity remains fully T-linear down to the lowest temperatures, indicating strange-metal behavior associated with a nearby quantum critical point (QCP). At higher doping of δ = 0.3 the T^2 recovery reappears, signaling exit from the quantum-critical regime. The nodal QP scattering rate and the first-Matsubara-frequency rule analysis independently confirm the same FL*NFL crossover, providing consistent support for the T-dependent transport obtained within LDΓA

MA 11.7 Mon 16:45 POT/0151

Toward ab-initio simulation for resonant inelastic X-ray scattering in strongly correlated materials — •Yun Yen[1,2], Matthias Krack[2], and Michael Schüler[2,3] — [1]Institute for Theoretical Physics, Bremen Center for Computational Materials Science, University of Bremen, Bremen, Germany — [2]PSI Center for Scientific Computing, Theory and Data, Villigen PSI, Switzerland — [3]Department of Physics, University of Fribourg, Fribourg, Switzerland

X-ray absorption spectroscopy (XAS) and resonant inelastic X-ray scattering (RIXS) can be used to study low-energy excitations in complex materials, which are challenging to interpret due to strong correlations during the photoexcitation processes. We aim to develop ab-initio methods for XAS and RIXS, by constructing Anderson impurity models using Wannier-based tight-binding parameters and constrained random phase approximation. The spectrums are then computed via exact diagonalization and Krylov subspace methods. We will show a benchmark on spin spiral materials, where the d-d excitation intensity dependence can be related to the onset of magnetic order with the support of our methods.

MA 11.8 Mon 17:00 POT/0151

Magnetic Persistence in PrAlGe via RIXS and XAS modeling — •Juan Felipe Pulgarin Mosquera[1,2], Yun Yen[3], Tianlun Yu[4], Yeong-Ah Soh[4], Thorsten Schmitt[4], and Michael Schueler[1,2] — [1]PSI Center for Scientific Computing, Theory and Data, Villigen PSI, Switzerland — [2]University of Fribourg, Department of Physics, University of Fribourg, Fribourg , Switzerland — [3]Institute for Theoretical Physics and Bremen Center for Computational Materials Science, University of Bremen, Bremen, Germany — [4]PSI Center for Photon Sciences, Villigen-PSI, Switzerland

The interplay between topological electronic states and magnetism is in the spotlight of condensed matter for potential applications. PrAlGe is a prime candidate in this context, with several works reporting it as a magnetic Weyl semimetal. However, the microscopic relationship between the magnetic ordering, anomalous Hall effect and local spectroscopic signatures remains an open question. We study this phenomenon based on a combination of X-ray spectroscopy and first-principle calculations. We present our ab-initio approach to computing X-ray absorption spectroscopy and resonant inelastic X-ray scattering based on accurate Anderson Impurity model derived from density-functional theory with Hubbard corrections. This comparison is crucial for understanding the experimental finding that the ferromagnetic transition occurs at $T_c \sim 16$ K, significantly lower than the temperature scale at which the AHE and circular dichroism vanish $T_{AHE} \sim 35$ K). The survival of circular dichroism above T_c serves as a local probe for the persistence of local magnetic moments.

MA 11.9 Mon 17:15 POT/0151

Ab initio spin Hamiltonians and magnetism of Ce and Yb triangular-lattice compounds — Leonid V. Pourovskii[1,2], •Rafael D. Soares[3], and Alexander Wietek[3] — [1]CPHT, CNRS, École polytechnique, Institut Polytechnique de Paris, 91120 Palaiseau, France — [2]Collège de France, Université PSL, 11 place Marcelin Berthelot, 75005 Paris, France — [3]Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Straße 38, 01187 Dresden, Germany

We calculate the crystal-field splitting, ground-state Kramers doublet and intersite exchange interactions within the ground-state doublet manifold for a representative set of Ce and Yb triangular-lattice compounds. These include the putative quantum spin liquids (QSL) $RbCeO_2$ and $YbZn_2GaO_5$ and the antiferromagnets $KCeO_2$ and $KCeS_2$. The calculated nearest-neighbor (NN) couplings are antiferromagnetic and exhibit noticeable anisotropy. The next-nearest-neighbor (NNN) couplings are ferromagnetic in the Ce systems and dominated by classical dipole–dipole interactions in the Yb case. Solving the resulting effective spin-1/2 models by exact diagonalization up to $N = 36$ sites, we predict ordered magnetic ground states for all systems, including the two QSL candidates. We explore the phase space of an anisotropic NN + isotropic NNN triangular-lattice model finding that a significant antiferromagnetic NNN coupling is required to stabilize QSL phases, while the NN exchange anisotropy is detrimental to them. Our findings highlight a possibly important role of deviations from the perfect triangular model in real materials.

MA 11.10 Mon 17:30 POT/0151

Transition metal dihalides: from band structure to magnetic properties — •Alexander Yaresko[1], Sebastien Hadjadj[2], and Maxim Ilyn[2] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]Centro de Física de Materiales, Donostia-San Sebastián, Spain

Transition metal dihalides TX_2 (T=Fe, Ni, X=Cl, Br) have recently attracted attention because of successful growth of monolayer-thick TX_2 films on various substrates, such as Au or $NbSe_2$, allowing to study 2D magnetism. We compare results of band structure calculations for bulk and monolayer FeX_2 and NiX_2. By mapping the total energies calculated for helical spin structures with various q to the Heisenberg model we show that the change of magnetic order within a layer from ferro- in $NiCl_2$ to helimagnetic in $NiBr_2$ can be explained by the increased strength of antiferromagnetic (AF) 3-rd neighbor exchange interaction J_3 which competes with FM nearest neighbor J_1. We found that inter-layer coupling J_{2c} stabilizes FM order within a layer. Thus, one can expect stronger tendency to a helimagnetic state in a NiX_2 monolayer.

In contrast to NiX_2, J_1 estimated from LDA+U spin-spiral calculations for FeX_2 is weak but shows substantial dependence on the strength of the Coulomb repulsion U. In agreement with experimental findings, calculations including spin-orbit coupling result in appreciable easy axis anisotropy with Fe magnetic moments normal to layers.

We also discuss various microscopic contributions to intra- and inter-layer exchange interactions.

MA 11.11 Mon 17:45 POT/0151

Coexistence of charge order and antiferromagnetism in three-dimensional Hubbard-Holstein model: A study (exploring phases) at and away from half-filling — •Sandip Halder and Moshe Schechter — Ben-Gurion University of the Negev, Beer-Sheva, Israel

The physics of correlated electron systems has long been explored through the Hubbard model and its extensions, including models with long-range hopping. Likewise, phenomena arising from electron-phonon coupling- such as charge order and superconductivity- have been extensively studied within the Holstein model, though largely in lower dimensions. In transition-metal oxides, however, both electron correlations (U) and electron-phonon coupling (V) coexist intrinsically, motivating a comprehensive study of the Hubbard-Holstein model in three dimensions.

Using an exact diagonalization-based semi-classical Monte Carlo (s-MC) method, we investigate the intriguing properties of this model. At half-filling, the system undergoes a first-order transition between a charge-ordered (CO) phase and an antiferromagnetic (AF) phase as U and V are varied. In the AF regime, near the phase boundary, hole doping drives the system from the AF state (n=1) to a CO state (n=0.5), and eventually to a disordered phase at low densities. Notably, a robust coexistence of AF and CO emerges around x=0.35 (n=0.65), with T_{CO} exceeding T_N, consistent with experiments on $La_{2-x}Sr_xNiO_4$. The study provides new insight into correlated materials and guiding future experimental explorations.

MA 12: Terahertz Spintronics

Time: Monday 15:00–16:30 Location: POT/0351

MA 12.1 Mon 15:00 POT/0351

Interface Modification of Spintronic THz emitters — •David Stein[1], Krishna Rani Sahoo[2], Alexander Heise[1], Stephan Glamsch[1], Jannis Bensmann[2], Robert Schmidt[2], Steffen Michaelis de Vasconcellos[2], Rudolf Bratschitsch[2], and Manfred Albrecht[1] — [1]Universität Augsburg, Augsburg, Germany — [2]Universität Münster, Münster, Germany

The spintronic Terahertz (THz) emission of thin magnetic/heavy metal bilayers with fs laser excitation is an excellent alternative to the well-known bulk nonlinear crystals. Many works have been published about different material combinations of spintronic emitters, but the properties of the bilayer interface and its influence on the THz emission is not well understood. We study Fe/Pt interfaces, which were modified by implantation with foreign atoms to investigate the influence of the interface on the THz emission. THz-Time Domain Spectroscopy and SQUID-VSM Magnetometry, as well as high-resolution Scanning Transmission Electron Microscopy (STEM) with Energy Dispersive X-Ray Spectroscopy (EDS) were performed to understand the effects of the modifications.

MA 12.2 Mon 15:15 POT/0351

Lightwave-driven spintronics by coherent breaking of time-reversal symmetry — •Philipp Weissenberger[1], Josef Riepl[1], Adrian Seith[1], Michael Aschenbrenner[1], Josef Freudenstein[1], Omer Kneller[1], Daniel Riese[1], Manuel Meierhofer[1], Konstantin Kokh[2], Oleg Tereshchenko[2], Jörg Wunderlich[1], Ulrich Höfer[1], Ferdinand Evers[1], Jan Wilhelm[1], and Rupert Huber[1] — [1]University of Regensburg, Germany — [2]Novosibirsk, Russia

Lightwave electronics has the potential to revolutionize high-speed information technology by using the carrier field of light to steer electrons at optical clock rates. Yet, expanding this subcycle control scheme to the spin, one of the most important quantum attributes, has remained a challenge. Additionally, time-reversal symmetry (TRS) prohibits a net spin polarization in non-magnetic solids, limiting ultrafast spintronics to magnetic systems with intrinsically broken TRS. Here, we transcend these boundaries by leveraging intense, phase-stable terahertz (THz) pulses to accelerate Dirac fermions in the topological state of Bi2Te3. Due to spin-momentum locking, the THz field drives ballistic, spin-

polarized currents. The nonequilibrium occupation coherently breaks TRS and leads to a net surface magnetization. Our all-optical measurements show that these dynamics follow the driving vector potential, proving their dissipationless nature and our magnetic switching abilities. Astonishingly, the data reveals an anisotropic coupling to higher-lying topological states. Our scheme could be transferred to a host of non-magnetic systems and boost ultrafast magnetic metrology.

MA 12.3 Mon 15:30 POT/0351

Spin Inertia as a Source of Topological Magnons — •Subhadip Ghosh[1], Mikhail Cherkasskii[2], Ritwik Mondal[1], Alexander Mook[3], and Levente Rozsa[4] — [1]IIT (ISM) Dhanbad, India. — [2]RWTH Aachen University, Germany. — [3]University of Munster, Germany — [4]BME, Budapest, Hungary

Ferromagnets exhibit not only the familiar precessional magnon bands, but also high-frequency nutational modes originating from spin inertia [1]. In this work, we show that the hybridization between these nutational and precessional branches opens a magnonic gap whose topology can become nontrivial. In a honeycomb ferromagnet, this topological phase is caused by the pseudodipolar coupling, which not only gaps out the well-known precessional Dirac cones [2,3] but also causes precessional and nutational modes to anticross. By computing the Chern numbers of the full magnon spectrum, we demonstrate that the nutational-precessional gap can host chiral, topologically protected edge states. We highlight the role of spin inertia as a source of topological magnonic phenomena.

MA 12.4 Mon 15:45 POT/0351

THz light field driven unidirectional spin Hall magnetoresistance in magnetic heterostructures — •Sergey Kovalev[1], Ruslan Salikhov[2], Igor Ilyakov[2], Anneke Reinold[1], Jan Deinert[2], Thales Oliveira[2], Alexey Ponomaryov[2], Gulloo Prajapati[2], Patrick Pilch[1], Ahmed Ghalgaoui[1], Steffen Kober[1], Jürgen Fassbender[2], Jürgen Lindner[2], and Zhe Wang[1] — [1]Technische Universität Dortmund, Dortmund, Germany — [2]Helmholtz Zentrum Dresden Rossendorf, Dresden, Germany

We demonstrate unidirectional spin Hall magnetoresistance (USMR) in magnetic heterostructures driven by terahertz (THz) light electric fields [1]. To isolate USMR from other spin transport phenomena, we performed anisotropy characterization of spintronic THz second-harmonic generation as a function of sample magnetization and THz pump polarization states. By investigating the temperature dependence of THz-driven USMR, we reveal distinct contributions to USMR dynamics on picosecond time scales. Our approach enables the characterization of ultrafast, field-driven spin-related magnetoresistance in free-standing heterostructures without the need for lithographic processing.

MA 12.5 Mon 16:00 POT/0351

Orbital-torque driven excitation of Terahertz perpendicular standing spin wave (PSSW) modes — •Harshita Devda[1], Peter M. Oppeneer[2], and Ulrich Nowak[1] — [1]Fachbereich Physik, Universität Konstanz, Konstanz, Germany — [2]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

Layered ferromagnets support interface-sensitive THz spin dynamics, making the controlled excitation of such THz magnon modes relevant for spintronics applications. Recent experiments show that asymmetric NM/FM/NM trilayers couple efficiently to THz fields via interfacial spin-orbit torques (SOTs)[1], emphasizing the importance of interface effects in THz spin dynamics.

Here, we employ atomistic spin-dynamics simulations using ab-initio exchange parameters in thin NM/Co/NM trilayers to investigate ultrafast magnon excitation in presence of asymmetric and symmetric SOT interfaces. SOTs are implemented using the induced spin and orbital moments from first principles calculations. Our simulations show that nanometer thick Co-layers host exchange-dominated PSSWs in 1-3 THz range. Crucially, the efficient excitation of these THz modes is governed by interfacial field-like orbital torques, which follow directly from our recent study on layer-resolved SOTs[2]. This work establishes orbital torques as a robust route to ultrafast magnon generation.

[2]Devda et al.,Phys. Rev. B 112, 144438 (2025)

MA 12.6 Mon 16:15 POT/0351

Tuning terahertz emission from spintronic devices via interface engineering — Rahul Gupta[1,2], •Francesco Foggetti[3], Francesco Cosco[3], Venkatesh Mottamchetty[4], Martin Pavelka[3], Kasturie Jatkar[5], Anders Rydberg[3], Rimantas Brucas[3], Peter M. Oppeneer[3], and Peter Svedlindh[3] — [1]University of South Florida, Tampa, Florida, USA — [2]University of Gothenburg, Gothenburg, Sweden — [3]Uppsala University, Uppsala, Sweden — [4]Aarhus University, Aarhus, Denmark — [5]Stockholm University, Stockholm, Sweden

Spintronic terahertz (THz) emitters are emerging as compact and broadband sources. While common optimization approaches consist in the exploration of different materials and stacking geometries, the effects of the external interfaces have been poorly understood. Here we show that THz radiation amplitude from Pt/Fe grown on MgO and MgAl2O4 depends significantly on the interface reflection of spin currents, which is controlled by lattice mismatch and strain of the Fe/substrate interface, providing a powerful lever to tune THz emission. We use the superdiffusive transport theory to simulate the Pt/Fe bilayer, modeling the different interfaces via tunable interface reflection or via simulated substrate layer, resulting in very good agreement with the experimental data. Our results establish interface reflection governed by strain and lattice mismatch as a general design knob for optimizing spintronic THz emitters, opening new routes to engineer material platforms for next-generation THz technologies.

MA 13: Magnetic Heuslers and Semiconductors

Time: Monday 15:00–17:15 Location: POT/0361

MA 13.1 Mon 15:00 POT/0361

Investigation on the interplay of antisite disorder and magnetic ordering in $Co_2FeAl_{1-x}Si_x$ Heusler system — •Ahmad Omar[1], Matthias Frontzek[2], Robin Kramer[1], Bernd Büchner[1], and Sabine Wurmehl[1] — [1]Leibniz Institute for Solid State and Materials Research Dresden, Germany — [2]PSI Villigen, Switzerland

Quaternary Co-based Heusler compounds such as $Co_2FeAl_{1-x}Si_x$ system are predicted to demonstrate half-metallic ferromagnetism for the $L2_1$ ordered structure. However, the observed physical properties, are often in contrast to theory due to antisite disorder commonly present in practical samples. The $L2_1$-B_2 order-disorder transition is further convoluted with the ferromagnetic transition and is not well understood. Therefore, it is pertinent to understand the ordering phenomenon and develop routes to improve the order for practical realization of the desired properties. Herein, we present a systematic study of the impact of synthesis route and annealing parameters on the obtained order fraction in the samples, through detailed structural and magnetic characterization. In-situ neutron diffraction is performed during annealing to directly investigate the order-disorder transition. The interplay of disorder and the magnetic ordering is further studied through magnetic field annealing experiments. We aim to elucidate the structure-property relationships in the quaternary $Co_2FeAl_{1-x}Si_x$ system, developing methodology for tuning of the disorder through synthesis or post-processing routes, thus enabling a practical realization of half metallic ferromagnetism in the Heusler system.

MA 13.2 Mon 15:15 POT/0361

Impact of disorder on magnetic and vibrational properties of Ni-Mn-Sn Heusler alloys — •Olga Miroshkina[1], Benedikt Eggert[1], Benedikt Beckmann[2], Franziska Scheibel[2], Katharina Ollefs[1], Oliver Gutfleisch[2], Heiko Wende[1], and Markus E. Gruner[1] — [1]University of Duisburg-Essen, Duisburg, Germany — [2]Technical University of Darmstadt, Darmstadt, Germany

Ni-Mn-Sn Heusler alloys are attractive candidates for multi-stimuli caloric cooling. They undergo a magneto-structural phase transition at temperature that can be tuned via chemical disorder. In this work, we investigate the austenitic and martensitic phases near the composition $Ni_{50}Mn_{35}Sn_{15}$ by means of density functional theory complemented by magnetometry and nuclear resonant inelastic x-ray scattering (NRIXS). Bain-path calculations reveal strong competition between ferro-(FM) and ferrimagnetic (FiM) states in austenite and a clear FiM configuration in the $L1_0$ martensite. The FiM contribution in the cubic phase is confirmed by comparing the calculated Sn vibrational DOS with that extracted from NRIXS. In martensite, frustrated exchange introduced by Mn excess can prevail in the tetragonal FiM $L1_0$ phases and make nano-twinns competitive. We find that twins constructed according to the continuum theory of martensite are energetically even more favorable than $L1_0$. A striking outcome is that all Mn/Sn-disordered configurations are energetically more favorable than the ordered ones, with the FiM 4O and 10M phases remaining the most competitive structures. Financial support within the DFG Projects MI 3273/1 and CRC/TRR 270 is gratefully acknowledged.

MA 13.3 Mon 15:30 POT/0361

Finite Size-Effects in Martensite Microstructure of Magnetic Shape Memory Films — Satyakam Kar[1,2], Aman Singh[1], Kornelius Nielsch[1], Heiko Reith[1], and •Sebastian Fähler[3] — [1]Leibniz IFW Dresden, 01069 Dresden, Germany — [2]TU Dresden, Institute of Materials Science, 01062 Dresden, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

Magnetic shape memory alloys, owing to their multifunctional properties, are a promising material system for integration into microsystems. Their multifunctionality arises from the coexistence of ferroelasticity and ferromagnetism. While size-effects in ferromagnetic microstructure are well understood, corresponding experiments on the influence of finite size on the ferroelastic martensite microstructure are sparse. In this study, we use epitaxially grown Ni-Mn-Ga-based films as a model system to investigate the influence of a finite size in the martensite microstructure under constrained and freestanding conditions. Our results show that the microfabricated patterns, in both conditions, retain the characteristics of their continuous film microstructures. Film thickness has a strong influence, as this is the smallest extension investigated in our study. We analyze similarities and differences between ferromagnetic and ferroelastic microstructure, as understanding finite size effects is decisive for using these multifunctional materials in microsystems with reduced size.

MA 13.4 Mon 15:45 POT/0361

Microstructure Design via Additive Manufacturing of Heusler Alloys for Multicaloric Applications — •Nene Narh Teinor[1,2], Adrian Guder[3], Johannes Puy[1], Christian Lauhoff[3], Thomas Niendorf[3], Oliver Gutfleisch[1], and Franziska Scheibel[1,2] — [1]Institute of Materials Science, Technical University of Darmstadt, Germany — [2]Additive Manufacturing Center, Technical University of Darmstadt, Darmstadt, Germany — [3]Institute of Materials Engineering, University of Kassel, Germany

Heusler alloys like NiMnSn and NiCoMnTi show strong potential for solid-state cooling due to their first-order magnetostructural transitions (FOMST). However, their functional performance is highly sensitive to processing conditions. In this work, bulk samples are produced via Laser Powder Bed Fusion (PBF-LB/M) using gas-atomized powders to explore the influence of additive manufacturing parameters on microstructure and caloric properties. By varying laser power, scan speed, and strategy, we achieve controlled tuning of martensitic, austenitic, and Curie temperatures, as well as reduced thermal hysteresis. Structural, compositional, and magnetic analyses reveal how rapid solidification enhances the sharpness and reversibility of FOMST. We demonstrate that additive manufacturing not only preserves the functional properties of these alloys but also enables active enhancement of their tunability of transition behavior compared to conventionally processed samples. We acknowledge Deutsche Forschungsgemeinschaft (DFG) support through the CRC/TRR 270 (Project ID 405553726)

MA 13.5 Mon 16:00 POT/0361

Modelling the martensitic transformation in Ni-Mn-based Heusler compounds with machine-learning force-fields — •Markus E. Gruner, Mike J. Bruckhoff, and Olga Miroshkina — Faculty of Physics and CENIDE, University of Duisburg-Essen, D-47048 Duisburg

Functional properties of Ni-Mn-based Heusler alloys, such as Ni_2MnGa, depend on the presence of hierarchically twinned, modulated structures in the martensite phase. These can be interpreted as an adaptive, self-organized arrangement of [101]-aligned nanotwins consisting of non-modulated tetragonal building blocks. Density functional theory (DFT) suggests that these martensites are connected to cubic austenite via a downhill transformation path. This is owed to a Fermi surface reconstruction, softening the corresponding acoustic phonons of austenite. Modeling free energy surfaces at finite temperatures or the dynamics of the martensitic transition as probed in recent ultrafast laser heating experiments [1] is too expensive for conventional DFT. Machine-learning force fields (ML-FF) trained on DFT data offer a possibility to account for electronic instabilities and allow to explore the impact of adaptive nanotwining on the martensitic transition using ML-FF in classical molecular dynamics simulations. Funding by the DFG via TRR270 (B06), SFB1242 (C02) and MI3273/1 is gratefully acknowledged.

MA 13.6 Mon 16:15 POT/0361

Enhanced anomalous Hall response via nodal line tuning in Co2VSn(1-x)Alx topological semimetal — •Sunil Wilfred DSouza[1], Shivani Rastogi[2], Gaurav Shukla[3], Nidhi Shukla[2], Jan Minár[1], and Sanjay Singh[2] — [1]New Technologies Research Centre, University of West Bohemia, 30100 Pilsen, Czech Republic — [2]School of Materials Science and Technology, Indian Institute of Technology (Banaras Hindu University), Varanasi 221005, India — [3]National Institute for Materials Science (NIMS), Tsukuba 305-0047, Japan

Topological semimetals (TSMs) with nodal-line states exhibit strong Berry-curvature driven transport. We Investigate Co2VSn(1-x)Alx (x = 0-0.75) to understand how hole doping tunes the nodal line relative to the Fermi level. Al substitution shifts the nodal-line states upward, leading to a maximum intrinsic anomalous Hall conductivity (AHC) of 203 S/cm at x = 0.5, representing a significant enhancement over the undoped compound. First-principles calculations corroborate the nodal line in Co2VSn, its gapping under SOC, and its progressive alignment with the Fermi level upon Al doping. The correlation between nodal-line tuning and enhanced AHC highlights an effective strategy for controlling Berry-curvature driven transport in magnetic TSMs.

MA 13.7 Mon 16:30 POT/0361

Manipulating the first-order magnetostructural phase transition in Ni-Mn-Sn Heusler alloy through nano-functionalization — •Johannes Puy[1], Nadine Stratmann[2], Hamed Shokri[3], Bilal Gökce[3], Stephan Barcikowski[2], Oliver Gutfleisch[1], Anna Ziefuss[2], and Franziska Scheibel[1] — [1]TU Darmstadt, Darmstadt, Germany — [2]Universität Duisburg-Essen, Essen, Germany — [3]BU Wuppertal, Wuppertal, Germany

Ni-Mn-based Heusler alloys are considered as a promising candidate for magnetocaloric or multicaloric cooling applications, as they exhibit an inverse magnetocaloric and conventional elastocaloric effect, which arise from a first-order magnetostructural phase transition (FOMST). However, the practical use of these alloys is limited by the thermal hysteresis associated with the FOMST and their intrinsic brittleness. This work demonstrates a novel approach to tailor the FOMST characteritics and the mechanical stability of spark-plasma-sintered (SPS) Ni-Mn-Sn by nano-functionalization. Silver and zirconium diboride nanoparticles (NP) are synthesized by pulsed laser fragmentation of microparticles (MP-LFL) and subsequently used to functionalize Ni-Mn-Sn powder (150 - 75 μm) at varying mass loadings. This enables targeted modification of the sintered particle interfaces, which act as martensite nucleation sites, but also as origin of fracture under compressive stress. We systematically characterize the influence of NP-functionalization on the microstructure, the temperature-induced FOMST and the mechanical stability. This work was supported by the DFG within the CRC/TRR 270 (Project ID No. 405553726).

MA 13.8 Mon 16:45 POT/0361

Fe^{3+}-Centers as Structural Probes in Fe-Doped $Cs_2AgBiBr_6$ Semiconducting Perovskite — •Volodymyr Vasylkovskyi[1], Timur Biktagirov[2], Anastasiia Kultaeva[1], Carlos Canhassi[3], Mykola Slipchenko[4], Yakov Kopelevich[3], and Vladimir Dyakonov[1] — [1]Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany — [2]Physics Department, Paderborn University, D-33098 Paderborn, Germany — [3]Gleb Wataghin Institute of Physics, University of Campinas, 13083-859 Campinas, Brazil — [4]Institute for Scintillation Materials, Kharkiv, Ukraine

Fe-doping introduces new functionality into halide double perovskites alongside modifying optical properties. We report controlled growth of Fe-doped $Cs_2AgBiBr_6$ single crystals and correlate their structural, optical, and magnetic parameters. ICP analysis confirms Fe incorporation below 0.1% relative to Bi, which induce defect-related sub-gap absorption and photoluminescence shift. EPR measurements reveal an S = 5/2 Fe^{3+} spin center whose anisotropy follows the phase transition below 120 K. DFT calculations, guided by angular-dependent EPR, identify these centers as impurity-vacancy complexes, likely Fe_{Bi}-V_{Br}. SQUID magnetometry shows ferromagnetic-type hysteresis at room temperature, with rising spontaneous magnetization below 20-30 K and magnetization irreversibility under zero-field and field-cooling, confirming ferromagnetism from Fe-related defect complexes. Even small Fe amounts significantly alter optical and magnetic behavior of $Cs_2AgBiBr_6$, emphasizing the role of controlled doping and defect engineering in lead-free double perovskites.

MA 13.9 Mon 17:00 POT/0361

Pressure-dependence of the thermoelectric properties of $MnIn_2Te_4$ — •Shubham Rakesh Singh, Mohammed Ghadiyali, and Udo Schwingenschlögl — Physical Science and Engineering Division (PSE), King Abdullah University of Science and Technology (KAUST), Thuwal 23955-6900, Saudi Arabia

We investigate the thermoelectric properties of $MnIn_2Te_4$ in its two experimentally characterized phases. The tetragonal phase ($I\bar{4}2m$) undergoes a pressure-induced transition to an orthorhombic phase ($Pnma$) at 1.3 GPa. First-principles calculations reveal for both phases a small energy difference between antiferromagnetic and ferromagnetic states. The band gap is 1.04 (0.70) eV in the tetragonal phase and 1.25 (1.10) eV in the orthorhombic phase for the antiferromagnetic (ferromagnetic) state. A higher power factor is achieved by n-type than by p-type carriers. At 700 K, for example, the more densely packed orthorhombic phase exhibits a 56% reduction in the lattice thermal conductivity as compared with the tetragonal phase, yielding high thermoelectric figures of merit of 1.23 for n-type carriers and 0.96 for p-type carriers at optimal carrier concentration.

MA 14: PhD Focus Session: What about the lattice? Lessons from (ultrafast) magnetism

This focus session brings together experimental, theoretical and numerical perspectives to highlight recent discoveries and unresolved questions on ultrafast magnetization effects facilitated by spin-lattice interactions. In recent years, the transfer of magnetic angular momentum during ultrafast demagnetization processes has been observed experimentally. Studies have revealed both the microscopic mechanism through circularly polarized phonons and the macroscopic mechanical response in the form of the ultrafast Einstein-de Haas effect. Further, the complementary ultrafast Barnett effect has been demonstrated, where angular momentum is transferred into the spin system from non-equilibrium angular momentum sources (e.g. lattice vibrations or optical fields) Furthermore, inertial effects in spin dynamics were measured by observing additional nutation frequencies on top of the precessional motion Theoretical work suggests that these frequencies arise due to the spin-lattice coupling, however, the underlying mechanisms are not yet fully understood. In order to predict and explain these different types of phenomena, spin-lattice dynamics simulations have been developed in recent years. These allow energy and angular momentum to be exchanged between the magnetic spin system and the lattice.

