Dear Conference Guests,

On behalf of the German Physical Society (DPG), I would like to warmly welcome you to the DPG Spring Meeting of the Condensed Matter Section (SKM) at Dresden University of Technology. Dresden is an important and long-established venue for DPG Spring Meetings. This support from Dresden University of Technology, renowned for its outstanding science and research, is also invaluable in strengthening the visibility and appreciation of physics in society and politics.

I am particularly pleased that France, represented by the Société Française de Physique (SFP), is our guest country at this conference in Dresden. To mark this special occasion, various prominent events will be held during the conference to promote scientific exchange and networking with our French partners. All conference participants are cordially invited to attend these events!

Our DPG Spring Meetings, which attract several thousands participants each year, have been very successful for decades – and they are also regularly among the largest physics conferences in Europe! That alone is a great achievement by all those involved. This year's outstanding conference programme in Dresden, with its wide range of topics, is also of inestimable importance for communication aimed at strengthening the perception and appreciation of physics in our society: it impressively demonstrates the strength of physics research and the special social responsibility that comes with it, namely to contribute to solutions for major global challenges through scientific findings from basic research.

I am also delighted that numerous companies from industry and business regularly show great interest in the DPG Industry and Book Exhibition. For this reason, this exhibition will also take place at our conference in Dresden. The exhibition also offers conference participants the opportunity to network with representatives from industry and business in a relaxed conference atmosphere through direct personal exchange, while also helping companies to attract skilled talents.

I would also like to point out that the DPG's communication focus for 2026 is artificial intelligence in the context of physics. Our goal is to promote discussion within physics and raise public awareness of the relevance of physics to AI research and development – and, last but not least, of the importance of AI in physics studies. Our DPG Spring Meeting in Dresden, with the participation of the Working Group on "Physics, Modern IT, and Artificial Intelligence" (AKPIK), offers ideal opportunities for discussions on these aspects as well.

The success of this Spring Meeting is only possible with the greatest commitment of many persons. I would like to express my sincere thanks to everyone involved. First of all, I would like to thank Dresden University of Technology for their hospitality and support. Many thanks also to the Wilhelm und Else Heraeus-Stiftung for generously supporting all DPG Spring Meetings. I would also like to thank the spokespersons of the DPG Condensed Matter Section, Prof. Sarah Köster and Prof. Elke Scheer, and the chairpersons of participating DPG Divisions and Working Groups for organising the excellent scientific programme. My special thanks go to the local organising committee at TU Dresden, headed by Prof. Jochen Geck, Institute of Solid State and Materials Physics. Finally, I would like to thank the DPG Head Office for its great support of all Spring Meetings.

Prof. Dr. Klaus Richter

President
Deutsche Physikalische Gesellschaft e. V.

Programme

The scientific programme consists of **4,788** contributions:

11	Plenary Talks
1	Evening Talk
8	Prize Talks
1	Ceremonial Talk
4	Lunch Talks
255	Invited Talks
68	Topical Talks
3,157	Contributions
13	Tutorials
1,264	Posters
6	Discussions

The programme stated in this document corresponds to the status of January 30, 2026 and will not be updated!

MORE INFO

Information for Participants

The conference will be held March 8 – 13, 2026.

Guest Country at the Conference
For the 2026 edition of the Spring Meeting of the Condensed Matter Section we are very happy to welcome France, represented by the Société Française de Physique (SFP), as our guest country.

On this special occasion, we will feature a number of events during the conference. We invite all conference participants to join these events and use the opportunity to strengthen their networks with our neighbours.

Conference Information

Mutual Respect at Conferences
All participants are requested to contribute to a conference that values respect and a spirit of open communication. Please be mindful in your interactions with other participants – whether during individual sessions or elsewhere during the conference, and consider that individuals with diverse backgrounds may be sensitive to different forms and manifestations of social behavior, scientific criticism, and appreciation. Also note that any form of encroaching behaviour has no place at the DPG's meetings. Do not hesitate to contact the conference's awareness team, the conference office or the local conference organisers in the event of disturbances. The conference organiser will take appropriate action.

Conference Venue
Technische Universität Dresden (TUD)
Campus Südvorstadt
Bergstraße 64
01069 Dresden

The conference will take place on the campus Südvorstadt of the TUD. The central activities like registration etc. will take place in the Lecture Hall Center (HSZ) of the TUD (Bergstraße 64). For a detailed map of the campus and the buildings please see "Maps" at the end of this document. The position of the lecture rooms on the campus can be found at the campus navigator of TU Dresden *https://navigator.tu-dresden.de/* or the DPG-App.

Conference Office / Information Desk
The conference office and the information desk are located in the Lecture Hall Center, HSZ E01. The opening hours are the following:

		Registration	**Information Desk**
Sunday	March 08	15:00 – 19:00	15:00 – 20:00
Monday	March 09	08:00 – 18:00	08:00 – 20:00
Tuesday	March 10	08:00 – 16:00	08:00 – 18:00
Wednesday	March 11	08:00 – 16:00	08:00 – 18:00
Thursday	March 12	08:00 – 16:00	08:00 – 18:00
Friday	March 13	08:00 – 12:00	08:00 – 15:00

You will receive your name tag, a receipt for your conference fee, the login password for using WiFi as well as food and drink vouchers for the Welcome Evening (Sunday 18:30-21:30). The name tag must be worn visibly during the entire conference.
The organisers, staff of the conference desk and student assistants will be identifiable by colored name tags and T-shirts. Please contact them if you have any questions. Do not hesitate to come to the information desk and inquire about all necessary information concerning the conference, orientation in Dresden, accommodation, restaurants, going out and cultural events.

Lecture Rooms
The lecture rooms will be signposted by abbreviations for the respective buildings and the room number. The campus map and location of the buildings are printed at the end of this document.

Abbr.	**Building**		
BAR	Barkhausen-Bau	POT	Gerhard-Potthoff-Bau
BEY	Beyer-Bau	SCH	Georg-Schumann-Bau
CHE	Chemiegebäude (Chemistry Building)	TRE	Trefftz-Bau
REC	Recknagel-Bau	Tent A	Tent behind the Lecture Hall Center / Exhibition
GER	von-Gerber-Bau	Tent C	Mommsenstr. 10 (in front of the 'Alte Mensa' Mommsenstraße)
GÖR	Görges-Bau	WIL	Willers-Bau

HÜL	Hülsse-Bau	ZEU	Zeuner-Bau
HSZ	Hörsaalzentrum (Lecture Hall Center)	MER	Merkel-Bau

Presentations
Scientific presentations will be held either as oral presentations or posters. Presentations are typically held in English.

Oral Presentations
Speakers are requested to provide their presentations electronically. All lecture rooms are equipped with a projector ("beamer") with HDMI input.

Laptops as well as necessary hdmi adapters must be provided by the speakers. Furthermore, please bring a copy of your presentation in pdf or pptx format on a USB flash drive.

All laptops must be set up and connected with the projector before the start of the respective session. All rooms will be opened at latest 30 minutes prior to the session. Speakers are requested to be in the lecture room at least 20 minutes prior to the start of the session, to report to the chairperson as well as the technical staff, to ensure that the laptops handshake with the projector, and to receive a brief introduction to the equipment in the lecture room.

Poster Presentation
Sites for poster sessions are named and located as follows:

P1	Tent A behind the Lecture Hall Center (Exhibition Tent)
P2	Tent C Mommsenstraße 10 (in front of the Mensa 'Mommsenstraße')
P4	Room HSZ/0304, 3rd floor
P5	Room ZEU/0250, 2nd floor

Posters must fit within a rectangle 90 cm wide and 120 cm high (DIN A0), portrait format!

The poster boards will be marked with the number according to the scientific programme. Authors are asked to mount their poster when the poster board is prepared with the corresponding poster number. Usually this will be arranged in the morning, or one hour before the session when there are several poster sessions per day. Each poster should display the number according to the scientific programme.

For the mounting of the poster please use the prepared "power strips" at the poster frame or contact the available student staff. Please make sure to use only power strips for mounting the poster (residue-free removing). The presenting authors should be available for discussion at their poster during for at least half of the poster session and should announce by a note this time at the poster.

The posters have to be removed after the poster session. Any posters remaining on display walls after the poster session will be removed and disposed of without requesting your permission. The conference management accepts no liability for the posters.

Notice Board
All changes to the conference programme (i.e. cancellation of presentations, change of rooms, etc.) are transferred directly to the online version of the programme which is available in different formats (sorted by publication date, filterable by conference parts and as an rss-feed). Please use the form *dresden26.dpg-tagungen.de/programme/notice-board-form* to notify changes or cancellations. All changes are also displayed in the DPG app so that the displayed programme is always up-to-date.

Communication / Internet Access
EDUROAM
The TU Dresden is member of the eduroam-network. Users from eduroam institutions, who have registered for eduroam, can use WLAN at the TU Dresden without local registration in Dresden. Eduroam in Dresden is possible with WLAN SSID eduroam.

WiFi in the buildings of TU-Campus
For internet access at TU Dresden, please use your individual login-password on your registration document. Please search for and connect to the network named "VPN/WEB". After you have been connected, please visit any website with your browser to get redirected to the login page of the network. Enter your username and password and click on "Login". Afterwards you should be able to access the internet. This connection is not encrypted.

Public Working Area
Public working rooms which you can use as workspace are located in BEY/0117, BEY/0E25 and MER/0003.

Cloakroom
In the basement of the Lecture Hall Centre (HSZ) you will find a cloakroom free of charge managed by student assistants. The opening hours are as follows:

Sunday	March 08	15:00 — 21:30
Monday	March 09	08:00 — 21:30
Tuesday	March 10	08:00 — 20:30
Wednesday	March 11	08:00 — 20:30
Thursday	March 12	08:00 — 22:00
Friday	March 13	08:00 — 14:00

Lost and Found Property
Please bring found items to the Lecture Hall Center, room E03 (next to the information desk). There you can also get your lost property back.

Catering

Coffee Breaks
Coffee and tea are offered for free during the breaks in nearly all conference locations (see also in the legend of the campus map). You want to actively contribute to protect our climate and environment? Then please bring your own cup or use your paper cup several times. Thank you!

Snacks
You can get coffee, tea, refreshments and snacks as indicated in the campus map at the:

• Tent B behind the Lecture Hall center	Monday to Thursday, 08:00 – 15:00; Friday 08:00 – 14:00
• Restaurant of the Leibniz-Institute IFW Dresden	Monday to Friday, 08:00 – 15:00
• „insgrüne coffeebar“ in the Georg-Schumann-Bau (SCH)	Monday to Friday, 10:00 – 15:00
• Cafeteria & Mensa ‘Alte Mensa’, Mommsenstraße 13	Monday to Thursday, 08:00 – 16:00; Friday 08:00 – 15:00
• Cafeteria & Mensa Zeltschlösschen, Nürnberger Str. 55	Monday to Friday, 08:00 – 15:30
• Cafeteria & Mensa Siedepunkt, Zellescher Weg 17	Monday to Friday, 11:00 – 14:30

as well as at Bergstr. 68 „FIRAT-Kebap-Haus“ and Münchner Str. „DERSIM-Dürüm-Kebab-Haus“ and bakery „Möbius“.

Lunch
The Mensa Zeltschlösschen, Mensa Siedepunkt and the ‘Alte Mensa’ Mommsenstraße offer plenty of opportunities for lunch at moderate prices (self-payment). The IFW restaurant offers regular meals for a limited number of conference participants.

Wilhelm and Else Heraeus Communication Programme
Important notes for participants who apply for a grant in the WEH Communication Programme:
When registering at the conference office, you will receive your receipt of the conference fee along with a certificate for the WE-Heraeus Communication Programme. Please keep this document safe. Participation in the conference must be certified at the conference office with a stamp on the WEH receipt on the day of departure. You have the possibility to leave the stamped certificate with the staff members of the DPG (recommended!) or submit it to the DPG head office *weh@dpg-physik.de* by April 3, 2026 at the latest. For more detailed information refer to *weh.dpg-physik.de.*

The Deutsche Physikalische Gesellschaft thanks the Wilhelm and Else Heraeus Foundation for the generous financial support of young academic talents. We hope that young physicists will continue to seize the offered opportunity for active scientific communication at scientific conferences. A total of about 44,800 young academics were supported by this programme so far.

CO_2 Compensation for the DPG Conferences
By decision of its council, the DPG will compensate for fossil CO_2 emissions resulting from mobility for DPG conferences and committee meetings.

Acknowledgement
The Deutsche Physikalische Gesellschaft (DPG) and the local organisers want to thank the following institutions for supporting the conference:

- the Wilhelm and Else Heraeus Foundation, Hanau
- the TU Dresden
- the official sponsors of the DPG-Frühjahrstagung
- and all staff, who make the success of the conference possible.

SAY CHEESE!
The DPG Spring Meetings are basically public to the press. Please note: On behalf of DPG, photos and videos will be recorded during the Spring Meetings. In the context of public relations, these recordings (as the case may be) will be published on our website, in social media or within prints of the DPG for example.

Liability Exclusion
Participants are asked to look carefully after their wardrobe, valuables, laptops, and other belongings. The organisers decline any liability.

Social Events (in chronological order)

Welcome Evening
On Sunday, March 8, 18:30 – 21:30 the Welcome Evening will be held in the 'Alte Mensa', Mommsenstraße 13. Snacks, beer and soft drinks will be served. Do not miss the opportunity to register (15:00 – 19:00) before the official beginning of the conference and to meet people in an informal atmosphere. When registering for the conference you will receive your badge and food and drink vouchers for the Welcome Evening. Please wear your badge which you have received at the registration.

Opening of the Conference
A short opening address will be given by the chair of the Condensed Matter Section (SKM) on Monday, March 9 from 8:25 until 8:30 in HSZ/AUDI.

Einstein Slam
Monday, March 9, 20:00, HSZ/AUDI
Einstein Slam is the competitive art of making complex science accessible to a broad audience. There are just 10 minutes for every attendee to present their self-made performance. The event will finish with a public poll in order to evaluate if a particular contribution was either instructive and amusing or rather should have never been performed. All presentations will be given in English. For more information please refer to *www.einstein-slam.de*.

Ceremonial Session with Award Ceremony
On Tuesday, March 10, at 16:00 the Ceremonial Session with Award Ceremony will take place in HSZ/AUDI. The programme is as follows:

Music
"*SCHOOKO DUO*"

Welcome
Prof. Dr. Jochen Geck, TU Dresden
Local Organiser

Speech
Prof. Dr. Klaus Richter
President of the Deutsche Physikalische Gesellschaft e.V.

Music

Award Ceremony

Walter-Schottky-Prize 2026
to Dr. Marcel Reutzel, Georg-August-Universität Göttingen / Philipps-Universität Marburg

Gaede-Prize 2026
to Dr. Anna Rosławska, MPI für Festkörperforschung, Stuttgart

Dissertation Prize of the Condensed Matter Section 2026
(The Laureate will be announced after the SKM-Dissertations-Prize Symposium)

Music

Ceremonial Lecture
Prof. Dr. Frank Wilhelm-Mauch, Forschungszentrum Jülich GmbH
"*Quantum computers as large research instruments – what can we expect and how do we develop them?*"

jDPG Pub Crawl
Tuesday, March 9, 20:00
Meeting Point: in front of the Hörsaalzentrum HSZ (Bergstraße side)
On Tuesday evening, the young DPG invites to a pub crawl through Dresden. Next to the opportunity to be on a move outside and network with others, the members of the local regional group will tell about the Dresden physics, the life in the city and other facts worth knowing.

Exhibition of Scientific Instruments and Literature
From Tuesday to Thursday there will be an exhibition of Scientific Instruments and Literature. The exhibition will take place in the exhibition tents A (beside the Lecture Hall Centre) and C (Mommsenstraße 10). More than 130 companies (see list of exhibitors at the end of this document) will present their products. Opening hours are from 09:30 to 18:00 (Thursday until 15:00). All conference participants are welcome to attend the exhibition. The entrance is free.