Introduction and Welcome

Invited Talk MA 14.1 Tue 9:35 HSZ/0002

Femtophonomagnetism — •Sangeeta Sharma[1] and John Dewhurst[1,2] — [1]Max Born Institute, Berlin, Germany — [2]Max Planck Inst. Halle, Germany

From the outset of research into femtomagnetism, the field in which spins are manipulated by light on femtosecond or faster time scales, several questions have arisen and remain highly debated: How does the light interact with spin moments? How is the angular momentum conserved between the nuclei, spin, and angular momentum during this interaction? What causes the ultrafast optical switching of magnetic structures? What is the ultimate time limit on the speed of spin manipulation? What is the impact of nuclear dynamics on the light-spin interaction?

In my talk I will advocate a parameter free ab-initio approach to treating ultrafast light-matter interactions, and discuss how this approach has led both to new answers to these old questions but also to the uncovering of novel and hitherto unsuspected early time spin dynamics phenomena [1, 2]. In particular I will show that phonons strongly influence the spin dynamics[3], demonstrating nuclear system can play a profound role in controlling femtosecond magnetization of materials.

Invited Talk MA 14.2 Tue 10:20 HSZ/0002

THz-driven dynamical ferroicity in paraelectric and diamagnetic perovskites — •Martina Basini — ETH Zürich, Department of Phyisics, August-Piccard-Hoff,1, 8049, Zürich, Switzerland

The emergence of collective order in matter is among the most fundamental and intriguing phenomena in physics. In recent years, the dynamical control and creation of novel ordered states of matter not accessible in thermodynamic equilibrium have received much attention. The theoretical concept of dynamical multiferroicity has been introduced to describe the emergence of magnetization due to time-dependent electric polarization in non-ferromagnetic materials. Here, we provide experimental evidence of magnetization in the archetypal paraelectric and diamagnetic perovskites SrTiO3 and KTaO3 due to this mechanism. To induce such a magnetic response, we resonantly drive the infrared-active soft phonon mode with an intense circularly polarized terahertz electric field and detect the time-resolved magneto-optical Kerr effect. Our findings show a new path for the control of magnetism, for example, for ultrafast magnetic switches, by coherently controlling the lattice vibrations with light.

Invited Talk MA 14.3 Tue 10:50 HSZ/0002

Angular momentum transfer and chiral phonons from first principles — •Markus Weissenhofer[1], Philipp Rieger[1], MS Mrudul[1], Luca Mikadze[1], Sergiy Mankovsky[2], Svitlana Polesya[2], Hubert Ebert[2], Ulrich Nowak[3], and Peter M. Oppeneer[1] — [1]Uppsala University, Uppsala, Sweden — [2]Ludwig Maximilian Universität, München, Germany — [3]Universität Konstanz, Konstanz, Germany

Transfer and manipulation of angular momentum is a key aspect in spintronics. Recently, it has been shown that angular momentum transfer between spins and lattice is possible on ultrashort timescales [1].

To contribute to the understanding of this transfer, we have developed a theoretical multiscale framework for spin-lattice coupling, which is linked to ab-initio calculations on the one hand and magnetoelastic continuum theory on the other [2], allowing for the study of a wide range of magnetomechanical phenomena.

Here I will demonstrate how this framework can be used to calculate magnon-phonon coupling parameters, emphasizing the importance of a Dzyaloshiskii-Moriya type interaction for angular momentum transfer [2] and revealing the existence of chiral phonons in iron arising from a chirality-selective coupling [3].

Invited Talk MA 14.4 Tue 11:35 HSZ/0002

Inertial Spin Dynamics: A Signature of Non-Markovian Interactions in Ferromagnets — •Vivek Unikandanunni[1,5], Felix Hartmann[2], Matias Bargheer[2], Eric Fullerton[3], Stefano Bonetti[4,5], and Janet Anders[2] — [1]Institute of Applied Physics, University of Bern,Switzerland — [2]Institute of Physics and Astronomy, University of Potsdam, Germany — [3]Center for Memory and Recording Research, University of California San Diego, USA — [4]Department of Molecular Sciences and Nanosystems, Ca Foscari University of Venice, Italy — [5]Department of Physics, Stockholm University, Stockholm, Sweden

We report direct experimental observation of intrinsic inertial spin dynamics in ferromagnetic thin films, manifested as a damped THz frequency oscillation of the magnetization. Using a broadband tabletop THz source, we resonantly drive epitaxial cobalt and directly measure the frequency and relaxation time of the inertial response, which is well described by the inertial Landau-Lifshitz-Gilbert (LLG) equation. We find that the frequency and relaxation time of the inertial dynamics are dependent on the structural symmetry of the sample.

Broadband measurements further reveal a multi-peaked magnetic spectrum that cannot be captured by the inertial LLG alone. An open-quantum-system approach incorporating spin-phonon coupling through a memory kernel yields a non-Markovian LLG equation that reproduces the full experimental spectra demonstrating the fundamental role of non-Markovian memory effects in ultrafast spin dynamics.

Invited Talk MA 14.5 Tue 12:05 HSZ/0002

Atomistic simulations of ultrafast spin-lattice dynamics — •Richard Evans[1] and Mara Strungaru[2] — [1]University of York, York, United Kingdom — [2]University of Manchester, Manchester, United Kingdom

Atomistic spin dynamics (ASD) has become a standard method for studying finite temperature processes in magnetic materials and devices. In some systems, such as magnetic insulators, coupled spin-lattice dynamics can play a dominant role in the thermal and dynamic properties that have so far been neglected in spin-only models. Recent exciting results in ultrafast dynamics have shown that the spin-lattice interaction is a critically important component to the physical properties of a magnetic material. Spin-Lattice Dynamics (SLD) is a relatively recent theoretical development aiming to directly couple an atomistic spin model with a molecular dynamics solver to incorporate the fascinating and complicated dynamics of these coupled systems into a practical numerical framework. In this talk I will introduce the theoretical background and numerical methods for SLD as recently implemented in the VAMPIRE software package, including its parallelisation and scalability on the UK National Supercomputer

ARCHER2. I will present recent results on coherent ultrafast THz switching where we found that it is possible to induce magnetic switching through a coherent phonon excitation. I will conclude with a brief perspective on open problems in spin-lattice dynamics, including numerical challenges, quantum thermostats and correlated noise, and how to model electron processes in metallic magnetic systems.

Closing Remarks

MA 15: Focus Session: Quantum Sensing with Solid State Spin defects I (joint session TT/MA)

The electron spins of defects in solid state materials show remarkable quantum coherence, making them excellent sensors. Recent advances in material engineering and measurement techniques lead to continuous improvements in the sensitivity and resolution of established single spin sensors such as the Nitrogen-Vacancy center in diamond, and the development of new defect sensors in materials such as Silicon Carbide and hexagonal Boron Nitride. In condensed matter physics, such sensors are often being used for exploring the structure of magnets, superconductors, topological phases, etc. This focus session will highlight most of the recent experimental and theoretical advances, current challenges, and emerging directions, focusing both on the improvements of the defects themselves, and their use for exploring novel phenomena in condensed matter physics.

Coordinators: Aparajita Singha (TU Dresden), Uri Vool (Max Planck Institute for Chemical Physics of Solids)

Time: Tuesday 9:30–12:45 Location: HSZ/0003

See TT 24 for details of this session.

MA 16: Skyrmions I

Time: Tuesday 9:30–12:45 Location: HSZ/0004

MA 16.1 Tue 9:30 HSZ/0004

Charge Order, Spin textures, and Electronic Structure of Eu(Ga,Al)4 — Steven Gebel[1], Aleksandr Sukhanov[2], Artem Korshunov[3], Jaime Moya[4], Kevin Allen[5], Emilia Morosan[5], and •Marein Rahn[2] — [1]TU Dresden, Germany — [2]Universität Augsburg, Germany — [3]ESRF, Grenoble, France — [4]Princeton University, USA — [5]Rice University, USA

The tetragonal intermetallic series $Eu(Ga,Al)_4$, is known for a range of interesting phenomena, ranging from the nodal line semimetal EuGa4 to centrosymmetric skyrmion phases in $EuAl_4$. It would be of great interest to design the band topology of these materials and, in particular, to understand how it may couple to electronic correlations. To this end, one must clarify by what mechanisms the multifaceted spin- and charge-ordering instabilities of this series arise from the underlying electronic band structure. For instance, structural modifications and charge density waves exist throughout the series, but show a variable response to hydrostatic pressure – hinting at competing mechanisms. We provide an overview of the ordered phases in $Eu(Ga,Al)_4$ and then show how X-ray crystallography using diamond anvil pressure cells draws a clear line between different structural instabilities. Complementary measurements using inelastic X-ray scattering also provide evidence on the underlying electron-phonon coupling mechanisms. Our results provide a tentative x-P-T phase diagram of $Eu(Ga_{1-x}Al_x)_4$ and highlight interesting questions, e.g. regarding the origin of anomalous Hall effects in $EuGa_4$ and the nature of a new pressure-induced structural phase of $EuAl_4$.

MA 16.2 Tue 9:45 HSZ/0004

Topological pumping of skyrmionic textures in spiral multiferroics — •Luca Maranzana[1,2], Maxim Mostovoy[3], Naoto Nagaosa[4,5], and Sergey Artyukhin[1] — [1]Quantum Materials Theory, Italian Institute of Technology, Via Morego 30, Genoa, Italy — [2]Department of Physics, University of Genoa, Via Dodecaneso 33, Genoa, Italy — [3]Zernike Institute for Advanced Materials, University of Groningen, Nijenborgh 3, 9747 AG Groningen, Netherlands — [4]RIKEN Center for Emergent Matter Science (CEMS), Wako, Saitama 351-0198, Japan — [5]Fundamental Quantum Science Program, TRIP Headquarters, RIKEN, Wako 351-0198, Japan

Precise positioning of topological defects is crucial for racetrack memories, where their positions along a magnetic nanotrack encode information. Conventional approaches rely on engineered pinning landscapes, which increase power consumption. Here, we show that spiral multiferroics serve as a natural ruler for electric-field-driven positioning of skyrmionic textures, extending the concepts introduced in [1]. An oscillating electric field, assisted by anisotropy or a static magnetic field, displaces the topological defect by exactly one spiral period per full oscillation of the field. Such adiabatic pumping, reminiscent of Thouless pumping, is topologically protected and remains robust against small perturbations. Our work proposes a route to electrically driven, topologically protected transport of spin textures and positions spiral multiferroics as a natural platform for skyrmion racetracks.

MA 16.3 Tue 10:00 HSZ/0004

Statistical Signature of Chirality as a Probe of Skyrmion Topology and Collapse Dynamics — Shiyu Zhou[1], •Kai Litzius[2], Felix Büttner[2,3], and Lucas Caretta[1,4] — [1]Department of Physics, Brown University, Providence, Rhode Island 02912, USA — [2]Center for Electronic Correlations and Magnetism, University of Augsburg, Augsburg, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, 14109 Berlin, Germany — [4]School of Engineering, Brown University, Providence, Rhode Island 02912, USA

Magnetic skyrmions are topological spin textures whose robustness has driven intense interest for spintronic applications, yet direct experimental evidence linking topology to stability has been limited. We introduce an accessible, material-agnostic method to probe skyrmion topology statistically by measuring annihilation field distributions using Kerr microscopy. By tuning in-plane magnetic fields, we drive transitions from topologically nontrivial to trivial skyrmion states and observe a clear shift in annihilation behavior: skyrmions show broad, thermally activated distributions, while trivial bubbles collapse deterministically with narrow distributions. Micromagnetic simulations corroborate this correlation between topology and collapse statistics. Our approach enables straightforward chirality detection and skyrmion state control without specialized imaging or transport probes. The ability to toggle between deterministic and stochastic collapse suggests new device concepts, including synchronized deletion for memory and topology-tunable randomness for probabilistic applications.

MA 16.4 Tue 10:15 HSZ/0004

observation of a distorted tilted conical spiral at the surface of Cu_2OSeO_3 — •Sina Mehboodi[1], Victor Ukleev[2], Chen Luo[2], Radu Abrudan[2], Florin Radu[2], Christian Back[1], and Aisha Aqeel[3] — [1]School of Natural Sciences, Technical University of Munich, Garching, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [3]Institute of Physics, University of Augsburg, Augsburg, Germany

Chiral magnets such as Cu_2OSeO_3 host a rich variety of noncollinear spin textures [1]. Using resonant elastic X-ray scattering (REXS), where the magnetic satellites are captured as scattered intensity on a CCD detector, we observed a well-ordered surface texture referred to as a distorted tilted conical (dTC) spiral phase. This phase displays strong anharmonicity, evidenced by pronounced higher-order magnetic satellites. Tilting the applied magnetic field causes a continuous reorientation of the dTC propagation vector and increases its modulation wavevector, revealing a high sensitivity of the surface spiral to field direction. Importantly, by combining REXS with rocking-curve analysis, we determine the full scattering vector of dTC, about 0.0718 nm^{-1}. This value is significantly smaller than the reported bulk TC wavevector (≈ 0.095 nm^{-1}) [2], providing direct evidence that the surface spiral is intrinsically distorted and cannot be explained by a simple bulk-like conical modulation [3].

MA 16.5 Tue 10:30 HSZ/0004

Optical manipulation of magnetic skyrmions and antiskyrmions — •Dola Chakrabartty[1], Andreas Wendeln[2,3], Manuel Zahn[1,4], Sascha Schäfer[2,3], and István Kézsmárki[1] — [1]Experimentalphysik V, Center for Electronic Correlations and Magnetism, Institute for Physics, University of Augsburg, Augsburg, D-86135, Germany — [2]Regensburg Center for Ultrafast Nanoscopy, University of Regensburg, Regensburg, 93040, Germany. — [3]Department of Physics, University of Regensburg, Regensburg, 93040, Germany. — [4]NTNU Trondheim, Trondheim, 7034, Norway

Topological magnetic textures like skyrmions and antiskyrmions, have potential applications in next-generation spintronic devices. Notably, skyrmions and antiskyrmions can be viewed as particle- and antiparticle-like entities, respectively, with opposite topological charges and the potential to annihilate each other or be created in pairs. The controlled and fast manipulation of these spin textures are crucial for their practical applications.

In this work, we utilized in-situ femtosecond optical pulses in Lorentz microscopy and investigated the possibility of manipulating skyrmions and antiskyrmions. Our preliminary results show that ultrafast laser excitation can induce a helicity switching of elliptical skyrmions as well as the transformation between different spin textures, such as skyrmions, antiskyrmions, non-topological bubbles and stripes. A statistical analysis of our observations provides insights into the energy landscape of these magnetic patterns. Our findings suggest that laser pulses can control topological magnetic states.

MA 16.6 Tue 10:45 HSZ/0004

Emergent reactance induced by the deformation of a current-drive skyrmion lattice — •Matthew Littlehales[1,2], Max Birch[3], Akiko Kikkawa[3], Yasujiro Taguchi[3], Diego Alba Venero[2], Peter Hatton[1], Naoto Nagaosa[3,4], Yoshinori Tokura[3,5,6], and Tomoyuki Yokouchi[3] — [1]Department of Physics, Durham University, South Road, Durham, DH1 3LE, UK — [2]ISIS Neutron and Muon Source, Rutherford Appleton Laboratory, Didcot, OX11 0QX, UK — [3]RIKEN Center for Emergent Matter Science (CEMS), Wako, Japan — [4]Fundamental Quantum Science Program (FQSP), TRIP Headquarters, RIKEN, Wako, Japan — [5]Department of Applied Physics, University of Tokyo, Tokyo, Japan — [6]Tokyo College, University of Tokyo, Tokyo, Japan

Emergent electromagnetism offers an opportunity to develop novel applications by exploiting quantum mechanics. In condensed matter systems, the Berry phase acquired by conduction electrons acts as an emergent electromagnetic field, facilitating phenomena akin to classical electromagnetism. Magnetic skyrmions, spin vortices with non-trivial topology, offer a unique opportunity to investigate emergent electromagnetism. For example, non-trivial transport responses from magnetic skyrmions arise from the emergent Lorentz force and electromagnetic induction. Here, we present two new examples of emergent electric fields arising simultaneously from skyrmion lattice dynamics in MnSi. We find out-of-phase components in the electrical transport, reminiscent of a reactance, and attribute their existence to inertial, and deformative, current-driven skyrmion lattice dynamics.

MA 16.7 Tue 11:15 HSZ/0004

***Ab inito* quantum transport for sub-10 nm skyrmions in 2D magnets** — •Moritz A. Goerzen, Salomé Trillot, and Dongzhe Li — CEMES, Université de Toulouse, CNRS, France

Topological spin textures, such as magnetic skyrmions, play a central role in modern magnetism and have attracted significant interest in both fundamental studies and spintronics applications. *Ab initio* theory can provide a direct connection to experiments, giving access to the material-dependent physics behind the observed effects. However, the high computational cost makes it difficult to model chiral skyrmions, which typically span several nanometers and arise from competing magnetic interactions. Here, we present a novel workflow capable of treating the electronic structure and transport properties of sub-10 nm skyrmions at the full *ab initio* level. We then apply this technique to investigate the electrical detection and chirality-induced orbitronics effects in 2D magnets. In particular, we demonstrate how non-collinear magnetoresistance, chirality-induced orbital moments, and orbital Hall effects evolve with skyrmion size, helicity, and spin-orbit coupling.

MA 16.8 Tue 11:30 HSZ/0004

Magnetic anisotropies resolved in the skyrmion-host GaV_4S_8 by high-field electron spin resonance spectroscopy — •Ignác Fejes[1], Titusz Fehér[1], Norbert Marcell Nemes[1], András Jánossy[2], Dávid Szaller[1,2,3], Sándor Bordács[3,5], Vladimir Tsurkan[3], and István Kézsmárki[4] — [1]Department of Physics, Institute of Physics, Budapest University of Technology and Economics, Muegyetem rkp. 3., H-1111 Budapest, Hungary — [2]HUN-REN-BME Condensed Matter Physics Research Group, Budapest University of Technology and Economics, Muegyetem rkp. 3., H-1111 Budapest, Hungary — [3]Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, D-86135 Augsburg, Germany — [4]GFMC, Departamento de Fisica de Materiales Universidad Complutense de Madrid, 28040 — [5]Institute of Applied Physics, MD 2028, Chisinau, R. Moldova

Appearance of exotic types of magnetic ordering, such as skyrmions, strongly depends on the magnetic anisotropies present in a material, particularly in axially symmetric systems where second-order anisotropy in spin-orbit coupling is allowed. Here, we used high-field electron spin resonance spectroscopy (ESR) to study the field and orientation dependence of the spin excitation in the field-polarized state of GaV_4S_8. Below T_S = 44 K, the material transforms from a cubic phase to a polar rhombohedral phase, giving rise to multiple structural domains at low temperatures. We assigned the observed resonance modes to the corresponding polar domains and identified the relevant anisotropies - magnetocrystalline and g-factor - of GaV_4S_8.

MA 16.9 Tue 11:45 HSZ/0004

Isolated Magnetic Hopfions — Xiaowen Chen[1], •Nikolai S. Kiselev[2], Filipp N. Rybakov[3], Donghai Yang[1], and Fengshan Zheng[1] — [1]South China University of Technology, Guangzhou, China — [2]Forschungszentrum Jülich, Germany — [3]Uppsala University, Sweden

Hopfions are three-dimensional topological solitons formed by closed loops of vortex strings. In magnetic crystals, hopfions have so far been observed only in unusual configurations in which they are linked to skyrmion strings [1]. Although theory predicts the existence of stable, isolated hopfions in frustrated magnets [2] and chiral magnets [3], their experimental realization has remained elusive. Here we report laser-induced nucleation and direct TEM observation of isolated magnetic hopfions in the B20-type FeGe crystal [4]. We map out the nucleation conditions as a function of laser fluence and external magnetic field. Good agreement between experimental data and micromagnetic simulations unambiguously confirms the emergence of isolated hopfions and reveals their detailed structure. We derive the relevant topological invariant for hopfions embedded in helical or conical backgrounds and calculate its integer values for the observed objects. We demonstrate that these hopfions are stable without geometrical confinement and can coexist and interact with other topological spin textures. [1] F. Zheng, et al., Nature **623**, 718 (2023). MA 16.10 Tue 12:00 HSZ/0004

Strain-controlled topological magnetic textures in antiskyrmion hosting materials — •Somasree Bhattacharjee[1], István Kézsmárki[2], and Jan Masell[1] — [1]Institute of Theoretical Solid State Physics (TFP), Karlsruhe Institute of Technology (KIT), 76049 Karlsruhe, Germany — [2]Experimental Physics V, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, 86159 Augsburg, Germany

In non-centrosymmetric crystal structures with D_{2d} or S_4 symmetry, anisotropic Dzyaloshinskii-Moriya interaction (DMI) stabilizes antiskyrmions which was recently confirmed experimentally [1,2]. In these materials, easy-axis anisotropy additionally stabilizes skyrmions and non-topological bubbles in certain ranges of external magnetic fields and lamella thicknesses. The competition between magnetic dipolar interaction and DMI renders skyrmions elliptical depending on their handedness. Also, dipolar interaction stabilizes skyrmion caps on top of antiskyrmions which renders them rectangular [3]. In this work, we investigate how external mechanical strain can be used as an additional tuning parameter for the stability of these topological magnetic textures. We show that strain breaks the degeneracy of distinct types of elongated skyrmions and antiskyrmions, which can be used to controllably switch the helicity of the textures. [1] A. Nayak et al. Nature 548, 561 (2017), [2] K. Karube et al. Nat. Mater. 20, 335 (2021), [3] F. S. Yasin, J. Masell, et al., Adv. Mater. 36 (16), 2311737 (2024)

MA 16.11 Tue 12:15 HSZ/0004

Multistable skyrmions in thin nanodots — •Mateusz Zelent[1,2] and Maciej Krawczyk[2] — [1]Fachbereich Physik and Landesforschungszentrum Optimas, Rheinland-pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Faculty of Physics and Astronomy, Adam Mickiewicz University, Poznan, ul. Uniwersytetu Poznańskiego 2, Poznan, Poland

We present a new method for controlling and manipulating magnetic skyrmions in ultrathin multilayer structures by employing spatially tailored magnetostatic

fields produced by ferromagnetic rings. Through a combination of analytical calculations and micromagnetic simulations, we demonstrate that the stray field generated by a Co/Pd ferromagnetic ring with perpendicular magnetic anisotropy can markedly increase the stability of skyrmions in an Ir/Co/Pt nanodot even when the Dzyaloshinskii Moriya interaction is entirely absent. Our analysis reveals a multistable behaviour, in which skyrmions can exist with two or even three distinct diameters, depending on the magnetization direction of the ring. The associated energy barriers separating these states are substantial, indicating possible applications in binary or multilevel magnetic data storage. We further show that transitions between these states can be triggered in a controlled and robust manner using short magnetic-field pulses. Overall, our approach offers a versatile strategy for engineering the magnetostatic energy landscape and designing skyrmion-based devices with customizable stability characteristics.

MA 16.12 Tue 12:30 HSZ/0004

First-Principles calculation of skyrmion collapse via the geodesic nudged elastic band approach — •Nihad Abuawwad[1], Daniel Wortmann[1], Gregor Michalicek[1], and Stefan Blügel[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany — [2]Institute for Theoretical Physics, RWTH Aachen University, 52074 Aachen, Germany

Magnetic skyrmions are often investigated using spin models parameterized from first-principles calculations and achieving a fully *ab initio* description of skyrmion energetics and collapse mechanisms remains a significant challenge. In this work, we present a high-performance computing density functional theory (DFT) framework to compute both the skyrmion structure and its minimum-energy collapse pathway. Using the all-electron FLEUR code [1] within the AiiDA-FLEUR workflow environment [2], we construct an automated geodesic nudged elastic band (GNEB) workflow designed to determine the skyrmion collapse mechanism entirely from first principles. The method generates a sequence of intermediate magnetic states via geodesic interpolation between an initial skyrmion configuration and the final ferromagnetic state, and each image is evaluated under constrained magnetic moments to obtain accurate total energies and true magnetic forces. The resulting energy profile reveals the minimum energy path (MEP) and the associated barrier governing the topological skyrmion collapse. We compared these with the spin-model approach.

MA 17: Multiferroics and Magnetoelectric Coupling (joint session MA/FM)

Time: Tuesday 9:30–12:30 Location: POT/0112

MA 17.1 Tue 9:30 POT/0112

Electric polarization driven by non-collinear spin alignment: first principles calculations — •Sergiy Mankovsky[1,3], Svitlana Polesya[1], Jan Minar[2], Hongbin Zhang[3], and Hubert Ebert[1] — [1]Ludwig Maximilian University of Munich, Munich, DE — [2]University of West Bohemia, Pilsen, CZ — [3]TU Darmstadt, Darmstadt, DE

We present an approach for first principles investigations of the spin driven electric polarization in type II multiferroics. We propose a parametrization of the polarization with the parameters calculated using the multiple scattering Green function (KKR-GF) formalism. On this basis, the induced electric polarization of a unit cell can be represented in terms of three-site parameters. Those antisymmetric with respect to a spin permutation can be seen as an ab-initio based counter-part to the phenomenological parameters used in the inverse-DMI model. Beyond to this, our new approach gives direct access to the element- and site-resolved electric polarization. To demonstrate the capability of the approach, we consider several examples, for which the magneto-electric effect is observed either as a consequence of an applied magnetic field (Cr_2O_3), or as a result of a phase transition to a spin-spiral magnetic state (MnI_2 and $AgCrO_2$).

MA 17.2 Tue 9:45 POT/0112

Competition Between Multiferroic and Magnetic Soliton Lattice States in DyFeO3 — •Nikita Andriushin[1], Stanislav Nikitin[2], Oystein Fjellvag[1,3], Ekaterina Pomjakushina[2], Alexandra Turrini[2], Sergey Artyukhin[4], Christof Schneider[2], and Maxim Mostovoy[5] — [1]TU Dresden, Germany — [2]PSI, Switzerland — [3]IFE, Norway — [4]IIT, Italy — [5]University of Groningen, The Netherlands

Simultaneous breaking of time-reversal and inversion symmetries in multiferroics couples ferroelectricity to magnetism and produces unusual phenomena relevant for next-generation electronics. A notable case is $DyFeO_3$, which under magnetic fields shows a giant linear magnetoelectric response and a large spontaneous polarization arising from coexisting Fe and Dy orders. Using high-resolution neutron diffraction, we demonstrate that at zero field $DyFeO_3$ hosts an incommensurate magnetic soliton lattice formed by spatially ordered Dy domain walls with an average size of 231(8) Å. Long-range interactions between these walls are mediated by magnons in the Fe subsystem, analogous to a Yukawa force. An applied magnetic field destroys the incommensurate order, restores the linear magnetoelectric response, and stabilizes the ferroelectric state. The magnetic domain walls carry electric charge, and the soliton array dimerizes when both electric and magnetic fields are applied. Simulations using experimental parameters indicate that competition between ferroelectric and incommensurate states can be effectively tuned by an electric field.

MA 17.3 Tue 10:00 POT/0112

Magnetoelectric coupling in antiferromagnetic $BiCoO_3$ — •Veronica Goian[1], Fedir Borodavka[1], Petr Proschek[2], Maxim Savinov[1], Christelle Kadlec[1], Hong Dong Nguyen[1], Andrei A. Belik[3], and Stanislav Kamba[1] — [1]Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic — [2]Department of Condensed Matter Physics, Charles University, Prague Czech Republic — [3]National Institute for Materials Science: Tsukuba, Ibaraki, Japan

$BiCoO_3$ is a potential multiferroic material with a C-type antiferromagnetic phase transition at T_N=470 K and a hypothetical ferroelectric phase transition around 1000 K (the sample decomposes at around 470 °C).[1] First-principles calculations predict an unusually strong antimagnetoelectric coupling in $BiCoO_3$.[2] However, no experimental measurements have been reported in the literature to determine the magnetoelectric coupling or related structural properties. This is mainly because $BiCoO_3$ requires high-pressure and high-temperature sintering. We have measured the dielectric permittivity, ferroelectric hysteresis loops, and Raman, THz, and IR spectra to probe the ferroelectric behavior. In addition, we found that $BiCoO_3$ exhibits well-measurable nonlinear magnetoelectric coupling.

[1] Oka et al., J. Am. Chem. Soc., 132, 9438-9443 (2010)
[2] Braun et al., Phys. Rev. B, 110, 144442(2024)

MA 17.4 Tue 10:15 POT/0112

Investigation of the piezomagnetic effect in $CaBaCo_4O_7$ — •Jyotiranjan Rout[1], Yusuke Tokunaga[2], Yasujiro Taguchi[2], Yoshinori Tokura[2], Bernd Büchner[1,3], and Vilmos Kocsis[1] — [1]IFW-Dresden — [2]RIKEN, CEMS, Japan — [3]TU-Dresden

In a magnetoelectric material the electric and magnetic responses are intertwined and cross control via the application of external magnetic and electric field are enabled. Ferroelectric polarization implies a special distortion of the lattice where dipolar moment related to the separation of the positive and negative ions are not compensated within the unit cell. Therefore we immediately can imagine the intricate and complicated connection between the magnetoelectric and magnetoelastic properties of a multiferroic.

The Swedenborgite $CaBaCo_4O_7$ exhibits a polar structure, which is accompanied by a ferrimagnetic order at T_C=62 K and a record large change in the ferroelectric polarization. Correspondingly, former magnetoelastic measurements have indeed confirmed the presence of a giant magnetoelastic distortion close to T_C; However, less is known about the magnetoelastic anisotropies.

Here, we report a detailed study of the magnetoelastic anisotropy, completing the connection between magnetoelasticity and magnetoelectricity in this material family. We also report on an unusual feature of the piezomagnetic effect, which suggests the importance of the orbitals in the piezomagnetoelectric effects.

MA 17.5 Tue 10:30 POT/0112

Multiferroic altermagnetism and magneto-orbital excitations in monolayer VCl3 — •Luigi Camerano[1,2], Adolfo Otero Fumega[3], Alessandro Stroppa[2], Jose Lado[3], and Gianni Profeta[1,2] — [1]University of L'aquila, 67100 L'Aquila, Italy — [2]CNR-SPIN L'Aquila, 67100 L'Aquila, Italy — [3]Aalto University, 02150 Espoo, Finland

Van der Waals monolayers featuring magnetic states provide fundamental building blocks for artificial quantum matter. In this contribution I will present the emergence of a symmetry broken multiferroic ground state featuring magneto-orbital excitations and nematic d-wave altermagnetism in monolayer VCl3 [1-4]. All these physics arises from a pure electronic symmetry breaking ultimately stabilizing an antiferro-orbital order ground state showing the emergence of an electronic polarization. Recent experimental evidence report signatures of symmetry breakings and ferroelectricity combined with 2D magnetism, establishing monolayer VCl3 as a novel 2D multiferroic driven by orbital ordering.

MA 17.6 Tue 10:45 POT/0112

Electric control of antiferromagnetic states in an insulator — •Somnath Ghara[1], Maximilian Winkler[1], Sebastian Schmid[1,2], Lilian Prodan[1], Korbinian Geirhos[1], Vladimir Tsurkan[1,3], Wenbo Ge[4], Weida Wu[4], András Halbritter[2], Stephan Krohns[1], and István Kézsmárki[1] — [1]EP5, Institute of Physics, University of Augsburg, Germany — [2]Department of Physics, Budapest University of Technology and Economics, Hungary — [3]Institute of Applied Physics, Moldova State University, Republic of Moldova — [4]Department of Physics and Astronomy, Rutgers University, USA

Electric control of antiferromagnetic (AFM) order is highly desirable for the development of ultrafast and energy-efficient spintronic devices. In this talk, I will show that the strong linear magnetoelectric coupling in the collinear AFM insulator Co_3O_4 enables full isothermal control of AFM order by electric fields deep within its AFM phase, i.e. the Néel vector can be either reversed instantaneously or rotated smoothly. Importantly, we found that even in macroscopic volumes of Co_3O_4, the non-volatile switching between time-reversed AFM states occurs on timescales as short as a few tens of nanoseconds. These observations suggest that the quasi-cubic AFM insulators, such as Co_3O_4, provide an ideal platform for ultrafast manipulation of microscopic AFM domains and may lead to the realization of antiferromagnet-based spintronic devices.

15 min break

MA 17.7 Tue 11:15 POT/0112

Optical detection of magnetic order in SmFe3(BO3)4 — •Bálint Beke[1], Bence Szász[1], I. A. Gudim[2], L. N. Bezmaternykh[2], Dávid Szaller[1], and Sándor Bordács[1] — [1]Budapest University of Technology and Economics, Budapest, Hungary — [2]Krasnoyarsk, Russia

The chiral crystal structure of $SmFe_3(BO_3)_4$ hosts an easy-plane antiferromagnetic phase below 32 K. Due to the broken inversion, the magnetic order induces electric polarization in this compound, but this polarization averages out to zero when domains are randomly oriented in the ab plane. We studied the 4f-4f excitations of Sm^{3+} ions using polarization resolved magneto-optical spectroscopy. Low magnetic fields, <2 T give rise to linear dichroism that we associate with the rearrangement of antiferromagnetic domains. In finite fields, we could determine the polarization selection rules in a state where the orientation of the antiferromagnetic domains is well defined. Moreover, we detected non-reciprocal absorption of light, which is a finite frequency fingerprint of the optical magnetoelectric effect.

MA 17.8 Tue 11:30 POT/0112

A high-temperature multiferroic $Tb_2(MoO_4)_3$ — •Shimon Tajima, Hidetoshi Masuda, Yoichi Nii, Shojiro Kimura, and Yoshinori Onose — Institute for Materials Research, Tohoku University, Sendai, Japan

We demonstrated magnetic control of ferroelectric polarization at 432 K in ferroelectric and ferroelastic $Tb_2(MoO_4)_3$, in which the polarity of ferroelectric polarization is coupled to the orthorhombic strain below the transition temperature 432 K.

The paramagnetic but strongly magnetoelastic Tb^{3+} magnetic moments enable the magnetic control of ferroelectric and ferroelastic domains; the ferroelectric polarization is controlled depending on whether the magnetic field is applied along [110] or [1$\bar{1}$0].

MA 17.9 Tue 11:45 POT/0112

Towards topological switching in multiferroics — •Alessandro Granero and Sergey Artyukhin — Italian Institute of Technology (IIT), Genova, Italy

Magnetoelectric switching in GdMn2O5 [1] is the first known example of topological ferroic switching, where magnetic field sweeps across the spin-reorientation transition induce incremental 90° spin rotations described by a topological winding number. While the behavior has been rationalized with a microscopic model, symmetry conditions and minimal model ingredients that enable this behavior are poorly understood. Here we use a symmetry-based Landau theory approach and demonstrate that a toy model with two frustrated antiferromagnetic subsystems and a low-symmetry anisotropy captures the topological switching behavior. The model reveals how sweeps of the driving field move the free-energy minimum continuously in spin-orientation space, in contrast to conventional ferroelectric switching that relies on fixed *P minima and domain-wall nucleation. Multiple switching pathways enabled by the simultaneous presence of E and H fields are summarized by a "switching diagram" [2], linking regions of the H and E field amplitudes to distinct sequences of magnetoelectric transitions. Small parameter variations near diagram boundaries redirect the system along different routes. The results establish a minimal model for topological switching in GdMn2O5 and guide the search for topological switching phenomena in other materials. [1] L. Ponet, et al.: Nature 607, 81-85 (2022) [2] M. Ryzhkov, A. Granero et al.: Communication Materials, in press

MA 17.10 Tue 12:00 POT/0112

Observation of antiferromagnetic domains by low-temperature photoluminescence microscopy — •Bence Szász — Physics Department, Budapest University of Technology and Economics, Budapest, Hungary

The optical oscillator strengths of crystal-field transitions in magnetoelectric antiferromagnets can serve as specific signatures of the underlying magnetic order. In this work, I investigate the feasibility of identifying magnetic domains using a low-temperature optical photoluminescence microscopy system.

MA 17.11 Tue 12:15 POT/0112

Spectroscopy of coupled magnetic and electric resonances — •Dávid Szaller[1,2], Artem M Kuzmenko[3], Alexander A Mukhin[3], Alexey Shuvaev[2], and Andrei Pimenov[2] — [1]HUN-REN-BME Condensed Matter Physics Research Group, and Department of Physics, Institute of Physics, Budapest University of Technology and Economics, Muegyetem rkp. 3., H-1111 Budapest, Hungary — [2]Institute of Solid State Physics, TU Wien, 1040 Vienna, Austria — [3]Moscow, Russia

Controllable non-reciprocal propagation of light is an intensively investigated field of optics, with studies motivated both by fundamental questions and possible telecommunication applications. So far, polarization-independent, switchable one-way transparency has been demonstrated at certain resonances of multiferroic crystals at cryogenic temperatures and in high magnetic fields, limiting the practical implementation. As an alternative approach, we present one-way transparency of an artificial layered structure consisting of split-ring metamaterial and magnetic substrate layers interacting in the dynamic regime [1]. Our quasi-optical experiments in the GHz frequency range show that this unique combination breaks time and space inversion symmetries in external magnetic field. The ease of tuning the dynamic response and the controllable one-way transparency make this approach promising for real-world applications.

MA 18: Caloric Effects in Ferromagnetic Materials (joint session MA/TT)

Time: Tuesday 9:30–11:30 Location: POT/0151

Invited Talk MA 18.1 Tue 9:30 POT/0151

Magnetic Cooling: From applications at room temperature to hydrogen liquefaction — •T. Gottschall[1], E. Bykov[1], M. Strassheim[1], T. Platte[2], C. Fujta[2], D. Benke[2], M. Fries[2], W. Liu[3], A. Döring[3], K. Skokov[3], O. Gutfleisch[3], and J. Wosnitza[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]MAGNOTHERM Solutions GmbH, Darmstadt, Germany — [3]Technical University of Darmstadt, Darmstadt, Germany

Magnetic cooling can be utilized to construct environmentally friendly cooling devices, air conditioners, and heat pumps. Recently, low temperatures became the focus of attention as an area of application for magnetocaloric cooling, namely for hydrogen liquefaction. The conventional liquefaction process uses up to 40 % of the lower heating value of the gas we are compressing, just to liquefy it! Magnetocaloric materials enable an alternative and more efficient approach. A large number of compounds are already known that show magnetocaloric effects in the desired temperature range and new candidates are constantly being added. In this work, we would like to discuss our current progress for the creation of a materials library for cryogenic applications. The basis for this is our characterization infrastructure for materials research at TU Darmstadt and the Dresden High Magnetic Field Laboratory in static and pulsed magnetic fields. Furthermore, we also provide an overview of the recent results in the demonstrator development of a magnetic hydrogen liquefier within the framework of the European project HyLICAL.

MA 18.2 Tue 10:00 POT/0151

Hydrogen tunned transition temperature of GdFeSi for magnetocaloric hydrogen liquefaction application — •Allan Döring[1], Wei Liu[1], Marc Strassheim[2], Tino Gottschall[2], Konstantin Skokov[1], and Oliver Gutfleisch[1] — [1]Institute of Materials Science, Functional Materials, Technical University of Darmstadt, Darmstadt, Germany — [2]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany

Hydrogen can play an important role in the future carbon-neutral society. Among several alternatives to store this energy carrier, the liquid H2 (LH2) stands out for its higher volume-to-energy ratio. However, the actual method of H2 liquefaction sums up to 34% of the costs of LH2. The magnetocaloric cooling could be one alternative to improve the efficiency of the process. Thus, it is essential to conduct research on materials exhibiting a strong magnetocaloric effect (MCE) within the temperature range of 20 K to 77 K. The peak of the MCE is at transition temperatures, such as the Curie temperature (TC). The mag-

netocaloric effect peak of GdFeSi is at 125 K. In this study, the TC of GdFeSi was shifted to lower temperatures by hydrogenation process, achieving a shift of over 90 K. By the anisotropic crystal expansion, GdFeSiH exhibited and higher magnetocaloric effect than the pristine alloy, not only by the isothermal entropy change, but also directly measured adiabatic temperature change. We acknowledge the HyLICAL project for the funding of this research through grant 101101461, and Deutsche Forschungsgemeinschaft (DFG) within the CRC/TRR 270 (Project-ID 405553726).

MA 18.3 Tue 10:15 POT/0151

First-principles investigation of chemical substitution and interstitial doping in La(Fe,Si)$_{13}$ — •Anita Yadav and Markus E. Gruner — University of Duisburg-Essen, 47057 Duisburg, Germany

$La(Fe_xSi_{1-x})_{13}$ is a prominent magnetocaloric material, characterized by a sharp first-order phase transition and a large associated entropy change. Its behavior arises from an intricate coupling among the magnetic, electronic, and lattice degrees of freedom, which makes the material highly responsive to external factors and enables targeted tuning of its magnetocaloric response [1,2]. The operating range can be modified through substitution and interstitial loading, which can alter the local atomic environment and reshape the coupling between structural and magnetic subsystems. In this work, we employ first-principles calculations in the framework of density functional theory (DFT) to systematically screen the impact of chemical substitution and loading of light elements on interstitial sites with respect to structural stability, lattice expansion, magnetic interactions, and thermodynamic behavior. Furthermore, we explore the benefits of machine-learning force-fields based on our DFT results for an efficient modeling of the thermodynamic properties of $La(Fe_xSi_{1-x})_{13}$-based compounds. Funding by the DFG via TRR270 (B06) is gratefully acknowledged.

MA 18.4 Tue 10:30 POT/0151

Magnetocaloric Laves phases based on light rare earths: Addressing Criticality — •M. Strassheim[1,2], L. Beyer[3,4], J. Wosnitza[1,2], and T. Gottschall[1] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden, Germany — [3]Leibniz Institute for Solid State and Materials Research Dresden, Germany — [4]TU Bergakademie Freiberg, Germany

Laves-phase intermetallic compounds based on heavy rare-earth elements have long been recognized for their excellent magnetocaloric performance at low temperatures, making them promising candidates for cryogenic cooling applications. However, the reliance on heavy rare earths poses challenges in terms of cost, availability, and sustainability. In this work, we explore the magnetocaloric properties of the light rare-earth-based Laves phase $CeFe_2$. By the substitution of Al, its unstable ferromagnetism can be disturbed enough to establish an antiferromagnetic phase below 80 K. Using a combination of structural, magnetic, and direct adiabatic temperature change measurements at the Dresden High Field Laboratory, we investigate the potential of this antiferromagnetic state for its potential in magnetocaloric hydrogen liquefaction.

MA 18.5 Tue 10:45 POT/0151

Pressure effect on the magnetocaloric response of RCo_2 Laves Phases — •Catalina Salazar-Mejia[1], E. Bykov[1], W. Liu[2], K. Skokov[2], O. Gutfleisch[2], J. Wosnitza[1,3], and T. Gottschall[1] — [1]High Magnetic Field Laboratory (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, Germany — [2]Institut für Materialwissenschaft, TU Darmstadt, Germany — [3]Institut für Festkörper- und Materialphysik, TU Dresden, Germany

Rare-earth Laves phases are potential candidates for magnetic refrigeration at cryogenic temperatures. They exhibit large magnetocaloric effects and their transition temperatures can be tuned through elemental substitutions. In this work, we investigate the effect of hydrostatic pressure on the magnetism and magnetocaloric effect of RCo_2 Laves phases with rare-earth elements R = Tb, Dy, Ho, and Er. In general, we observe that the Curie temperature, T_C, decreases with applied pressure in all alloys. T_C is most sensitive to pressure in $TbCo_2$, with $dT_C/dp \approx -22$ K/GPa, and this value decreases systematically along the series, reaching $dT_C/dp \approx -7.7$ K/GPa in $ErCo_2$. More interestingly, hydrostatic pressure has an almost negligible effect on the magnetocaloric response - specifically on the isothermal entropy change, ΔS_T, with the exception of $HoCo_2$, where ΔS_T increases by about 26% under an applied pressure of approximately 1 GPa and for a magnetic field change of 5 T.

MA 18.6 Tue 11:00 POT/0151

Manipulating Magnetocaloric Properties Through Magnetic Exchange at $Mn_{3-x}GaC$/Fe Interfaces — •Ivan Tarasov and Ulf Wiedwald — Faculty of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany

Magnetocaloric materials enable solid-state cooling by exploiting temperature changes under magnetic-field variation. Manganese-based antiperovskites (APVs, Mn_3AX) are promising materials due to their sharp, tunable first-order magnetostructural transition (FOMST). A key challenge is to control the working temperature window and enhance the magnetocaloric response within a given material system. Tailoring magnetic exchange interactions offers a new strategy.

Here, we investigate APV/Fe bilayers, focusing on interface-driven exchange effects. Uncoupled $Mn_2GaC_{1.1}$ films show a sharp FOMST at 189 K with a strong $\partial M/\partial T$ peak. A 5 nm Fe cap lowers the transition to 175 K, broadens hysteresis, and suppresses the $\partial M/\partial T$ peak above 1 T. The bare APV exhibits $\Delta S_m \approx 10$ J kg^{-1} K^{-1} at $B = 6$ T, whereas coupling reduces this to ~ 1 J kg^{-1} K^{-1} at $B = 5$ T. In multi-domain bilayers, $\partial M/\partial T$ increases by 15% (AFM–FM) and 46% (FM–PM) for a Fe film thickness of $t = 2.6$ nm, but disappears for $t = 21$ nm, accompanied by an anomaly near 50 K linked to interfacial AFM ordering.

Funding by the Deutsche Forschungsgemeinschaft (DFG) within CRC/TRR 270, project B02 (Project-ID 405553726) is gratefully acknowledged.

MA 18.7 Tue 11:15 POT/0151

Frustration and Antiferromagnetic Ordering in Low-Temperature Materials for Adiabatic Demagnetization — •Anton Jesche, Tim Treu, Marvin Klinger, Jorginho Villar Guerrero, and Philipp Gegenwart — EP VI, Institute of Physics, University of Augsburg, Germany

The development of improved materials for adiabatic demagnetization refrigeration (ADR) has been driven increasingly by research on magnetically frustrated systems, where competing interactions can suppress magnetic ordering to very low temperatures [1]. Such behavior is particularly attractive for low-temperature cooling and has led to several promising rare-earth-based compounds. Notable examples include $KBaYb(BO_3)_2$, which reaches temperatures near 20 mK [2], and $NaGdP_2O_7$, which demonstrates extended hold times below 2 K in standard cryogenic environments [3].

This contribution will highlight selected Yb- and Gd-based materials and discuss the influence of frustration and antiferromagnetic (AFM) ordering on their cooling performance. Using $NaGdP_2O_7$ as a representative case, we examine how magnetic entropy near AFM transitions affects ADR behavior under varying magnetic fields and temperatures. We further show that high-resolution thermodynamic information, such as heat capacity, can be extracted directly from ADR curves.

MA 19: Frustrated Magnets I (joint session MA/TT)

Time: Tuesday 9:30–12:30 Location: POT/0361

MA 19.1 Tue 9:30 POT/0361

Spontaneous symmetry breaking in the Heisenberg antiferromagnet on a triangular lattice — •Bastian Pradenas[1,2], Grigor Adamyan[1,3], and Oleg Tchernyshyov[1] — [1]William H. Miller III Department of Physics and Astronomy, Johns Hopkins University, Baltimore, USA — [2]Leibniz Institute for Solid State and Materials Research, IFW, Dresden, Germany — [3]Department of Physics, Massachusetts Institute of Technology, Cambridge, USA

We present a detailed investigation of an overlooked symmetry structure in non-collinear antiferromagnets that gives rise to an emergent quantum number for magnons. Focusing on the triangular-lattice Heisenberg antiferromagnet, we show that its spin order parameter transforms under an enlarged symmetry group, $SO(3)_L \times SO(2)_R$, rather than the conventional spin-rotation group SO(3). Although this larger symmetry is spontaneously broken by the ground state, a residual subgroup survives, leading to conserved Noether charges that, upon quantization, endow magnons with an additional quantum number—*isospin*—beyond their energy and momentum. Our results provide a comprehensive framework for understanding symmetry, degeneracy, and quantum numbers in non-collinear magnetic systems, and bridge an unexpected connection between the paradigms of symmetry breaking in non-collinear antiferromagnets and chiral symmetry breaking in particle physics.

MA 19.2 Tue 9:45 POT/0361

Antiferro octupolar order in the 5d^1 double perovskite Sr_2MgReO_6 and its spectroscopic signatures — •Dario Fiore Mosca[1] and Leonid Pourovskii[2,3] — [1]University of Vienna, Faculty of Physics and Center for Computational Materials Science, Vienna, Austria — [2]CPHT, CNRS, Ecole polytechnique, Institut Polytechnique de Paris, 91120 Palaiseau, France — [3]College de France, Université PSL, 11 place Marcelin Berthelot, 75005 Paris, France

Hidden-order phases governed by high-rank multipolar order parameters have recently been identified in several cubic 5d double perovskites. Because experimental probes often couple weakly to high-rank moments, multipolar orders can remain elusive or be misinterpreted as lower-rank phases. A notable example is the $5d^1$ double perovskite Sr_2MgReO_6, originally proposed as a spin glass and later reclassified as a conventional dipolar antiferromagnet.

In this work, we show instead that Sr_2MgReO_6 hosts a hidden antiferroic order of magnetic octupoles. The dominant tetragonal crystal field isolates a doublet carrying octupolar degrees of freedom, while weak dipolar moments arise only through admixture of the excited j = 1/2 spin-orbit multiplet. This octupolar order produces characteristic quasigapless magnetic excitations and superstructural neutron-diffraction intensities that peak at large scattering momenta.

This results highlights the tunability of multipolar interactions in spin-orbit entangled materials and places Sr_2MgReO_6 with unconventional octupolar phases.

MA 19.3 Tue 10:00 POT/0361

Field-dependent CEF excitations in Ce_2Bi — •Nikolai Pavlovskii[1], Alexander Sukhanov[2], Anton Kulbakov[1], Michael Smidman[3], Federico Mazza[4], Darren Peets[1], Kaushick Parui[1], Ross Stewart[5], Ross Piltz[6], and Dmytro Inosov[1] — [1]TU Dresden, Germany — [2]University of Augsburg, Germany — [3]Zhejiang University, China — [4]TU Vienna, Austria — [5]ISIS, UK — [6]ANSTO, Australia

Ce_2Bi is a cerium-based intermetallic compound where crystal-field (CEF) splitting and anisotropic magnetic interactions occur on comparable energy scales. To identify the relevant low-energy degrees of freedom, we investigate the field dependence of CEF-related excitations in single-crystalline Ce_2Bi using neutron-scattering techniques. Single-crystal diffraction establishes the crystallographic symmetry at the Ce site, providing the structural framework required for interpreting the magnetic excitations. The excitation spectrum shows a clear magnetic mode within the $J = 5/2$ manifold whose energy and intensity vary strongly with applied field. Crucially, the mode displays clear dispersion, demonstrating the presence of exchange interactions; as a result, what was previously interpreted as a localized CEF level is revealed to be a dispersive magnetic exciton. The field-induced evolution of this exciton constrains the mixing within the CEF manifold and the anisotropy of the ground-state Kramers doublet.

MA 19.4 Tue 10:15 POT/0361

High-field magnetic excitations in a kagome antiferromagnet — •Yoshihiko Ihara[1], Dmytro Inosov[2], Darren Peets[2], Moyu Kato[1], and Hiroyuki Yoshida[1] — [1]Hokkaido University, Sapporo, Japan — [2]TU Dresden, Dresden, Germany

Magnetic ground states in kagome antiferromagnets have been intensively studied to reveal the quantum mechanically disordered magnetic states. By applying high magnetic fields, further intriguing phenomena have been introduced such as the plateau in magnetization curve at the 1/9 of the full saturation value in $YCu_3(OH)_{6.5}Br_{2.5}$. [S. Jeon et al., Nat. Phys. **20**, 435 (2024), S. Suetsugu et al., PRL **132**, 226701 (2024), G. Zheng et al., PNAS **122**, e2421390112 (2025)]. Although higher magnetic fields induce another magnetization plateau at the 1/3 of the full saturation, the field strength required to access the 1/3 plateau is more than 50 T and is too large to perform most of the microscopic experiments. Thus, we focus on another Cu-based mineral $InCu_3(OH)_6Cl_3$, which shows the 1/3 plateau around 10 T due to smaller energy scale of exchange interactions [M. Kato et al., Commun. Phys. **7**, 424 (2024)]. This allows us to perform NMR experiments in the entire field range reaching the full saturation. The measured nuclear spin-lattice relaxation rate demonstrates that the magnetic excitations are gapped in the 1/3 plateau state and the gap size increases with fields [M. Kato et al., JPSJ **94**, 083704 (2025)]. We will also discuss the magnetic excitations above the 1/3 plateau based on the results obtained in the high-field magnet in Tohoku Univ.

MA 19.5 Tue 10:30 POT/0361

Evidence for a Near-Ideal Jeff = 1/2 Ground State in Triangular-Lattice Na2BaCo(PO4)2 — •Miguel M. F. Carvalho[1,2], Sheng H. Chen[1], Yu C. Ku[3,4], Anagha Jose[5], Ryan Morrow[5], Chang Y. Kuo[3,4], Chun F. Chang[1], Zhiwei Hu[1], Maurits W. Haverkort[6], and Liu H. Tjeng[1] — [1]Max Planck Institute for Chemical Physics of Solids,Dresden — [2]Institute of Physics II, University of Cologne — [3]Department of Electrophysics, National Yang Ming Chiao Tung University, Hsinchu, Taiwan — [4]National Synchrotron Radiation Research Center, Hsinchu, Taiwan — [5]Institut fuer Festkoerperphysik, Leibniz IFW, Dresden — [6]Institute for theoretical physics, Heidelberg University

We investigated the local Co 3d electronic structure of Na2BaCo(PO4)2 using polarization-dependent X-ray absorption spectroscopy (XAS) together with full multiplet cluster calculations. To obtain reliable spectra from this strongly insulating material, we employed the line-fitting inverse partial fluorescence yield (IPFY) method. Our combined experimental and theoretical analysis shows that the CoO6 octahedra exhibit only a very small effective trigonal distortion of about 11 meV, placing the system close to the ideal conditions for a Jeff = 1/2 ground state. Using our cluster model, we are also able to simulate the magnetic susceptibility along different crystallographic directions, . Overall, these results establish Na2BaCo(PO4)2 as a promising platform for investigating exotic magnetic behavior linked to Jeff = 1/2 states on triangular lattices.

MA 19.6 Tue 10:45 POT/0361

Dimensional reduction and fractionalized magnetization plateaus in the scalene-distorted triangular-lattice magnet kobyashevite — •Kaushick Parui[1], Anton Kulbakov[1], Roman Gumeniuk[2], Maria Teresa Fernandez-Diaz[3], Sergey Granovsky[1], Sergei Zvyagin[4], Dmytro Inosov[1], and Darren Peets[1,5] — [1]TU Dresden, Germany — [2]TU Bergakademie Freiberg, Germany — [3]ILL, France — [4]HZDR, Germany — [5]ct.qmat, TU Dresden, Germany

Quantum magnetism intertwined with lattice distortion can give rise to exotic ground states, yet studies on scalene-distorted triangular-lattice antiferromagnets remain scarce. Here, we report the crystal and magnetic structures, as well as magnetic and thermodynamic properties, of kobyashevite, $Cu_5(SO_4)_2(OH)_6{\cdot}4H_2O$. This compound hosts a scalene-distorted triangular lattice and exhibits antiferromagnetic order at 4 K, with a possible second transition at 0.64 K. High-field magnetization and specific-heat measurements reveal a cascade of field-induced states, manifested as magnetization plateaus, suggestive of a rich magnetic phase diagram. Neutron diffraction uncovers a dimensionally-reduced commensurate magnetic structure with propagation vector $\mathbf{k} = (0\,0\,\frac{1}{2})$, consisting of coupled alternating ferromagnetic and antiferromagnetic spin chains, while the Cu4 spins remain idle at 1.5 K. Collectively, these results establish kobyashevite as a promising platform for exploring the interplay of frustration, distortion, and dimensional reduction in quantum magnets.

Atomically sharp magnetic solitons for racetrack memory at the spatial limit — K Allen[1], K Du[2], J Bouaziz[3], S Mishra[1], G Bihlmayer[3], Y Zhang[1], Y Hao[4], V Ukleev[5], C Luo[5], F Radu[5], Y Gao[1], Ch Lane[6], J-X Zhu[6], M Yi[1], H Cao[4], S-W Cheong[2], •Stefan Blügel[3], and Emilia Morosan[1] — [1]Dept. of Physics and Astronomy & Rice Center for Quantum Materials, Rice University, Houston, 77005, TX, USA — [2]Dept. of Physics and Astronomy, Rutgers University, Piscataway, 08854, NJ, USA — [3]Peter-Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany — [4]Neutron Scattering Division, Oak Ridge Natl Lab, Oak Ridge, 37831, TN, USA — [5]Helmholtz-Zentrum Berlin, 14109 Berlin, Germany — [6]Theoretical Division, Los Alamos Nat. Lab., Los Alamos, 87545, NM, USA

We discuss the physics of a metallic square-net lattice rare-earth compound that exhibits RKKY interactions leading to magnetic frustration whose effective exchange interactions competes with the uniaxial anisotropy resulting in a rare ferrimagnetic up-up-down phase. Applying magnetic fields, atomically sharp solitons can be precipitated that have all the foundational credentials for a racetrack memory at the spatial limit. We present DFT calculations relating the RKKY interaction and the magnetic anisotropy to the electronic structure. We performed atomistic spin-dynamics calculations relating the interaction parameters to the soliton formation. A combination of experiments will be presented that provide evidence of the 1D magnetic solitons.

MA 19.8 Tue 11:30 POT/0361

Guest*Controlled Quantum Magnetism in a Flexible Metal-Organic Framework — •Fang Liu[1], Armin Schulz[2], Axel Lubk[4], Alexej Pashkin[3], Sergej Granovski[1], Shuhan Wang[1], Weinel Kristina[4], Herzog Max[4], and Stefan Kaiser[1] — [1]Institute of Solid State and Materials Physic, Dresden University of Technology — [2]Max Planck Institute for Solid State Research, Stuttgart — [3]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden — [4]Leibniz Institute for Solid State and Materials Research, Dresden

Metal-organic frameworks provide an unusual setting where magnetic frustration and structural flexibility coexist. In our system, two distinct states emerge: a guest-stabilized regime with signatures of a potential quantum spin liquid, and a guest-free state exhibiting weak magnetic ordering. Raman and infrared spectroscopy reveal pronounced differences in lattice modes between these phases. Complementary Raman and THz measurements further uncover contrasting magnetic backgrounds. These findings establish a guest-controlled route to tuning magnetic quantum states in MOFs.