Public Evening Talk (in german language)
Wednesday, March 11, 19:00 – 20:00, HSZ/AUDI
Prof. Dr. Michèle Heurs, Leibniz Universität Hannover, will speak about "*Gravitationswellenastronomie — quo vadis?*"
The public evening talk is open for the interested public and all conference participants. The entrance is free.

Members' Assemblies of the Divisions and Working Groups
During the DPG Spring Meeting, Members' Assemblies of the DPG divisions and working groups take place. Please refer to the scientific programme for the time and place of the meetings.

16:00	BEY/0137	TUT 2	**Tutorial des Fachverbands Didaktik der Physik**
16:00	BEY/0137	TUT 2.1	Rethinking University Teaching: Creating interactive and sustainable learning environments in lectures •Susanne Heinicke
16:00	HSZ/0003	TUT 3	**Tutorial: Machine Learning Use Cases in Materials Science**
16:00	HSZ/0003	TUT 3.1	Welcome Remarks Arbeitskreis Physik, moderne Informationstechnologie und Künstliche Intelligenz •Arash Rahimi-Iman
16:05	HSZ/0003	TUT 3.2	A practical machine learning case study in materials science: Stumbling blocks, lucky breaks, and helpful colleagues •Max Grossmann, •Malte Grunert
16:50	HSZ/0003	TUT 3.3	Machine Learning-based Analysis of Electron Microscopy Images: Preprocessing and Synthetic Data Generation •Amir Omidvarnia
17:35	HSZ/0003	TUT 3.4	Machine Learning-based Analysis of Electron Microscopy Images: Segmentation •Amir Omidvarnia
16:00	HSZ/0004	TUT 4	**Tutorial: Physics of Behavior**
16:00	HSZ/0004	TUT 4.1	Physics of Behavior •Greg Stephens
17:15	HSZ/0004	TUT 4.2	Physics of Behavior •Antonio Carlos Costa
16:00	TRE/PHYS	TUT 5	**Hands-On Tutorial: Magnetic Structure Determination Using Fullprof and SARAh Representation Analysis**
16:00	TRE/PHYS	TUT 5.1	Recent advances and challenges in magnetic structure determination •Dmytro Inosov
16:30	TRE/PHYS	TUT 5.2	Hands-On Tutorial: Magnetic Structure Determination Using Fullprof and SARAh Representation Analysis •Matthias Frontzek
16:00	TRE/MATH	TUT 6	**Hands on Tutorial: Linking large language models with digital workflows for materials science simulations**
16:00	TRE/MATH	TUT 6.1	Hands on Tutorial: Linking large language models with digital workflows for materials science simulations •Jörg Neugebauer

18:30	Mensa Mommsenstraße	**Welcome Evening** (for registered participants)

Monday, March 9, 2026

Plenary Talks

08:30	HSZ/AUDI	PV I	Cavity-altered superconductivity •Dmitri Basov
14:00	HSZ/AUDI	PV II	Towards Intelligent Matter: Energy-Efficient In-Materio Computing •Karin Everschor-Sitte
14:00	HSZ/0002	PV III	Simulating the Hubbard model with moiré semiconductors •Jie Shan

Prize Talk

13:00	HSZ/0002	PRV I	Driven Quantum Materials: Controlling Emergent Phenomena away from Equilibrium •Andrea Cavalleri (Laureate of the Stern-Gerlach-Medal)

Lunch Talk, Discussion

13:00	HSZ/AUDI	PSV I	Sustainability! And now? – Opportunities for young researchers •Roxana Scharpegge
13:00	HSZ/0004	PSV II	Physics Meets Statistics: Advancing Data Analytics in Semiconductor Manufacturing •Sarah Fischbach

SYFC

Invited Talks

09:30	HSZ/AUDI	SYFC 1.1	Subcycle videography of strong-field controlled band structures •Rupert Huber
10:00	HSZ/AUDI	SYFC 1.2	Engineering Quantum Materials through Structured Cavity Vacuum Fluctuations •Angel Rubio
10:30	HSZ/AUDI	SYFC 1.3	Floquet engineering of quantum materials: from semiconductors to semimetals •Shuyun Zhou
11:15	HSZ/AUDI	SYFC 1.4	(Quantum) Light Control of Materials •Dante Kennes
11:45	HSZ/AUDI	SYFC 1.5	Lightwave-driven electrons in a Floquet topological insulator •Peter Hommelhoff

Session

09:30	HSZ/AUDI	SYFC 1	Designing Quantum Materials With Light: from Floquet to Cavity Engineering

SYSC

Invited Talks

15:00	HSZ/AUDI	SYSC 1.1	Open-Endedness and Community-Based Approaches to Sustainability Challenges •Hiroki Sayama
15:30	HSZ/AUDI	SYSC 1.2	Education as a Social Tipping Element: Evidence from Climate and Physics Education Research •Thomas Schubatzky
16:00	HSZ/AUDI	SYSC 1.3	Mechanistic and Material Perspectives on Enzymatic Hydrolysis of Semicrystalline Polyesters •Birte Höcker
16:45	HSZ/AUDI	SYSC 1.4	Decarbonization Options for Industry •Uwe Riedel
17:15	HSZ/AUDI	SYSC 1.5	Impacts of Cosmic Dust and Space Debris in the Terrestrial Atmosphere •John Plane

Session

15:00	HSZ/AUDI	SYSC 1	The Sustainability Challenge: A Decade of Transformation

Monday, March 9, 2026

SYSD

Invited Talks

09:30	HSZ/0002	SYSD 1.1	Stochastic-Calculus Approach to Non-equilibrium Statistical Physics •Cai Dieball
10:00	HSZ/0002	SYSD 1.2	Nonuniform magnetic spin textures for sensing, storage and computing applications •Sabri Koraltan
10:30	HSZ/0002	SYSD 1.3	Anomalous Quantum Oscillations beyond Onsager's Fermi Surface Paradigm •Valentin Leeb
11:00	HSZ/0002	SYSD 1.4	Coherent Control Schemes for Semiconductor Quantum Systems •Eva Schöll
11:30	HSZ/0002	SYSD 1.5	On stochastic thermodynamics under incomplete information: Thermodynamic inference from Markovian events •Jann van der Meer

Session

09:30	HSZ/0002	SYSD 1	SKM Dissertation Prize Symposium 2026

BP

Invited Talks

11:15	BAR/SCHÖ	BP 1.7	Modeling and inference of magnetotactic motility in complex environments •Stefan Klumpp
09:30	BAR/0205	BP 3.1	The unreasonable effectiveness of computational models in biological patterning and morphogenesis •Michel Milinkovitch
15:00	BAR/SCHÖ	BP 4.1	The Multi-faceted Role of Cholesterol in Cellular Membranes and Lipid Nanoparticles •Rainer Böckmann
17:15	BAR/0106	BP 8.3	Constructing synthetic life-like vesicle systems by integration of artificial metabolic reaction networks •Laura Heinen
16:45	BAR/0205	BP 9.1	Breaking the photobleaching limit in single-molecule FRET with nanophotonic DyeCycling. •Sonja Schmid

Sessions

09:30	BAR/SCHÖ	BP 1	Active Matter I
09:30	BAR/0106	BP 2	Computational Biophysics I
09:30	BAR/0205	BP 3	Tissue Mechanics I
15:00	BAR/SCHÖ	BP 4	Computational Biophysics II
15:00	BAR/0205	BP 5	Membranes, Vesicles and Synthetic Life-like Systems I
15:00	ZEU/0160	BP 6	Active Matter II
15:00	P5	BP 7	Poster Session I
16:45	BAR/0106	BP 8	Systems and Networks Biophysics
16:45	BAR/0205	BP 9	Single Molecule Biophysics

CPP

Invited Talks

09:30	ZEU/LICH	CPP 3.1	Theory and Modeling of Fluid Adsorption and Transport in Nanoporous Materials •Benoit Coasne
09:30	ZEU/0255	CPP 4.1	Exploration of Cathode Materials for Li-S Batteries •Yan Lu
09:30	ZEU/0260	CPP 5.1	Cleaning of dusty surfaces •Doris Vollmer
11:15	ZEU/LICH	CPP 6.1	Hierarchical Porosity Meets Nanoconfined Water: Toward Water-Driven Functional Materials •Patrick Huber

Monday, March 9, 2026

CPP

15:00	ZEU/LICH	CPP 9.1	Why Polymers Swell or Collapse: Molecular Insights into Cosolute Effects •Nico van der Vegt
15:00	ZEU/0255	CPP 12.1	Multifunctional films by tailoring chemistry and morphology of polymer brushes at the nanoscale •Petra Uhlmann
16:30	ZEU/0255	CPP 12.6	Thin-film and interface properties in energy conversion devices unveiled by X-rays •Marcus Bär
15:00	ZEU/0260	CPP 13.1	Modelling and simulation of pH-sensitive polyelectrolyte microgels •Stefanie Schneider
17:15	ZEU/0260	CPP 16.1	Understanding the Passivation Properties of Solid Electrolyte Interphases (SEIs) in Batteries: Generator-Collector Experiments combined with a Transport and Reaction Model •Bernhard Roling

Sessions

09:30	BAR/SCHÖ	CPP 1	Active Matter I
09:30	MER/0002	CPP 2	Sustainability: Challenges and Solutions
09:30	ZEU/LICH	CPP 3	French-German Session: Membranes and Porous Materials I
09:30	ZEU/0255	CPP 4	Energy Storage Materials and Devices I
09:30	ZEU/0260	CPP 5	Wetting, Fluidics and Liquids at Interfaces and Surfaces I
11:15	ZEU/LICH	CPP 6	French-German Session: Membranes and Porous Materials II
11:30	ZEU/0255	CPP 7	Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods I
11:30	ZEU/0260	CPP 8	Wetting, Fluidics and Liquids at Interfaces and Surfaces II
15:00	ZEU/LICH	CPP 9	French-German Session: Simulation Methods and Modeling of Soft Matter I
15:00	ZEU/0118	CPP 10	Droplets, Wetting, and Microfluidics
15:00	ZEU/0160	CPP 11	Active Matter II
15:00	ZEU/0255	CPP 12	French-German Session: 2D Materials, Thin Films and Interfaces I
15:00	ZEU/0260	CPP 13	Charged Soft Matter, Polyelectrolytes and Ionic Liquids
17:15	ZEU/LICH	CPP 14	French-German Session: Simulation Methods and Modeling of Soft Matter II
17:15	ZEU/0255	CPP 15	Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods II
17:15	ZEU/0260	CPP 16	Energy Storage Materials and Devices II
19:00	P5	CPP 17	Poster I

DS

Sessions

09:30	REC/C213	DS 1	Organic Thin Films
15:00	HSZ/0003	DS 2	Focus Session: Tunable Correlations in van der Waals Quantum Materials I
15:00	REC/C213	DS 3	Thin Film Properties I: Methods
16:30	REC/C213	DS 4	Thin Film Properties II

DY

Invited Talks

09:30	ZEU/0114	DY 7.1	Fast Rare Events in Exit Times Distributions of Jump Processes •Raffaella Burioni
11:15	ZEU/0114	DY 7.6	Large deviations in resetting Brownian motions •Satya Majumdar
10:30	ZEU/0118	DY 8.5	Mean-field approach to finite-size fluctuations in coupled oscillator systems •Oleh Omelchenko
15:00	ZEU/0114	DY 15.1	Monte Carlo Simulation Methods for Rare-Event Sampling •Wolfhard Janke
17:00	ZEU/0160	DY 17.8	Topological transition in filamentous cyanobacteria: from motion to structure •Marco Mazza

Monday, March 9, 2026

DY

Sessions

09:30	HSZ/0003	DY 2	Focus Session: New Routes to Localization and Quantum Non-Ergodicity I
09:30	HSZ/0101	DY 3	Quantum-Critical Phenomena
09:30	BAR/SCHÖ	DY 4	Active Matter I
09:30	GÖR/0226	DY 5	Focus Session: Physics of Behavior
09:30	HÜL/S186	DY 6	Machine Learning in Dynamics and Statistical Physics I
09:30	ZEU/0114	DY 7	Focus Session: Large Deviations and Rare Events I
09:30	ZEU/0118	DY 8	Nonlinear Dynamics, Synchronization, and Chaos
09:30	ZEU/0160	DY 9	Statistical Physics far from Thermal Equilibrium I
09:30	ZEU/0260	DY 10	Wetting, Fluidics and Liquids at Interfaces and Surfaces I
11:30	ZEU/0260	DY 11	Wetting, Fluidics and Liquids at Interfaces and Surfaces II
15:00	CHE/0089	DY 12	Focus Session: Relaxation Timescales in Open Quantum Systems
15:00	CHE/0091	DY 13	Focus Session: New Routes to Localization and Quantum Non-Ergodicity II
15:00	HÜL/S186	DY 14	Machine Learning in Dynamics and Statistical Physics II
15:00	ZEU/0114	DY 15	Focus Session: Large Deviations and Rare Events II
15:00	ZEU/0118	DY 16	Droplets, Wetting, and Microfluidics
15:00	ZEU/0160	DY 17	Active Matter II

FM

Invited Talk

15:00	BEY/0138	FM 4.1	(Anti)Ferroelectric HfZrO2: from non volatile memory to energy storage applications •Bertrand Vilquin

Sessions

09:30	BEY/0138	FM 2	Energy Materials
09:30	POT/0151	FM 3	Focus Session: Novel mechanisms of ferroic switching
15:00	BEY/0138	FM 4	Focus Session: (Anti)ferroic states – Non-conventional states I
15:00	BEY/0E40	FM 5	Focus Session: Holistic structural and safety assessment of battery materials and cells

HL

Invited Talks

09:30	POT/0051	HL 2.1	Intrinsically stretchable polymers and devices for biosensing applications •Ulrike Kraft
10:00	POT/0051	HL 2.2	Complexity in Organic Mixed Ionic Electronic Conductors and its Application in Neuromorphic Computing •Hans Kleemann
10:30	POT/0051	HL 2.3	Organic Neuromorphic Interfaces for Biohybrid Systems: Material and Structural Biomimicry of Synaptic Plasticity •Francesca Santoro
11:15	POT/0051	HL 2.4	Fully-organic flexible detectors for real-time dose monitoring during radio/proton therapy •Beatrice Fraboni
11:45	POT/0051	HL 2.5	Organic LEDs and photodetectors for light-based diagnostics and therapy •Caroline Murawski
09:30	POT/0251	HL 4.1	X-ray nanodiffraction studies of lead-halide perovskite supercrystals •Ivan Zaluzhnyy
15:00	POT/0251	HL 11.1	Quantum Repeater Hardware made from Silicon Carbide •Jörg Wrachtrup
15:30	POT/0251	HL 11.2	Diamond based quantum sensing for drug testing •Romana Schirhagl
16:00	POT/0251	HL 11.3	The oxygen-related ST1 centre in diamond: a room temperature coherently controllable electron spin •Sebastien Pezzagna

Monday, March 9, 2026

HL

16:45	POT/0251	HL 11.4	Silicon quantum emitters emitting in the optical telecommunication range for scalable quantum photonic circuits •Yonder Berencén
17:15	POT/0251	HL 11.5	Advances in materials processing for quantum sensing •Adam Gali