MA 19.9 Tue 11:45 POT/0361

Investigation of spin-correlated phases in quasi two-dimensional layered honeycomb oxide — •Aprajita Joshi[1], Anjali Kumari[2,3], Shalini Badola[1], Anup Kumar Bera[2,3], and Surajit Saha[1] — [1]Indian Institute of Science Education and Research Bhopal, 462066, India — [2]Bhabha Atomic Research Centre, Mumbai 400085, India — [3]Homi Bhabha National Institute, Mumbai 400094, India

Honeycomb oxides are an intriguing class of materials characterised by low dimensionality and strong magnetic frustration, which leads to exotic quantum spin correlations. Here, we investigated a quasi-two-dimensional magnetic ox-

ide Na2Co2TeO6, which exhibits several intriguing magnetic phases, including the zigzag antiferromagnetic interaction and Kitaev paramagnetic spin interactions. We explored the intricate relationship between these phases and phonons using temperature-dependent Raman measurements. Our findings reveal the signature of magnetoelastic coupling across the long-range and short-range magnetic ordering temperatures. Furthermore, Na2Co2TeO6, which has a noncentrosymmetric crystal structure, showcases ferroelectric order below 80 K. The evolution of Raman spectra reveals the presence of a ferroelectric order coupled phonon mode in Na2Co2TeO6 below this temperature.

MA 19.10 Tue 12:00 POT/0361

Characterizing entanglement at finite temperature: how does a paramagnet become a quantum spin liquid? — Snigdh Sabharwal[1,2], •Matthias Gohlke[1], Paul Skrzypczyk[2], and Nic Shannon[1] — [1]Okinawa Institute of Science and Technology, Onna, Japan — [2]H. H. Wills Physics Lab., University of Bristol, Bristol, UK

Quantum spin liquids (QSL) are generically many body entangled states of matter that form when quantum fluctuations meet the extensive ground state degeneracy of a classical spin liquid. Entanglement properties have enabled to characterise gapped QSL at zero temperature, however, much less is known about how quantum many body entanglement evolves at finite temperature.

Here, we use entanglement depth and genuine multipartite entanglement (GME) to study how entanglement and its local structure emerge when cooling a frustrated magnet from the high-temperature paramagnet down to the low-temperature QSL state. Within a case study on the Kitaev Honeycomb model, we obtain two characteristic bounds: (1) a lower bound on the upper temperature below which separability breaks and quantum entanglement must be present, while (2) a lower temperature scale is obtained when GME on plaquettes becomes finite signifying the coherent, structured entanglement that is characteristic for QSL ground states [1], i.e. the flux free state of the Kitaev spin liquid. We provide a framework to discuss the relevant temperature scales for QSL in frustrated magnets [2].

Fate of the Triangular Dirac spin liquid under an external magnetic field — •Sasank Budaraju[1,2], Josef Willsher[3], Federico Becca[4], Johannes Knolle[1,2], and Frank Pollmann[1,2] — [1]Technical University of Munich, TUM School of Natural Sciences, Physics Department, 85748 Garching, Germany — [2]Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — [3]Max-Planck-Institut fur Physik komplexer Systeme, 01187 Dresden, Germany — [4]Dipartimento di Fisica, Universita di Trieste, Strada Costiera 11, I-34151 Trieste, Italy

We investigate the J1-J2 Heisenberg model under an external Zeeman field using the Variational Monte Carlo approach. Simple variational ansatzes are proposed for several candidate ordered states, and their energetics are compared on large clusters to obtain the phase diagram for small/moderate fields. For small J2, we capture a continuous transition from the Y to the "Up-Up-Down" (UUD) states as predicted by spin-wave theory. Additionally, around the highly frustrated region, we demonstrate that the ground state in the presence of a small field is a condensate of monopoles, which are gapless gauge excitations of the U (1) spin liquid. The monopole condensate is shown to be the ground state for a significant region of phase diagram, which we estimate using finite size numerics. Our results imply that the Dirac spin liquid is unstable to a condensation of monopoles in the presence of external fields.

MA 20: Altermagnets III

Time: Tuesday 14:00–15:30 Location: HSZ/0002

MA 20.1 Tue 14:00 HSZ/0002

Curvature-induced magnetization of altermagnetic films — •Kostiantyn Yershov[1,2], Volodymyr Kravchuk[1,2], and Jeroen van den Brink[1] — [1]Leibniz Institute for Solid State and Materials Research, 01069 Dresden, German — [2]Bogolyubov Institute for Theoretical Physics, 03143 Kyiv, Ukraine

Here we generalize the previously developed phenomenology of the d-wave altermagnetic films for the case of a curvilinear film bent in a stretching-free manner. We show that a stretching-free bending of a thin altermangnetic film with nonzero curvature gradients induces local magnetization that is approximately tangential to the film. The origin of curvature-induced magnetization is nonuniformity of the Neel vector distribution generated by the non-zero curvature gradients. The magnitude of the curvature-induced magnetization is determined by the curvature gradient and the direction of bending relative to the crystallographic axes. The maximal effect is achieved when bending is in the direction of maximum altermagnetic splitting in the magnon spectrum. For a periodically bent film of sinusoidal shape possesses a total magnetic moment per period $\propto A^2 q^4$ where A and q are the bending amplitude and wave vector, respectively. The total magnetic moment is perpendicular to the plane of the unbent film and its direction (up or down) is determined by the bending direction.

MA 20.2 Tue 14:15 HSZ/0002

Strain controlled g -to d-wave transition in altermagnetic CrSb — Bennet Karetta[1], •Xanthe Verbeek[1], Rodrigo Jaeschke-Ubiergo[1], Libor Šmejkal[2,3,4], and Jairo Sinova[1,5] — [1]Insitut für Physik, Johannes Gutenberg-Universität Mainz, D-55099 Mainz, Germany — [2]Max-Planck-Institut für Physik Komplexer Systeme, Nöthnitzer Str. 38, 01187 Dresden, Germany — [3]Max-Planck-Institut für Chemische Physik Fester Stoffe, Nöthnitzer Str. 40, 01187 Dresden, Germany — [4]Institute of Physics, Academy of Sciences of the Czech Republic, Cukrovarnická 10, Prague 6, Czech Republic — [5]Department of Physics, Texas A&M University, College Station, Texas 77843-4242, USA

We demonstrate a strain-induced transition in the g-wave altermagnet CrSb, revealing how shear strain can tune spin symmetries and enable new responses. Focusing on the spin-splitter effect, which allows for pure spin currents but is forbidden in unstrained CrSb, we identify four shear-strain directions that lower the symmetry and enable spin conductivity. These strains induce three d-wave altermagnetic states and one uncompensated magnetic phase, each with distinct spin symmetries. Using both a minimal model and first-principles calculations, we confirm the emergence of these phases and show that their key features remain robust in the presence of spin-orbit coupling. We predict a spin-splitter effect of up to 5% under just 1% strain, showing that even small deformations can generate sizable spin-splitter currents. Our findings highlight strain as a precise and effective tool for controlling symmetry-driven spin phenomena in altermagnets.

MA 20.3 Tue 14:30 HSZ/0002

Designing non-relativistic spin-splitting in transition metal oxide bulk and heterostructures — •Subhadeep Bandyopadhyay and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen, Duisburg, Germany

Non-relativistic spin splitting (NRSS) of bands in collinear antiferromagnets is an exotic phenomenon, that has currently shifted in the focus, owing to the great potential for various spintronic applications. Studies showed that the inhomogeneous distribution of the real space magnetization density, originating from the ferroically ordered magnetic octupole moments[1] is the key to this exotic phenomenon, which stems from the global time reversal symmetry (TRS) breaking in antiferromagnets. In perovskite ABO_3 materials, we find an intriguing correlation between the antiferroic distortion patterns and the antiferromagnetic order, that breaks TRS to induce NRSS[2].

Here we explore how structural distortions and antiferromagnetism combine to induce NRSS in perovskites. Building on that insight, we demonstrate the recipe to design and control the NRSS. Beyond the bulk compounds, the discussion is extended to the perovskite heterostructures, where interface-driven structural distortions and modifications of the electronic properties are crucial.

MA 20.4 Tue 14:45 HSZ/0002

hall viscosity of altermagnet — •iksu jang[1], rui aquino[2], rafael fernandes[3,4], and jörg schmalian[1,5] — [1]Institute for Theory of Condensed Matter, Karlsruhe Institute of Technology, Karlsruhe 76131, Germany — [2]ICTP, South American Institute for Fundamental Research Instituto de Física Teórica da UNESP, Universidade Estadual Paulista, Rua Doutor Bento Teobaldo Ferraz 271, 01140-070 São Paulo, Brasil — [3]Department of Physics, The Grainger College of Engineering, University of Illinois Urbana-Champaign, Urbana, Illinois 61801, USA — [4]Anthony J. Leggett Institute for Condensed Matter Theory, The Grainger College of Engineering, University of Illinois Urbana-Champaign, Urbana, Illinois 61801, USA — [5]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, Karlsruhe 76131, Germany

Altermagnets have garnered significant interest due to their ability to exhibit spin splitting without spin orbit coupling and their symmetry-driven phenomena, such as elastic quantum criticality and elasto-Hall responses. In this work, we investigate the Hall viscosity of altermagnets subject to strain. Using group-theoretical analysis and tight-binding calculations, we show that altermagnetic systems with various form factors can host a finite Hall viscosity. We additionally propose that the acoustic Faraday effect offers a viable route for its experimental detection.

MA 20.5 Tue 15:00 HSZ/0002

Dynamical orbital pumping in altermagnets — •Guidobeth Sáez-Toro[1], Mirco Sastges[2], Myunil Choi[3], Dongwook Go[3], and Yuriy Mokrousov[2] — [1]Departamento de Física, Facultad de Ciencias, Universidad de Chile, Santiago 7800024, Chile — [2]Peter Grünberg Institute (PGI-6), Forschungszentrum Jülich, 52425 Jülich, Germany — [3]Department of Physics, Korea University, Seoul 02841, Republic of Korea

Altermagnets constitute a recently recognized class of magnetic materials in which symmetry breaking between sublattices and orbital degrees of freedom gives rise to unconventional magnetic responses. A direct consequence of this symmetry structure is that time-dependent magnetization generates a purely orbital pumping mechanism, $\partial_t \langle \mathbf{L} \rangle_\alpha = \chi^L_{\alpha\beta} (\hat{\mathbf{m}} \times \partial_t \hat{\mathbf{m}})_\beta$, mediated by spin-orbit coupling. We investigate this effect by driving the Néel order in a minimal tight-binding model on a square altermagnetic lattice, based on an antiferromagnetic array of spins with an orbital crystal field breaking both C_4 rotational and sublattice exchange symmetries. Our results reveal a pronounced sublattice dependence of the orbital response, providing a clear microscopic distinction between antiferromagnetic and ferromagnetic configurations. Using the Bastin-Smrcka-Streda Kubo formula, we compute the full response tensor and show that orbital pumping naturally decomposes into two robust contributions, analogous to field-like and damping-like components. These findings establish orbital pumping as a distinctive dynamical signature of altermagnets and highlight its potential for next-generation orbitronic functionalities.

MA 20.6 Tue 15:15 HSZ/0002

Unique responses in odd-parity nodal p-wave magnets — •Atasi Chakraborty[1], Anna Birk Hellenes[1], Rodrigo Jaeschke Ubiergo[1], Tomas Jungwirth[2,3], Libor Šmejkal[2,4], and Jairo Sinova[1,5] — [1]Institut für Physik, Johannes Gutenberg Universität Mainz — [2]Institute of Physics, Academy of Sciences of the Czech Republic — [3]School of Physics and Astronomy, University of Nottingham — [4]Max Planck Institute for the Physics of Complex Systems,Dresden — [5]Department of Physics, Texas A & M University

The recent discovery of Altermagnetism – spin-split even-parity compensated magnets – highlights how spin symmetries can reveal exchange-driven phenomena that has previously been overlooked. Building on this insight, we explore spin symmetry criteria [1,3] to identify the odd-parity magnetic states in non-collinear systems, focusing on effects driven purely by exchange interactions, independent of spin-orbit coupling. In this talk, I will focus on the lowest-order (pwave) nodal odd-parity magnets, and discuss their characteristic responses [1, 2]. We show that these p-wave magnetic phases spontaneously break crystal symmetries, leading to pronounced exchange-mediated resistive anisotropy [1] and exhibit a large, purely non-relativistic, anisotropic out-of-plane charge-to-spin conversion [2], fundamentally distinct from the conventional Rashba-Edelstein effect.

MA 21: Skyrmions II

Time: Tuesday 14:00–15:30 Location: HSZ/0004

MA 21.1 Tue 14:00 HSZ/0004

Real-Time Modeling of Skyrmion Dynamics in Arbitrary 2D Spatially Dependent Pinning Potential Landscapes — •Simon M. Fröhlich, Tobias Sparmann, Maarten A. Brems, Jan Rothörl, Fabian Kammerbauer, Klaus Raab, Sachin Krishnia, Mathias Kläui, and Peter Virnau — Institute of Physics, Johannes Gutenberg University Mainz

We investigate how non-flat pinning landscapes influence skyrmion dynamics and develop a quantitative framework that links experimental measurements to predictive simulations. Using real-time magneto-optical Kerr microscopy, we track skyrmion hopping and dynamics in a magnetic thin-film system and extract dwell times and transition statistics across pinning sites. This data is used to construct parameters for a coarse-grained Thiele model, for which we introduce a two-stage parameter identification procedure that directly maps experimental observables onto simulation units. This calibration resolves a key barrier to quantitative quasiparticle-level modeling by enabling reconstruction of pinning energies not directly accessible on experimental timescales. We validate the resulting simulation framework by predicting the density dependence of skyrmion diffusion and confirming it through long-time measurements. The approach provides a robust, simulation-ready description of the pinning landscape and establishes a pathway for predictive in-silico exploration of skyrmion dynamics and device concepts on experimentally relevant time and length scales.

MA 21.2 Tue 14:15 HSZ/0004

Theoretical study on excitation in anti-Skyrmion lattice — •László Udvardi, Mátyás Török, and László Szunyogh — Department of Theoretical Physics, Budapest University of Technology and Economic

Magnetic Skyrmions exhibit intriguing and novel phenomena due to their topologically non-trivial spin textures. Their exceptional stability makes them possible candidates for information carriers for future spintronic devices.

We have determined the parameters appearing in a classical spin model from first principle for $Pt_{95}Ir_{05}$/Pd(111) overlayer. Optimizing the energy of the spin model several local minima have been identified as a Skyrmion with various topological charges. We demonstrate that the frustration of the isotropic exchange interactions is responsible for the creation of these various types of skyrmionic structures. Our study is focused on objects with topological charge of Q=1 anti-Skyrmion. Anti-skyrmions exhibit attractive inter-particle interaction and they have tendency to form clusters or skyrmionic lattice. The excitation spectrum of an anti-skyrmon lattice with various external magnetic field has been calculated. The low energy excitation responsible for the low temperature behavior of the system shows similarities to nematic liquid crystals.

MA 21.3 Tue 14:30 HSZ/0004

Skyrmion topological Hall effect in Ta/CoFeB/MgO at room temperature detected with Kerr microscopy — •Hauke Lars Heyen[1], Michael Vogel[2], Florian Gossing[2], Jakob Walowski[1], Jeffrey McCord[2], and Markus Münzenberg[1] — [1]Institute of Physics, University Greifswald, Germany — [2]Institute of Materials Science, Nanoscale Magnetic Materials and Magnetic Domains, CAU Kiel, Germany

The topological Hall effect is interesting for characterizing materials and their non-trivial spin structures. It arises from spin textures with a finite topological charge, such as skyrmions. In this work, we measured the topological Hall effect originating from topologically protected skyrmions in Ta/CoFeB/MgO single-layer films. Since the small topological Hall contribution appears on top of the dominating anomalous Hall effect, its direct detection in this material system is challenging. Electrical Hall effect measurements contain both effects and to separate these, Kerr-microscopy (MOKE) measurements are carried out simultaneously to Hall effect measurements. We further verify the results with thermal and electrical transport measurements to calculate a topological quantity that contains the topological Nernst and Hall effect respectively. Those measurements are conducted using the experimental scheme introduced in [1].

MA 21.4 Tue 14:45 HSZ/0004

Optimization of magnetic skyrmion diffusion in thin films — •Alen John[1,2], Maria Andromachi Syskaki[1], Jürgen Langer[1], Gerhard Jakob[2], and Mathias Kläui[2] — [1]Singulus Technologies AG, 63796 Kahl am Main, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany

Topological magnetic solitons, particularly skyrmions, have garnered significant interest for their potential in unconventional computing and sensing applications. In this work, we outline an optimized fabrication strategy for generating and stabilizing low-pinning magnetic skyrmions in magnetic thin films using magnetron sputtering. We focus on Ta/CoFeB/MgO heterostructures with perpendicular magnetic anisotropy and systematically vary key deposition parameters including sputter power and Ar pressure to optimize skyrmion formation. Furthermore, we incorporate an ultrathin Ta dusting layer at the CoFeB/MgO interface to precisely tune the interfacial anisotropy. This combined approach enables the realization of ultralow-pinning thin-film systems that reliably host room-temperature, thermally diffusing skyrmions. Such samples represent a promising platform for emerging applications in unconventional computing paradigms, including reservoir computing[1].

MA 21.5 Tue 15:00 HSZ/0004

Impact of higher-order exchange on the lifetime of skyrmions and anti-skyrmions — Hendrik Schrautzer[1], Moritz Goerzen[2,3], •Bjarne Beyer[3], Pavel Bessarab[1,4], Soumyajyoti Haldar[3], and Stefan Heinze[3,5] — [1]Science Institute and Faculty of Physical Sciences, University of Iceland, Reykjavik, Iceland — [2]CEMES, Université de Toulouse, CNRS, Toulouse, France — [3]Institute of Theoretical Physics and Astrophysics, University of Kiel, Germany — [4]Department of Physics and Electrical Engineering, Linnaeus University, Kalmar, Sweden — [5]Kiel Nano, Surface, and Interface Science (KiNSIS), University of Kiel, Germany

Reliable control of skyrmion lifetime is essential for realizing spintronic devices, yet the role of higher-order interactions (HOI) – which can lead to skyrmion

stabilization – remains largely unexplored. Here we calculate lifetimes of isolated skyrmions and antiskyrmions at transition-metal interfaces based on an atomistic spin model that includes fourth-order exchange [1]. Within harmonic transition-state theory, we evaluate both energetic and entropic contributions and find substantially enhanced lifetimes when HOI are included. The four-spin four-site interaction raises the energy barrier and lowers the curvature of the energy landscape in the vicinity of the collapse saddle point, increasing the pre-exponential factor of the arrhenius Law. Further HOI allow thermally stable skyrmions and antiskyrmions even in absence of Dzyaloshinskii-Moriya interaction, interesting in the context of 2D van der Waals magnets lacking inversion symmetry.

MA 21.6 Tue 15:15 HSZ/0004

Real-time observation of topological defect dynamics mediating two-dimensional skyrmion lattice melting — Raphael Gruber[1], •Edoardo Mangini[1], Maria-Andromachi Syskaki[1], Elizabeth Jefremovas[1], Sachin Krishnia[1], Asle Sudbø[2], Peter Virnau[2], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University, Staudingerweg 7, Mainz, Germany — [2]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway

Magnetic skyrmions, topologically non-trivial chiral magnetic quasi-particles, can be stabilized in magnetic thin-film stacks [1]. By precisely controlling the externally applied in-plane and out-of-plane magnetic fields, two-dimensional dense arrays of skyrmions—so-called skyrmion lattices—can be formed [2]. Through suitable geometrical confinement, both orientational and translational order can be induced in these lattices. Such systems provide experimental insight into the dynamics of phase transitions in two-dimensional particle systems.

In this work, we show a two-step topological lattice-melting experiment, in which phase transitions are triggered in a skyrmion lattice by tuning the skyrmion size. The Kerr microscopy setup, in conjunction with machine learning approaches, enables real-time tracking of skyrmions, allowing us to investigate the emergence and dynamics of topological lattice defects throughout the phase transitions [3].

MA 22: Focus Session: Materials Discovery II – High throughput searches for functional magnetic materials (joint session FM/MA)

chairs: Jan Schultheiß (Norwegian University of Science and Technology, NO), Hiroki Taniguchi (Nagoya University, JP)

Discovering new functional materials is crucial to advance today's technologies, ranging from caloric cooling via catalysis to next-generation energy conversion and storage, such as thermoelectric, ferroelectric, and ionic conductor materials. New materials also form the basis for potential applications in quantum information technologies. This session provides a platform to highlight functional materials discoveries and how they come about. Notably, systematic searches with high-throughput synthesis approaches, as well as predictions from materials informatics, have helped to go beyond serendipitous discoveries in recent years. However, intuition guided by general principles remains an important factor. In this session, we particularly welcome contributions that showcase the discovery of new functional materials with original approaches. Diverse material systems - from well-established to emerging and niche classes across condensed-matter and materials physics - will be featured. Bringing together diverse discoveries in a single session will help delineate general principles and inspire future work.

Time: Tuesday 14:00–15:30 Location: BEY/0138

MA 23: Cooperative Phenomena: Spin Structures and Magnetic Phase Transitions (joint session MA/TT)

Time: Tuesday 14:00–15:30 Location: POT/0151

MA 23.1 Tue 14:00 POT/0151

Stochastic Simulation of Phase Transitions in the Dissipative 2D XYZ-Model — •Franz Pöschl[1,2,3], Przemyslaw Zielinski[1,2,3], Xin Zhang[1,2,3], and Peter Rabl[1,2,3] — [1]Technical University of Munich, TUM School of Nat- ural Sciences, Physics Department, 85748 Garching, Germany — [2]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

The simulation of large, open quantum spin systems is a hard problem and for most cases it is not possible to get exact solutions. Therefore, we use methods in the class of the Truncated Wigner Approximations to tackle this problem. In our work we investigated the hybrid discrete-continuous truncated Wigner approximation and used it to determine the phase diagram of the dissipative 2D XYZ-model. We were able to simulate systems with several thousands of spins due to the linear scaling of the method and numerical optimization of our code. Hence we were able to simulate the phase transitions of the model and also characterize the different phases in the open quantum system.

MA 23.2 Tue 14:15 POT/0151

Large magnetoreflectance and optical anisotropy due to 4f flat bands in the frustrated kagome magnet HoAgGe — •Felix Schilberth[1,2], Luke DeFreitas[3], Khan Zhao[4,5], Florian Le Mardelé[6], Ivan Mohelsky[6], Milan Orlita[6], Philipp Gegenwart[5], Hua Chen[3], István Kézsmárki[1], and Sándor Bordács[2] — [1]Experimentalphysik V, Unversity of Augsburg — [2]Department of Physics, BME Budapest — [3]Department of Physics, Colorado State University — [4]School of Physics, Beihang University — [5]Experimentalphysik VI, Unversity of Augsburg — [6]LNCMI, Université Grenoble Alpes

We report peculiar optical properties of the frustrated itinerant magnet HoAgGe, which exhibits multiple magnetically ordered states obeying the kagome spin-ice rule. The optical conductivity is higher for light polarization perpendicular to the kagome plane both for the free carrier response and the interband transitions. The latter have strong contributions from Ho 4f flat bands located near the Fermi level, as revealed by our *ab initio* calculations, explaining the unusual anisotropy of the optical properties and the pronounced temperature dependence of the interband transitions for out-of-plane light polarization. The key role of Ho 4f states is further supported by the large variation of the magneto-reflectivity, following the field dependence of the magnetization in contrast to that of the magnetotransport data. Such heavy-electron bands near the Fermi level offer an efficient way to control transport and optical properties and we show that their ultrafast magneto-optical response is susceptible to the magnetic order.

MA 23.3 Tue 14:30 POT/0151

Transition between critical antiferromagnetic phases in the J1-J2 spin chain — Adam McRoberts[1], •Chris Hooley[2], and Andrew Green[3] — [1]International Centre for Theoretical Physics, Trieste, Italy — [2]Coventry University, Coventry, United Kingdom — [3]University College London, London, United Kingdom

The J1-J2 spin chain is one of the canonical models of quantum magnetism, and has long been known to host a critical antiferromagnetic phase with power-law

decay of spin correlations. We show that there are, in fact, two distinct critical antiferromagnetic phases, where the roles of the local dimer field and its dual field are interchanged: the 'Affleck-Haldane' phase near the Heisenberg point J2 = 0, where the dimer field that parametrises local singlet order is gapless and part of a joint O(4) Neel-singlet order parameter; and the 'Zirnbauer' phase which appears at sufficiently large ferromagnetic J2, where the dimer field is gapped out and its dual field - the instanton density of the O(3) Neel field - is critical instead. The phases are so-named because each realises one of the competing pictures for how the O(3) non-linear sigma model with a topological theta term renormalises to the su(2) level 1 Wess-Zumino-Witten model. We support these predictions with density matrix renormalisation group calculations.

MA 23.4 Tue 14:45 POT/0151

Field-induced transitions in the charge-ordered Kagome metal FeGe — •Lilian Prodan[1], Jeremy Sourd[2], Pavlo Khanenko[2], Yurii Skourski[2], Sergei Zherlitsyn[2], and István Kézsmárki[1] — [1]EPV, Institute of Physics, University of Augsburg - Augsburg, Germany — [2]HLD-EMFL, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Kagome metals with strong electronic correlations have recently attracted significant interest as fertile platforms for emergent phenomena such as unconventional magnetism, topological transport, and symmetry-breaking instabilities. Among them, FeGe stands out due to its intriguing combination of noncollinear magnetism and charge ordering, making it a prime candidate for studying the coupling between spin, charge, and lattice degrees of freedom [1]. This compound orders antiferromagnetically below $\sim$ 410 K, develops a charge-density-wave state near $\sim$ 110 K, and forms a noncollinear spin structure below $\sim$ 60 K. To explore how these orders interact, we performed magnetization, sound-velocity, and magnetostriction measurements in static and pulsed magnetic fields up to 60 T. Our results reveal previously unreported transitions at high magnetic fields and allow us to construct an extended H-T phase diagram for FeGe. [1] X. Teng, et al., Nature **609**, 490-495 (2022).

MA 23.5 Tue 15:00 POT/0151

Successive field-induced phase transitions in the kagome magnet $ErMn_6Sn_6$ — •A. Kurtanidze[1,2], Sh. Yamamoto[1], K. Uhlirova[3], Y. Skourski[1], S. Zherlitsyn[1], J. Sourd[1], T. Herrmannsdörfer[1], E. Weschke[4], O. Prokhnenko[4], H. Nojiri[5], B. Eggert[6], A. Aubert[7], K. Kummer[8], K. Skokov[7], H. Wende[6], and J. Wosnitza[1,2] — [1]Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden, Germany — [3]Materials Growth and Measurement Laboratory (MGML), Charles University, Prague, Czech Republic — [4]Helmholtz-Zentrum Berlin für Materialien und Energie, BESSY II, Berlin, Germany — [5]Institute for Materials Research, Tohoku University, Sendai, Japan — [6]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Germany — [7]Functional Materials, Material Science, TU Darmstadt, Germany — [8]ESRF, The European Synchrotron, Grenoble, France

The ternary stannides RMn_6Sn_6 (R = Sc, Y, Gd-Lu) with hexagonal $HfFe_6Ge_6$-type structure ($P6/mmm$) are a key platform for exploring coupled topological electronic and magnetic properties. We focused on single crystals of $ErMn_6Sn_6$ and observed successive field-induced phase transitions. Using element-specific x-ray magnetic circular and linear dichroism (XMCD/XMLD) measurements in pulsed magnetic fields up to 30 T, we revealed the microscopic nature of these transitions, supported by thermodynamic data. We discuss Er and Mn moment reorientations and their link to macroscopic results.

MA 23.6 Tue 15:15 POT/0151

Depinning by shaking of skyrmions by oscillating magnetic fields — •Rajendra Loke[1], Alla Bezvershenko[2], Petra Becker Bohaty[3], Achim Rosch[2], and Joachim Hemberger[1] — [1]II. Physikalisches Institut, University of Cologne, Zülpicher Str. 77, 50937 Cologne, Germany — [2]Institut for Theoretical Physics, University of Cologne , Zülpicher Str. 77, 50937 Cologne, Germany — [3]Institut for Geology und Mineralogy, University of Cologne , Zülpicher St. 49b, 50674 Cologne, Germanyy

Here we present our recent result on shaking the skyrmion lattice by oscillating transvers magnetic field. When a transvers field is applied in addition to the longitudinal external field, skyrmion strings try to align themselves parallel to the effective field. To do so, the tips of the skyrmion strings have to move large distances and thus have to overcome pinning forces before being able to follow the field lines. We employ linear and non-linear AC susceptometry as experimental probe. The signature of this pinning-depinning transition is observable as contribution to the magnetic susceptibility, to the magnetic loss, and as well in the higher harmonic susceptibility. According to theoretical predictions, due to the chiral nature of the material the depinning is connected to translational motion of the skyrmions.

MA 24: Weyl Semimetals (joint session MA/TT)

Time: Tuesday 14:00–15:30 Location: POT/0361

MA 24.1 Tue 14:00 POT/0361

Ferrimagnetism and the causes of discontinuous magnetic behavior in Kagome Weyl-semimetal Co3Sn2S2 — •Abdul-Vakhab Tcakaev[1], Benjamin Katter[1], Stefan Enzner[2], Eugen Weschke[3], Sebastian Wintz[3], Gohil S. Thakur[4], Michael Ruck[4], Giorgio Sangiovanni[2], and Vladimir Hinkov[1] — [1]Experimentelle Physik IV, Fakultät für Physik und Astronomie, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — [2]Computational Quantum Materials, Fakultät für Physik und Astronomie, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — [3]Helmholtz-Zentrum Berlin for Materials and Energy, Albert-Einstein-Straße 15, 12489 Berlin, Germany — [4]Technical University of Dresden, Helmholtzstr. 10 01069 Dresden

The Kagome Weyl semimetal Co3Sn2S2 shows puzzling magnetic anomalies that have been interpreted as hidden phase transitions. Combining element-specific XMCD, SQUID magnetometry, STXM, DFT, and inelastic neutron scattering, we establish a ferrimagnetic ground state in which Co moments are partially compensated by antiparallel Sn moments and stabilized by strong uniaxial magnetocrystalline anisotropy. Temperature-dependent XMCD and STXM show that the discontinuous drop of remanent magnetization on zero-field warming arises from abrupt domain nucleation controlled by demagnetization effects, rather than from an intrinsic change of the spin structure. This yields a consistent microscopic picture of the magnetism in Co3Sn2S2 relevant for its Weyl and anomalous Hall properties.