Sessions

09:30	POT/0006	HL 1	Optical Properties I
09:30	POT/0051	HL 2	Focus Session: Biocompatible Organic Semiconductors for Artificial Intelligence
09:30	POT/0081	HL 3	2D Materials I – Excitonic properties
09:30	POT/0251	HL 4	Perovskite and Photovoltaics: Synthesis and Performance
10:30	TRE/MATH	HL 5	2D Materials: Electronic structure, excitations, etc. I
15:00	HSZ/0003	HL 6	Focus Session: Tunable Correlations in van der Waals Quantum Materials I
15:00	HSZ/0204	HL 7	2D Materials beyond graphene: Growth, structure and substrate interaction
15:00	POT/0006	HL 8	Ultra-fast Phenomena I
15:00	POT/0051	HL 9	Oxide Semiconductors: Growth and Fabrication
15:00	POT/0081	HL 10	2D Materials II – Electronic and transport properties
15:00	POT/0251	HL 11	Focus Session: Quantum Emitters in 3D Semiconductors
16:45	POT/0051	HL 12	Heterostructures, Interfaces and Surfaces: Photonics
16:45	POT/0081	HL 13	2D Materials III – Interlayer excitons

MA

Invited Talks

09:30	POT/0151	MA 4.1	From ML to Kinetics: Modeling the Switching in Ferroelectric Wurtzites •Andrew Rappe
10:00	POT/0151	MA 4.2	Topological order parameter switching •Sergey Artyukhin
10:30	POT/0151	MA 4.3	Optical Control of Ferroaxial Order via Circular Phonon Excitation •Zhiyang Zeng
15:00	POT/0112	MA 10.1	Multi-field analysis of magnetic materials: Phase-field based simulations of magnetic domains and phase transition •Mobina Alaeddini
15:20	POT/0112	MA 10.2	Realistic Modelling of Finite Temperature Electron Transport Properties in Ferromagnets •Fabian Engelke
15:55	POT/0112	MA 10.3	Exploring magneto- and multicaloric materials for room and cryogenic temperature applications •Benedikt Beckmann
16:20	POT/0112	MA 10.4	Nonlinear magnon dynamics: From the discovery of Floquet magnons to CMOS-compatible magnon computing •Christopher Heins
16:45	POT/0112	MA 10.5	The geometric memory of quantum wave functions •Niclas Heinsdorf
17:10	POT/0112	MA 10.6	Altermagnets and Odd-parity-wave Magnets •Anna Birk Hellenes

Sessions

09:30	HSZ/0004	MA 2	Altermagnets I
09:30	POT/0112	MA 3	Complex Magnetic Oxides
09:30	POT/0151	MA 4	Focus Session: Novel mechanisms of ferroic switching
09:30	POT/0351	MA 5	Surface Magnetism and Topological Insulators
09:30	POT/0361	MA 6	Magnetic Imaging Techniques I
09:30	P2	MA 7	Poster Magnetism I
15:00	HSZ/0002	MA 8	Altermagnets II
15:00	HSZ/0004	MA 9	Magnonics I
15:00	POT/0112	MA 10	INNOMAG e.V. Prizes 2026 (Diplom-/Master and Ph.D. Thesis)
15:00	POT/0151	MA 11	Electron Theory of Magnetism and Correlations
15:00	POT/0351	MA 12	Terahertz Spintronics
15:00	POT/0361	MA 13	Magnetic Heuslers and Semiconductors

Monday, March 9, 2026

MM

Invited Talks, Topical Talks

09:30	SCH/A251	MM 2.1	Deep-Learning and Generative AI for the Discovery of Electron-Phonon Superconductors •Richard Hennig
10:15	SCH/A216	MM 4.1	Photoelectric properties of dislocations in SrTiO3 single crystals •Marin Alexe
10:15	SCH/A251	MM 5.1	Machine Learning for Materials Discovery: from Big Data to Predictive Insights •Silvana Botti
11:45	SCH/A251	MM 5.5	Leveraging data science technologies to enable AI-driven materials design •Tilmann Hickel
15:00	SCH/A251	MM 6.1	Transformation-induced plasticity in zirconia ceramics: simulations and experiments •David Rodney
15:45	SCH/A251	MM 9.1	Atomistic simulations in the ternary Fe-O-H system: interatomic potential development and applications •Baptiste Bienvenu

Sessions

09:30	SCH/A251	MM 2	Invited Talk: Richard Hennig
10:15	SCH/A215	MM 3	Mechanical Properties and Alloy Design I
10:15	SCH/A216	MM 4	Materials for the Storage and Conversion of Energy I
10:15	SCH/A251	MM 5	Topical Session: Physics-driven Artificial Intelligence for Materials I
15:00	SCH/A251	MM 6	Invited Talk: David Rodney
15:45	SCH/A215	MM 7	Mechanical Properties and Alloy Design II
15:45	SCH/A216	MM 8	Materials for the Storage and Conversion of Energy II
15:45	SCH/A251	MM 9	Topical Session: Physics-driven Artificial Intelligence for Materials II

O

Invited Talks, Topical Talk

09:30	TRE/PHYS	O 1.1	Vortices, inter-band coupling and inelastic QPI in two band superconductors •Wulf Wulfhekel
11:00	HSZ/0201	O 2.3	Superconducting Fermi arcs. •Andrii Kuibarov
10:30	HSZ/0403	O 5.1	Can the mineral-water interface save the world? Mineral carbonation, enhanced weathering and negative emissions •Philip Pogge von Strandmann
11:30	HSZ/0403	O 5.4	Machine learning exploration of water binding and ice nucleation at silicate and carbon surfaces •Mie Andersen
10:30	TRE/MATH	O 7.1	Magnetic Order in 2D Materials Beyond Bulk Constraints •Jeison Fischer
11:00	WILL/A317	O 8.3	Controlling nanostructures on surfaces via intermolecular interactions •Yunjun Cao
15:00	TRE/MATH	O 14.1	Spin and time-resolved ARPES and the orbital angular momentum of light •Mauro Fanciulli
15:00	WILL/A317	O 15.1	Tuning Spin-1/2 Interactions in Graphene: From Long-Range Coupling to Altermagnetic Order •Beatriz Viña-Bausá

Sessions

09:30	TRE/PHYS	O 1	Topical Talk Wulfhekel
10:30	HSZ/0201	O 2	Electronic structure of surfaces: Spectroscopy, surface states I
10:30	HSZ/0204	O 3	Scanning probe techniques: Method development I
10:30	HSZ/0401	O 4	Metal & Semiconductor substrates: Adsorption and reaction of small molecules I
10:30	HSZ/0403	O 5	Focus Session: Mineral-water interfaces I
10:30	TRE/PHYS	O 6	Organic molecules on inorganic substrates: Adsorption and growth I
10:30	TRE/MATH	O 7	2D Materials: Electronic structure, excitations, etc. I
10:30	WILL/A317	O 8	Nanostructures at surfaces:1D, 2D, networks I

Monday, March 9, 2026

O

15:00	HSZ/0201	O 9	Organic molecules on inorganic substrates: electronic, optical and other properties I
15:00	HSZ/0204	O 10	2D Materials beyond graphene: Growth, structure and substrate interaction
15:00	HSZ/0401	O 11	Metal & Semiconductor substrates: Adsorption and reaction of small molecules II
15:00	HSZ/0403	O 12	Scanning probe microscopy: light matter interaction at atomic scales
15:00	TRE/PHYS	O 13	Solid-liquid interfaces: Reactions and electrochemistry I
15:00	TRE/MATH	O 14	Ultrafast electron dynamics at surface and interfaces I
15:00	WILL/A317	O 15	Spins on surfaces at the atomic scale I
18:00	P2	O 16	Focus Session: Structure and Dynamics of Solvent at Electrochemical Interfaces – Poster
18:00	P2	O 17	Spins on surfaces at the atomic scale – Poster
18:00	P2	O 18	New methods: Theory – Poster
18:00	P2	O 19	Vacuum Science & Technology: Theory and Applications – Poster
18:00	P2	O 20	Electronic structure theory – Poster
18:00	P2	O 21	Surface magnetism – Poster
18:00	P2	O 22	Surface dynamics – Poster
18:00	P2	O 23	Catalysis and surface reactions – Poster
18:00	P2	O 24	Solid-liquid interfaces: Reactions and electrochemistry – Poster
18:00	P2	O 25	Solid-liquid interfaces: Structure, spectroscopy – Poster
18:00	P2	O 26	Plasmonics and nanooptics: Fabrication, characterization and applications – Poster
18:00	P2	O 27	Plasmonics and nanooptics: Light-matter interaction, spectroscopy – Poster
18:00	P2	O 28	Oxide and insulator surfaces: Structure, epitaxy and growth – Poster
18:00	P2	O 29	Oxides and insulators: Adsorption and reaction of small molecules – Poster
18:00	P2	O 30	Metal & Semiconductor substrates: Structure, epitaxy and growth – Poster
18:00	P2	O 31	Metal & Semiconductor substrates: Adsorption and reaction of small molecules – Poster

SOE

Invited Talk

09:30	GÖR/0226	SOE 2.1	Memory and equilibrium in collective animal behaviour •Thierry Mora

Sessions

09:30	GÖR/0226	SOE 2	Focus Session: Physics of Behavior
09:30	MER/0002	SOE 3	Sustainability: Challenges and Solutions
18:00	P4	SOE 4	Poster Session

TT

Topical Talks

09:30	HSZ/0003	TT 1.1	Eigenstate thermalization in thermal first-order phase transitions •Maksym Serbyn
10:00	HSZ/0003	TT 1.2	Stabilizing Floquet orders to infinite time •Anushya Chandran
10:30	HSZ/0003	TT 1.3	Dynamical landscape of out of equilibrium emergent lattice gauge theories in two dimensions •Nilotpal Chakraborty
11:15	HSZ/0003	TT 1.4	Interference, topology, and new Hilbert-space routes to quantum non-ergodicity •Yi-Ping Huang
11:45	HSZ/0003	TT 1.5	Fock-space cages and their spectral signatures •Cheryne Jonay
15:00	HSZ/0003	TT 12.1	Charge confinement in twisted bilayer graphene •Christoph Stampfer
15:30	HSZ/0003	TT 12.2	Tuning Coulomb interactions and Hubbard bands in 1T-TaS_2 •Anna Galler
16:00	HSZ/0003	TT 12.3	Optical signatures of interlayer electron coherence in a bilayer semiconductor •Nadine Leisgang

Monday, March 9, 2026

TT

16:45	HSZ/0003	TT 12.4	Faithful modeling of quantum geometry and electronic correlations in van der Waals heterostructures •Ammon Fischer
17:15	HSZ/0003	TT 12.5	Mesoscale Atomic Engineering in a Crystal Lattice •Julian Klein
15:00	CHE/0089	TT 18.1	Markovian and non-Markovian approaches to quantum relaxation •Heinz-Peter Breuer
15:30	CHE/0089	TT 18.2	Asymptotic relaxation in quantum Markovian dynamics •Susana Huelga
16:00	CHE/0089	TT 18.3	Floquet engineering of open quantum Systems •André Eckardt
16:45	CHE/0089	TT 18.4	Nonequilibrium thermodynamics of time-dependent quantum transport •Janine Splettstoesser
17:15	CHE/0089	TT 18.5	Connecting time-nonlocal and time-local quantum master equations •Maarten Wegewijs

Sessions

09:30	HSZ/0003	TT 1	Focus Session: New Routes to Localization and Quantum Non-Ergodicity I
09:30	HSZ/0101	TT 2	Quantum-Critical Phenomena
09:30	HSZ/0103	TT 3	Correlated Electrons: Electronic Structure Calculations
09:30	HSZ/0105	TT 4	Graphene, 2D and Twisted Materials
09:30	CHE/0089	TT 5	Superconductivity: Sample Preparation and Characterization
09:30	CHE/0091	TT 6	Topological Superconductors
09:30	POT/0351	TT 7	Surface Magnetism and Topological Insulators
09:30	TRE/PHYS	TT 8	Topical Talk Wulfhekel
10:30	TRE/MATH	TT 9	2D Materials: Electronic structure, excitations, etc. I
11:00	HSZ/0103	TT 10	Correlated Electrons: Other Theoretical Topics
11:15	CHE/0091	TT 11	$PtBi_2$
15:00	HSZ/0003	TT 12	Focus Session: Tunable Correlations in van der Waals Quantum Materials I
15:00	HSZ/0101	TT 13	Correlated Electrons: Method Development I
15:00	HSZ/0103	TT 14	Superconductivity: Properties and Electronic Structure
15:00	HSZ/0105	TT 15	Topology: Majorana Physics
15:00	HSZ/0204	TT 16	2D Materials beyond graphene: Growth, structure and substrate interaction
15:00	BEY/0245	TT 17	Quantum Manybody Systems
15:00	CHE/0089	TT 18	Focus Session: Relaxation Timescales in Open Quantum Systems
15:00	CHE/0091	TT 19	Focus Session: New Routes to Localization and Quantum Non-Ergodicity II
15:00	POT/0081	TT 20	2D Materials II – Electronic and Transport Properties
15:00	POT/0151	TT 21	Electron Theory of Magnetism and Correlations
18:00	P1	TT 22	Superconductivity – Poster I
18:00	P1	TT 23	Correlated Electrons – Poster I

DD

Invited Talk

09:30	HÜL/S386	DD 2.1	Zukunft gestalten: Physik als Werkzeug zum Verstehen und Gestalten unserer Umwelt •Bianca Watzka

Sessions

09:30	HÜL/S386	DD 2	Eröffnung und Hauptvortrag I
10:45	SCH/A101	DD 3	Quantenphysik I
10:45	SCH/A252	DD 4	Digitale Medien I
10:45	SCH/A284	DD 5	Astronomie, Inklusion und Lernforschung
10:45	SCH/A285	DD 6	Lehrkräfteaus- und -fortbildung I
12:00	SCH/A101	DD 7	Quantenphysik II
12:00	SCH/A252	DD 8	Außerschulische Lernorte I
12:00	SCH/A284	DD 9	Neue Konzepte I
12:00	SCH/A285	DD 10	Hochschuldidaktik I

Monday, March 9, 2026

QI

Invited Talks

09:30	BEY/0245	QI 2.1	Advances in Frequency-Multiplexed Readout and Subsequent Qubit-State Reset •Benjamin Lienhard
15:00	BEY/0245	QI 4.1	Reducing Noise, Complexity, and Optimization Barriers in Quantum Simulations of Strongly Correlated Systems •Werner Dobrautz

Sessions

09:30	BEY/0137	QI 1	Quantum Computing and Algorithms I
09:30	BEY/0245	QI 2	Implementations I
15:00	BEY/0137	QI 3	Quantum Simulation
15:00	BEY/0245	QI 4	Quantum Manybody Systems

UP

Session

09:30	MER/0002	UP 1	Sustainability: Challenges and Solutions

AKBP

Topical Talks

09:30	SCH/A117	AKBP 1.1	Recent Developments at S-DALINAC •D. Schneider
10:00	SCH/A117	AKBP 1.2	Status of Source and Delivery of Spin-Polarized Electron Beams at ELSA •Michael Switka
11:00	SCH/A117	AKBP 2.1	From ELBE to DALI - Superconducting Electron Accelerators in Dresden •Andreas Wagner

Sessions

09:30	SCH/A117	AKBP 1	Electron Accelerators and Sources I
11:00	SCH/A117	AKBP 2	Electron Accelerators and Sources II
15:00	SCH/A117	AKBP 3	Diagnostics
16:45	SCH/A117	AKBP 4	Beam Dynamics

20:00	HSZ/AUDI	**Einstein Slam**

Tuesday, March 10, 2026

Plenary Talk

08:30	HSZ/AUDI	PV IV	Spins in Quantum Dots: The Quiet Revolution •Dorian Gangloff

Prize Talks

13:00	HSZ/0002	PRV II	Polymers / Soft Matter as Model Systems for Physics •Kurt Kremer (Laureate of the Max-Planck-Medal 2026)
13:00	HSZ/0004	PRV III	Optics of single molecules explored with sub-nm precision •Anna Rosławska (Laureate of the Gaede-Prize 2026)

Lunch Talk, Discussion

13:00	HSZ/AUDI	PSV III	Soft Science Skills – Self-branding for Scientists •Lucas Kreuzer, •Christian Kuttner, •Alexander Schlaich
13:00	HSZ/0003	PSV IV	Funding Opportunities for International Collaborations at the German Research Foundation •Joanna Kowalska

Ceremonial Session with Award Ceremony and Ceremonial Talk

16:00	HSZ/AUDI	PSV V	Quantum computers as large research instruments – what can we expect and how do we develop them? •Frank Wilhelm-Mauch

SYBS

Invited Talks

09:30	HSZ/AUDI	SYBS 1.1	Odd viscosity in three-dimensional fluids: flows, wakes, and eddies •Tali Khain
10:00	HSZ/AUDI	SYBS 1.2	Odd viscosity in two-dimensional hydrodynamic electron transport •Igor Gornyi
10:30	HSZ/AUDI	SYBS 1.3	Odd slip on chiral active surfaces •Andrej Vilfan
11:15	HSZ/AUDI	SYBS 1.4	Parity-odd transport in electron fluids •Johanna Erdmenger
11:30	HSZ/AUDI	SYBS 1.5	Curved Odd Elasticity •Piotr Surówka

Session

09:30	HSZ/AUDI	SYBS 1	Fluids with broken time-reversal symmetry: Odd/Hall viscosity between active matter and electron flows

BP

Invited Talks

11:15	BAR/0106	BP 11.7	Physics of bacterial adhesion: heterogeneity, patchiness, and surface interactions •Karin Jacobs
09:30	BAR/0205	BP 12.1	Tuning the Tracks: Functional Diversity Encoded in Microtubule Lattice States •Lukas Kapitein

Sessions

09:30	BAR/SCHÖ	BP 10	Active Matter III
09:30	BAR/0106	BP 11	Franco-German Session: Bacterial Biophysics I
09:30	BAR/0205	BP 12	Cytoskeleton I
14:00	ZEU/0160	BP 13	Active Matter IV
18:00	P2	BP 14	Poster Session II

CPP

Invited Talks, Topical Talks

09:30	ZEU/LICH	CPP 19.1	Surface adsorption and protonation equilibrium of atmospheric organics at the aqueous surface •Nønne Prisle

Tuesday, March 10, 2026

CPP

09:30	ZEU/0255	CPP 21.1	Molecular modelling of gas solubility and free volume trends in Si-functionalized ionic liquids •Kateryna Goloviznina
09:30	ZEU/0260	CPP 22.1	From Solution to Thin Films: Structure Formation Pathways in Organic Photovoltaic Films •Eva M. Herzig
14:00	HÜL/S386	CPP 26.1	Investigating lignin graphitisation depending on botanical source and extraction method •Pascale Launois
14:00	ZEU/LICH	CPP 27.1	Why water in plants survives negative pressure •Matej Kandu\v{c}
14:00	ZEU/0260	CPP 30.1	Solvent effects on amphiphile self-assembly in Deep Eutectic Solvents •Karen Edler

Sessions

09:30	BAR/SCHÖ	CPP 18	Active Matter III
09:30	ZEU/LICH	CPP 19	Focus Session: Water – from Atmosphere to Space I
09:30	ZEU/0160	CPP 20	Complex Fluids and Soft Matter
09:30	ZEU/0255	CPP 21	French-German Session: Simulation Methods and Modeling of Soft Matter III
09:30	ZEU/0260	CPP 22	Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics I
11:15	ZEU/LICH	CPP 23	Focus Session: Water – from Atmosphere to Space II
11:30	ZEU/0255	CPP 24	French-German Session: Simulation Methods and Modeling of Soft Matter IV
11:30	ZEU/0260	CPP 25	Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics II
14:00	HÜL/S386	CPP 26	French-German Session: 2D Materials, Thin Films and Interfaces II
14:00	ZEU/LICH	CPP 27	Focus Session: Water – from Atmosphere to Space III
14:00	ZEU/0160	CPP 28	Active Matter IV
14:00	ZEU/0255	CPP 29	Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods III
14:00	ZEU/0260	CPP 30	Complex Fluids, Colloids, Micelles and Vesicles I

DS

Invited Talks

09:30	REC/C213	DS 6.1	Soft X-ray Microscopy of Ferroic Thin Films •Tim A. Butcher
11:15	REC/C213	DS 6.6	Charge transfer at interfaces of free-standing oxide membranes and heterostructures •Felix Gunkel

Sessions

09:30	HSZ/0105	DS 5	Focus Session: Tunable Correlations in van der Waals Quantum Materials II
09:30	REC/C213	DS 6	Thin Oxides and Oxide Layers
10:00	REC/B214	DS 7	Thermoelectric and Phase Change Materials
14:00	REC/B214	DS 8	Transport Properties
14:00	REC/C213	DS 9	Thin Film Properties III: Oxides

DY

Invited Talks

09:30	HÜL/S186	DY 19.1	Mechanics of entangled fibers •Olivier Pouliquen
11:15	ZEU/0114	DY 21.7	Why Life Is Hot •Tanja Schilling
14:00	ZEU/0118	DY 28.1	Geometry of turbulent mixing in thermal convection •Jörg Schumacher
15:00	ZEU/0160	DY 29.5	Designing topological edge states in bacterial active matter •Kazumasa A. Takeuchi

Tuesday, March 10, 2026

DY

Sessions

09:30	BAR/SCHÖ	DY 18	Active Matter III
09:30	HÜL/S186	DY 19	Franco-German Session on Granular Matter I
09:30	ZEU/LICH	DY 20	Focus Session: Water – from Atmosphere to Space I
09:30	ZEU/0114	DY 21	Stochastic Thermodynamics
09:30	ZEU/0118	DY 22	Pattern Formation
09:30	ZEU/0160	DY 23	Complex Fluids and Soft Matter
11:15	ZEU/LICH	DY 24	Focus Session: Water – from Atmosphere to Space II
14:00	HÜL/S186	DY 25	Franco-German Session on Granular Matter II
14:00	ZEU/LICH	DY 26	Focus Session: Water – from Atmosphere to Space III
14:00	ZEU/0114	DY 27	Statistical Physics far from Thermal Equilibrium II
14:00	ZEU/0118	DY 28	Fluid Physics and Turbulence
14:00	ZEU/0160	DY 29	Active Matter IV

FM

Invited Talks

09:30	BEY/0138	FM 6.1	Robust Data Generation, Heuristics and Machine Learning for Materials Design •Janine George
14:00	BEY/0138	FM 9.1	Thin film combinatorial studies of functional magnetic materials •Nora Dempsey

Sessions

09:30	BEY/0138	FM 6	Focus Session: Materials Discovery I -- Material informatics
09:30	BEY/0E40	FM 7	Crystal Defects and Real Structure Physics in Diamond and Functional Materials I
09:30	POT/0112	FM 8	Multiferroics and Magnetoelectric Coupling
14:00	BEY/0138	FM 9	Focus Session: Materials Discovery II – High throughput searches for functional magnetic materials
14:00	BEY/0E40	FM 10	Crystal Defects and Real Structure Physics in Diamond and Functional Materials II
18:00	P4	FM 11	Poster Session Functional Materials

HL

Invited Talks

09:30	POT/0081	HL 16.1	Tailoring the performance of WSe_2 quantum emitters via cavity quantum electrodynamics and coherent driving •Ivan Solovev
10:00	POT/0081	HL 16.2	Deterministic single-photon emitters in 2D materials •Ursula Wurstbauer
10:30	POT/0081	HL 16.3	Resolving atomic and electronic structure of point defects in MoS_2 by first-principles calculations and scanning tunneling microscopy •Hannu-Pekka Komsa
11:15	POT/0081	HL 16.4	Polarization dynamics of isolated defects in hexagonal boron nitride •Serkan Ateş
11:45	POT/0081	HL 16.5	Defect-driven quantum emission in 2D materials •Magdalena Grzeszczyk

Sessions

09:30	HSZ/0105	HL 14	Focus Session: Tunable Correlations in van der Waals Quantum Materials II
09:30	POT/0006	HL 15	Organic Semiconductors: Optics and Photonics
09:30	POT/0081	HL 16	Focus Session: Quantum Emitters in 2D Semiconductors
09:30	POT/0251	HL 17	Quantum Dots and Wires: Rings, Wires and Transport
10:00	POT/0051	HL 18	Nanomechanical systems
10:30	HSZ/0201	HL 19	Graphene: Growth, structure and substrate interaction
18:00	P1	HL 20	Poster I

Tuesday, March 10, 2026

MA

Invited Talks

09:35	HSZ/0002	MA 14.1	Femtophonomagnetism •Sangeeta Sharma
10:20	HSZ/0002	MA 14.2	THz-driven dynamical ferroicity in paraelectric and diamagnetic perovskites •Martina Basini
10:50	HSZ/0002	MA 14.3	Angular momentum transfer and chiral phonons from first principles •Markus Weißenhofer
11:35	HSZ/0002	MA 14.4	Inertial Spin Dynamics: A Signature of Non-Markovian Interactions in Ferromagnets •Vivek Unikandanunni
12:05	HSZ/0002	MA 14.5	Atomistic simulations of ultrafast spin-lattice dynamics •Richard Evans
09:30	POT/0151	MA 18.1	Magnetic Cooling: From applications at room temperature to hydrogen liquefaction •T. Gottschall

Sessions

09:30	HSZ/0002	MA 14	PhD Focus Session: What about the lattice? Lessons from (ultrafast) magnetism
09:30	HSZ/0003	MA 15	Focus Session: Quantum Sensing with Solid State Spin defects I
09:30	HSZ/0004	MA 16	Skyrmions I
09:30	POT/0112	MA 17	Multiferroics and Magnetoelectric Coupling
09:30	POT/0151	MA 18	Caloric Effects in Ferromagnetic Materials
09:30	POT/0361	MA 19	Frustrated Magnets I
14:00	HSZ/0002	MA 20	Altermagnets III
14:00	HSZ/0004	MA 21	Skyrmions II
14:00	BEY/0138	MA 22	Focus Session: Materials Discovery II – High throughput searches for functional magnetic materials
14:00	POT/0151	MA 23	Cooperative Phenomena: Spin Structures and Magnetic Phase Transitions
14:00	POT/0361	MA 24	Weyl Semimetals

MM

Invited Talk

09:30	SCH/A251	MM 10.1	Chemically graded materials for accelerated exploration of the TRIP-TWIP Ti-alloy family •Lola Lilensten

Sessions

09:30	SCH/A251	MM 10	Invited Talk: Lola Lilensten
10:15	SCH/A215	MM 11	Structurally and Chemically Complex Alloys
10:15	SCH/A216	MM 12	Materials for the Storage and Conversion of Energy III / Functional Materials I
10:15	SCH/A251	MM 13	Data-driven Materials Science: Big Data and Workflows I
11:30	SCH/A315	MM 14	Liquid and Amorphous Materials I
14:00	SCH/A215	MM 15	Phase Transformations I
14:00	SCH/A216	MM 16	Functional Materials II
14:00	SCH/A251	MM 17	Data-driven Materials Science: Big Data and Workflows II
14:00	SCH/A315	MM 18	Liquid and Amorphous Materials II
18:00	P5	MM 19	Poster Session

O

Invited Talks, Topical Talk

09:30	TRE/PHYS	O 32.1	Excitons in molecular solids: from unitary films to donor-acceptor co-crystals •Gregor Witte
10:30	HSZ/0201	O 33.1	During-synthesis functionalization of graphene layers •Cristina Africh
10:30	HSZ/0403	O 36.1	Acidity in nanoconfinement from ab initio and NNPs simulations •Marialore Sulpizi

Tuesday, March 10, 2026

O

11:30	HSZ/0403	O 36.4	Living Interfaces: Dissolution and Precipitation Processes at Mineral-Brine Interfaces Revealed by AFM •Igor Siretanu
10:30	TRE/PHYS	O 37.1	Calculations of excited electronic states by converging on saddle points on the electronic energy surface •Hannes Jonsson
11:30	TRE/PHYS	O 37.4	Many-Body Theory meets Electrochemistry: Electronic Structure of Cathode Materials •Silke Biermann
11:00	WILL/A317	O 39.3	Electric double layer of platinum electrodes •Marc Koper
12:00	WILL/A317	O 39.6	First-principles modelling of electrochemical interfaces •Axel Groß
14:30	TRE/MATH	O 51.1	Ultrafast aqueous electric double-layer dynamics •Mischa Bonn
15:15	TRE/MATH	O 51.3	Interface-specific nonlinear THz spectroscopy •Chuanshan Tian
14:30	WILL/A317	O 52.1	Dynamics of catalytically active, atomically precise clusters on reducible oxide supports under the (fast) scanning tunneling microscope •Friedrich Esch

Sessions

09:30	TRE/PHYS	O 32	Topical Talk Witte
10:30	HSZ/0201	O 33	Graphene: Growth, structure and substrate interaction
10:30	HSZ/0204	O 34	Catalysis and surface reactions I
10:30	HSZ/0401	O 35	Organic molecules on inorganic substrates: Adsorption and growth II
10:30	HSZ/0403	O 36	Focus Session: Mineral-water interfaces II
10:30	TRE/PHYS	O 37	Electronic structure theory I
10:30	TRE/MATH	O 38	Ultrafast electron dynamics at surface and interfaces II
10:30	WILL/A317	O 39	Focus Session: Structure and Dynamics of Solvent at Electrochemical Interfaces I
14:00	P2	O 40	Ultrafast electron dynamics at surface and interfaces – Poster
14:00	P2	O 41	Topology and symmetry protected materials & Topological insulators – Poster
14:00	P2	O 42	Electronic structure of surfaces: Spectroscopy, surface states – Poster
14:00	P2	O 43	Scanning probe microscopy: light matter interaction at atomic scales – Poster
14:00	P2	O 44	Scanning probe techniques: Method development – Poster
14:00	P2	O 45	Organic molecules on inorganic substrates: Adsorption and growth – Poster
14:00	P2	O 46	Organic molecules on inorganic substrates: electronic, optical and other properties – Poster
14:30	HSZ/0201	O 47	New methods: Theory
14:30	HSZ/0204	O 48	Metal & Semiconductor substrates: Structure, epitaxy and growth
14:30	HSZ/0403	O 49	Plasmonics and nanooptics: Light-matter interaction, spectroscopy I
14:30	TRE/PHYS	O 50	Electronic structure theory II
14:30	TRE/MATH	O 51	Focus Session: Structure and Dynamics of Solvent at Electrochemical Interfaces II
14:30	WILL/A317	O 52	Oxide and insulator surfaces: Structure, epitaxy and growth I

SOE

Prize Talk, Invited Talk, Topical Talk

09:30	GÖR/0226	SOE 5.1	Network Science in Criminology: Insights from Empirical Case Studies •Masarah Paquet-Clouston
14:00	GÖR/0226	SOE 7.1	What's that noise? Why does it make a difference? And why am I thinking about it all the time? •Dirk Brockmann
14:45	GÖR/0226	SOE 7.2	How things spread: Complexity and criticality of inhomogeneous spreading models •Laurent Hébert-Dufresne (Laureate of the YSA 2026)

Sessions

09:30	GÖR/0226	SOE 5	Network Science
10:45	GÖR/0226	SOE 6	Mobility, Traffic Dynamics, Urban and Regional Systems
14:00	GÖR/0226	SOE 7	Award Session: Young Scientist Award for Socio- and Econophysics (YSA)