MA 24.2 Tue 14:15 POT/0361

High-field THz Probing of the Crossover between Weyl and Weyl-Kondo Physics in $Mn_{3+x}Sn_{1-x}$ — •Erik W. de Vos[1], Zekai Chen[1], Debankit Priyadarshi[1], Anusree V. Puleri[2], Uri Vool[2], Claudia Felser[2], Edouard Lesne[2], and Manfred Fiebig[1] — [1]Department of Materials, ETH Zurich, Zurich, Switzerland — [2]Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany

We present temperature-dependent high-field THz spectroscopy measurements on a substitution series of the noncollinear antiferromagnet $Mn_{3+x}Sn_{1-x}$. When the Mn substitution is increased from x=0 to x=0.5, $Mn_{3+x}Sn_{1-x}$ has been found to transition from a pure Weyl semimetal to a Weyl-Kondo insulator. This is accompanied by the emergence of a hybridization gap of 10.2 meV [1]. Our study uses high-field THz radiation to probe and drive the non-linear response of $Mn_{3+x}Sn_{1-x}$ through the onset of Kondo-driven correlations. Via this high-field resonant excitation, we directly probe the dynamic response across the transition from a Weyl semimetal to a Weyl-Kondo insulating state.

[1] Sci. Adv. 6, eabc1977 (2020)

MA 24.3 Tue 14:30 POT/0361

Peierls-induced topological Weyl semimetal in $PtBi_2$ — •Anders C. Mathisen[1], Stefanie S. Brinkman[1], Xin L. Tan[1], Øyvind Finnseth[1], Fabian Göhler[1], Chul-Hee Min[1], Jens Buck[2], Kai Rossnagel[2], Grisha Shipunov[3], Anna Isaeva[3], Jorge I. Facio[4], and Hendrik Bentmann[1] — [1]Center for Quantum Spintronics, Department of Physics, NTNU, Norway — [2]Kiel University & DESY, Germany — [3]Institute of Physics, University of Amsterdam, The Netherlands — [4]Instituto Balseiro, National University of Cuyo, Argentina

$PtBi_2$ is attracting interest because of its exotic electronic properties, including bulk Weyl nodes, Fermi-arc surface states, and unconventional surface superconductivity. The emergence of Weyl nodes in materials is commonly attributed to accidental crossings between non-degenerate valence and conduction bands, while little emphasis has been placed on the physical mechanisms that induce Weyl physics. Recent theory indicates that reduced translational symmetry in the Peierls-distorted crystal structure of $PtBi_2$ constitutes a mechanism for the formation of Weyl nodes [1]. In this talk, we will present an investigation of the bulk electronic structure of $PtBi_2$ using soft X-ray angle-resolved photoelectron spectroscopy. Based on an analysis of the spectral weight across wide regions in momentum space, we show how the Peierls-distortion in $PtBi_2$ promotes the formation of Weyl nodes.

Phonon-driven axial fields enable terahertz Kerr rotation in WTe2 — •Soma Dutta, Vishal Shokeen, Ruslan Chulkov, David Muradas Belinchón, M. Venkata Kamalakar, Oscar Gråsäs, and Hermann Dürr — Department of Physics and Astronomy, Uppsala University, Box 516, 75120 Uppsala, Sweden

Weyl semimetals provide a platform for studying the coupling between lattice dynamics and topological electronic structure through the motion of Weyl nodes and their associated Berry curvature (see Sie et al., Nature 565, 61, 2019). Here we report the observation of terahertz-frequency Kerr rotation in the noncentrosymmetric Weyl semimetal WTe_2, generated in the absence of an external magnetic field. Using ultrafast pump-probe polarimetry, we identify coherent oscillations at 0.24 THz and 2.4 THz that originate from interlayer shear vibrations and optical phonon modes, respectively. The 0.24 THz shear mode exhibits maximum amplitude along the a-axis and is strongly suppressed along b, indicating an odd mirror-symmetry character. By modeling the strain-induced modification of the Weyl-node separation, we show that this shear phonon produces an axial vector potential whose sign depends on the direction of atomic displacement. Spatial gradients of this axial potential generate a pseudo-magnetic field with a sign structure that naturally accounts for the observed phase inversion. Our results provide direct evidence for phonon-driven axial electromagnetic fields in a Weyl semimetal and demonstrate a route for ultrafast control of topological optical responses through coherent lattice motion. *Ab initio* calculations will further clarify the Kerr response mechanism.

MA 24.5 Tue 15:00 POT/0361

Magnetoconductance in Chiral Topological Semimetals — •Ricardo Manuel Sousa Barbosa and Annika Johansson — Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle (Saale), Germany

Chiral topological semimetals [1] are a class of quantum materials whose crystal symmetries enforce multifold band crossings with nonzero topological charge, hosting symmetry-protected chiral fermionic quasiparticles, long surface Fermi arcs, and enhanced optical and transport responses. These Weyl semimetals [2] are three-dimensional materials that exhibit multiple Weyl nodes that act as point-like sources and sinks of Berry curvature in momentum space, and provide a condensed-matter realization of the chiral anomaly [3], a field-induced non-conservation of electrons associated with a given Weyl node, which manifests as a positive longitudinal magnetoconductance.

We investigate the magnetotransport properties of compounds in space group 198 [4], which host four- and six-fold degenerate Weyl nodes at the Γ and *R* points, respectively, with Chern numbers up to ±4. Using a semiclassical approach, we compute the resulting magnetoconductance, enabling a detailed analysis of the unconventional electronic responses characteristic of these materials.

Giant Anomalous Hall Effect Tuned by Atomic Order in Fe3Pt — •Yibo Wang and Enke Liu — Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China

The Berry curvature induced anomalous Hall effect (AHE) has attracted considerable interest in recent years [1,2]. In Fe3Pt, a nodal line situated near the Fermi level generates a pronounced Berry curvature hotspot [3], giving rise to an intrinsic anomalous Hall conductivity (AHC) of 1250 S/cm according to our measurement. Building on this large intrinsic contribution, we sought to enhance the total AHE by deliberately increasing the extrinsic AHC through control of atomic ordering. By annealing Fe3Pt samples at various temperatures and for different durations, we were able to tune the extrinsic AHC continuously from nearly 0 S/cm up to 550 S/cm. The most striking result was obtained for a specimen that was annealed for ten days; at 2 K this sample exhibited a total AHC of 1892 S/cm. This value is a significant value among magnetic topological materials and represents a 50 % increase over the intrinsic contribution alone. These findings confirm the success of the proposed strategy: leveraging a substantial intrinsic Berry curvature AHC and subsequently amplifying the total AHC through extrinsic AHC through mechanisms such as atomic engineering. The approach provides a practical pathway for achieving exceptionally large anomalous Hall responses in magnetic topological systems. [1]Nat. Phys. 14, 1125-1131 (2018). [2] Nat. Phys. 14, 1119-1124 (2018). [3] Adv. Mater. 35, 2301339 (2023).

MA 25: Focus Session: Chiral phonons and crystals coupled to magnetic order I

Conventional magnetism arises from electron spin and orbital angular momentum, forming the basis of spintronics and orbitronics. Recent advances, however, have revealed that magnetism is also intimately linked to the chirality and angular momentum of the crystal lattice itself, often mediated by circular lattice vibrations known as chiral or axial phonons. These discoveries have uncovered novel mechanisms of spin and phonon transport and enabled direct access to phonon chirality and angular momentum as fundamental physical quantities. These developments prompt a re-examination of angular momentum coupling in solids, including well-established phenomena such as the Einstein-de Haas and Barnett effects, as well as the role of phonon angular momentum in the equilibrium state of magnetic materials. Chiral and axial phonons emerge as a powerful new platform for controlling magnetic order and dynamics, bridging lattice, spin, and angular momentum physics. This focus session aims to highlight recent breakthroughs in phonon angular momentum and magnetism and to connect the rapidly expanding field of chiral phononics with the broader magnetism community, spanning both experimental and theoretical perspectives.

As part of this focus session, we offer an excursion to the high-field THz user facilities at HZDR with an introduction to the planned Dresden Advanced Light Infrastructure (DALI). See MA 32 for details.

Time: Wednesday 9:30–12:45 Location: HSZ/0002

Invited Talk MA 25.1 Wed 9:30 HSZ/0002

Coherent phononic control of chirality — •Michael Först — Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

Chirality is a pervasive property of matter that underpins many important phenomena across physics, chemistry and biology. Given its broad significance, the development of protocols for rational control of chirality in solid state systems is highly desirable, especially if this effect can be tuned continuously and in two directions.

I will show that coherent optical excitation of the crystal lattice at terahertz frequencies can induce chirality in the non-chiral solid BPO_4. By resonantly driving one of two orthogonal, doubly degenerate phonon modes and exploiting their nonlinear coupling to symmetry-lowering lattice distortions, chiral structures of either handedness can be selectively created. These findings offer new prospects for controlling of out-of-equilibrium phenomena in complex materials.

Invited Talk MA 25.2 Wed 10:00 HSZ/0002

Towards a modern theory of chiralization (and can chiral phonons help us get there?) — •Nicola Spaldin — Materials Theory, ETH Zürich, Switzerland

The goal of this talk is to answer the question: Given two chiral crystals, which one is the most chiral? In order to compare the amount of chirality, we propose the concept of "chiralization", representing the amount of chiral moment per unit volume, as a bulk macroscopic thermodynamic quantity, analogous to magnetization or polarization. Such a quantity will allow us to identify the conjugate field for chirality, classify achiral to ferrochiral phase transitions in terms of an appropriate order parameter, determine the multipole(s) associated with chirality, and predict phenomena in chiral materials. We begin by analyzing ferroaxial materials, which are protochiral, in the sense that they have a symmetry-lowering structural phase transition that breaks mirrors but preserves inversion, and are often characterized by rotations of sub-units around an axis yielding domains of opposite handedness. We show that the electric toroidal dipole, calculated as the

cross product of the spin and orbital angular momenta, is a suitable order parameter for ferroaxial phase transitions. We outline the difficulties in extending the physics of ferroaxial materials to ferrochiral materials, and indicate how our emerging understanding of chiral phonons might help.

MA 25.3 Wed 10:30 HSZ/0002

Coherent Transfer of Pseudo- and Real Angular Momentum via Lattice Anharmonicity — •Olga Minakova[1], Carolina Paiva[2], Maximilian Frenzel[1], Michael Spencer[1], Joanna Urban[1], Martin Wolf[1], Dominik Juraschek[2,3], and Sebastian Maehrlein[1,4,5] — [1]FHI Berlin — [2]Tel Aviv U. — [3]TU Eindhoven — [4]HZDR — [5]TU Dresden

Rotational symmetry in crystals enforces conservation of phonon pseudo-angular momentum. However, direct evidence for angular momentum transfer between phonon modes has been lacking. We demonstrate coherent angular momentum transfer between doubly degenerate phonons through a resonant three-phonon interaction [1]. Circularly polarized THz pulses drive an IR-active phonon in Bi2Se3, imprinting the helicity of the field and generating ionic loops possessing real angular momentum. Anharmonic coupling then upconverts two such IR phonons into a Raman-active phonon at twice the frequency, transferring energy, linear momentum, and angular momentum. The THz-driven Kerr effect directly resolves the Raman phonon trajectory, revealing a helicity reversal, which perfectly fulfills pseudo-angular momentum conservation in the discrete C3 rotational symmetry of the lattice. Group theory analysis and DFT confirm this helicity flip and simultaneously reveal transfer of real angular momentum as circular ionic motion. These results constitute the first direct experimental evidence of angular momentum conservation in phonon-phonon interactions.

MA 25.4 Wed 10:45 HSZ/0002

Rotational Umklapp scattering in chiral nonlinear phononics — •Yu-Chi Huang[1], Carolina Paiva[2], and Dominik Juraschek[1] — [1]Eindhoven University of Technology, Eindhoven, Netherlands — [2]Tel Aviv University, Tel Aviv, Israel

Chiral phonons, circularly polarized lattice vibrations propagating perpendicular to their rotational plane, commonly arise in chiral materials and have attracted considerable attention in condensed matter physics lately. Due to *n*-fold rotational crystal symmetry, they enable rotational phonon-phonon Umklapp scattering through nonlinear phonon coupling. This process is the angular-momentum analog of the conventional Umklapp scattering conserving linear crystal momentum. Recent pump-probe experiments have measured the effect in Bi_2Se_3, and we here develop a general theory using α-quartz (α-SiO_2) as an example. Our results offer insight into the fundamentals of angular momentum conservation in solids.

Invited Talk MA 25.5 Wed 11:15 HSZ/0002

Observation and control of chiral phonons in non-centrosymmetric materials — •Hiroki Ueda — Paul Scherrer Institute, Villigen, Switzerland

The field of chiral phonons has rapidly grown with the emergence of various intriguing phenomena, including magnetism, transport, and light-matter interactions. Chiral phonons are rotational phonon modes propagating out of the rotational plane, breaking improper rotational symmetry. I will present direct demonstrations of chiral phonons in chiral crystal α-SiO2 and polar crystals LiNbO3 and BaTiO3 using resonant inelastic X-ray scattering (RIXS) with circularly polarized X-rays. Angular momentum transfer between circularly polarized photons and chiral phonons imposes the selection rule in the RIXS process, enabling observation of chiral phonons through circular dichroism in phonon excitation peaks. Furthermore, in BaTiO3, we demonstrate in situ electrical switching of phonon chirality, opening pathways for dynamic control of chiral phononic properties.

MA 25.6 Wed 11:45 HSZ/0002

Associated magnetism of circular ionic motion probed with ultrafast x-ray pulses — •Clifford Allington[1], Matthew Lutz[2], E. Ho[2], F. Graf[3], M. Basini[3], H. Ueda[2], A. Elliot[2], M. Biggs[2], R. Finn[2], S-W Huang[1], M. Grimes[1], M. Henstridge[4], M. Hoffmann[4], R. Alonso-Mori[4], D. Zhu[4], Q. Nguyen[4], V. Esposito[4], T. Sato[4], E. Skoropota[1], E. Paris[1], A. Camps[1], E. Razzoli[1], R. Mankowsky[1], F. Capotondi[5], N. Jaouen[6], M. Radovic[1], M. Savoini[1,3], E. Abreu[3], S. Johnson[1,3], Jeremy Johnson[2], and Urs Staub[1] — [1]Paul Scherrer Institute — [2]Brigham Young University — [3]ETH Zurich — [4]SLAC National Accelerator Laboratory — [5]Elettra Sincrotrone Trieste — [6]Synchrotron SOLEIL

It has been proposed that the coherent circular motion of ions creates a magnetic field. This effect, termed dynamical multiferroicity (DM), has been evidenced experimentally in diamagnetic materials such as SrTiO3 using circular terahertz (THz)-pump optical-probe methodologies. However, the fields reported are much larger than predicted, raising questions on the exact nature of the transient state. Thus, we performed a suite of circular THz-pump experiments on the paramagnetic EuTiO3, a material directly analogous to SrTiO3 but with a S = 7/2 spin on the Eu2+ ion. We have measured the circular motion of ions by femtosecond x-ray diffraction as well as an optical-probe signal which changes sign upon changing the helicity of the THz-pump, consistent with DM. However, no induced Eu2+ moment was found within the resolution of time-resolved x-ray magnetic circular dichroism, providing a quantitative upper limit on the resulting field.

MA 25.7 Wed 12:00 HSZ/0002

Real-time laser-driven (chiral) phonon dynamics from atomistic simulations — •Mike Pols and Nicola A. Spaldin — Materials Theory, ETH Zürich, Zürich, CH-8093, Switzerland

I will present an approach to simulate the real-time dynamics of excited phonons in materials. Using machine-learning interatomic potentials (MLIPs) together with laser-driven molecular dynamics simulations, we can capture the response of materials to driven (chiral) phonon excitations and directly capture their nonlinear vibrational dynamics. Driving phonon modes into the nonlinear regime can induce a wide range of material properties, such as strain and magnetism [1]. While first-principles modeling has provided valuable insights into these dynamics, the commonly used coupled-oscillator method requires the computation of numerous higher-order coupling coefficients [2], limiting its scalability.

Our MLIP-based approach enables the direct simulation of the full anharmonic lattice response. It effectively models both IR- and Raman-active modes, with finite-temperature effects, and the nonlinear couplings to high orders. Using this method, we explore the vibrational dynamics of linear and chiral phonons in oxide perovskites, enabling predictive simulations of the behavior and coupling of phonons in functional materials.

MA 25.8 Wed 12:15 HSZ/0002

THz field-induced magnetic-like response in the quantum paraelectric diamagnet $KTaO_3$ — •Christelle Kadlec[1], Filip Kadlec[1], Dalibor Repček[1], Martina Basini[2], Petr Kužel[1], Jan-Christoph Deinert[3], Sergey Kovalev[3], Mattia Udina[4], Igor Ilyakov[3], Alexey Ponomaryov[3], and Stanislav Kamba[1] — [1]Institute of Physics, Prague, Czechia — [2]ETH Zurich, Switzerland — [3]HZDR, Dresden, Germany — [4]CESQ-ISIS, Strasbourg, France

The current efforts on developing new ways of data manipulation are aimed at ultrafast control of magnetization in magnetic materials, as well as at inducing magnetic moments in diamagnetics. We demonstrate that in the diamagnetic quantum paraelectric $KTaO_3$, the electric field of circularly polarized THz pulses with an amplitude of 300 kV/cm induces a transient magnetic-like response by resonantly pumping its degenerate soft phonon. The transient phonon-mediated magnetic-like response was measured via the rotation of the polarisation of a probe light. However, such response usually contains contributions from both the magneto-optic THz-field-induced Faraday effect and the electro-optic THz-field-induced Kerr effect (TKE). In order to distinguish between them, we separately measured the TKE by applying a linearly polarized THz pump beam. Moreover, we present a theoretical analysis of the TKE, showing that its contribution can be suppressed by subtracting the experimental data generated by opposite elliptically polarized THz radiation. Thus, we are able to unambiguously identify a magnetic-like behavior of the $KTaO_3$ crystal manifested by the extracted Faraday rotation.

MA 25.9 Wed 12:30 HSZ/0002

Phonon-induced chirality — •Dominik Juraschek — Eindhoven University of Technology, Eindhoven, Netherlands

Controlling and utilizing solid-state chirality is a central challenge in condensed matter physics, because it does not couple to applied magnetic or electric fields, in contrast to magnetism and ferroelectricity. In this talk I show that geometric chiral phonons, lattice vibrations whose instantaneous atomic displacements break inversion and mirror symmetries, can transiently drive an achiral crystal into a chiral state. Using group-theoretical analysis, we identified selection rules for phonon-induced geometric chirality across all 32 point groups and demonstrate that ultrashort mid-infrared and terahertz pulses can excite pairs of IR-active phonons whose nonlinear coupling rectifies a geometric chiral phonon. I further demonstrate that chiral order exhibits fundamental excitations which we term "chiralons," similar to the recently discovered ferrons in ferroelectric order. Our results highlight an emerging functionality of chiral phononics beyond phonon angular momentum.

MA 26: Focus Session: Nickelate Superconductivity: Insights into Unconventional Pairing and Correlation Effects I (joint session TT/DS/MA)

Nickel, a direct neighbor of copper in the periodic table, has been considered a promising candidate for high-temperature superconductivity since the early 1990s. After more than three decades of research, this prediction was confirmed with the discovery of superconductivity in nickelates, marking the beginning of the "nickel age" of superconductivity. Recent advances include Sm-based infinite-layer nickelates with transition temperatures approaching 40 K, as well as bilayer nickelates exhibiting superconductivity above 90 K under pressure and up to 60 K under compressive epitaxial strain. These results highlight the crucial roles of structural engineering, epitaxial strain, and precise synthesis control, and they open new frontiers for both fundamental understanding and materials design. This focus session aims to define key scientific challenges ahead, strengthen collaboration within Germany and Europe, and accelerate progress toward higher superconducting transition temperatures.

MA 27: Ultrafast Magnetization Effects I

Time: Wednesday 9:30–12:45 Location: HSZ/0004

Invited Talk MA 27.1 Wed 9:30 HSZ/0004

Towards sub-10fs magnetization switching — Reza Rouzegar[1], Oliver Franke[1], Gal Lemut[1], Oliver Gueckstock[1], Junwei Tong[1], Dieter Engel[2], Xianmin Zhang[3], Georg Woltersdorf[4], Piet W. Brouwer[1], Tobias Kampfrath[1], and •Quentin Remy[1] — [1]Department of Physics, Freie Universität Berlin, 14195 Berlin, Germany — [2]Max-Born-Institut für nichtlineare Optik und Kurzzeitspektroskopie, 12489 Berlin, Germany — [3]Key Laboratory for Anisotropy and Texture of Materials (Ministry of Education), School of Material Science and Engineering, Northeastern University, Shenyang 110819, China — [4]Institut für Physik, Martin-Luther-Universität Halle, 06120 Halle, Germany

Femtosecond laser pulses can induce sub-picosecond demagnetization, enabling ultrafast magnetic writing, spin transport, and broadband THz generation. Yet the microscopic processes in the first ~ 10 fs remain poorly understood. Three-temperature models describe energy flow among electrons, spins, and the lattice but neglect angular-momentum transfer, essential for spin dissipation.

Using ultrabroadband THz emission spectroscopy with ~ 10 fs resolution, we find that electron-magnon (em) scattering drives the nonequilibrium spin dynamics, generating both spin flips and magnons in under 10 fs, well before ~ 100 fs demagnetization. Angular momentum is then dissipated primarily through magnon-lattice interactions. Having established em scattering as the dominant sub-10-fs mechanism, we show that THz pulses can harness this coupling to reverse magnetization, pointing to sub-10-fs spin control.

MA 27.2 Wed 10:00 HSZ/0004

Ultrafast Control of Spin Periodicity in a Helical Heisenberg Antiferromagnet — •Hyein Jung[1,2], Abeer Arora[2], Deeksha Gupta[3], Franziska Walther[4], Kristin Kliemt[4], Victoria C. A. Taylor[2], Túlio de Castro[2], Hanqian Lu[1,2], Christian Schüssler-Langeheine[3], Niko Pontius[3], Urs Staub[5], Cornelius Krellner[4], Laurenz Rettig[2], Ralph Ernstorfer[1,2], and Yoav W. Windsor[1,2] — [1]Technische Universität Berlin, Berlin, Germany — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [4]Goethe-Universität Frankfurt, Frankfurt, Germany — [5]Paul Scherrer Institut, Villigen, Switzerland

The ultrafast manipulation of spin structures is a promising route toward the next generation spintronic devices. In this work, we study the helical Heisenberg antiferromagnet $EuCo_2P_2$ using resonant soft X-ray diffraction (RXD). By probing the magnetic Bragg reflections, we are experimentally sensitive both to the antiferromagnetic (AF) order parameter and to the 4f spin periodicity. We measure their response under three distinct perturbations: (a) femtosecond laser excitation (ultrafast RXD), (b) external magnetic fields, and (c) temperature variation. Employing a Heisenberg model, we directly reveal how the observables respond to each of the perturbations we apply. We further probe the response of the crystal lattice under the same conditions as the spin order and draw a relation between the dynamics of the two. These results offer insight into different routes to control AF spin order and its couplings.

MA 27.3 Wed 10:15 HSZ/0004

Time-resolved coherent small-angle EUV scattering of magnetic thin film structures — •Konstanze Korell[1], Sergey Zayko[1], Hung-Tzu Chang[1], Timo Schmidt[2], Murat Sivis[1,3], Manfred Albrecht[2], and Claus Ropers[1,3] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]Experimental Physics IV, University of Augsburg, Germany — [3]4th Physical Institute - Solids and Nanostructures, University of Göttingen, Germany

Laser excitation yields control over magnetic structures on the femtosecond timescale, yet the corresponding nanoscale response remains difficult to access. Ultrafast coherent diffractive imaging has recently provided real-space insights [1], limited, however, to reversible dynamics. Here, by carrying out coherent speckle diffraction, we combine the strengths of diffraction with the coherence of a source capable of coherent imaging. Through this, we get insights to reversible and irreversible processes. Using a femtosecond high harmonic generation source, we measure pump-probe scattering from magnetic thin films in a laboratory-based setup. We discuss both the opportunities and limitations of this approach providing a basis for the interpretation of nanoscale magnetic dynamics in future ultrafast experiments.

[1] H.-T. Chang et. al, arXiv:2504.17917 (2025)

MA 27.4 Wed 10:30 HSZ/0004

Exploitation of Spin Wave Resonances in Miniaturized Magnetic Electron Optics for Ultrafast Electron Beam Manipulation — •Max Herzog[1], Johannes Schultz[1], and Axel Lubk[1,2] — [1]IFF, IFW Dresden, Helmholtzstraße 20, 01069 Dresden — [2]IFMP, TU Dresden, Haeckelstraße 3, 01069 Dresden

Magnetic electron optics that can be switched on sub-nanosecond time scales are useful for the setup of stroboscopic measurements in scanning and transmission electron microscopes. Scaling laws indicate that devices become permeable for alternating magnetic fields with GHz frequency by miniaturizing them to micrometer length scales, therefore decreasing their induction. On these length scales, spin waves can be excited in the magnetic pole pieces which can drastically increase the micro optics effectivity when their resonance condition is met. We fabricate such magnetic multipole optics using lithographic techniques with pole piece sizes in the tens of μm, a thickness of up to 800 nm, a pole piece distance of 25 μm as well as variable geometries in order to optimize the resonant behavior. Due to those resonances, the characterized micro optics show an especially strong deflection of the TEMs 300 keV electron beam of more than 100 μrad at 3 GHz excitation frequency. Conducted electron spin resonance measurements confirm the possibility to excite spin waves in the magnetic pole pieces in the same frequency range. This allows for the application of models of the dispersion relation to determine favorable values for parameters like thickness, exchange interaction, and saturation magnetization in order to achieve the desired resonance frequency.

MA 27.5 Wed 10:45 HSZ/0004

Terahertz Spectroscopy of non-collinear magnetic state in ferrimagnetic iron garnet — •Tushar Baruah[1], Andrzej Stupakiewicz[2], Paul H. M. van Loosdrecht[1], and Evgeny A. Mashkovich[1] — [1]II. Physikalisches Institut, Universität zu Köln, 50937 Köln, Germany. — [2]Faculty of Physics, University of Bialystok, Ciolkowskiego 1L, 15-245 Bialystok, Poland.

Data storage technologies and magnetic control research, in general, focuses primarily on magnets with anti-ferromagnetic exchange interactions for their ultra-

fast picosecond-scale dynamics. Among them, ferrimagnets are particularly appealing, as they combine high Terahertz (THz)-scale eigenfrequencies with the feasibility of ground state control. Non-collinear magnetic states in ferrimagnets exhibit complex spin dynamics, whose ultrafast behaviour remains partly understood. Using a table-top high-power broadband THz pump-optical probe setup integrated with a 10T superconducting magnet, we directly probe the field and temperature dependent spin dynamics in Bi-substituted Gadolinium iron garnet, which is a ferrimagnet with non-collinear magnetic state and a magnetic moment compensation point temperature. Our results show magnetisation dynamics in non-collinear state driven by overlap of exchange modes and THz cavity modes formed by multiple reflections inside the sample.

MA 27.6 Wed 11:15 HSZ/0004

Spin-lattice coupling control of ultrafast order melting in antiferromagnetic insulators — Aleksandr Buzdakov[1], •Ravi Kaushik[1], Nikolai Khokhlov[2], Johan Mentink[2], Sergey Artyukhin[1], and Aleksei Kimel[2] — [1]Istituto Italiano di Tecnologia, Via Morego 30, 16163 Genova, Italy — [2]Radboud University Nijmegen, Institute for Molecules and Materials, 6525 AJ Nijmegen, The Netherlands

Ultrafast order melting in magnetic insulators is governed by two processes: intrinsic intra-spin relaxation and spin-lattice energy transfer. Antiferromagnets, which lack net magnetization, can in principle evade angular-momentum constraints and display markedly faster order-parameter dynamics than ferromagnets, but experimental rates vary widely across materials. Here we combine first-principles magnetostriction calculations, phonon and magnon spectral analysis, atomistic spin-dynamics simulations and time-resolved second-harmonic generation to disentangle these pathways and explain material-dependent disparities. Focusing on two structurally similar antiferromagnets, Cr_2O_3 and $FeBO_3$, we show that the strength of spin-phonon coupling - revealed by magnetostrictive response and phonon-magnon spectral overlap - dictates the dramatic difference in order-melting rates. We also achieved accelerated dynamics in Cr_2O_3 and show sub-2-ps order melting in both experiment and simulation. Our results identify spin-phonon coupling as the decisive control parameter for ultrafast antiferromagnetic dynamics and provide a practical framework to design faster switching in antiferromagnetic spintronic devices.