Tuesday, March 10, 2026

TT

Invited Talk, Topical Talks

09:30	HSZ/0003	TT 24.1	Exploring nanoscale van der Waals magnetism using single spin microscopy •Patrick Maletinsky
10:00	HSZ/0003	TT 24.2	Optically addressable spin defects in two-dimensional materials •Vladimir Dyakonov
10:30	HSZ/0003	TT 24.3	Nitrogen vacancy centers in diamond as novel sensing and imaging tool for magnetic nanostructures, in life science and chemistry •Elke Neu-Ruffing
11:15	HSZ/0003	TT 24.4	Electron spin, nuclear spin, and optical properties of transition-metal defects in silicon carbide with perspectives for quantum technologies •Guido Burkard
11:45	HSZ/0003	TT 24.5	Statics and dynamics of complex magnetic states in microstructures •Aurore Finco
09:30	HSZ/0105	TT 27.1	Simulating high-temperature superconductivity in a triangular moiré lattice •Kin Fai Mak

Sessions

09:30	HSZ/0003	TT 24	Focus Session: Quantum Sensing with Solid State Spin defects I
09:30	HSZ/0101	TT 25	f-Electron Systems
09:30	HSZ/0103	TT 26	Correlated Magnetism – Frustrated Systems
09:30	HSZ/0105	TT 27	Focus Session: Tunable Correlations in van der Waals Quantum Materials II
09:30	CHE/0089	TT 28	Superconducting Electronics: SQUIDs and other Josephson Circuits and Components
09:30	CHE/0091	TT 29	Unconventional Superconductors
09:30	POT/0151	TT 30	Caloric Effects in Ferromagnetic Materials
09:30	POT/0361	TT 31	Frustrated Magnets I
10:00	POT/0051	TT 32	Nanomechanical systems
11:00	HSZ/0105	TT 33	Correlated Magnetism – Dynamics and Spectroscopy
14:00	HSZ/0101	TT 34	Members' Assembly
14:00	POT/0151	TT 35	Cooperative Phenomena: Spin Structures and Magnetic Phase Transitions
14:00	POT/0361	TT 36	Weyl Semimetals
14:00	P2	TT 37	Ultrafast electron dynamics at surface and interfaces – Poster
14:00	P2	TT 38	Topology and symmetry protected materials & Topological insulators – Poster

DD

Invited Talk

09:30	HÜL/S386	DD 11.1	Lernen mit KI, Lernen über KI: Perspektiven für die Naturwissenschaftsdidaktik •Arne Bewersdorff

Sessions

09:30	HÜL/S386	DD 11	Hauptvortrag II
10:45	SCH/A101	DD 12	Praktika und Experimente
10:45	SCH/A252	DD 13	Digitale Medien II
10:45	SCH/A284	DD 14	Bildung für nachhaltige Entwicklung
10:45	SCH/A285	DD 15	Interesse I
12:00	SCH/A101	DD 16	Experimente
12:00	SCH/A252	DD 17	Außerschulische Lernorte II
12:00	SCH/A284	DD 18	BNE Workshop
12:00	SCH/A285	DD 19	Hochschuldidaktik II
14:00	P5	DD 20	Poster – Lehrkräfteaus- und -fortbildung
14:00	P5	DD 21	Poster – Außerschulische Lernorte
14:00	P5	DD 22	Poster – Astronomie
14:00	P5	DD 23	Poster – Bildung für nachhaltige Entwicklung
14:00	P5	DD 24	Poster – Digitale Medien
14:00	P5	DD 25	Poster – Experimente und Praktika
14:00	P5	DD 26	Poster – Hochschuldidaktik
14:00	P5	DD 27	Poster – Lehr- und Lernforschung
14:00	P5	DD 28	Poster – Neue Konzepte

Tuesday, March 10, 2026

DD

14:00	P5	DD 29	Poster – Nature of Science
14:00	P5	DD 30	Poster – Quantenphysik
14:00	P5	DD 31	Poster – Physikdidaktik und Inklusion
14:00	P5	DD 32	Poster – Sprache und Physikunterricht
14:00	P5	DD 33	Poster – Sonstiges
18:00	SCH/A101	DD 34	Mitgliederversammlung

QI

Invited Talk

09:30	BEY/0245	QI 6.1	Erbium dopants for quantum networks •Andreas Reiserer

Sessions

09:30	BEY/0137	QI 5	Quantum Computing and Algorithms II
09:30	BEY/0245	QI 6	Implementations II
09:30	BEY/0E17	QI 7	Quantum Thermodynamics
14:00	BEY/0137	QI 8	Implementations III
14:00	BEY/0245	QI 9	Decoherence and Open Systems I

UP

Invited Talks

10:15	MER/0002	UP 2.4	Klimakommunikation in der Schule? Mehr als nur darüber reden! •Michael Sach
11:15	MER/0002	UP 3.1	Supporting the monitoring and tracking of carbon dioxide and methane emissions with satellites •Dominik Brunner
14:00	MER/0002	UP 5.1	A path to seamless modelling of the convective atmospheric boundary layer •Mirjana Sakradzija

Sessions

09:30	MER/0002	UP 2	Climate Communication
11:15	MER/0002	UP 3	Air Quality, Exposure and Atmospheric Dynamics
13:00	MER/0002	UP 4	Members' Assembly
14:00	MER/0002	UP 5	Modelling and Prediction Across Scales

AKBP

Topical Talks

09:30	SCH/A117	AKBP 5.1	Generation and Acceleration of In-Target Gold Fission Fragments using the ATLAS-3000 Laser System •Laura D. Geulig
11:00	SCH/A117	AKBP 6.1	Efficient high energy and high-repetition-rate proton acceleration from cryogenic hydrogen foil targets •Stefan Assenbaum

Sessions

09:30	SCH/A117	AKBP 5	Plasma Accelerators, Ions I
11:00	SCH/A117	AKBP 6	Plasma Accelerators, Ions II
14:00	SCH/A117	AKBP 7	Ion and Medical Accelerators

AKPIK

Invited Talks

11:45	BEY/0127	AKPIK 3.4	Model-free training of optical neural networks based on multimode semiconductor lasers •Anas Skalli
12:15	BEY/0127	AKPIK 3.5	Virtual Reality Gamification for Photonics, AI and More •Arash Rahimi-Iman

Tuesday, March 10, 2026

AKPIK

14:00	BEY/0127	AKPIK 4.1	Beyond the Hype: Can AI Truly Transform Photonics? •Mehdi K. Hedayati
14:30	BEY/0127	AKPIK 4.2	Machine-learning assisted design of metasurfaces •Marco Rahm
			Sessions
09:30	BEY/0127	AKPIK 2	Machine Learning Prediction and Optimization Tasks
11:00	BEY/0127	AKPIK 3	Research with AI: Hardware, Software, Tools
14:00	BEY/0127	AKPIK 4	Focus: Deep Learning in Electromagnetics Research

JOB

			Invited Talks
11:00	HSZ/0405	JOB 1.1	d-fine GmbH: Entwicklung einer ERP-Software für Sanitätshäuser •Maximilian Sommer, •Philipp Banker-Busch
13:00	HSZ/0405	JOB 1.2	Ritzenhoefer GmbH: Agentic Journey •Andreas Ringleb, •Alice von Bassewitz
			Session
11:00	HSZ/0405	JOB 1	Job Market I

09:30	Tents A and C	**Exhibition of Scientific Instruments and Literature** (free entrance)

20:00	HSZ Main Entrance Bergstraße	**jDPG Pub Crawl**

Wednesday, March 11, 2026

Plenary Talks

08:30	HSZ/AUDI	PV V	Reimagining Physics Education for a Planet in Transformation •Giulia Tasquier
14:00	HSZ/AUDI	PV VI	Materials selection methods: a compass in the jungle •Yves Bréchet
14:00	HSZ/0002	PV VII	Stronger yet weaker: Long-range orientational order in 2D active matter •Hugues Chaté

Prize Talk

13:00	HSZ/0003	PRV IV	Fractionalisation, fractals and strong coupling QED in spin liquids •Roderich Moessner (Laureate of the Max-Born-Prize 2026)

Lunch Talk, Discussion

13:00	HSZ/AUDI	PSV VI	Career Paths: Academia or Industry? •Joanna Kowalska, •Elisabeth Trommer, •Jonas Schubert, •Annegret Rößler
13:00	HSZ/0002	PSV VII	The French Research Landscape in Physics •Elisabeth Giacobino

SYBT

Invited Talks

09:30	HSZ/AUDI	SYBT 1.1	Finding Neuromorphic Advantage with Magnetism •Johan Mentink
10:00	HSZ/AUDI	SYBT 1.2	Accelerating Neural Networks Computation with Ferroelectric Oxides •Laura Bégon-Lours
10:30	HSZ/AUDI	SYBT 1.3	a photonic approach to probabilistic computing •Wolfram Pernice
11:15	HSZ/AUDI	SYBT 1.4	Tackling Reliability and Scalability in Neuromorphic Computing via Noise-aware Learning •Eleni Vasilaki
11:45	HSZ/AUDI	SYBT 1.5	Bayesian nanodevices for trustworthy artificial intelligence •Damien Querlioz

Session

09:30	HSZ/AUDI	SYBT 1	Beyond Transistors: Material-Based Edge Computing Paradigms

SYGF

Invited Talks

15:00	HSZ/AUDI	SYGF 1.1	Liquid crystal geometries in type I collagen-based tissues •Nadine Nassif
15:30	HSZ/AUDI	SYGF 1.2	Self-organization of the cytoplasm by physical instabilities •Jan Brugues
16:00	HSZ/AUDI	SYGF 1.3	From morphogenesis to space partitioning by microtubules and molecular motors. •Manuel Thery
16:45	HSZ/AUDI	SYGF 1.4	More than the sum: how composite interfaces govern function •Alba Diz-Muñoz
17:15	HSZ/AUDI	SYGF 1.5	Swimming and Swarming of Intelligent Active Particles •Gerhard Gompper
17:45	HSZ/AUDI	SYGF 1.6	Perturbing the collective motion of fish with challenging environments •Aurélie Dupont

Session

15:00	HSZ/AUDI	SYGF 1	Guest Country Symposium France: Soft, Active and Alive: Emergent Properties in Living Matter (SYGF)

Wednesday, March 11, 2026

BP

Invited Talks

09:30	BAR/0205	BP 16.1	Illuminating mitochondrial permeabilisation in apoptosis •Ana J. Garcia Saez
10:30	BAR/0106	BP 18.1	Protein complex structure prediction, state-of-the-art and challenges •Ezgi Karaca
11:45	BAR/0106	BP 18.4	From Sparse Restraints to All-Atom Models: Integrative Reconstruction of Hidden GPCR Conformations •Matthias Elgeti
15:45	BAR/0106	BP 20.4	Solution scattering and MD simulation as quantitative probes of protein-specific and temperature-dependent hydration •Jochen S Hub
15:00	HÜL/S386	BP 21.1	Microbial Behavior in Context •Fernanda Pinheiro
16:15	HÜL/S386	BP 21.4	The navigability of fitness landscapes shaped by global and universal epistasis •Joachim Krug

Sessions

09:30	BAR/SCHÖ	BP 15	Computational Biophysics III
09:30	BAR/0205	BP 16	Membranes, Vesicles and Synthetic Life-like Systems II
09:30	ZEU/0114	BP 17	Statistical Physics of Biological Systems I
10:30	BAR/0106	BP 18	Focus session: Integrative Structural Modeling
11:45	ZEU/LICH	BP 19	Round Table Discussion: The Future of Neutrons in France and Germany
15:00	BAR/0106	BP 20	Protein Structure and Dynamics
15:00	HÜL/S386	BP 21	Focus Session: Sequence Spaces, Populations and Evolution
15:00	ZEU/0114	BP 22	Statistical Physics of Biological Systems II
15:00	ZEU/0255	BP 23	Biopolymers, Biomaterials and Bioinspired Functional Materials I
17:00	ZEU/0255	BP 24	Biopolymers, Biomaterials and Bioinspired Functional Materials II
18:30	BAR/0205	BP 25	Members' Assembly

CPP

Invited Talks, Topical Talk, Discussion

09:30	ZEU/0255	CPP 31.1	Hydrogels with a Pinch of Embodied Intelligence •Andreas Walther
09:30	ZEU/0260	CPP 32.1	Synchrotron X-Ray Studies on Structural Transitions in Water and Alcohol containing Ice Analogues •Christina M. Tonauer
10:00	ZEU/LICH	CPP 33.1	Shape-induced superstructure formation in concentrated ferrofluids •Sabrina Disch
11:45	ZEU/LICH	CPP 36.1	Round Table: Novel Opportunities for France/Germany Cooperation in Neutron Science •Julian Oberdisse, •Frank Schreiber, •Arnaud Desmedt, •Stephan Förster, •Jacques Jestin, •Pascale Launois, •Christian Pfleiderer, •Sabrina Disch
15:00	ZEU/LICH	CPP 37.1	Predicting molecular ordering in deposited molecular films •Denis Adrienko
15:00	ZEU/0255	CPP 38.1	Engineering, processing and application of recombinant spider silk proteins •Thomas Scheibel
15:00	ZEU/0260	CPP 39.1	A polarizable model for atomistic simulations of metals and graphitic material/liquid interfaces •Marialore Sulpizi
17:00	ZEU/0260	CPP 42.1	Mesopores filled with (poly)ionic liquids: phase transitions under confinement, and structure seen by SAXS and SANS •Julian Oberdisse

Sessions

09:30	ZEU/0255	CPP 31	Responsive and Adaptive Systems
09:30	ZEU/0260	CPP 32	Focus Session: Water – from Atmosphere to Space IV
10:00	ZEU/LICH	CPP 33	Complex Fluids, Colloids, Micelles and Vesicles II
11:00	ZEU/0260	CPP 34	Focus Session: Water – from Atmosphere to Space V

Wednesday, March 11, 2026

CPP

11:15	ZEU/0118	CPP 35	Glasses and Glass Transition
11:45	ZEU/LICH	CPP 36	Round Table Discussion: The Future of Neutrons in France and Germany
15:00	ZEU/LICH	CPP 37	Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics III
15:00	ZEU/0255	CPP 38	Biopolymers, Biomaterials and Bioinspired Functional Materials I
15:00	ZEU/0260	CPP 39	French-German Session: Nanomaterials, Composites and Hybrids I
17:00	ZEU/LICH	CPP 40	Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics IV
17:00	ZEU/0255	CPP 41	Biopolymers, Biomaterials and Bioinspired Functional Materials II
17:00	ZEU/0260	CPP 42	French-German Session: Nanomaterials, Composites and Hybrids II

DS

Invited Talk

15:00	REC/B214	DS 13.1	Tailored thermal treatments for multi-layer, multi-material polymer devices •Katherina Haase

Sessions

09:30	HSZ/0003	DS 10	Focus Session: Nickelate Superconductivity: Insights into Unconventional Pairing and Correlation Effects I
09:30	REC/B214	DS 11	Layer Deposition
09:30	REC/C213	DS 12	2D Materials I
15:00	REC/B214	DS 13	Layer Properties
15:00	REC/C213	DS 14	2D Materials II

DY

Invited Talks

09:30	ZEU/0160	DY 34.1	Active turbulence and odd viscosity in a colloidal chiral active system in bulk and in patterned environments •Marisol Ripoll
11:15	ZEU/0118	DY 37.1	Topological defects in 2D amorphous ensembles •Peter Keim
15:00	ZEU/0114	DY 40.1	Learning the statistical folding of bacterial chromosomes •Chase Broedersz

Sessions

09:30	CHE/0091	DY 30	Nonequilibrium Quantum Systems I
09:30	GÖR/0226	DY 31	Networks, From Topology to Dynamics – Part I
09:30	HÜL/S186	DY 32	Many-body Systems: Equilibration, Chaos, and Localization
09:30	ZEU/0114	DY 33	Statistical Physics of Biological Systems I
09:30	ZEU/0160	DY 34	Focus Session: Fluids with Broken Time-Reversal Symmetry – Odd/Hall Viscosity Between Active Matter and Electron Flows
09:30	ZEU/0260	DY 35	Focus Session: Water – from Atmosphere to Space IV
11:00	ZEU/0260	DY 36	Focus Session: Water – from Atmosphere to Space V
11:15	ZEU/0118	DY 37	Glasses and Glass Transition
15:00	HSZ/0105	DY 38	Nonequilibrium Quantum Systems II
15:00	GÖR/0226	DY 39	Networks, From Topology to Dynamics – Part II
15:00	ZEU/0114	DY 40	Statistical Physics of Biological Systems II
15:00	P5	DY 41	Poster: Nonlinear Dynamics, Granular Matter, and Machine Learning
15:00	P5	DY 42	Poster: Quantum Dynamics and Many-body Systems
15:00	P5	DY 43	Poster: Statistical Physics
15:00	P5	DY 44	Poster: Active Matter, Soft Matter, and Fluids

FM

Invited Talk

09:30	BEY/0138	FM 12.1	Shedding Light on Polar Topological Textures •Salia Cherifi-Hertel

Wednesday, March 11, 2026

FM

Sessions

09:30	BEY/0138	FM 12	German-French Focus Session: Materials Research in Polar Oxides – From Domain Engineering to Photonic and Electronic Devices I
10:15	SCH/A251	FM 13	Topical Session: Dislocations in Functional Materials I
15:00	BEY/0138	FM 14	Focus Session: Materials Research in Polar Oxides – From Domain Engineering to Photonic and Electronic Devices II
15:00	BEY/0E40	FM 15	Nanoscale Probing of Functional Properties
15:45	SCH/A251	FM 16	Topical Session: Dislocations in Functional Materials II

HL

Invited Talks

09:30	POT/0251	HL 25.1	Quantum dots for single-electron current sources •Johannes C. Bayer
10:00	POT/0251	HL 25.2	Optical readout of reconfigurable in-plane magnetic domains in CrSBr •Aleksandra Łopion
10:30	POT/0251	HL 25.3	Ferroelectric switching in Mn-doped epitaxial $BaTiO_3$ films and superlattices on silicon •Alfredo Blázquez Martínez
11:15	POT/0251	HL 25.4	Tunability of quantized Hall plateaus •Serkan Sirt
11:45	POT/0251	HL 25.5	How to achieve high gain in organic photodetectors? •Johannes Benduhn
15:00	POT/0081	HL 30.1	Dual proximity engineering of spin-orbit and magnetic effects in graphene heterostructures •Christoph Kastl

Sessions

09:30	HSZ/0101	HL 21	Focus Session: Quantum Sensing with Solid State Spin defects II
09:30	POT/0006	HL 22	Biocompatible Organic Semiconductors
09:30	POT/0051	HL 23	Transport Properties
09:30	POT/0081	HL 24	2D Materials IV – Emerging materials and properties
09:30	POT/0251	HL 25	Focus Session: Young Semiconductor Forum
09:30	P1	HL 26	Poster II
10:30	TRE/MATH	HL 27	2D Materials: Electronic structure, excitations, etc. II
15:00	HSZ/0401	HL 28	Topology and symmetry protected materials & Topological insulators
15:00	POT/0006	HL 29	Quantum Transport and Quantum Hall effects
15:00	POT/0081	HL 30	2D Materials V – Magnetic, spintronic, and topological properties
15:00	POT/0251	HL 31	Materials and Devices for Quantum Technology I
15:00	REC/C213	HL 32	2D Materials 2
16:30	POT/0006	HL 33	Nitrides I – Growth and fabrication
16:30	POT/0051	HL 34	Quantum Dots and Wires: Telecom Wavelength
16:30	POT/0251	HL 35	Optical Properties II
17:30	POT/0081	HL 36	2D Materials VI – Optoelectronic properties

MA

Invited Talks

09:30	HSZ/0002	MA 25.1	Coherent phononic control of chirality •Michael Först
10:00	HSZ/0002	MA 25.2	Towards a modern theory of chiralization (and can chiral phonons help us get there?) •Nicola Spaldin
11:15	HSZ/0002	MA 25.5	Observation and control of chiral phonons in non-centrosymmetric materials •Hiroki Ueda
09:30	HSZ/0004	MA 27.1	Towards sub-10fs magnetization switching •Quentin Remy
09:30	POT/0112	MA 29.1	Exploring the interplay between spin and chirality •Angela Wittmann

Wednesday, March 11, 2026

MA

15:00	POT/0112	MA 35.1	Magneto-optic Kerr effects of higher order in magnetization in thin films of different crystal orientations •Timo Kuschel

Sessions

09:30	HSZ/0002	MA 25	Focus Session: Chiral phonons and crystals coupled to magnetic order I
09:30	HSZ/0003	MA 26	Focus Session: Nickelate Superconductivity: Insights into Unconventional Pairing and Correlation Effects I
09:30	HSZ/0004	MA 27	Ultrafast Magnetization Effects I
09:30	HSZ/0101	MA 28	Focus Session: Quantum Sensing with Solid State Spin defects II
09:30	POT/0112	MA 29	Spin Transport and Orbitronics, Spin-Hall Effects I
09:30	POT/0151	MA 30	Functional Antiferromagnetism
09:30	POT/0361	MA 31	Frustrated Magnets II
14:00	HZDR	MA 32	Excursion: Current and Future High-Field THz User Facilities at HZDR
15:00	HSZ/0002	MA 33	Altermagnets IV
15:00	HSZ/0004	MA 34	Computational Magnetism I
15:00	POT/0112	MA 35	Spintronics (other effects)
15:00	POT/0151	MA 36	Molecular Magnetism and Magnetic Particles / Clusters I
15:00	POT/0351	MA 37	Non-Skyrmionic Magnetic Textures
15:00	POT/0361	MA 38	Ultrafast Magnetization Effects II
18:00	P2	MA 39	Poster Magnetism II

MM

Invited Talk, Topical Talks

09:30	SCH/A251	MM 20.1	Neural Network Atomistic Modeling of Dislocation Plasticity in Ceramics •Shigenobu Ogata
15:00	SCH/A251	MM 24.1	Recent advances in processing of rare-earth free MnBi magnets by severe plastic deformation •Andrea Bachmaier
15:45	SCH/A251	MM 27.1	Dislocations in perovskite oxides: similarities and differences •Pierre Hirel

Sessions

09:30	SCH/A251	MM 20	Topical Talk: Shigenobu Ogata
10:15	SCH/A215	MM 21	Phase Transformations II
10:15	SCH/A216	MM 22	Data-driven Materials Science: Big Data and Workflows III
10:15	SCH/A251	MM 23	Topical Session: Dislocations in Functional Materials I
15:00	SCH/A251	MM 24	Invited Talk: Andrea Bachmaier
15:45	SCH/A215	MM 25	Interface Controlled Properties, Nanomaterials, and Microstructure Design I
15:45	SCH/A216	MM 26	Transport in Materials: Diffusion, Charge, or Heat Conduction I
15:45	SCH/A251	MM 27	Topical Session: Dislocations in Functional Materials II
17:15	SCH/A251	MM 28	MM Members Assembly

O

Invited Talks, Topical Talk

09:30	TRE/PHYS	O 53.1	Single-Atom Catalysis: Insights From Model Systems •Gareth S. Parkinson
11:00	HSZ/0204	O 55.3	Cationic Mixing in Ultrathin Oxide Films: How substrate and oxygen conditions control nanoalloying. •Jacek Goniakowski
10:30	HSZ/0403	O 57.1	From Plasmonic Near-Fields to Electron Dynamics - A Photoemission Perspective •Pascal Dreher
10:30	WILL/A317	O 60.1	Disentangling the origins of spin polarization in (inverse) photoemission from solid surfaces •Jürgen Henk

Wednesday, March 11, 2026

O

15:00	HSZ/0403	O 64.1	Cantilever based Scanning Force Microscopy: Ultimate Sensitivity and Quantitative Imaging of Nanoscale Spin Textures •Hans J. Hug
16:30	HSZ/0403	O 64.6	Single-spin sensing: A molecule-on-tip approach •Laurent Limot
15:00	TRE/MATH	O 66.1	Ultrafast exciton dynamics in 2D semiconductors and electric field gated devices •Jan Philipp Bange
15:00	WILL/A317	O 67.1	New frontiers of one step model of photoemission for quantum materials •Jan Minar

Sessions

09:30	TRE/PHYS	O 53	Topical Talk Parkinson
10:30	HSZ/0201	O 54	Nanostructured surfaces and thin films
10:30	HSZ/0204	O 55	Oxide and insulator surfaces: Structure, epitaxy and growth II
10:30	HSZ/0401	O 56	Scanning probe techniques: Method development II
10:30	HSZ/0403	O 57	Plasmonics and nanooptics: Light-matter interaction, spectroscopy II
10:30	TRE/PHYS	O 58	Organic molecules on inorganic substrates: Adsorption and growth III
10:30	TRE/MATH	O 59	2D Materials: Electronic structure, excitations, etc. II
10:30	WILL/A317	O 60	Focus Session: Unoccupied States by Inverse Photoemission I
15:00	HSZ/0201	O 61	Organic molecules on inorganic substrates: electronic, optical and other properties II
15:00	HSZ/0204	O 62	Graphene: Electronic structure, excitations, etc.
15:00	HSZ/0401	O 63	Topology and symmetry protected materials & Topological insulators
15:00	HSZ/0403	O 64	Surface Magnetism
15:00	TRE/PHYS	O 65	Solid-liquid interfaces: Reactions and electrochemistry II
15:00	TRE/MATH	O 66	Ultrafast electron dynamics at surface and interfaces III
15:00	WILL/A317	O 67	Focus Session: Unoccupied States by Inverse Photoemission II
18:00	P2	O 68	Nanostructured surfaces and thin films – Poster
18:00	P2	O 69	Nanostructures at surfaces:1D, 2D, networks – Poster
18:00	P2	O 70	2D materials: Stacking and heterostructures – Poster
18:00	P2	O 71	2D Materials: Electronic structure, excitations, etc. – Poster
18:00	P2	O 72	2D Materials beyond graphene: Growth, structure and substrate interaction – Poster
18:00	P2	O 73	Graphene: Growth, structure and substrate interaction – Poster
18:00	P2	O 74	Graphene: Electronic structure, excitations, etc. – Poster

SOE

Invited Talk

09:30	GÖR/0226	SOE 8.1	Dynamics and Structure in Temporal Networks •Natasa Djurdjevac Conrad

Sessions

09:30	GÖR/0226	SOE 8	Networks, From Topology to Dynamics I
11:30	GÖR/0226	SOE 9	Economic Models
15:00	GÖR/0226	SOE 10	Networks, From Topology to Dynamics II
15:45	GÖR/0226	SOE 11	Polarization
17:15	GÖR/0226	SOE 12	Statistical Physics of Politics
18:00	GÖR/0226	SOE 13	Members' Assembly

TT

Topical Talks

09:30	HSZ/0003	TT 39.1	Unconventional Superconductivity in Infinite-layer Samarium Nickelates •Danfeng Li
10:00	HSZ/0003	TT 39.2	Recent insights into infinite-layer nickelate heterostructures from x-ray spectroscopy •Eva Benckiser
10:30	HSZ/0003	TT 39.3	Theory of infinite-layer nickelate superconductors •Karsten Held

Wednesday, March 11, 2026

TT

11:15	HSZ/0003	TT 39.4	Disorder and distortions: what electrons tell us about nickelate superconductivity •Berit H. Goodge
11:45	HSZ/0003	TT 39.5	Superconducting gap structure and bosonic mode in $La_2PrNi_2O_7$ thin films at ambient pressure •Hai-Hu Wen
15:00	HSZ/0003	TT 50.1	Josephson Quantum Tunneling at Odd Parity •Julia S. Meyer
15:30	HSZ/0003	TT 50.2	Superconducting qubits and amplifiers resilient to Tesla-scale magnetic fields •Ioan Pop
16:00	HSZ/0003	TT 50.3	Josephson metamaterials as near-quantum-limited microwave amplifiers •Nicolas Roch
16:45	HSZ/0003	TT 50.4	Second Order Topological Insulators probed with mesoscopic physics •Sophie Gueron
17:15	HSZ/0003	TT 50.5	Proximity superconductivity in chiral Kagome antiferromagnets •Piet Brouwer

Sessions

09:30	HSZ/0003	TT 39	Focus Session: Nickelate Superconductivity: Insights into Unconventional Pairing and Correlation Effects I
09:30	HSZ/0101	TT 40	Focus Session: Quantum Sensing with Solid State Spin defects II
09:30	HSZ/0103	TT 41	Topological Semimetals
09:30	HSZ/0105	TT 42	Other Transport Topics
09:30	CHE/0089	TT 43	Superconducting Electronics: Qubits
09:30	CHE/0091	TT 44	Nonequilibrium Quantum Systems I
09:30	HÜL/S186	TT 45	Many-body Systems: Equilibration, Chaos, and Localization
09:30	POT/0112	TT 46	Spin Transport and Orbitronics, Spin-Hall Effects I
09:30	POT/0361	TT 47	Frustrated Magnets II
10:30	TRE/MATH	TT 48	2D Materials: Electronic structure, excitations, etc. II
10:45	HSZ/0101	TT 49	Correlated Electrons: Charge Order
15:00	HSZ/0003	TT 50	German-French Focus Session: Superconducting Junctions and Quantum Circuits
15:00	HSZ/0101	TT 51	Correlated Electrons: Method Development II
15:00	HSZ/0103	TT 52	Heavy Fermions
15:00	HSZ/0105	TT 53	Nonequilibrium Quantum Systems II
15:00	HSZ/0204	TT 54	Graphene: Electronic structure, excitations, etc.
15:00	HSZ/0401	TT 55	Topology and symmetry protected materials & Topological insulators
15:00	CHE/0089	TT 56	Superconductivity: Theory I
15:00	CHE/0091	TT 57	Correlated Magnetism Kagome Systems
15:00	POT/0006	TT 58	Quantum Transport and Quantum Hall effects
15:00	POT/0081	TT 59	2D Materials V – Magnetic, spintronic, and topological properties
15:00	POT/0112	TT 60	Spintronics (other effects)
15:00	P4	TT 61	Topology – Poster
15:00	P4	TT 62	Correlated Electrons – Poster II
15:00	P5	TT 63	Quantum Dynamics and Many-body Systems – Poster
16:45	HSZ/0103	TT 64	BKT Physics
18:00	P2	TT 65	2D materials: Stacking and heterostructures – Poster
18:00	P2	TT 66	2D Materials: Electronic structure, excitations, etc. – Poster
18:00	P2	TT 67	2D Materials beyond graphene: Growth, structure and substrate interaction – Poster
18:00	P2	TT 68	Graphene: Electronic structure, excitations, etc. – Poster

DD

Prize Talk

09:30	HÜL/S386	DD 35.1	Die Bonner Physikshow – ein Öffentlichkeitsprojekt mit Studierenden •Herbi Dreiner (Laureate of the Georg-Kerschensteiner-Prize 2026)

Wednesday, March 11, 2026

DD

Sessions

09:30	HÜL/S386	DD 35	Kerschensteiner-Preisvortrag
10:45	SCH/A101	DD 36	Quantenphysik III
10:45	SCH/A252	DD 37	Lehr- und Lernforschung
10:45	SCH/A284	DD 38	Nature of Science
10:45	SCH/A285	DD 39	Interesse II
12:00	SCH/A101	DD 40	Quantenphysik IV
12:00	SCH/A252	DD 41	Lehrkräfteaus- und -fortbildung II
12:00	SCH/A285	DD 42	Neue Konzepte II
13:00	SCH/A101	DD 43	Abschlussplenum

QI

Invited Talk

09:30	BEY/0245	QI 11.1	Nb-trilayer Josephson junction based parametric amplifiers for microwave frequency signals •Lukas Grünhaupt

Sessions

09:30	BEY/0137	QI 10	Quantum Information: Concepts and Methods I
09:30	BEY/0245	QI 11	Implementations IV
15:00	BEY/0137	QI 12	Quantum Foundations
15:00	BEY/0245	QI 13	Quantum Control
18:00	P4	QI 14	Quantum Information Poster Session