MA 27.7 Wed 11:30 HSZ/0004

Nonlinear optical probing of a strongly correlated phase transition in epitaxial $NdNiO_3$ thin films — •Christian Tzschaschel[1,2], Felix Utsch[1], Qi Song[2], Spencer Doyle[3], Grace A. Pan[3], Julia A. Mundy[3], and Stefan Eisebitt[2,4] — [1]Department of Physics, University of Zurich, Switzerland — [2]Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy, Berlin, Germany — [3]Department of Physics, Harvard University, USA — [4]IOAP, TU Berlin, Germany

The family of rare-earth nickelates is a prime example of strongly correlated oxide materials displaying a wealth of physical phenomena from antiferromagnetism to superconductivity. $NdNiO_3$ specifically exhibits a metal-to-insulator phase transition upon cooling that is concomitant with the emergence of antiferromagnetic order.

Here, we use nonlinear optical second harmonic generation (SHG) in the near-infrared regime to gain insight into the symmetry and ultrafast dynamics of this correlated electronic and magnetic phase transition. In static measurements, we observe a symmetry reduction from orthorhombic in the paramagnetic phase to monoclinic in the antiferromagnetically ordered phase. Upon optical excitation, we observe a quench of the SHG signal and a restoration of the orthorhombic state within 125 fs. Our study highlights the capabilities of nonlinear optics and advances the understanding of strongly correlated quantum materials.

MA 27.8 Wed 11:45 HSZ/0004

Ultrafast angular momentum transfer in RKKY-coupled 4f antiferromagnets — S.-E. Lee[1], Y.W. Windsor[1,2], D. Zahn[1], A. Kraiker[3], K. Kummer[3], K. Kliemt[4], C. Krellner[4], C. Schüssler-Langeheine[5], N. Pontius[5], U. Staub[6], D.V. Vyalikh[7], A. Ernst[8], and •L. Rettig[1,9] — [1]Fritz-Haber-Institut der MPG, DE — [2]TU Berlin, DE — [3]ESRF, Grenoble, FR — [4]Goethe-Universität Frankfurt, DE — [5]Helmholtz-Zentrum Berlin, DE — [6]PSI, Villigen, CH — [7]DIPC, San Sebastian, ES — [8]Johannes Kepler University, Linz, AU — [9]RPTU Kaiserslautern-Landau, DE

Antiferromagnets allow for direct angular momentum (AM) transfer between opposing spins, thereby avoiding AM transfer to the lattice, which limits ultrafast magnetization dynamics in ferromagnets. Here, we study the ultrafast magnetization dynamics in 4f antiferromagnetic intermetallics of type $LnRh_2Si_2$ (Ln=Pr, Nd, Sm, Gd, Tb, Dy, Ho) where we modify the magnitude of the on-site RKKY coupling strength via substitution of Ln ions. By combining time-resolved soft X-ray diffraction with ab-initio calculations, we find that the rate of AM transfer between opposing moments is directly determined by this coupling [1]. Moreover, the influence of itinerant conduction electrons has been explored in the Series GdT_2Si_2 by varying the transition metal T (T=Co, Rh, Ir). Here, we find a more than twofold increase in ultrafast AM transfer rate between the materials, which we associate with modifications in the conduction electron susceptibility due to differences in their density of states [2].

MA 27.9 Wed 12:00 HSZ/0004

Time-resolved wide-field SHG imaging of ferroic materials — •Andrin Caviezel, Jan Gerrit Horstmann, Thomas Lottermoser, and Manfred Fiebig — Department of Materials, ETH Zurich, Zurich, Switzerland

We investigate the ultrafast dynamics of van der Waals ferroics using time-resolved second harmonic generation (SHG) wide-field imaging. Controlling antiferromagnetic order on ultrafast timescales is of central relevance for spintronic applications, and van der Waals ferroics constitute highly promising material platforms. However, achieving such control requires an experimental technique that is simultaneously sensitive to ferroic order and combines micrometer spatial with femtosecond temporal resolution. Here, we present a setup for direct wide-field visualization of ferroic domain structures by exploiting SHG generated from high-energy pulses of an amplified laser system. The adjustable wavelength and polarization of pump and probe pulses, together with tailored pulse sequences for excitation, enable sensitive detection and selective manipulation of magnetic order. Our approach provides access to ultrafast processes in bulk ferroics with microscopic domain patterns as well as in micrometer-sized flakes of van der Waals ferroics under cryogenic conditions, opening new pathways for understanding and steering their nonequilibrium dynamics.

MA 27.10 Wed 12:15 HSZ/0004

Photoinduced demagnetization and carrier dynamics in $SrRuO_3$ thin films probed by time resolved THz spectroscopy — •Ankhijur Islam Sekh[1], Harun Mert Iyiisler[1], Phillip Leiprecht[2], Mathias Beck[2], Paul Leiderer[2], Gad Koren[3], Ionela Lindfors-Vrejoiu[4], Paul H.M. van Loosdrecht[4], and Jure Demsar[1] — [1]JGU Mainz — [2]University of Konstanz — [3]Technion, Haifa — [4]University of Cologne

$SrRuO_3$ is an itinerant ferromagnet (Tc ≈ 150 K) whose T^2 resistivity below 30K signals a ferromagnetic Fermi-liquid ground state. We present the temperature (T) and excitation fluence (F) dependent photoinduced conductivity dynamics of thin films grown by MBE and PLD, following excitation with fs near-infrared pulses. We show that photoinduced changes in THz conductivity are governed by the changes in the scattering rate of the intraband Drude response. The T- and F-dependent photoconductivity dynamics suggest that rapid carrier thermalization is accompanied by magnon generation, consistent with a high spin-flip scattering rate due to strong spin-orbit coupling. Accordingly, over a broad T and F-range, the photoconductivity transients track the evolution of the magnon population. At temperatures below 20K and at lowest F, we observe a delayed rise in photoconductivity, which reflects the reduced e-e thermalization rate with its characteristic Fermi-liquid T^2 dependence.

MA 27.11 Wed 12:30 HSZ/0004

Element-specific magnetization dynamics of epitaxial ultrathin Co/Pt heterostructures — •Puloma Singh[1], Corentin Aulagnet[2], Thomas Jauk[3], Sangeeta Sharma[1,4], Martin Schultze[3], Stéphane Mangin[2], Clemens von Korff Schmising[1], and Stefan Eisebitt[1,5] — [1]Max Born Institut für Nichtlineare Optik und Kurzzeitspektroskopie, Berlin, Germany — [2]Université de Lorraine, CNRS, Institut Jean Lamour, Nancy, France — [3]Institut für Experimentalphysik, Technische Universität Graz, Graz, EU, Austria — [4]Institute for Theoretical Solid-state Physics, Freie Universität Berlin, Berlin, Germany — [5]Technische Universität Berlin, Institut für Optik und Atomare Physik, Berlin, Germany

Magnetic systems comprising 3d ferromagnetic transition metals and 4d/5d heavy metals are of interest because of their potential application in future energy storage technology. The microscopic process involved after femtosecond laser excitation is complex and is still controversially discussed in the existing literature. We present a systematic and element specific study of epitaxial, ultrathin Co films (0.8 and 1.0 nm) sandwiched by Pt layers. We compare the ultrafast response for the different Co thicknesses as well as for out-of-plane and in-plane magnetic anisotropy by a combination of pump-probe spectroscopy in the optical and extreme ultraviolet spectral range. Exploiting the Pt $O_{2,3}$ and N_7 and Co $M_{2,3}$ resonances, we accurately disentangle the intrinsic and proximity induced magnetic moments of Co and Pt. We find consistently larger demagnetization amplitudes of the Pt magnetization compared to Co and a very pronounced thickness dependence.

Invited Talk MA 29.1 Wed 9:30 POT/0112

Exploring the interplay between spin and chirality — •Angela Wittmann — Johannes Gutenberg University Mainz, Germany

Chirality is omnipresent in nature, bridging magnetic and molecular spin phenomena. At the core of this connection lies the chiral-induced spin selectivity (CISS) effect, describing the highly efficient generation of spin polarized currents in chiral molecules. Despite extensive experimental evidence, the underlying mechanisms of CISS remain debated. Here, we explore how chirality is directly linked to the intrinsic magnetic moments in molecules and how molecular design can be harnessed to control spin phenomena at hybrid chiral molecule magnetic interfaces [1]. Our findings pave a pathway towards functional "chiralitronic" devices - turning a fundamental puzzle into a technological opportunity.

MA 29.2 Wed 10:00 POT/0112

Chiral Molecule-Induced Magnetic Anisotropies — •Simon Sochiera[1], Ashish Moharana[1], Yael Kapon[2], Fabian Kammerbauer[1], Shira Yochelis[2], Mathias Kläui[1], Yossi Paltiel[2], and Angela Wittmann[1] — [1]Johannes Gutenberg University, Mainz, Germany — [2]Hebrew University of Jerusalem, Jerusalem, Israel

The chiral-induced spin selectivity effect promises novel spintronic devices. Despite numerous interdisciplinary experiments revealing its implications and trends, this phenomenon challenges our theoretical understanding of the interplay between spin and chirality, particularly regarding apparent time-reversal symmetry breaking. This symmetry breaking can be observed by measuring a magnetic thin film's anisotropy upon chiral-molecule adsorption. We quantify this phenomenon by measuring the magnetic anisotropy through electrical magnetotransport measurements. Upon chiral-molecule adsorption, we observe a 35% change in out-of-plane hard-axis anisotropy. This approach enables sensitive probing of magnetic property changes induced by different chiral molecular systems on various conductive or insulating magnetic thin films. Correlating molecular properties, such as spin-orbit coupling, with their impact on magnetic anisotropy will be crucial for understanding the fundamental mechanisms of chiral-induced spin selectivity and for facilitating the design of spintronic devices that require a precisely tuned anisotropy.

MA 29.3 Wed 10:15 POT/0112

Generation, Transmission, and Conversion of Orbital Torque by an Antiferromagnetic Insulator — •Shilei Ding[1,2], Paul Noël[2], Gunasheel Kauwtilyaa Krishnaswamy[2], Niccolò Davitti[2], Giacomo Sala[2], Marzia Fantauzzi[3], Antonella Rossi[2,3], and Pietro Gambardella[2] — [1]School of Physical and Mathematical Sciences, Nanyang Technological University, Singapore 637371, Singapore — [2]Department of Materials, ETH Zürich, 8093 Zürich, Switzerland — [3]Dipartimento di Scienze Chimiche e Geologiche, Università degli Studi di Cagliari, Campus di Monserrato S.S. 554, Italy

Orbital currents and orbital torques have recently emerged as powerful tools for controlling magnetization, yet their transport has been studied almost exclusively in metals. We report the first demonstration of orbital generation, transport, and conversion through an insulating antiferromagnet CoO. By inserting CoO between Cu* and Co, we show that orbital transport is preserved and the orbital-torque efficiency is strongly enhanced. Temperature-dependent measurements indicate that orbital transport above the Néel temperature is mediated by thermal fluctuations, while antiferromagnetic order and exchange bias provide additional transport channels at low temperature. These results identify insulating antiferromagnets as effective mediators of orbital angular momentum and highlight transition-metal oxides with unquenched orbital moments as promising materials for efficient spin-orbitronic technologies.

MA 29.4 Wed 10:30 POT/0112

Modern theory of the Orbital Hall effect from Wannier Representation — •Mirco Sastges[1,2], Insu Baek[3], Hojun Lee[3], Hyun-Woo Lee[3], Yuriy Mokrousov[1,2], and Dongwook Go[4] — [1]Peter Grüunberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany — [3]Department of Physics, Pohang University of Science and Technology, Pohang, Kyungbuk 37673, South Korea — [4]Department of Physics, Korea University, Seoul 02841, South Korea

In the field of orbital dynamics and orbital transport a particularly important quantity is the so-called orbital Hall conductivity (OHC), which is expressed in terms of operators of velocity and orbital angular momentum (OAM). To overcome the difficulties in treating the unbounded position operator, very often the so-called atom-centered approximation (ACA) is used. However, while being very practical, this approach captures only some local contributions to the OAM operator. Here, we will report on developing a new approach to quantify the OAM operator in the basis of Wannier functions, which is based on the modern theory of orbital magnetization. This method allows us to capture both local and itinerant contributions to the OHC. By performing first principles calculations for selected transition metals we show that a significant correction to the OHC due to non-local contributions arises, while the local effects are captured in accordance to the ACA. Our approach is very promising since it improves our understanding of OAM and allows for a precise estimation of the OHC.

MA 29.5 Wed 10:45 POT/0112

Chirality-induced orbital Edelstein effect in an analytically solvable model — •Lennart Schimpf, Börge Göbel, and Ingrid Mertig — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg

Chirality-induced spin selectivity (CISS), a phenomenon wherein chiral structures selectively determine the spin polarization of electron currents flowing through the material, has garnered significant attention due to its potential applications in areas such as spintronics, enantioseparation, and catalysis. The underlying physical effect is the Edelstein effect that converts charge to angular momentum. Besides a spin contribution, there exists a contribution based on the orbital angular momentum but the precise mechanism for its generation remains yet to be understood. Here, we introduce the minimal model for explaining the phenomenon based on the orbital Edelstein effect [1]. We consider nonlocal intersite contributions to the current-induced orbital angular momentum and reveal the underlying mechanism by analytically calculating the Edelstein susceptibilities in a tight-binding and Boltzmann approach. While the orbital angular momentum is directly generated by the chirality of the crystal, the spin contribution of each spin-split band pair relies on spin-orbit coupling. Using tellurium as an example, we show that the orbital contribution surpasses the spin contribution by orders of magnitude.

Spin-charge and Orbital-charge Interconversion on SrTiO3-based Two-dimensional Electron Gases: A Semiclassical Approach — •Le Viet Duc Pham and Annika Johansson — Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle (Saale), Germany

Two-dimensional electron gases (2DEGs) at SrTiO3-based oxide interfaces display large, gate-tunable Rashba-like spin-orbit coupling (SOC) that enables spin-charge interconversion via the spin Edelstein effect [1, 2]. It has also been demonstrated that the orbital Edelstein effect, i.e, current-induced orbital magnetization, is larger than the spin Edelstein effect by more than one order of magnitude [3]. Yet, most transport studies assume a constant relaxation time [1, 3], potentially underestimating the role of anisotropic relaxation times and scattering-in contributions. Here, we systematically study charge-spin and charge-orbital conversion in SrTiO3-based 2DEGs, combining the Boltzmann semiclassical transport theory and various ansatzes for the scattering terms, such as constant relaxation time, momentum relaxation time, as well as scattering on various impurity potentials. Comparing different scattering approaches, we gain insights into the influence of impurity scattering on charge-spin and charge-orbital interconversion phenomena.

Quantum geometry for orbital magnetization and spintronics from parallel transport of Bloch states — •Johannes Mitscherling, Jan Priessnitz, and Libor Šmejkal — Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Str. 38, 01187 Dresden, Germany

Quantum geometry emerges as a unifying, quantitative guiding principle for the linear and nonlinear response functions of quantum matter. Going beyond current-current responses [1,2], we identify the generator of parallel transport of Bloch states, given by the commutator of the band projector and its momentum derivative, as a further essential building block of quantum geometry [3]. I will show that orbital magnetism arises from the non-commutativity of adiabatic transport in orthogonal directions. We will see that the spin Berry curvature and the spin quantum metric, which control the linear spin conductivity, are not fundamentally geometric but yield three geometric contributions of distinct physical origin. Our theory enables efficient numerical and analytical evaluations for general Bloch Hamiltonians with an arbitrary number of potentially degenerate bands. I will exemplify the results in application to altermagnets [4] and p-wave magnets [5].

MA 29.8 Wed 11:45 POT/0112

Signatures of magnon dispersion in spin transport — •Sebastian Sailler, Denise Reustlen, Michaela Lammel, Sebastian T. B. Goennenwein, and Richard Schlitz — Department of Physics, University of Konstanz, 78457 Konstanz, Germany

The spin Hall magnetoresistance (SMR) provides electrical access to the magnetization of a magnetically ordered material. It recently became clear that changes in the net magnetization due to magnon creation and annihilation can be observed in the SMR. However, the number of magnons - and thus the magnetization - can also be modified by changing the energy of the system. In this work, we experimentally demonstrate that the changes of magnon occupation due to magnetic fields and crystal orientation sensitively modify the SMR response. Higher magnetic fields reduce the magnon population by pushing the magnon manifold to higher energies, leading to an increase of magnetization and thus the SMR. In turn, the influence of the anisotropic magnon gap in yttrium iron garnet films leads to a crystal orientation dependence of the SMR. The magnetic field and orientation dependence can be rationalized in terms of the changing magnon occupation. Our results showcase that magnetoresistive effects not only probe the properties of the static magnetization, but also reveal information about the dynamics, i.e., the magnons.

MA 29.9 Wed 12:00 POT/0112

Non-reciprocal spin-orbital-charge interconversion via magnon transport in nonlocal devices — •Jose Omar Ledesma-Martin[1], Sachin Krishnia[1], Edgar Galindez-Ruales[1], Duc Tran[1], Marcel Gasser[1], Dongwook Go[1,2], Gerhard Jakob[1], Yuriy Mokrousov[1,2], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Mainz, Germany — [2]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Jülich, Germany

In magnetic systems, angular momentum is carried by electrons' spin and orbital angular momentum. We use devices based on Pt nanowires on insulating magnets to study angular-momentum transport mediated by magnons, enabling angular-momentum information to propagate without charge flow. In these systems, magnons are generated by spin accumulation from the Spin Hall Effect (SHE) and detected via the inverse Spin Hall Effect (iSHE). In conventional Pt-YIG nonlocal geometries, this spin-charge interconversion is fully reciprocal: interchanging the injector and detector yields equal efficiencies. We further confirm that this power-to-power efficiency remains reciprocal when the thickness of one Pt wire is varied. However, when Ru is used as a source and detector of orbital currents via the orbital Hall effect (OHE) and inverse OHE, the reciprocity is broken. In our devices, the combined SHE + OHE-driven magnon generation, followed by detection through the iSHE, becomes ~35% more efficient than the reverse process, demonstrating nonreciprocity in the system. MA 29.10 Wed 12:15 POT/0112

Giant orbital magnetoresistance in orbital magnets — •Sachin Krishnia[1], Christin Schmitt[1], Edgar Galindez Ruales[1], Takashi Kikkawa[2], Timo Kuschel[1], Eiji Saitoh[2], Olena Gomonay[1], Yuriy Mokrousov[1], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg-University Mainz, Mainz, Germany — [2]Department of Applied Physics, The University of Tokyo, Tokyo, Japan

Generation and transport of large orbital angular momentum (OAM) currents have recently emerged as a key research area in the field of orbitronics. In contrast to spin currents, whose generation depends on weak spin-orbit coupling, OAM currents arise directly from the coupling between crystal momentum and electronic OAM even in light and environmentally friendly materials (Cu, Al, Cr)[1]. A major challenge has been to exploit these giant orbital currents in magnetic systems, where static magnetization is dominated by spin. We show that this limitation can be overcome by employing magnetic materials in which OAM contributes significantly to the static magnetization. Using these orbital magnets, we demonstrate two orders of enhancement of orbital Hall magnetoresistance, compared to the spin counterpart. This enhancement originates from the interaction of the dynamic OAM generated in light metals with the static orbital moments of the orbital magnet. Our results establish a pathway to harness giant OAM currents for device functionalities that cannot be achieved with conventional spin-dominated magnets[2]. [1] S. Ding et al, PRL 125, 177201 (2020). [2] C. Schmitt, S. Krishnia et al. (under review).

MA 29.11 Wed 12:30 POT/0112

Spin-Current Sensitivity in $CuSeO_3$ Across the Antiferromagnetic Transition — •Ankita Nayak[1], Mathew James[1], Maxim Mostovoy[2], and Aisha Aqeel[1] — [1]University of Augsburg, 86135Augsburg, Germany — [2]Zernike Institute for Advanced Materials, University of Groningen, Nijenborgh 4, 9747 AG Groningen, The Netherlands

Antiferromagnets are promising materials for next-generation spintronics due to their robustness against magnetic fields and ultrafast dynamics. Spin Hall magnetoresistance (SMR) provides a sensitive method to probe spin transport at normal-metal–antiferromagnetic-insulator interfaces. In antiferromagnets, SMR can detect Néel-vector reorientation, spin-flop behaviour, and short-range correlations above the ordering temperature, as shown in systems such as NiO and α-Fe_2O_3.

Here, we use SMR in a Pt/$CuSeO_3$ bilayer to investigate spin transport in the unconventional antiferromagnet $CuSeO_3$. An AC current in the Pt Hall bar generates a transverse spin accumulation, whose interface reflection modulates the Pt resistance and enables electrical detection of the magnetic state.

$CuSeO_3$ consists of Cu(1) spin dimers and Cu(2) spins that order antiferromagnetically below 8 K. SMR measurements between 5 and 100 K with magnetic-field rotation in three planes reveal clear SMR signals, including a finite response above the Néel temperature, indicating persistent spin correlations. The plane-dependent SMR amplitude also reflects the intrinsic magnetic anisotropy of $CuSeO_3$.

MA 30: Functional Antiferromagnetism

MA 30.1 Wed 9:30 POT/0151

Electric Current Control of Helimagnetic Chirality from a Multidomain State — •Yuta Kimoto[1], Hidetoshi Masuda[1], Jun-ichiro Ohe[2], Shoya Sakamoto[1], Takeshi Seki[1,3], and Yoshinori Onose[1,3] — [1]Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan — [2]Department of Physics, Toho University, Funabashi 274-8510, Japan — [3]Center for Science and Innovation in Spintronics (CSIS), Core Research Cluster, Tohoku University, Sendai 980-8577, Japan

In helimagnets, magnetic moments form a helical spin order possessing chirality. In centrosymmetric crystals, two helical states with opposite handedness are degenerate; thus, chiral domains can coexist and form domain walls. Here, we study the domain wall dynamics under electric current in the helimagnet $MnAu_2$. We found that the threshold current required for the transition from the multidomain state to a single-chiral domain state in a magnetic field is much lower than that for chirality reversal from a single-chiral domain within certain ranges of temperature and magnetic field. The chirality after the transition depends on whether the magnetic field and electric current were parallel or antiparallel. Numerical calculations based on the Landau-Lifshitz-Gilbert equation reproduce our observations. These results indicate that the domain walls are highly mobile in the helimagnet, reflecting a pinning potential much smaller than the domain-nucleation energy. They also suggest that helimagnetic domain walls could serve as efficient information carriers, opening new avenues for spintronic applications, such as racetrack-type memory devices.

MA 30.2 Wed 9:45 POT/0151

Multistate probabilistic computing in the chiral kagome antiferromagnet Mn3Sn — •Prajwal Rigvedi[1], Jae-Chun Jeon[1], Kevin Callahan-Coray[2], Kerem Y. Camsari[2], and Stuart S.P Parkin[1] — [1]Max-Planck Institute of Microstructure Physics, Halle (Saale), Germany — [2]Department of Electrical and Computer Engineering, University of California, Santa Barbara, CA, USA

Chiral kagome antiferromagnets such as Mn3Sn are promising candidates for spintronic applications due to their ultrafast spin dynamics and negligible stray

fields. Their magnetic ground state exhibits six-fold degeneracy, which naturally supports multistate information processing. In this work, we investigate ultra-thin W/Mn3Sn bilayers and demonstrate spin-orbit torque-driven multistate probabilistic switching. Above a critical current density, stochastic fluctuations in the anomalous Hall resistance (Rxy) emerge, and their probability distribution can be continuously tuned with nanosecond electrical pulses. This tunability results in a sigmoidal response of Rxy to the applied current, enabling electrically controlled antiferromagnetic probabilistic bits with multiple accessible states. Leveraging experimentally obtained state statistics, we implement a graph coloring task, an NP-hard optimization problem. These results constitute the first experimental realization of multistate probabilistic switching in an antiferromagnet and demonstrate its applicability to non-deterministic computing tasks. Our findings position non-collinear antiferromagnets as a promising material platform for multibit spintronics, highlighting their potential for unconventional computing architectures.

MA 30.3 Wed 10:00 POT/0151

Antiferromagnetic Writing by Magneto-electric Field in Cr_2O_3 — Nikolai Khokhlov[1], •Aleksandr Buzdakov[2], Timur Gareev[1], Anatoly Zvezdin[3], Sergey Artyukhin[2], and Aleksei Kimel[1] — [1]Radboud University Nijmegen, Institute for Molecules and Materials, Nijmegen 6525 AJ, The Netherlands — [2]Istituto Italiano di Tecnologia, Via Morego 30, Genova 16163, Italy — [3]Moscow, Russia

Antiferromagnetic (AFM) spintronics is a promising platform for next-generation storage, offering high domain wall velocities and immunity to stray fields. However, a bottleneck remains: the lack of a low-power method to write arbitrary domains without high-density currents and Joule heating. Here, we demonstrate full, non-volatile control of AFM domains in magnetoelectric Cr_2O_3 at room temperature. Utilizing an electrically charged needle to "draw" domains under a magnetic bias, we find that approaching the Néel temperature is critical. In this regime, domain walls lose their elastic "rubber band" behavior, allowing complex shapes to stabilize. We rationalize this via the Larkin length, establishing that reliable storage requires a Larkin length smaller than the bit size. Our findings provide a model for domain writability in insulating antiferromagnets, paving the way for low-energy, electrically controlled AFM memory.

MA 30.4 Wed 10:15 POT/0151

Magnetic-phase-entangled orbital anisotropy in the van der Waals antiferromagnet $CrPS_4$ revealed by resonant inelastic X-ray scattering — •Zhijia Zhang[1], Yuan Wei[1], Carlos William Galdino[1], Cedomir Petrovic[2], and Thorsten Schmitt[1] — [1]Centre for Photon Science, Paul Scherrer Institut, Villigen PSI 5225, Switzerland — [2]Shanghai Advanced Research in Physical Sciences, Shanghai 201203, P.R. China

The emergence of exfoliable magnetic van der Waals (vdW) materials with weak inter-layer correlations enables physicists to study magnetism directly in two dimensions (2D). Their sustained magnetic order and other novel magnetic properties down to the 2D limit make them promising candidates for spintronic applications. $CrPS_4$ is an A-type antiferromagnetic vdW material with strong correlations between spin, orbital, and structural degrees of freedom, and its highly unusual magnetic properties has been the subject of considerable scientific and practical interests. In this talk, I will present our temperature-dependent X-ray absorption spectroscopy (XAS) and resonant inelastic X-ray scattering (RIXS) measurements on bulk $CrPS_4$ crystals. Both the XAS and RIXS spectra display significant linear dichroism. In particular, the linear-dichroic RIXS intensity of one of the orbital excitations shows an order-parameter-like temperature dependence below the Néel temperature; and the dichroism entirely disappears in the paramagnetic phase. This evidence strongly supports the role of the orbital anisotropy as the shaping agent of the magnetic states in $CrPS_4$.

MA 30.5 Wed 10:30 POT/0151

Impact of deposition parameters on magnonic properties of α-Fe_2O_3 thin films. — •Katharina Müller[1,2], Tobias Herrlich[1,2], Monika Scheufele[1,2], Matthias Opel[1], Hans Huebl[1,2,3], Rudolf Gross[1,2,3], Akashdeep Kamra[4], Matthias Althammer[1,2], and Stephan Geprägs[1] — [1]Walther-Meißner-Institut, BAdW, Garching, Germany — [2]TUM School of Natural Sciences, Munich, Germany — [3]Munich Center for Quantum Science and Technology, Munich, Germany — [4]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, Kaiserslautern, Germany

Magnons in magnetic insulators are promising spin information carriers in future spintronic devices. For such applications, investigating and understanding the magnonic properties of thin films is crucial. Among the antiferromagnetic insulators, α-Fe_2O_3 is a prime example to study. Upon cooling, it features a Morin transition at 263 K from an antiferromagnetic easy-plane to an easy-axis phase below the Néel temperature. We obtain the magnetic anisotropy, the Dzyaloshinskii-Moriya interaction, as well as the magnon decay length from the magnon Hanle effect in all-electrical magnon transport experiments [1]. We study the dependence of these properties on the deposition parameters of α-Fe_2O_3 thin films grown on differently oriented Al_2O_3-substrates. Starting from a multi-domain state and driving the system with an external magnetic field, we use spin Hall magnetoresistance measurements to assess how the monodomainization field is influenced by the deposition parameters. [1] M.Scheufele *et al.*, APL Mater. **11**, 091115 (2023).

MA 30.6 Wed 10:45 POT/0151

Investigation of magnetic symmetries and domain imaging in antiferromagnetic Mn_2As via methods of electron microscopy — •Oleksandr Zaiets[1,2], Kamil Olejník[3], Filip Křížek[3], Jose Angel Castellanos-Reyes[4], Jan Rusz[4], Darius Pohl[2], and Axel Lubk[1,2] — [1]IFW Dresden, Germany — [2]TU Dresden, Germany — [3]Institute of Physics of the Czech — [4]Uppsala University, Sweden

Antiferromagnets are promising candidates for spintronic applications due to their ultrafast dynamics, low magnetic susceptibility, and lack of stray fields. Their switching behaviour is determined by the undisturbed antiferromagnetic ordering, the distribution of magnetic defects (notably domain walls) and their pinning to structural defects of the underlying crystal structure.

In this work we investigate antiferromagnetic Mn_2As thin films epitaxially grown on GaAs via methods of transmission electron microscopy, in particular high resolution imaging and electron diffraction. The antiferromagnetic ordering of Mn_2As entails a doubled magnetic unit cell compared to the structural one. This allows us to study purely magnetic Bragg reflections. The analysis of these reflections suggests the presence of a previously unknown antiferromagnetic phase. We furthermore reveal the presence of an antiferromagnetic domain structure by mapping the intensity of these reflections. We discuss stabilization mechanisms of this new AF ordering with the help of ab-initio methods. The strength of the antiferromagnetic signal is sufficient for domain mapping with sub-nanometer scale.