UP

Sessions

09:30	MER/0002	UP 6	Upper Atmosphere, Polar Chemistry and Volcanic Aerosols
11:15	MER/0002	UP 7	Aquatic Systems: Limnology, Natural Waters, Wetlands and Soilmoisture
15:00	P1	UP 8	Poster

AKBP

Topical Talk

15:00	SCH/A117	AKBP 10.1	Multiscale longitudinal electron bunch characteristics of LWFA bunches determined by single-shot CTR spectroscopy •Alexander Debus

Sessions

09:30	P4	AKBP 8	Poster AKBP
11:00	SCH/A117	AKBP 9	RF Cavities I
15:00	SCH/A117	AKBP 10	Plasma Accelerators, Diagnostics I
16:30	SCH/A117	AKBP 11	Plasma Accelerators, Diagnostics II

AIW

Invited Talks, Discussions

14:10	BAR/SCHÖ	AIW 1.2	From Particle Physics to Patient Care – The Evolution of Accelerator-Based Tumor Therapy in Germany •Andrea Denker
14:30	BAR/SCHÖ	AIW 1.3	High Energy X-rays: Pioneering Hope and Success in Cancer Therapy •Stefan Scheib
14:50	BAR/SCHÖ	AIW 1.4	A Compact Accelerator Driven Neutron Source for Industry and Medicine •Holger Höltermann
15:10	BAR/SCHÖ	AIW 1.5	Panel discussion: Precision, Particles, Patients – The Future of Accelerator-Based Therapies •Andrea Denker, •Stefan Scheib, •Holger Höltermann, •John Kettler

Wednesday, March 11, 2026

AIW

16:00	BAR/SCHÖ	AIW 2.2	Accelerating Research with Particle Accelerators •Christoph Quitmann
16:20	BAR/SCHÖ	AIW 2.3	Advancements in Superconductor Technology for High-Energy Accelerators and Fusion Applications •Klaus Schlenga
16:40	BAR/SCHÖ	AIW 2.4	Application of Electron Accelerators for the Crosslinking of Polymers in Industry •Andreas Ostrowicki
17:00	BAR/SCHÖ	AIW 2.5	Panel discussion: Accelerating Innovation – Industrial Applications of High-Energy Physics •Christoph Quitmann, •Klaus Schlenga, •Andreas Ostrowicki, •John Kettler
			Sessions
14:00	BAR/SCHÖ	AIW 1	Medical Applications – Accelerators in the Service of Health
15:55	BAR/SCHÖ	AIW 2	Medical Applications – Accelerators in the Service of Health
17:20	BAR/SCHÖ	AIW 3	Ceremony of the DPG Technology Transfer Award & Presentation
18:00	BAR/SCHÖ	AIW 4	Open Reception of the AIW for the winners

JOB

			Invited Talks
11:00	HSZ/0405	JOB 2.1	Data-Analytics in der HUK-COBURG – Wie Physiker den Weg in ein datengetriebenes Versicherungsunternehmen mitgestalten •Jannik Hofestädt, •Andreas Gleixner, •Goran Nakerst
13:00	HSZ/0405	JOB 2.2	Basycon Unternehmensberatung GmbH: Aus der Wissenschaft in die Beratung •Tobias Weisrock, •Katharina Gräßel
15:00	HSZ/0405	JOB 2.3	Pädagogischen Hochschule Karlsruhe: Physik studiert – und jetzt? Dein Weg ins Lehramt. •Kay Burger, •Yvonne Ewen
			Session
11:00	HSZ/0405	JOB 2	Job Market II

09:30	Tents A and C	**Exhibition of Scientific Instruments and Literature** (free entrance)

			Public Evening Talk (free entrance)
19:00	HSZ/AUDI	PSV VIII	Gravitationswellenastronomie – quo vadis? •Michèle Heurs

DPG Industry Day & Technology Transfer Award 2026

High Energy Meets High Impact – Industrial and Medical Applications of Accelerators

The Industry Day will be held as part of the DPG Spring Conference, which usually has over 6,000 participants. Around 250 people (mostly students and doctoral candidates) taking part in the Industry Day, which is organized and carried out by the Industry and Economy Working Group (AIW) of the DPG. The aim of the events is to inspire students and PhD candidates for careers in business and industry. Following the Industry Day the DPG Technology Transfer Award will be conferred.

2.00 p.m.	**Welcome and greeting** Dr. Hans-Georg Grothues / Chairman of the AIW Dr. John Kettler / Moderator
Topic 1	**Medical Applications – Accelerators in the Service of Health**
2.10 p.m.	**From Particle Physics to Patient Care – The Evolution of Accelerator-Based Tumor Therapy in Germany** Prof. Dr. Andrea Denker – Helmholtz-Zentrum für Materialien und Energie
2.30 p.m.	**High Energy X-rays: Pioneering Hope and Success in Cancer Therapy** Dr. Stefan Scheib – Varian Medical Systems Imaging Lab GmbH
2.50 p.m.	**A Compact Accelerator Driven Neutron Source for Industry and Medicine** Holger Höltermann – Bevatech GmbH
3.10 p.m.	**Panel discussion: Precision, Particles, Patients – The Future of Accelerator-Based Therapies**
3.30 p.m.	**Coffee break**
3:55 p.m.	**Find your way: Career orientation and support from the DPG** Gabriele Becker – Advisor to the DPG Board
Topic 2	**Industrial Applications – Accelerators for Safety, Quality, and Innovation**
4.00 p.m.	**Accelerating Research with Particle Accelerators** Dr. Christoph Quitmann – RI Research Instruments
4.20 p.m.	**Advancements in Superconductor Technology for High-Energy Accelerators and Fusion Applications** Dr. Klaus Schlenga – Bruker Energy & Supercon Technologies
4.40 p.m.	**Application of Electron Accelerators for the Crosslinking of Polymers in Industry** Dr. Andreas Ostrowicki – BGS Beta-Gamma-Service
5.00 p.m.	**Panel discussion: Accelerating Innovation – Industrial Applications of High-Energy Physics**
5.20 p.m.	**Ceremony of the DPG Technology Transfer Award & Presentation**
6.00 p.m.	**Open Reception of the AIW for the winners**

As of January 12, 2026, subject to program changes

Technical University of Dresden
Schönfeld-Hörsaal BAR/SCHÖ/E
Georg-Schumann-Straße 13
01069 Dresden

March, 11th 2026
2:00 – 7:30 p.m.

Thursday, March 12, 2026

Plenary Talks

08:30	HSZ/AUDI	PV VIII	Insights into aqueous solution oxide interfaces from ab initio neural network potential molecular dynamics •Annabella Selloni
14:00	HSZ/AUDI	PV IX	On the sunny side – polymer-based organic solar cells •Peter Müller-Buschbaum
14:00	HSZ/0002	PV X	Towards a Science of Cities: A Complex Systems Approach •Marta Gonzalez

Prize Talks

13:00	HSZ/0002	PRV V	Observation of Floquet states in graphene •Marcel Reutzel (Laureate of the Walter-Schottky-Prize 2026)
13:00	HSZ/0003	PRV VI	Knots and Links in Magnetism •Maria Azhar (Laureate of the Hertha-Sponer-Prize 2026)

Lunch Talk

13:00	HSZ/0004	PSV IX	The organic development and growth story of aSpect Systems GmbH •Marcus Verhoeven

SYAI

Invited Talks

09:30	HSZ/AUDI	SYAI 1.1	Data and Experimental Foundations for Reliable Self-Driving Laboratories •Dr. Marcus Tze-Kiat Ng
10:00	HSZ/AUDI	SYAI 1.2	Digital Catalysis – AI for Experiment Planning and Control •Christoph Scheurer
10:30	HSZ/AUDI	SYAI 1.3	Autonomous, Data-Driven Workflows for Materials Acceleration Platforms with pyiron •Jan Janssen
11:15	HSZ/AUDI	SYAI 1.4	Machine Learning for Autonomous Optimization and Discovery of Materials •Pascal Friederich
11:45	HSZ/AUDI	SYAI 1.5	Transforming Our View on Transformers in the Sciences •Kevin Maik Jablonka

Session

09:30	HSZ/AUDI	SYAI 1	AI and Data Challenges behind Emerging Self-Driving Laboratories

SYTP

Invited Talks

15:00	HSZ/AUDI	SYTP 1.1	Social Tipping in Heterogeneous and Polarized Populations •Sara Constantino
15:30	HSZ/AUDI	SYTP 1.2	Tipping points and regime shifts in coupled social-climate systems •Chris Bauch
16:00	HSZ/AUDI	SYTP 1.3	How to tune Earth system models toward tipping? •Sebastian Bathiany
16:45	HSZ/AUDI	SYTP 1.4	Algorithmic amplification and contextual sensitivity in political information exposure •Joana Gonçalves de Sá
17:15	HSZ/AUDI	SYTP 1.5	The complex interplay between democracy and platform power •Philipp Lorenz-Spreen

Session

15:00	HSZ/AUDI	SYTP 1	Tipping Points in Social and Climate Systems

BP

Invited Talks

11:15	BAR/SCHÖ	BP 26.7	Directed evolution of material-producing bacteria •André Studart

Thursday, March 12, 2026

BP

09:30	BAR/0205	BP 27.1	Tissue interplay and the coordination of morphogenesis •Elias Barriga
10:15	BAR/0106	BP 30.1	Mechanogenetics for Cell ImmunoTherapy •Yingxiao Wang
11:30	BAR/0106	BP 30.4	Recent theoretical progress on sound-propelled microsystems •Raphael Wittkowski
15:00	BAR/0205	BP 33.1	Expanding the Bag of Optical Tricks for (Neuro)Biology •Fabian F. Voigt

Sessions

09:30	BAR/SCHÖ	BP 26	Biomaterials and Biopolymers
09:30	BAR/0205	BP 27	Cell Mechanics I
09:30	ZEU/0160	BP 28	Active Matter V
09:30	ZEU/0260	BP 29	Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates I
10:15	BAR/0106	BP 30	Focus Session: Controlling Microparticles and Biological Cells by Ultrasound
11:30	ZEU/0260	BP 31	Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates II
15:00	BAR/SCHÖ	BP 32	Statistical Physics of Biological Systems III
15:00	BAR/0205	BP 33	Bioimaging
15:00	ZEU/0160	BP 34	Focus Session: Emergent Transport in Active Systems
15:15	ZEU/LICH	BP 35	Focus Session: 75 Years Division Polymer Physics: From Curiosity to Smart Materials

CPP

Invited Talk, Topical Talks

09:30	ZEU/LICH	CPP 44.1	Shedding light on wide bandgap perovskites •Michael Saliba
09:30	ZEU/0260	CPP 45.1	Wetting transitions in biomolecular coacervates •Susanne Liese
15:15	ZEU/LICH	CPP 51.1	The Loops of Life •Michael Rubinstein
15:45	ZEU/LICH	CPP 51.2	Polyelectrolytes and Biological Systems: A Charged Relationship •Matthias Ballauff
16:15	ZEU/LICH	CPP 51.3	From block copolymer morphologies to functional polymer membranes •Volker Abetz
16:45	ZEU/LICH	CPP 51.4	Molecular electronic materials and devices for solar energy conversion •Jenny Nelson
17:15	ZEU/LICH	CPP 51.5	Control of cell and tissue stiffness by biopolymer networks and particle inclusions •Paul Janmey

Sessions

09:30	BAR/SCHÖ	CPP 43	Biomaterials and Biopolymers
09:30	ZEU/LICH	CPP 44	Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics V
09:30	ZEU/0260	CPP 45	Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates I
09:30	P5	CPP 46	Poster II
10:15	BAR/0106	CPP 47	Focus Session: Controlling Microparticles and Biological Cells by Ultrasound
11:30	ZEU/LICH	CPP 48	Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics VI
11:30	ZEU/0255	CPP 49	Gels, Polymer Networks and Elastomers I
11:30	ZEU/0260	CPP 50	Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates II
15:15	ZEU/LICH	CPP 51	Focus Session: 75 Years Polymer Physics Division: From Curiosity to Smart Materials
18:00	ZEU/LICH	CPP 52	Members' Assembly

Thursday, March 12, 2026

DS

Invited Talk

17:00	REC/C213	DS 18.8	Insights from Quantum Dynamics Simulations: From Molecules to Organic-Material Interfaces •Frank Ortmann

Sessions

09:30	HSZ/0003	DS 15	Focus Session: Nickelate Superconductivity: Insights into Unconventional Pairing and Correlation Effects II
09:30	REC/C213	DS 16	Thin Film Application
15:00	HSZ/0003	DS 17	Focus Session: High-Temperature Superconductivity in Hydride Materials at High Pressures
15:00	REC/C213	DS 18	Spins in Molecular Systems
17:45	REC/C213	DS 19	Members' Assembly
18:30	P2	DS 20	Poster

DY

Invited Talks

09:30	ZEU/0160	DY 49.1	Active memory and non-reciprocity as pathways to pattern formation in conserved scalar fields •Suropriya Saha
15:00	ZEU/0160	DY 55.1	Out-of-equlibrium synthetic cells: the future of active matter •Laura Alvarez
15:45	ZEU/0160	DY 55.3	Chemotactic like behavior in by active Brownian particles: from single particles to to polymers •Hidde Vuijk
16:45	ZEU/0160	DY 55.5	From non-reciprocal torques towards shape-flexible and res-ponsive prototypic worms •Holger Stark

Sessions

09:30	GÖR/0226	DY 45	Focus Session: Physics of AI – Part I
09:30	HÜL/S186	DY 46	Many-body Quantum Dynamics I
09:30	ZEU/0114	DY 47	Statistical Physics: General I
09:30	ZEU/0118	DY 48	Nonlinear Dynamics and Time-Delay Systems
09:30	ZEU/0160	DY 49	Active Matter V
10:15	BAR/0106	DY 50	Focus Session: Controlling Microparticles and Biological Cells by Ultrasound
11:15	ZEU/0118	DY 51	Networks: From Topology to Dynamics – Part III
15:00	BAR/SCHÖ	DY 52	Statistical Physics of Biological Systems III
15:00	HÜL/S186	DY 53	Many-body Quantum Dynamics II
15:00	ZEU/0114	DY 54	Statistical Physics: General II
15:00	ZEU/0160	DY 55	Focus Session: Emergent Transport in Active Systems
18:00	ZEU/0160	DY 56	Members' Assembly

FM

Invited Talks

09:30	BEY/0138	FM 17.1	Piled higher, probed deeper: X-ray insights into ferroelectric devices •Martina Müller
10:15	BEY/0138	FM 18.1	Stabilizing antiferroelectricity in PbZrO3 thin films using epitaxial tensile strain •Vincent Garcia
10:45	BEY/0138	FM 18.2	Strain effects in free-standing membranes of antiferroelectric Lead Zirconate •Umair Saeed

Sessions

09:30	BEY/0138	FM 17	Highlighted Talk: Piled higher, probed deeper: X-ray insights into ferroelectric devices (Martina Müller)
10:15	BEY/0138	FM 18	German-French Focus Session: (Anti)ferroic states – ferroelectrics, ferroelastics and antiferroelectrics II

Thursday, March 12, 2026

FM

10:15	BEY/0E40	FM 19	Advanced Microscopy and Tomography for Functional Materials
13:30	Infineon	FM 20	Excursion and Network-Event at Infineon Dresden AG
18:00	BEY/0138	FM 21	Members Assembly

HL

Invited Talks

11:15	POT/0006	HL 42.1	Transition Metal Nitride Semiconductors for Photoelectrochemical Energy Conversion •Verena Streibel
15:30	POT/0051	HL 46.3	Antisymmetric vibrations in the excited state dynamics of quadrupolar dyes •Antonietta De Sio
16:15	POT/0081	HL 49.1	Phonon-mediated nonlinearity and defects in hexagonal boron nitride •Nahid Talebi