MA 30.7 Wed 11:15 POT/0151

Creation of antiferromagnetic skyrmions by edge manipulation — •Aleksey Berg, Tim Matthies, and Elena Vedmedenko — University of Hamburg

Novel magnetic storage technologies rely on ferromagnetic topological objects to represent information. These objects can be created, propelled and annihilated by electric currents in racetracks. We have recently demonstrated theoretically that arbitrary sequences of coexisting ferromagnetic skyrmions and antiskyrmions can be processed via local rotations of magnetic moments at the edge of a rectangular slab, eliminating the need for global charge or spin currents [1]. This local manipulation can be achieved experimentally using rotating local magnetic fields or currents. Here, we demonstrate that edge rotation can be effectively applied to antiferromagnetic skyrmions, too. Furthermore, antiferromagnetic quasiparticles can be created and propelled without rotating the edge magnetisation, but rather by switching the local magnetisation at the racetrack edge. This low-energy manipulation of stable antiferromagnetic topological quasiparticles via local excitation would be highly advantageous in the field of antiferromagnetic spintronics. 1. P. Siegl et al., Phys. Rev. B 106, 014421 (2022)

MA 30.8 Wed 11:30 POT/0151

Field-induced spin-reorientation transitions in collinear antiferromagnet Cr_2O_3 — •Paulina J. Prusik[1,2], Igor Veremchuk[1], Florin Radu[3], Pavlo Makushko[1], Jürgen Fassbender[1,2], Kirill D. Belashchenko[4], Denys Makarov[1], and Oleksandr V. Pylypovskyi[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., 01328 Dresden, Germany — [2]Dresden University of Technology, Dresden 01062, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin 12489, Germany — [4]University of Nebraska-Lincoln, Lincoln, NE 68588, USA

We classify collinear antiferromagnets (AMFs) by presence in their σ-model of a term of exchange origin that couples the external magnetic field and gradients of the Néel vector. One representative material is the magnetoelectric, room-temperature, collinear AFM Cr_2O_3, which is promising for spintronics applications [1,2] as well as for fundamental research [3,4]. In Cr_2O_3 this term leads to a texture-induced magnetization with a finite component along the crystallographic c axis. By analyzing the field-induced spin-reorientation transitions, we find the appearance of a phase in which a field-induced domain wall lies in the basal plane at fields below the spin-flop field. The theoretical predictions are supported by X-ray magnetic linear dichroism measurements, which show that the transition field in thin films is reduced by nearly half compared to the single crystal. MA 30.9 Wed 11:45 POT/0151

Direct Observation of Hidden Excitonic States via Exciton-Magnon Coupling in CrSBr — Sophie Bork[1], •Richard Leven[1], Vincent Wirsdörfer[1], Alessandro Ferretti[2], Rafael Rojas Lopez[1], Mattia Benini[1], David Maximilian Janas[1], Umut Parlak[3], Alberto Brambilla[2], Alexey Scherbakov[1], and Mirko Cinchetti[1] — [1]Department of Physics, TU Dortmund University, 44227 Dortmund, Germany — [2]CNR-IFN Dipartimento di

Fisica, Politecnico di Milano, 20133 Milan, Italy — [3]Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany

Two-dimensional van der Waals magnets exhibit strong exciton binding and intrinsic magnetic order, enabling exciton-magnon coupling that links collective spin excitations with excitonic states. However, detecting dark excitons and their coupling remains challenging. Here we employ broadband transient reflectivity on CrSBr, a quasi-two-dimensional antiferromagnetic semiconductor, to probe excitonic structures across 1.25 - 1.65 eV under varying magnetic fields. We identify two excitonic resonances: a bright 1s exciton at 1.36 eV and a dark exciton near 1.46 eV, the latter revealed solely through exciton-magnon interactions. The detected GHz magnon mode exhibits magnetic-field-dependent frequency shifts and coupling signatures with both excitons. High-energy excitation modifies magnon dispersion and enhances exciton-magnon hybridization. These findings provide direct insight into exciton-magnon coupling in CrSBr and demonstrate that ultrafast optical probes can uncover hidden excitonic states, advancing understanding of hybrid quasiparticles in van der Waals magnets.

MA 30.10 Wed 12:00 POT/0151

Rocket-like dynamics of ferrimagnetic domain walls in graded magnets — •Pietro Diona[1,2], Sergey Artyukhin[2], and Luca Maranzana[2,3] — [1]Scuola Normale Superiore di Pisa, Pisa, Italia — [2]Istituto Italiano di Tecnologia, Genova, Italia — [3]Università di Genova, Genova, Italia

The domain wall motion underpins emerging spintronic technologies, such as high-speed racetrack devices and THz logic. Spatially nonuniform magnetic exchange and anisotropy in ferromagnets can pin or accelerate domain walls [1,2]. In ferrimagnets, where Walker breakdown is suppressed, domain walls can therefore approach the magnon speed [3]. Here we show that in non-uniform ferrimagnets such gradients not only exert a net force on the ferrimagnetic domain walls, but also modify the effective mass of the wall, enabling an entirely new acceleration mechanism. As a domain wall travels through regions of varying exchange or anisotropy, it can shed or gain effective mass leading to a "rocket effect" as in variable-mass systems. This phenomenon becomes increasingly pronounced as the wall approaches the magnon velocity [3], providing a natural route to ultrafast domain-wall propulsion. Our analytical theory, supported by micromagnetic simulations, suggests strategies for mass control in racetrack devices. These results establish variable-mass domain walls as a new paradigm for efficient, high-velocity spintronics and THz-frequency magnetic technologies.

MA 30.11 Wed 12:15 POT/0151

Revealing Magnetic Chirality in Non-Collinear Kagome Antiferromagnets through Spin-Seebeck Measurements — •Feodor Svetlanov Konomaev, Mithuss Tharmalingam, and Kjetil Magne Dørheim Hals — Department of Engineering Sciences, University of Agder, 4879 Grimstad, Norway

Non-collinear antiferromagnets (NCAFMs) are appealing for antiferromagnetic spintronics, as they combine the advantages of collinear antiferromagnets with novel emergent phenomena stemming from their complex spin structures. These phenomena are often associated with the intrinsic spin chirality, which characterizes the handedness of the ground-state spin configuration. Here, we investigate a kagome NCAFM interfaced with a normal metal and demonstrate that the groundstate vector spin chirality can be probed through measurements of the spin Seebeck effect (SSE). Starting from a microscopic spin Hamiltonian, we derive the corresponding bosonic Bogoliubov-de-Gennes Hamiltonians for the two chiral configurations. Using linear response theory, we obtain a general expression for the spin current thermally pumped into the normal metal by the SSE. We show that a sizable in-plane spin current emerges exclusively in the negative-chiral state, providing a direct signature for real-time detection of chirality switching in kagome NCAFMs. In addition, we find a field-dependent out-of-plane spin current whose magnitude differs between the two chiralities, reflecting their distinct magnon band structures

MA 30.12 Wed 12:30 POT/0151

Strain engineering of antiferromagnetic $LaFeO_3$ films for magneto-optical investigations — •Antonia Rieche, Wolfgang Hoppe, Chis Körner, Aurora Diana Rata, Andreas Herklotz, and Kathrin Dörr — Martin-Luther-Universität Halle-Wittenberg

$LaFeO_3$ is a representative member of the orthoferrites. This antiferromagnet exhibits a high Néel temperature of 740 K. A weak net magnetization is created due to a small tilting of the magnetic moments. $LaFeO_3$ is considered to be a promising candidate for antiferromagnetic spintronics.

While the magneto-optical Kerr effect (MOKE) has been used to investigate bulk crystals, only a single study has reported MOKE data for $LaFeO_3$. [1]

Our work demonstrates the magnetic switching behavior of coherently strained $LaFeO_3$ films. The strain states were generated using different substrates and helium implantation. [2] The films were grown using pulsed laser deposition (KrF 248 nm), and their strain state was analyzed by X-ray diffraction.

Longitudinal MOKE hysteresis and microscopy measurements revealed a strain-dependent orientation of the magnetization axis, which is consistent with predictions from density functional theory. [3] Further single-domain remanence has been confirmed.

MA 31.1 Wed 9:30 POT/0361

Finite-size spectral signatures of order by quantum disorder: A perspective from Anderson's tower of states — •Subhankar Khatua[1], Griffin C. Howson[2], Michel J. P. Gingras[2], and Jeffrey G. Rau[3] — [1]IFW Dresden, Germany — [2]University of Waterloo, Canada — [3]University of Windsor, Canada

In frustrated magnetic systems with a subextensive number of classical ground states, quantum zero-point fluctuations can select a unique long-range ordered state, a celebrated phenomenon referred to as order by quantum disorder (ObQD). While ObQD is well understood in the semiclassical, large spin length limit, its behavior in quantum spin-1/2 systems is less clear. As exact analytical solutions are scarce for frustrated systems, numerical approaches are essential. We show that ObQD can be identified from exact diagonalization (ED) calculations through an analysis akin to the Anderson tower of states associated with spontaneous symmetry breaking. By defining an effective quantum rotor model, we describe the competition between ObQD-induced localization of the rotor and its tunneling between symmetry-related ground states, identifying the crossover lengthscale from the finite-size regime where the rotor is delocalized, to the infinite system-size limit where it becomes localized. This rotor model relates the characteristic splittings in the ED energy spectrum to the ObQD selection energy scale, providing an estimate that can be compared to spin wave calculations. We demonstrate the general applicability of this approach in one-, two- and three-dimensional frustrated spin models that exhibit ObQD.

MA 31.2 Wed 9:45 POT/0361

Magnetic resonance experiments on the quantum spin liquid candidate $YbCuSe_2$ — Madhurima Biswas[1], •Marlis Schuller[3], Khokan Bhattacharya[1], Yoshifumi Tokiwa[2], Mamoun Hemmida[3], Hans-Albrecht Krug von Nidda[3], Norbert Büttgen[3], István Kézsmárki[3], and Mayukh Majumder[1] — [1]Department of Physics, Shiv Nadar Institution of Eminence, IN — [2]Advanced Science Research Center, Japan Atomic Energy Agency, JPN — [3]EPV, Institut of Physics, University of Augsburg, DE

Frustrated magnetism in triangular-lattice delafossites offers a fertile route to realising quantum spin liquids (QSL) beyond conventional ordered phases. Among these materials a new candidate, $YbCuSe_2$, stands out as a QSL candidate from the present study. Magnetisation and ESR measurements on high-quality single crystals of $YbCuSe_2$ reveal easy-plane anisotropy. Furthermore, heat-capacity measurements down to 400 mK and μSR measurements down to 30 mK show no signatures of long-range magnetic ordering, establishing this compound as a promising QSL candidate. To probe the low-energy spin dynamics, we performed ^{63}Cu (I = 3/2) NMR measurements down to 20 mK. We document in-plane and out-of-plane spin-lattice relaxation T_1 as a function of temperature in an applied field of approximately 4 T. A dynamical phase separation was observed below 0.7 K, where one phase corresponds to the disorder-induced state, whereas the temperature evolution of the relaxation rate of the other phase exhibits a power-law divergence indicative of some quantum-critical spin fluctuations due to the proximity to a field-induced ordered state.

MA 31.3 Wed 10:00 POT/0361

Fluctuation driven phases in the triangular lattice — •P. Peter Stavropoulos[1], Roser Valentí[1], and Johannes Knolle[2] — [1]Goethe University, Frankfurt, Germany — [2]Technical University of Munich, Garching, Germany

The triangular lattice has proven to be a model platform of frustrated magnetism, with a rich landscape of emergent phases. It is also an experimentally accessible platform, with many family of materials showing quasi-2D triangular arrangements of magnetic ions. Motivated by this, we revisit magnetic exchange models

on the triangular lattice. We discuss phases that are stabilized by order by disorder mechanisms, and comment on their observable signatures.

MA 31.4 Wed 10:15 POT/0361

Frustrated spin-1/2 chains in a correlated metal Ti4MnBi2 — •Xiyang Li and Meng Lyu — No.8, 3rd South Street, Zhongguancun, Haidian District, Beijing, China, 100190

Electronic correlations lead to heavy quasiparticles in three-dimensional(3D) metals, and their collapse can destabilize magnetic moments. It is an open question whether there is an analogous instability in one-dimensional (1D) systems, unanswered due to the lack of metallic spin chain materials. We report neutron scattering measurements and density matrix renormalization group calculations establishing spinons in the correlated metal Ti4MnBi2, confirming that its magnetism is 1D. Ti4MnBi2 is inherently frustrated, forming near a quantum critical point that separates different phases at temperature T = 0. One-dimensional magnetism dominates at the lowest T, and is barely affected by weak interchain coupling. Ti4MnBi2 is a previously unrecognized metallic spin chain in which 3D conduction electrons become strongly correlated due to their coupling to 1D magnetic moments.

MA 31.5 Wed 10:30 POT/0361

Low-temperature spin-freezing in frustrated zirconates $Tb_2Zr_{2-x}Ti_xO_7$ — •Frederik Leon Carstens[1], Sujata Singh[2], C. S. Yadav[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]School of Physical Sciences, IIT Mandi, India

We report on magnetic studies of polycrystalline $Tb_2Zr_{1-x}Ti_xO_7$ ($x = 0, 0.5$). The zironates possess significant cationic disorder due to similar radii of the cations which introduces magnetic frustration. The materials are investigated by means of low-temperature ac and dc magnetization measurements in magnetic fields up to 7 T and down to 400 mK. Long-range magnetic order is not found down to $T = 400$ mK. However, in small magnetic fields, we observe a low-temperature spin-frozen state below $T = 1.4$ K and a slow spin relaxation regime which is significantly enhanced in static magnetic fields, e.g. to 15 K at $B = 2$ T. A similar behavior has been previously reported for the related rare-earth zirconate $Ho_2Zr_2O_7$ and in the hafnate $Tb_2Hf_2O_7$ [1,2].

MA 31.6 Wed 10:45 POT/0361

Magnetization plateaus, spin-canted orders and field-induced transitions in a spin-1/2 Heisenberg antiferromagnet on a distorted diamond-decorated honeycomb lattice — •Katarina Karlova and Jozef Strecka — Pavol Jozef Safarik University in Kosice, Slovakia

We investigate the spin-1/2 Heisenberg antiferromagnet on a distorted diamond-decorated honeycomb lattice in an external magnetic field. Using density-matrix renormalization group, sign-problem-free quantum Monte Carlo, exact diagonalization, and an effective lattice-gas approach based on localized-magnon physics, we determine the ground-state phase diagram and analyze the finite-temperature magnetization process.

The model hosts a rich variety of frustration-induced quantum phases, including Lieb-Mattis ferrimagnetic states, spin-canted regimes, monomer-dimer and dimer-tetramer phases, and dimensional-crossover states with 0D or 1D character. Depending on the lattice distortion, we identify robust magnetization plateaus at 0, 1/4, 1/2, and 3/4 of the saturation value, originating from competing local singlet clusters, composite spins, and flat-band localized magnons. Finite-temperature QMC data show how thermal fluctuations progressively smear the plateau structure, while the effective lattice-gas description reliably captures the corresponding low-temperature trends.

MA 31.7 Wed 11:15 POT/0361

Effect of Ca-doping on the exotic quantum spin liquid states of Y3Cu2Sb3O14 — •Muhammad Usama Akbar[1], Hans-Albrecht Krug von Nidda[1], Mamoun Hemmida[1], Avinash Mahajan[2], and Saikat Nandi[2] — [1]Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, D-86135 Augsburg, Germany — [2]Department of Physics, Indian Institute of Technology, Mumbai, 400076, India

The three-dimensional spin S = 1/2 compound Y3Cu2Sb3O14 was recently identified as a promising candidate for novel quantum spin liquid (QSL) behavior, with two inequivalent Cu2+ sites in edge-sharing triangles and no long-range order observed in multiple experiments [1]. NMR detects a transition near 120 K, associated with partial singlet formation, while muSR and DFT indicate frustrated antiferromagnetic interactions around both Cu+2 sites. ESR shows a Lorentzian line (g = 2.16) above 120 K that splits into two components on cooling, with only a part of spins being ESR-active. In the current work, we extend this investigation to Ca-doped Y3-xCaxCu2Sb3O14 (x = 0.05, 0.10, 0.25), to examine how chemical substitution at the Y site influences the spin dynamics of the compound.

MA 31.8 Wed 11:30 POT/0361

Synthesis and H-T phase diagram of $Cu_2(OH)_3HCOO$ — •Issei Niwata[1,2], Kaushick K. Parui[1], Maxim Avdeev[3], Anton A. Kulbakov[1], Dmytro S. Inosov[1], and Darren C. Peets[1] — [1]TU Dresden, Dresden, Germany — [2]Hokkaido University, Sapporo, Japan — [3]ANSTO, Sydney, Australia

$Cu_2(OH)_3X$ (X = monovalent anion) consists of quasi one-dimensional (1D) ferromagnetic (FM) and antiferromagnetic (AFM) chains which alternate to form two-dimensional triangular layers, which are stacked along the c axis. As the interchain interactions are frustrated and interlayer interactions are weak, the system can be regarded as weakly coupled 1D FM and AFM chains. In bulk measurements, these compounds typically show AFM behavior with a Néel temperature (T_N) below 10 K. Because of the coexistence of FM and AFM chains, exotic magnetic excitations are expected. As a matter of fact, for $X = Br^-$, inelastic neutron scattering revealed magnon excitations and a gapped spinon continuum in the same energy range. In addition, for $X = NO_3^-$, the realization of a Tomonaga-Luttinger-liquid state in the AFM chain was suggested in magnetic fields around 20 T, where the magnetization shows a half saturation indicating full polarization of the FM chains. Recently, we grew single crystals of the $X = HCOO^-$ compound. Magnetization measurements showed $T_N = 5.4$ K and a half saturation below 5 T, much lower than $X = NO_3^-$. This suggests that we can explore the excitation structure in relatively low magnetic fields. I will discuss the phase diagram obtained by physical properties measurements.

MA 31.9 Wed 11:45 POT/0361

H–T Phase Diagram of the Frustrated Quantum Magnet Antlerite, $Cu_3SO_4(OH)_4$ — •Darren C. Peets[1], Nikolai S. Pavlovskii[1], Roman Gumeniuk[2], Sergey Granovsky[1], and Dmytro S. Inosov[1] — [1]IFMP, TU Dresden, Germany — [2]IEP, TU Bergakademie Freiberg, Germany

The magnetic copper sites in antlerite, $Cu_3SO_4(OH)_4$, are arranged in three-leg triangular-lattice ladders, a unique magnetic lattice. In the ground state, the outer legs are ferromagnetic and antialigned, while the central leg is antiferromagnetic. This material has four distinct magnetic states in zero field alone, and we show that the phase diagram in applied fields is also remarkably rich.

MA 31.10 Wed 12:00 POT/0361

Magnetic structure of a geometrically frustrated Mn3V2Ge3O12 garnet oxide — •Sagar Mal Kumawat[1], Tsai-Ling Liu[1], Chin-Wei Wang[2], Jia-Xiang Hsu[1,3], En-Pei Liu[3], Wei-Tin Chen[3,4,5], and Chien-Lung Huang[1] — [1]Department of Physics and Center for Quantum Frontiers of Research & Technology (QFort), National Cheng Kung University, Tainan 701, Taiwan — [2]National Synchrotron Radiation Research Center, Hsinchu 30076, Taiwan — [3]Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan — [4]Center of Atomic Initiative for New Materials, National Taiwan University, Taipei 10617, Taiwan — [5]Taiwan Consortium of Emergent Crystalline Materials, National Science and Technology Council, Taipei 10622, Taiwan

We investigated the low-temperature magnetic structure and thermodynamic properties of Mn3V2Ge3O12 (MVGO) using neutron diffraction, magnetic, and heat capacity measurements. MVGO crystallizes in a cubic Ia-3d structure with a minor MnV2O4 impurity. Two successive transitions at TN1 = 4 K and TN2 = 2.4 K indicate noncollinear antiferromagnetic ordering of the frustrated V3+ and Mn2+ sublattices. Field-dependent heat capacity shows suppression of the TN1 anomaly and a shift of TN2, consistent with magnetic frustration and spin reorientation. The total magnetic entropy reaches approximately 51 J/mol K above 20 K, accounting for ~81% of the theoretical entropy for the full spin system. Temperature-dependent measurements reveal noncollinear antiferromagnetic order below TN2, with peak broadening up to TN1 indicating strong spin frustration.

MA 31.11 Wed 12:15 POT/0361

Crystallographic and magnetic structure of Pr_2PdSi_3: a single crystal neutron diffraction study — •Matthias Frontzek — Neutron Scattering Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA

The intermetallic compound series R_2PdSi_3 (R = rare earth metal) exhibits intriguing magnetic properties, including giant magnetoresistance, pronounced anisotropy in its electronic behavior, and a generic field-induced phase. The magnetic structures are complex, with large magnetic unit cells arising from the delicate interplay between competing crystal electric-field effects, magnetic exchange interactions, and geometric frustration. Recently, the discovery of a Skyrmion lattice in Gd_2PdSi_3 has renewed interest in the magnetic properties of this series.

In our contribution, we present a detailed neutron single crystal diffraction study using the WAND^2 diffractometer at the High-Flux Isotope Reactor (HFIR) at ORNL. In heavy rare earth members, Pd/Si ordering lowers the symmetry from hexagonal to monoclinic; in contrast, the Pr_2PdSi_3 compound adopts an

orthorhombic structure with a $2 * a, 2 * b, 4 * c$ unit cell relative to the primitive hexagonal cell. Magnetic order setting in at $T_N = 2.1$K is preceded by broad diffuse scattering around the nuclear reflections, and below T_N a long-wavelength spin-density wave is observed coinciding with the short-range order evidenced by the diffuse scattering.

MA 31.12 Wed 12:30 POT/0361

Dynamical heterogeneity and fractal subdiffusive transport in spin-ice — •Malte Bieringer[1], Gianluca Teza[1,2], Claudio Castelnovo[3], and Roderich Moessner[1] — [1]Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Straße 38, 01187 Dresden, Germany — [2]Department of Physics, University of Trieste, Strada Costiera 11, 34136 Trieste, Italy — [3]TCM Group, Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, UK

Spin ice is a paradigmatic model that, despite its simplicity, enables the exploration of rich and robust emergent phenomena in topological magnets. Here we uncover a novel set of spin-ice phenomenology typically associated with vitrification processes in disordered systems.

We identify a pronounced peak in dynamical heterogeneity in a classical spin-ice model on the three-dimensional pyrochlore lattice, in the complete absence of disorder and - remarkably - in thermal equilibrium. At low temperatures, additional dynamical constraints emerge that confine the motion of magnetic monopole excitations to three-dimensional percolation clusters. This gives rise to ergodic subdiffusion, opposing conventional emergent hydrodynamics. The observed dynamical heterogeneity arises without disorder or ergodicity breaking, distinguishing it from conventional glasses and systems with Hilbert space fragmentation, suggesting a generic feature of topological magnets hosting deconfined quasiparticles.

Our results motivate the search for materials and artificial spin-ice realizations of this physics and propose higher-order dynamical correlations as a distinctive experimental signature of topological magnetism.

MA 32: Excursion: Current and Future High-Field THz User Facilities at HZDR

As part of the Focus Session "Chiral phonons and crystals coupled to magnetic order" and open to all interested potential users, we offer a tour of the high-field THz user facilities at Helmholtz-Zentrum Dresden-Rossendorf (HZDR) and an introduction to the planned Dresden Advanced Light Infrastructure (DALI). The superconducting accelerator-based THz beam lines TELBE and FELBE currently provide extreme THz and mid-infrared pulse energies at high repetition rates for international users from around the globe. In 2025, DALI was announced as one of the 9 shortlisted priority research infrastructures in Germany. It has been selected as a world-leading THz facility by the Federal Ministry for Research, Technology, and Space (BMFTR) to secure and enhance Germany's long-term research capabilities for the next decades. The guided tour includes a bus transfer to the Rossendorf site, lab visits at the current ELBE facilities and an introduction to DALI.

As the number of participants is limited, registration is required latest by 6 March 2026, using the following link https://events.hifis.net/e/DPG-2026_HZDR-excursion. The meeting point will be provided after registration.

Contact: Sebastian F. Maehrlein, s.maehrlein@hzdr.de

MA 33: Altermagnets IV

Time: Wednesday 15:00–18:30 Location: HSZ/0002

MA 33.1 Wed 15:00 HSZ/0002

Magnon transport and surface effects in an altermagnetic toy model — •Moumita Kundu[1], Rabea Schmidhuber[2], Marian Duelli[1], and Ulrich Nowak[1] — [1]Fachbereich Physik, Universität Konstanz, Konstanz, Germany — [2]Ludwig-Maximilians-Universität München, Geschwister-Scholl-Platz 1, 80539 München, Germany

Altermagnets are a recently discovered class of magnetic materials that show non-relativistic spin-splitting of the magnon bands and on exposure to a thermal gradient can carry a net magnetization unlike conventional antiferromagnets. Here, we present a simplistic toy model of an altermagnet having asymmetric exchange interactions in a checkered antiferromagnetic lattice. Using atomistic spin dynamic simulations based on the stochastic-LLG equation we obtain the spin dynamics. The altermagnetic phase is confirmed from magnon dispersions under a steady thermal excitation revealing chiral spin splitting as expected along one of the high-symmetry directions [110] and directions orthogonal to it. Surface effects are a direct outcome from these calculations, showing an orientation dependent surface magnetization detected for each cut of the sample. The spin Seebeck and spin Nernst effects are investigated both showing unique orientation dependent net magnetization and magnon accumulations following the lattice symmetries. Owing to the nondegenerate magnons branches, the group velocities of the corresponding magnons vary leading to distinct propagation lengths of the RH- and LH- modes predominant along different directions. The robustness to external magnetic fields is explored revealing preferential band liftings with an additional gap at the Γ point.

MA 33.2 Wed 15:15 HSZ/0002

Skyrmion dynamics in altermagnets — •Nicolai Timon Bechler and Jan Masell — Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

Altermagnetism is a new type of magnetic order that combines the time-reversal symmetry breaking nature of ferromagnetism with the stray-field free nature of antiferromagnetism. [1] Altermagnets can host skyrmions - whirling magnetic textures that are characterized by an integer real-space topological winding number. In d-wave altermagnets, the skyrmions in both sublattices are elliptical, related by lattice symmetries, and the total winding number vanishes as the contributions of each sublattice cancel each other. In this talk, we explore the motion of skyrmions in d-wave altermagnets, driven by either spin transfer torque (STT) or a magnon current. We combine an analytical collective-coordinate approach with high-precision micromagnetic simulations. Our findings predict that the anisotropic skyrmion profile yields a genuine Hall response beyond conventional Zhang-Li STT. In turn, standard Zhang-Li STT yields no Hall-signal but large artifacts in simulations which were previously misinterpreted as a physical Hall effect. [2] Furthermore, we show that for a system driven by a magnon current, the anisotropic scattering cross-sections immediately lead to a skyrmion Hall effect.

MA 33.3 Wed 15:30 HSZ/0002

Unconventional Magnetism in Fe-Based Materials — Reuel Dsouza[1], Andreas Kreisel[1], Brian M. Andersen[1], Daniel Agterberg[2], and •Morten H. Christensen[1] — [1]Niels Bohr Institute, University of Copenhagen, 2200 Copenhagen, Denmark — [2]Department of Physics, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin 53201, USA

Odd-parity magnetism constitutes an intriguing phase of matter which breaks inversion symmetry while preserving time-reversal symmetry. Here we demonstrate that the Fe-based superconductors exhibiting coplanar magnetic order realize an odd-parity magnetic state by combining low-energy modeling with density-functional theory. In the absence of spin-orbit coupling, the electronic spins are polarized along the k_z-direction and the splitting of the up and down states exhibits an h- wave form-factor. The magnitude of the splitting depends sensitively on specific parameters of the low-energy model, including specific out-of-plane hopping parameters and the Fermi energies of the hole- and electron-pockets. Interestingly, despite this state breaking inversion symmetry and exhibiting a finite out-of-plane Berry curvature and non-linear anomalous Hall effect, the Edelstein effect vanishes. Incorporating spin-orbit coupling tilts the momentum-space electronic spins into the (k_x, k_y)-plane and imparts finite

in-plane components to the Edelstein response. Our findings highlight the Fe-based superconductors as platforms for exploring odd-parity magnetism both on its own and coexisting with unconventional superconductivity.

MA 33.4 Wed 15:45 HSZ/0002

Optical investigations of electron-doped $FeSb_2$ — Renjith Mathew Roy[1], •Maxim Wenzel[1], Maksim Povolotskiy[1], Christian Prange[1], Artem Pronin[1], Yujie Xie[2], Tiantian Zhang[2], Vignesh Sundaramurthy[3], Maximilian van de Loo[4], Jule Kirschke[4], Andreas Kreyssig[4], Anna Böhmer[4], and Martin Dressel[1] — [1]1. Physikalisches Institut, Universität Stuttgart — [2]Institute of Theoretical Physics, Chinese Academy of Science, 100190 Beijing, China — [3]Max-Planck-Institute for Solid State Research, 70569 Stuttgart — [4]Experimental Physics IV, Ruhr Universität Bochum

While the marcasite-structured semiconductor $FeSb_2$ is nonmagnetic, theoretical predictions suggest that hole or electron doping can stabilize an altermagnetic order with a substantial non-relativistic spin splitting of approximately 0.2 eV [1].

Here, we investigate a series of Co-doped $FeSb_2$ samples using optical spectroscopic techniques including broadband infrared spectroscopy, Müller-matrix ellipsometry, and Raman scattering. Combined with density-functional theory calculations, we discuss the effects of electron doping and the consequent magnetic ordering on the electronic structure and optical phonon modes. In particular, we address the possibility of an emerging altermagnetic state for dopings above $x = 0.12$.

MA 33.5 Wed 16:00 HSZ/0002

Realization of epitaxial thin films of CrSb altermagnetic candidate material — •Edouard Lesne and Claudia Felser — Max-Planck-Institute für Chemische Physik fester Stoffe

CrSb belongs to a newly identified class of antiferromagnetically ordered materials coined altermagnets, whose spin-sublattices arrangement breaks time-reversal symmetry, giving rise to alternating spin-split bands with lifted Kramers degeneracy throughout the Brillouin zone. CrSb crystallizes in the hexagonal NiAs-type structure ($P6_3/mmc$) and exhibits a high antiferromagnetic ordering temperature (700-710 K), making it an ideal altermagnetic candidate material for room-temperature studies and prospective technological use in antiferromagnetic spintronic architectures.

We resort to a combination of X-ray diffraction, SQUID magnetometry and electrical magnetotransport techniques to investigate the intertwined structural, magnetic, and electronic transport properties of CrSb epitaxial thin films. We explore the growth of CrSb crystalline films by magnetron sputtering on a variety of crystalline seed layers and underlying single-crystalline substrates with hexagonal or cubic symmetry, which allows the stabilization of different crystallographic orientations of CrSb, while also tuning epitaxial strain. This work, while providing a testbed for the fundamental study of altermagnets and their structure-properties relationship, also opens avenues for the use of altermagnetic CrSb for antiferromagnetic devices with new functionalities relying on the manipulation of charge, orbital and spin degrees of freedom.

MA 33.6 Wed 16:15 HSZ/0002

Emergent d-Wave Order from Altermagnetic Symmetry in Cuprate and Nickelate Superconductors — •Tom G. Saunderson[1], James F. Annett[2], and Samir Lounis[1] — [1]Institute of Physics and Halle-Berlin-Regensburg Cluster of Excellence CCE, Martin-Luther-University Halle-Wittenberg, Halle(Saale) 06120, Germany — [2]H. H. Wills Physics Laboratory, University of Bristol, Tyndall Avenue, Bristol BS8-1TL, United Kingdom

Since the discovery of cuprate high-T_c superconductivity, numerous theoretical frameworks have been proposed to explain its mechanism. Anderson's RVB picture [1] and U(1) gauge theory [2], for example, motivate a minimal one-band description that largely integrates out the role of oxygen. By contrast, 'altermagnetism' [3] produces a d-wave like k-space magnetic texture originating from alternatingly rotated *nonmagnetic* cages. In this talk, we take the central ideas of altermagnetism and apply them to both cuprate and nickelate families of superconductors. We show that the in-plane oxygen sublattice of CuO_2/NiO_2 layers, ubiquitous in these materials, intrinsically realizes the same symmetry. By imposing an *oxygen-centered*, staggered s-wave pairing, one obtains a d-wave gap with perfect C_4 symmetry, demonstrated self-consistently in $NdNiO_2$ from first principles. This description of superconductivity enables a direct mapping between a real-space order parameter and a lattice-based picture, opening the possibility of treating superconductivity and Hubbard-model physics on the same footing. Medium-Throughput Evaluation of Topological Transports for Altermagnets — •Fu Li[1], Bo Zhao[1], Shengqiao Wang[2], Chen Shen[1], Hao Wang[1], and Hongbin Zhang[1] — [1]Institute of Materials Science,Technical University of Darmstadt, 64287 Darmstadt, Germany — [2]School of Materials Science and Engineering, Jilin University, Changchun, 130012, China

The recent surge of interest in altermagnetism, distinct from both ferromagnetism and antiferromagnetism, highlights its potential for a wide range of technological applications. Quantifying their topological transport properties can provide essential guidance on the characterization of such materials while assessing their suitability for spintronic and optical applications. In this work, we collect around 200 known altermagnets (including also those with odd parity) based on symmetry arguments and perform medium-throughput density functional theory calculations to evaluate their topological transport properties such as anomalous Hall conductivity, magneto-optical Kerr effect, and shift current. Focusing on cases with broken inversion symmetry (i.e., polar altermagnets and odd-parity magnets), it is observed that the shift current can be large, making them promising for bulk photovoltaic applications. Furthermore, taking ferroelectric Fe2Mo3O8 as an example, it is demonstrated that its shift current can be controlled by external electric fields. Our results provide significant features characterizing altermagnets, and the obtained electronic structure can be starting point to investigate other intriguing physical properties.

MA 33.8 Wed 17:00 HSZ/0002

Electronic Raman spectroscopy in altermagnet MnTe — •Garima Garima[1,2,3], Thomas Böhm[1,3], Rudi Hackl[3], Bernd Büchner[1,3], and Jochen Geck[1,2] — [1]Institut für Festkörper- und Materialphysik, Technische Universität Dresden, 01062 Dresden, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany — [3]Leibniz Institute for Solid Sate and Materials Research Dresden, Helmholtzstrasse 20, D-01069 Dresden, Germany

Altermagnets, the new class of magnets, are promising candidates to realize spintronic and spin-information processing devices. The new magnetic state is characterized by broken time-reversal symmetry, resulting in spin-split bands in momentum space and hence provides a basis to foster chiral magnetic excitations. Here, we utilize electronic Raman scattering to investigate chirality in the hexagonal altermagnet MnTe. In consistency with RIXS experiments [1], our polarization-resolved results reveal optical signatures of 2-magnon excitations, appearing below the magnetic transition temperature of 310 K in the chiral A_{2g} channel. [1] Jost, D., et al. Chiral altermagnon in MnTe. arXiv preprint arXiv:2501.17380.

MA 33.9 Wed 17:15 HSZ/0002

Optically tunable spin transport in bilayer altermagnetic Mott insulators — Niklas Sicheler[1], Roberto Raimondi[2], Giorgio Sangiovanni[1], and •Lorenzo Del Re[1] — [1]Würzburg University — [2]Roma Tre

Altermagnets are a class of materials in which antiferromagnetic order coexists with non-relativistic spin splitting (NRSS), offering a promising route to spintronic functionalities without relying on strong spin*orbit coupling. In this work, we study a two-dimensional bilayer Mott insulator that realizes an altermagnetic phase shaped by the interplay between spin and layer degrees of freedom. This coupling produces a rich symmetry-breaking structure in which magnetic order is intertwined with inter-layer excitonic correlations. The layer polarization*tunable through an external gate voltage*acts as a key control parameter for this excitonic altermagnetic state. We demonstrate that an in-plane electric field applied with opposite signs across the layers generates a polarization current, which in turn drives a spin current within each layer. While the polarization current itself is isotropic, the induced spin current is highly anisotropic and can be reversed by tuning the photon energy. These results identify a mechanism for electrically and optically manipulating spin transport in correlated altermagnets, and highlight the central role of excitons in enabling controllable spin responses.

MA 33.10 Wed 17:30 HSZ/0002

Microscopic origin of the magnetic interactions and their experimental signatures in altermagnetic La2O3Mn2Se2 — •Laura Garcia-Gassull[1], Aleksandar Razpopov[1], Panagiotis P. Stavropoulos[1], Igor I. Mazin[2], and Roser Valentí[1] — [1]Goethe-Universität Frankfurt, Germany — [2]George Mason University, Fairfax, USA

Our analysis on the altermagnetic candidate La2O3Mn2Se2, realized on an inverse Lieb lattice, combines ab initio calculations, analytical modeling and spin-wave theory. We resolve a contradiction within the existing literature, where the GKA rules for half-filled orbitals have been applied, instead of the high-spin configuration ones. By studying the exchange pathways we show that the antiferromagnetic nearest-neighbor dominates over the next-nearest-neighbor coupling, since both direct exchange and superexchange cooperatively stabilize the magnetic ground state.

Going beyond static interactions, we compute the magnon spectrum within linear spin-wave theory and identify experimental signatures of the altermag-

netic exchange, a characteristic chiral splitting of magnon bands driven the inequivalent second-neighbor exchanges.

Our work not only clarifies the microscopic origin of altermagnetism, but also offers concrete predictions for its experimental verification, reinforcing La2O3Mn2Se2 as a model system for studying altermagnetic physics. You can find more details at: https://arxiv.org/pdf/2506.21661.

We thank the (DFG) through the TRR 288 (project B05).

MA 33.11 Wed 17:45 HSZ/0002

Altermagnetic Magnons in MnTe Probed by CD-RIXS — Daniel Jost[1,2], Resham B. Regmi[3,4], Eder G. Lomeli[5,1], Samuel Sahel-Schackis[6,2,7], •Monika Scheufele[8,9], Marcel Neuhaus[2], Rachel Nickel[10], Flora Yakhou[10], Kurt Kummer[10], Nicholas B. Brookes[10], Lingjia Shen[2], Georgi L. Dakovski[2], Nirmal J. Ghimire[3,4], Stephan Geprägs[8], and Matthias F. Kling[6,2,11] — [1]Stanford Inst. for Material and Energy Science, SLAC, USA — [2]Linac Coherent Light Source, SLAC, USA — [3]Dept. of Physics and Astronomy, Univ. of Notre Dame, USA — [4]Stravropoulos Center for Complex Quantum Matter, Univ. of Notre Dame, USA — [5]Dept. of Materials Science and Engineering, Stanford Univ., USA — [6]Stanford PULSE Inst., SLAC, USA — [7]Dept. of Physics, Stanford Univ., USA — [8]Walther-Meißner-Inst., BAdW, Germany — [9]TUM School of Natural Sciences, Physics Dept., TUM, Germany — [10]ESRF, France — [11]Dept. of Applied Physics, Stanford Univ., USA

Altermagnetism has emerged as a novel magnetic order combining features of both ferro- and antiferromagnetism. Despite their compensated spin structure, altermagnets exhibit symmetry-induced momentum-dependent splitting of magnon bands with well-defined chirality. This splitting must reflect the material's point-group symmetry. Here, we demonstrate the chiral character of these magnons by circular-dichroism resonant inelastic X-ray scattering (CD-RIXS) on altermagnetic α-MnTe [1]. We reveal momentum-dependent dichroism, indicating the polarization-dependent magnon splitting consistent with a g-wave symmetry. [1] D. Jost *et al.*, arXiv:2501.17380v2 (2025).

MA 33.12 Wed 18:00 HSZ/0002

Robust spin splitting and optical control in a layered altermagnet — •Alessandro De Vita[1,2], Chiara Bigi[3], Davide Romanin[4], Ralph Ernstorfer[1,2], Ilija Zeljkovic[5], Younghun Hwang[6], Matteo Calandra[7], Jill A. Miwa[8], and Federico Mazzola[9] — [1]Institut für Physik und Astronomie, Technische Universität Berlin — [2]Fritz Haber Institut der Max Planck Gesellshaft — [3]Synchrotron SOLEIL — [4]Université Paris-Saclay, CNRS — [5]Department of Physics, Boston College — [6]Electricity and Electronics and Semiconductor Applications Ulsan College — [7]Department of Physics, University of Trento — [8]Department of Physics and Astronomy, Interdisciplinary Nanoscience Center, Aarhus University — [9]Dipartimento di Fisica e Astronomia Galileo Galilei, Padova

Altermagnetism defies conventional classifications of collinear magnetic phases, with its unique combination of spin-dependent symmetries, net-zero magnetization, and anomalous Hall transport. Although altermagnetic states have been realized experimentally, their integration into functional devices has been hindered by the structural rigidity and poor tunability of existing materials. First, through cobalt intercalation of the superconducting 2H-NbSe2 polymorph, we induce and stabilize a robust altermagnetic phase and, via angle- and spin-resolved photoemission spectroscopy (spin-ARPES), we directly observe the lifting of Kramers degeneracy. Then, using ultrafast laser pulses, we demonstrate how a low-temperature phase can be quenched. Our findings open pathways to spin-based technologies and lay a foundation for advancing the emerging field of altertronics.

MA 33.13 Wed 18:15 HSZ/0002

Odd-parity-wave spin-polarized multiferroics — •Jan Priessnitz, Johannes Mitscherling, and Libor Šmejkal — Max Planck Institute for Physics of Complex Systems, Dresden, Germany

Combining ferroelectricity with spin polarization in ferromagnets is difficult due to the poor compatibility of insulating band structures and ferromagnetism. Recently, an alternative strategy based on combining time-reversal-broken spin polarization in altermagnetic insulators and ferroelectricity into type-I multiferroics was suggested [1]. Here we propose a different strategy based on time-reversal-symmetric odd-parity-wave spin polarization, which we demonstrate in type-II multiferroics induced by noncollinear magnetism [2,3]. Via state-of-the-art spin group theory and first-principle calculations, we demonstrate the spin polarization in $GdMn_2O_5$, a type-II multiferroic material combining coplanar p-wave magnetic order with ferroelectric order. Furthermore, we propose the antialtermagnetoelectric effect – cross-coupling between ferroelectric and odd-parity-wave time-reversal-symmetric spin polarization. The calculated switching path, influenced by exchange fields and spin-orbit coupling, and consistent with previous studies of ferroelectricity in this material, connects two distinct magnetic states with opposite signs of both electric and spin polarization.

GPU acceleration of atomistic spin dynamics simulations — Mariia Mohylna[1], Anders Bergman[2], Arkadijs Slobodkins[2], Olle Eriksson[2], Anna Delin[1], and •Johan Hellsvik[1] — [1]KTH Royal Institute of Technology, Stockholm, Sweden — [2]Uppsala University, Uppsala, Sweden

The Uppsala Atomistic Spin Dynamics (UppASD) [1,2] code implements algorithms for modelling magnetic materials on microscopic and mesoscopic length scales. In our recent implementation, kernels for magnetic field calculation for bilinear spin-spin pair interaction and one numerical integrator have been implemented with the CUDA programming model for use on NVIDIA GPUs, and the HIP programming model for AMD GPUs. Benchmarks for the simulation of bulk bcc Fe and the spin glass CuMn establish firmly the proposition of high speed-up for magnetization dynamics simulation on GPU hardware. The superior performance of the GPU implementations highlights the compatibility of spin-related problems with GPU architecture.

MA 34.2 Wed 15:15 HSZ/0004

Spin waves in double-layered antiferromagnets: insights from chain models and application to CrN — Seo-Jin Kim[1], Zdeněk Jirák[2], Jiří Hejtmánek[2], Karel Knížek[2], Helge Rosner[1], and •Kyo-Hoon Ahn[2] — [1]Max Planck Institute for Chemical Physics of Solids, D-01187 Dresden, Germany — [2]Institute of Physics, Czech Academy of Sciences, Cukrovarnická 10, 162 00 Praha 6, Czechia

The stability and magnonic properties of double-layered antiferromagnets are examined using two model systems, the linear chain (LC) and the railroad trestle (RT) geometry, and compared with the behavior of the real solid CrN. In the LC, the spin-paired order ($\cdots++--\cdots$) requires alternating ferromagnetic and antiferromagnetic (AFM) exchanges, whereas in the RT geometry an analogous order remains stable even with purely AFM interactions under specific analytical conditions. In CrN, the rock-salt structure causes strong magnetic frustration because each Cr atom has twelve symmetry-equivalent AFM nearest neighbors. Below T_N = 287 K, however, a magnetostructural transition to an orthorhombically distorted phase generates four distinct Cr-Cr distances and, consequently, a broad distribution of exchange strengths. This diversification suppresses frustration and stabilizes the double-layered AFM order. We trace this behavior to the competition between Cr–Cr direct exchange and 90° Cr–N–Cr superexchange, both exhibiting characteristic power-law dependencies on the interatomic distances. Finally, using *ab initio* exchange parameters, we derive the magnon spectrum and the temperature evolution of the ordered moments.

MA 34.3 Wed 15:30 HSZ/0004

Magnetoelastic behavior calculations in tetragonal systems — •Jakub Sebesta and Dominik Legut — IT4Innovations, VSB-TU Ostrava, 17.listopadu 2172/15, 708 00 Ostrava-Poruba, Czech Republic

In modern devices, various energy conversion effects are used for efficient operation. One of these effects represents magnetoelasticity – the conversion between the magnetic and mechanical energy. It is widely used in sensors or actuators *e.g.* force or torque sensors, fuel injectors, micro-pump, etc. So far, high symmetry systems, such as ferromagnetic 3d elements or rare-earth-based Laves phases, have been studied especially. In contrast ,here we provide a theoretical investigation of magnetoelastic behavior in tetragonal systems, focusing on the determination of the magnetoelastic properties influenced by the magnetic structure, and investigating the source of the observed modification. Eventually, we discussed a simple theoretical model for the magnetoelasticity in the considered systems.

Ontology-driven Metadata for Multiscale Magnetism: The mammos-entity tool — •Andrea Petrocchi[1], Swapneel Amit Pathak[1], Martin Lang[1], Samuel J. R. Holt[1], Wilfried Hortschitz[2], Santa Pile[2], Martin Dobiasch[2], Thomas Schrefl[2], and Hans Fangohr[1] — [1]MPSD, Hamburg, Germany — [2]UWK, Krems, Austria

In science numerical values are interpretable only when their units and semantic meanings are known. Ontologies are able to identify physical quantities (i.e. using unique labels) and the provenance of data (i.e. the source and process creating it). The magnetic materials ontology is developed within the MaMMoS project and defines magnetic material properties and their interrelationships across various length scales.

In this talk, we present the core capabilities and limitations of mammos-entity, a Python package focused on one essential subset of information (called entity) needed for reliable data exchange: value, unit, and ontology label. This package facilitates working with entities programmatically, streamlines reading and writing data enriched with units and ontology identifiers as metadata and improves FAIRness of data. The aim is to make semantic annotation of data simple enough for everyday use. The mammos-entity package emerges from the magnetism community but supports all quantities defined in the EMMO (https://emmc.eu/emmo/).

MA 34.5 Wed 16:00 HSZ/0004

Prediction of Iron Atom Magnetic Moments in Fe-Al Alloys via SOAP-based Neural Network Models — •Vojtěch Ráliš[1,2], Martin Friák[1], Jan Fikar[1], and Aleš Horák[2] — [1]Institute of Physics of Materials, v.v.i., Czech Academy of Sciences, Brno, Czech Republic — [2]Faculty of Informatics, Masaryk University, Brno, Czech Republic

We investigate neural network approaches for predicting local magnetic moments of iron atoms in Fe-Al disordered alloys using a dataset of 227 unit cells (27–216 atoms) with Al concentrations of 0–60%, totaling 6880 Fe atoms (mean: 2.013 μ_B, std: 0.424 μ_B) from DFT calculations.

Local environments are encoded using SOAP descriptors with a cutoff capturing the first three coordination shells, yielding rotation- and translation-invariant features. Our feedforward neural network achieves MAE = 0.0436 μ_B on the test set, significantly outperforming a first-neighbor baseline (MAE = 0.121 μ_B) and CHGNet (MAE = 0.215 μ_B), while requiring far less memory and compute time.

These results demonstrate the effectiveness of SOAP-based neural networks for fast, accurate prediction of electronic properties in metallic alloys, with implications for large-scale computational screening and local magnetic phenomena studies.

MA 34.6 Wed 16:15 HSZ/0004

Material Parameter Determination with Deep Learning — •Jack Smith[1,2], Dieter Suess[1], and Florian Slanovc[2] — [1]University of Vienna, Vienna, Austria — [2]Silicon Austria Labs, Villach, Austria

Measuring a set of material parameters from stray field measurements presents a challenging inverse problem. In this work, we introduce a data-driven approach for this task using a probabilistic neural network.

A standard regression approach can fail to capture the non-uniqueness of this task, leading to unphysical predictions. To mitigate this, we model the conditional probability distribution of the material parameters and measured stray field. We use a mixture density network (MDN)[1], which combines a neural network with a mixture density model, to model this conditional probability distributions. To capture spatial correlations, we employ a convolutional neural network feature extractor that projects the stray field map into a high-dimensional latent space before probabilistic decoding with the MDN.

We demonstrate that this method can extract ground-truth parameters with high accuracy, even for visually indistinguishable stray fields. It also provides a quantifiable uncertainty, identifying regimes where the stray field solution is non-unique and traditional inversion methods would fail.

Automated Magnetism Analysis via Tensorial Interacting Spins — •Haichang Lu[1,2] and Stefan Blügel[3,4] — [1]Fert Beijing Institute, MIIT Key Laboratory of Spintronics, School of Integrated Circuit Science and Engineering, Beihang University, Beijing, 100191, China — [2]Engineering Department, Cambridge University, Cambridge CB2 1PZ, UK — [3]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [4]Institute for Theoretical Physics, RWTH Aachen University, 52062 Aachen, Germany

Analyzing and describing magnetism in materials with localized moments requires accurate and generalizable spin models that go beyond conventional scalar or vector exchange interactions. Here we present *AMATIS*: an automated computational workflow that systematically incorporates tensorial spin interactions (non-relativistic and relativistic) into the effective Hamiltonian. Grounded in quantum spin properties and group theoretical analysis, tensorial components are extracted from the constrained least-squares fitting, ensuring fidelity to *ab initio* data. An integrated Monte Carlo module allows for the simulation of finite-temperature magnetic thermal equilibrium properties. We demonstrate the utility of this workflow on a series of two-dimensional magnetic materials and a van der Waals heterostructure, revealing the full spectrum of relevant tensorial interactions and their impact on magnetic properties. This approach offers a robust, high-throughput pathway from atomic structure to magnetic behavior, advancing the predictive design of novel magnetic materials.

MA 34.8 Wed 17:00 HSZ/0004

Forestalled phase separation as the precursor to stripe order and superconductivity — •Aritra Sinha and Alexander Wietek — Max Planck Institute for the Physics of Complex Systems

Stripe order is a key feature of the cuprate phase diagram and appears as the ground state of the two-dimensional Fermi-Hubbard and t-J models in relevant regimes. With increasing temperature, stripe and superconducting orders give way to the strange metal and pseudogap phases, whose microscopic origins remain unclear. Using advanced tensor-network simulations, we try to identify the real-space mechanisms behind this evolution. iPEPS reveals a strong peak in the uniform charge susceptibility above the stripe phase near hole doping p=0.1, sharpening on cooling. METTS simulations on finite cylinders trace this peak to fluctuating charge clusters, resembling incipient phase separation into hole-rich and hole-poor regions-ultimately prevented by stripe order at low temperature. In the doped Mott regime of the t-t'-J model, we find that fluctuating domain walls of doped holes act as precursors to superconductivity. At low T, transient mergers of hole-rich regions create larger clusters containing superconducting condensates, which gradually phase-lock upon cooling into a coherent, stripe-aligned d-wave superconductor. Together, these results suggest a unified picture where charge and pairing fluctuations evolve into stripe order and superconductivity, clarifying their intertwined roles in strongly correlated systems.

MA 34.9 Wed 17:15 HSZ/0004

Anisotropic Ligand-Mediated Magnetic Interactions in Strongly Correlated Layered Antiferromagnet $GdTe_3$ — •Sergii Grytsiuk[1], Patrik Thunström[2], Mikhail I. Katsnelson[1], and Malte Rösner[1] — [1]Radboud University, Institute for Molecules and Materials, Nijmegen, The Netherlands — [2]Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

In this study, we investigate the magnetic properties of $GdTe_3$ through first-principles calculations and spin-dynamics simulations. We reveal that its complex phase diagram arises from the interplay between the antiferromagnetic isotropic exchange of Gd localized f- and delocalized d-states and the substantial anisotropic exchange with Te ligand-conducting p-states. Despite the half-filled nature of Gd-f states suggesting a lack of magnetocrystalline anisotropy (MCA), we identify that the anisotropic coupling of it with ligand states serves as the primary source of MCA. This coupling is significantly influenced by the magnetic ordering of neighboring localized spins and is sensitive to charge density waves (CDW). It can also be tuned via magnetic field, temperature, and pressure. By linking the ligand spin-orbit coupling and induced magnetic moments to the effective interactions among localized spins, we successfully reproduce the experimental magnetic susceptibility across varying temperatures, magnetic fields, and pressures.

MA 34.10 Wed 17:30 HSZ/0004

operator Lanczos approach enabling neural quantum states as real frequency impurity solvers — •Jonas Rigo[1] and Markus Schmitt[1,2] — [1]Forschungszentrum Jülich GmbH, Peter Grünberg Institute, Quantum Control, 52425 Jülich, Germany — [2]University of Regensburg

To understand the intricate exchange between electrons of different bands in strongly correlated materials, it is essential to treat multi-orbital models accurately. For this purpose, dynamical mean-field theory (DMFT) provides an established framework, whose scope crucially hinges on the availability of efficient quantum impurity solvers. Here we present a real-frequency impurity solver based on neural quantum states (NQS) combined with an operator-space Lanczos construction. NQS are an asymptotically unbiased variational ground-state ansatz that employs neural networks to capture long-range correlations on complicated graph structures. We leverage this ability to solve complex multi-orbital impurity problems using a systematically improvable segmented commutator operator Lanczos (SCOL) construction. Our benchmarks on both the single-orbital Anderson model and the multi-orbital Hubbard–Kanamori impurity Hamiltonian reveal excellent ground state precision and the capacity to resolve key features of zero temperature spectral functions and self-energies. These promising results open avenues for extending DMFT to more challenging problems.

MA 34.11 Wed 17:45 HSZ/0004

Theoretical study of doping and pressure effects in organic magnets — Rohit Pathak[1,2], Isabella Rudengren[1,2], Torbjörn Wigren[1], Anna Delin[2,3], Olle Eriksson[1,2], Niklas Wahlström[1,2], and •Vladislav Borisov[1,2] — [1]Uppsala University, Sweden — [2]Wallenberg Initiative Materials Science for Sustainability, Sweden — [3]KTH Royal Institute of Technology, Stockholm, Sweden

Technologically important permanent magnets used nowadays rely on rare-earth elements and are associated with negative environmental impact and high energy costs, when produced. On the other hand, organic magnets are known, which can solve these problems, but their applications are limited due to low ordering temperature and coercivity. In this work, we aim to explore further the class of organic magnets to find ways of improving their magnetic properties, which would allow their applications and potentially even partial replacement of inorganic magnets. Also, fundamental aspects of organic magnets are studied in terms of delocalized nature of magnetism. Using first-principles electronic structure theory and atomistic spin dynamics (UppASD code [1]), we model magnetic properties of different compounds including the effects of chemical doping and mechanical pressure to understand the structural and chemistry-related trends. Machine-learning models for property prediction and structure reverse engineering will be applied to make the search for new magnets feasible.

MA 34.12 Wed 18:00 HSZ/0004

Ground-state phases and excitation spectra of dipole conserving spin-half chain — •Prabhakar Prabhakar[1], Soumya Bera[1], and Giuseppe De Tomasi[2] — [1]Department of Physics, Indian Institute of Technology Bombay, Mumbai 400076, India — [2]CeFEMA-LaPMET, Departamento de Fisica, Instituto Superior Tecnico, Universidade de Lisboa, Portugal

We explore the ground state phase diagram of a translationally invariant, non-integrable one-dimensional spin chain with dipole conservation. The model is typically realized in quantum simulators, such as cold-atom setups, in the presence of a large, tilted electric field. Despite the strong kinetic constraints imposed by dipole conservation, which prevent the propagation of isolated spin excitations and suppress single-spin order, the system stabilizes an antiferromagnetic dipole-ordered ground state. However, at a large Ising interaction strength, the model shows a phase transition to a spin-ordered phase. Using exact diagonalization along with density matrix renormalization group simulations, we examine the associated phases with different antiferromagnetic order parameters, the entanglement spectrum, and the dynamical spectral function.

Magneto-optic Kerr effects of higher order in magnetization in thin films of different crystal orientations — •Timo Kuschel — Johannes Gutenberg University Mainz, Germany

The magneto-optic Kerr effect (MOKE) is an important tool to study magnetic properties of thin films. While the MOKE contribution linear in magnetization (LinMOKE) is mainly used for Kerr imaging, Kerr spectroscopy, time-resolved MOKE, and vectorial magnetometry of ferromagnetic thin films [1], the MOKE contributions quadratic in magnetization (QMOKE) [2] have been used for investigations of antiferromagnetic materials, spin-orbit torques, and structural order of Heusler compounds [3]. Recently, we have identified MOKE contributions of third order in magnetization (cubic MOKE, CMOKE) [4] and studied its dependence on the structural domain twinning of Ni(111) thin films.

In this talk, I will introduce these MOKE effects of higher order and describe their angular dependencies with respect to the crystal orientations of the thin films. While it is quite simple to find CMOKE in (111)-oriented films, it is not straightforward to identify it in (001)-oriented samples. I will discuss the reasons. Furthermore, I will report on the material systems that have shown CMOKE so far and mention potential applications.

Ignition of spin-triplet supercurrent in a ballistic S/F/S Josephson junction with precessing magnetization — •Elizaveta Andriyakhina, Miad Mansouri, Maxim Breitkreiz, and Piet Brouwer — Freie Universität Berlin, Germany

We develop a theory for a ballistic Josephson junction with a ferromagnetic (including half-metallic) interlayer whose uniformly precessing magnetization generates a controllable equal-spin (triplet) supercurrent. In a co-rotating frame, the driven junction maps to an effective static problem that can be treated with a scattering-matrix approach to obtain Andreev bound states and the dc Josephson current.

A key result is that steady precession produces a spin-dependent non-equilibrium occupation in the rotating frame, yielding a finite dc supercurrent. In the half-metal limit the junction is "off" without precession, but becomes "on" when a finite precession angle induces phase-sensitive Andreev levels and a triplet current.

For small precession angles, the induced current is approximately sinusoidal in phase and the critical current scales quadratically with the precession angle (and with drive parameters), enabling microwave-controlled switching via ferromagnetic resonance.