Sessions

09:30	POT/0006	HL 37	Nitrides II – Designed properties and LED
09:30	POT/0051	HL 38	Materials and Devices for Quantum Technology II
09:30	POT/0081	HL 39	2D semiconductors VII – CrSBr and related heterostructures
09:30	POT/0251	HL 40	Oxide Semiconductors: Transport and Spectroscopy
11:00	HSZ/0101	HL 41	Quantum Dots and Point Contacts
11:15	POT/0006	HL 42	Nitrides III – Emerging thin films and electrochemistry
13:30	Infineon	HL 43	Excursion and Network-Event at Infineon Dresden AG
15:00	HSZ/0204	HL 44	2D Materials: Electronic structure, excitations, etc. III
15:00	POT/0006	HL 45	Perovskite and Photovoltaics: Spectroscopy
15:00	POT/0051	HL 46	Ultra-fast Phenomena II
15:00	POT/0081	HL 47	2D Materials VIII – Quantum emitters and defects
15:00	POT/0251	HL 48	Heterostructures, Interfaces and Surfaces: Fabrication and Structure
16:15	POT/0081	HL 49	Quantum Emitters in 2D Semiconductors
17:45	POT/0051	HL 50	Members' Assembly

MA

Invited Talks

09:30	HSZ/0002	MA 40.1	Magnetic order induced chiral phonons in a ferromagnetic Weyl semimetal •Luyi Yang
11:15	HSZ/0002	MA 40.6	Thermal Hall Effects of Magnons and Phonons •Alexander Mook
09:30	POT/0112	MA 43.1	Defect-Induced Phase Transitions in the 2D Magnetic Semiconductor CrSBr •Shengqiang Zhou
09:30	POT/0151	MA 44.1	2D and 3D racetracks: Interplay of geometric and magnetic chiralities •Stuart Parkin
10:00	POT/0151	MA 44.2	Combined MFM/KPFM at the Ultimate Sensitivity Limit for Probing Curvature-Engineered Micromagnetic States •Emily Darwin
10:30	POT/0151	MA 44.3	Curvilinear magnetism in superconducting spintronics •Sol Jacobsen
11:15	POT/0151	MA 44.4	Advanced Control of Magnetic Nanostructures via Metasurface Engineering and Voltage-Driven Functionalities •Anna Palau
11:45	POT/0151	MA 44.5	Magnetic tomography of noncollinear spin textures in curvilinear geometries •Sandra Ruiz-Gomez

Sessions

09:30	HSZ/0002	MA 40	Focus Session: Chiral phonons and crystals coupled to magnetic order II
09:30	HSZ/0003	MA 41	Focus Session: Nickelate Superconductivity: Insights into Unconventional Pairing and Correlation Effects II
09:30	HSZ/0004	MA 42	Molecular Magnetism and Magnetic Particles / Clusters II
09:30	POT/0112	MA 43	Spin-Dependent Phenomena in 2D

Thursday, March 12, 2026

MA

09:30	POT/0151	MA 44	Focus Session: Curvilinear magnetism: Magnetics with nanoscale curved geometries
09:30	POT/0351	MA 45	Magnetic Relaxation and Gilbert Damping
09:30	POT/0361	MA 46	Magnetic Imaging Techniques II
15:00	HSZ/0002	MA 47	Altermagnets V
15:00	HSZ/0004	MA 48	Magnonics II
15:00	POT/0112	MA 49	Magnetic Imaging, Information Technology, and Sensors
15:00	POT/0151	MA 50	Bulk Materials: Soft and Hard Permanent Magnets
15:00	POT/0361	MA 51	Spin Transport and Orbitronics, Spin-Hall Effects II
15:00	P4	MA 52	Poster Magnetism III
18:00	HSZ/0002	MA 53	Members' Assembly

MM

Invited Talks, Topical Talks

09:30	SCH/A251	MM 29.1	Three dimensional sub-Ångström resolution imaging from 4D-STEM experiments •Philipp Pelz
10:15	SCH/A251	MM 32.1	High-Throughput Nanomechanics and Data-Driven Workflows for Mapping Composition-Microstructure-Property Landscapes •Ruth Schwaiger
11:00	SCH/A251	MM 32.3	Expanding nanoindentation capabilities: Data-driven and novel experimental approaches •Michael Wurmshuber
11:45	SCH/A251	MM 32.4	Additive Manufacturing and Nanomechancics – where is the Link? •Ralph Spolenak
15:00	SCH/A251	MM 33.1	LPBF with Ultrashort Laser Pulses - Additive Manufacturing Beyond Current Limits •Stefan Nolte
15:45	SCH/A251	MM 36.1	High-temperature micropillar compression for understanding dislocation-precipitates interactions in Ni-Based superalloys •Subin Lee

Sessions

09:30	SCH/A251	MM 29	Invited Talk: Philipp Pelz
10:15	SCH/A215	MM 30	Interface Controlled Properties, Nanomaterials, and Microstructure Design II
10:15	SCH/A216	MM 31	Transport in Materials: Diffusion, Charge, or Heat Conduction II
10:15	SCH/A251	MM 32	Topical Session: Advanced Nanomechanics – Accelerating Materials Physics from the Bottom I
15:00	SCH/A251	MM 33	Invited Talk: Stefan Nolte
15:45	SCH/A215	MM 34	Hydrogen in Materials I
15:45	SCH/A216	MM 35	Additive Manufacturing / Transport in Materials III
15:45	SCH/A251	MM 36	Topical Session: Advanced Nanomechanics – Accelerating Materials Physics from the Bottom II
15:45	SCH/A315	MM 37	Development of Calculation Methods I

O

Invited Talks, Topical Talk

09:30	TRE/PHYS	O 75.1	Oxide interfaces as platforms for emergent quantum phenomena •Manuel Bibes
10:30	HSZ/0401	O 78.1	The Wendelstein 7-X plasma vessel vacuum system from a scientific perspective •Georg Schlisio
10:30	WILL/A317	O 82.1	Low-energy inverse photoelectron spectroscopy (LEIPS): probing unoccupied states and conduction band structure in functional materials •Hiroyuki Yoshida
11:00	WILL/A317	O 82.2	Enhanced Sensitivity in Low-Energy Inverse Photoemission Spectroscopy with an Off-Axis Parabolic Mirror for Efficient Light Collection •Yongsup Park

Thursday, March 12, 2026

O

15:00	HSZ/0401	O 85.1	From light to pressure: Laser-based quantum technologies for the realization of high-precision pressure and vaccum standards •Tom Rubin
15:00	HSZ/0403	O 86.1	Ultrafast Dynamics at Surfaces with Machine Learning Surrogates •Reinhard Maurer

Sessions

09:30	TRE/PHYS	O 75	Topical Talk Bibes
10:30	HSZ/0201	O 76	Electronic structure of surfaces: Spectroscopy, surface states II
10:30	HSZ/0204	O 77	Nanostructures at surfaces:1D, 2D, networks II
10:30	HSZ/0401	O 78	Vacuum Science & Technology: Theory and Applications I
10:30	HSZ/0403	O 79	Plasmonics and nanooptics: Light-matter interaction, spectroscopy III
10:30	TRE/PHYS	O 80	Gerhard Ertl Young Investigator Award Competition
10:30	TRE/MATH	O 81	Catalysis and surface reactions II
10:30	WILL/A317	O 82	Focus Session: Unoccupied States by Inverse Photoemission III
15:00	HSZ/0201	O 83	Organic molecules on inorganic substrates: electronic, optical and other properties III
15:00	HSZ/0204	O 84	2D Materials: Electronic structure, excitations, etc. III
15:00	HSZ/0401	O 85	Vacuum Science & Technology: Theory and Applications II
15:00	HSZ/0403	O 86	Surface dynamics
15:00	TRE/PHYS	O 87	Solid-liquid interfaces: Structure, spectroscopy
15:00	TRE/MATH	O 88	Catalysis and surface reactions III
15:00	WILL/A317	O 89	Spins on surfaces at the atomic scale II
17:15	HSZ/0401	O 90	Members' Assembly of the Vacuum Science and Technology Divison (VA)
19:00	HSZ/AUDI	O 91	Members' Assembly
19:30	HSZ/AUDI	O 92	Post-Deadline Session

SOE

Invited Talks

09:30	GÖR/0226	SOE 14.1	Generative AI and diffusion models: a statistical physics approach •Giulio Biroli
11:30	GÖR/0226	SOE 16.1	Tipping in Strongly Perturbed Open Networks •Marc Timme

Sessions

09:30	GÖR/0226	SOE 14	Focus Session: Physics of AI I
11:15	ZEU/0118	SOE 15	Networks: From Topology to Dynamics III
11:30	GÖR/0226	SOE 16	Tipping Points in Social and Climate Systems (accompanying session for SYTP)

TT

Topical Talks

15:00	HSZ/0003	TT 80.1	Computational searches for conventional high temperature superconductivity •Chris Pickard
15:30	HSZ/0003	TT 80.2	High-pressure synthesis of hydrides and their characterisation by single-crystal X-ray diffraction •Natalia Dubrovinskaia
16:00	HSZ/0003	TT 80.3	Electrical Transport Studies in bulk and thin-film hydride high-temperature superconductors •Sven Friedemann
16:45	HSZ/0003	TT 80.4	Near room-temperature conventional superconductivity in hydrogen-rich compounds at high pressures: Experimental evidences •Vasily Minkov
17:15	HSZ/0003	TT 80.5	Predictive Tc Calculations in Hydride Superconductors •Christoph Heil

Sessions

09:30	HSZ/0003	TT 69	Focus Session: Nickelate Superconductivity: Insights into Unconventional Pairing and Correlation Effects II

Thursday, March 12, 2026

TT

09:30	HSZ/0101	TT 70	Correlated Electrons: Method Development III

Plenary Talks

Plenary Talk PLV I Mon 8:30 HSZ/AUDI

Cavity-altered superconductivity — •Dmitri Basov — Columbia University, New York, USA

Is it feasible to alter the ground state properties of a material by engineering its electromagnetic environment? Inspired by theoretical predictions, experimental realizations of such cavity-controlled properties without optical excitation are beginning to emerge. A grand aspiration of cavity quantum materials research is to uncover fundamentally new routes for controlling properties of matter by judiciously tailoring the quantum electromagnetic environment. We devised and implemented a novel platform to realize cavity-altered materials. Single crystals of hyperbolic van der Waals (vdW) compounds provide a resonant electromagnetic environment with enhanced density of photonic states and prominent mode confinement. We interfaced hexagonal boron nitride (hBN) with the molecular superconductor κ-(BEDT-TTF)2Cu[N(CN)2]Br (κ-ET). Meissner effect measurements demonstrate a strongly altered superfluid density at the hBN/κ-ET interface. Our work highlights the potential of dark cavities devoid of external photons for engineering electronic ground state properties of complex quantum materials. To appear in Nature in 2026.

Plenary Talk PLV II Mon 14:00 HSZ/AUDI

Towards Intelligent Matter: Energy-Efficient In-Materio Computing — •Karin Everschor-Sitte — Faculty of Physics and Center for Nanointegration Duisburg-Essen, University of Duisburg-Essen, Duisburg, Germany

The rapid expansion of artificial intelligence has driven computational demands to unprecedented levels, making power consumption a central bottleneck for state-of-the-art hardware architectures. This presentation addresses how functional materials, including magnetic, ferroelectric, optical, and plasmonic systems, offer a path beyond this limitation by leveraging their intrinsic physical properties to compute and process information directly within matter. Our research centers on magnetic materials, whose nonlinear, complex hysteretic responses make them particularly well-suited for low-energy, efficient unconventional computing paradigms like reservoir computing. Advances in harnessing magnetic and ferroelectric textures for in-materio computation will be presented. These developments outline how coordinated integration of material properties, algorithmic design, and device engineering can enable high-performance, energy-efficient computing technologies and ultimately pave the way toward intelligent matter.

Plenary Talk PLV III Mon 14:00 HSZ/0002

Simulating the Hubbard model with moiré semiconductors — •Jie Shan — Max Planck Institute for the Structure and Dynamics of Matter — Cornell University

The Hubbard model is a simple theoretical model of interacting quantum particles in a lattice. It is believed to capture the essential physics of many strongly correlated phenomena, such as high-temperature superconductivity, magnetism, and metal-insulator transitions, but has proved difficult to solve accurately except in one dimension. Physical realizations of the Hubbard model therefore have a vital role to play in the study of correlation physics. Moiré materials, formed by overlaying two van der Waals materials of slightly different orientations or lattice constants, have recently emerged as a promising Hubbard model simulator. In this talk, I will review the recent experimental progress on the realization of both the triangular and honeycomb lattice Hubbard models, and how the electronic phase diagram evolves with the U/W ratio (where U and W denote the onsite Coulomb repulsion and the moiré bandwidth, respectively).

Plenary Talk PLV IV Tue 8:30 HSZ/AUDI

Spins in Quantum Dots: The Quiet Revolution — •Dorian Gangloff — Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom

Solid-state spins in semiconductors provide a natural interface between stationary qubits and single photons, forming key building blocks for future quantum communication networks. Historically, semiconductor quantum dots (QDs) were considered too noisy for spin physics: strong hyperfine interactions within a mesoscopic system, materials inhomogeneity, and limited control tools once cast doubt on their suitability as coherent spin qubits. In recent years this perception has shifted dramatically. Advances in growth, device engineering, coherent control, and nuclear-spin cooling have ushered in a quiet revolution in III-V QDs. They now exhibit excellent optical coherence, near-unity photon collection when integrated with photonic structures, and spin degrees of freedom with long coherence times.

In this talk I will present three developments that illustrate this transformation: (1) High-fidelity electron-spin control, (2) Quantum memories from nuclear spins, and (3) Deterministic design of QD properties prior to growth.

Together, these advances reveal how the long-standing "noise problem" in III-V quantum dots is being turned into a resource, and underline their emergence as a platform for quantum communication and quantum information processing.

Plenary Talk PLV V Wed 8:30 HSZ/AUDI

Reimagining Physics Education for a Planet in Transformation — •Giulia Tasquier — Department of Physics and Astronomy, ALMA MATER STUDIRUM - University of Bologna, Bologna, Italy

The accelerating climate crisis intensifies the need to interpret complex evidence and act upon it. While physics and climate science offer foundations for understanding global warming, scientific knowledge alone does not suffice to support informed action. This plenary examines how physics education can help bridge this gap. Drawing on research in climate change education, I discuss how modelling, causal reasoning, and the epistemology of complex systems can strengthen students' understanding of climate phenomena and uncertainty in scientific prediction. Insights from futures studies highlight the importance of anticipating alternative scenarios and moving beyond deterministic expectations. Integrating these perspectives supports what we define as agency: a capacity connecting scientific understanding with ethical reflection and imaginative anticipation. Empirical work shows that students engaging with complexity-based explanations expand their imaginative horizons and begin to position themselves as agents within complex climate futures. Activities such as exploring branching scenarios or reframing narratives of the climate crisis help them see the future not as fixed, but as a space of plurality, contingency, and imagination. The talk outlines a three-dimensional framework on agency to integrate these elements into physics education, reimagining it as a practice of freedom that turns complexity into a resource for imagination and solidarity.

Plenary Talk PLV VI Wed 14:00 HSZ/AUDI

Materials selection methods: a compass in the jungle — •Yves Bréchet — Monash University, Materials Science Department, Clayton Campus, Melbourne, Australia

Materials use and development have undergone a profound transformation in the last decades: the "book of specifications" is more and more demanding, more and more multifunctional, and additional requests such as sustainability have progressively strengthened conflicting requirements. At the same time, the variety of materials available to engineers has expanded in such a way that materials selection and materials design is a must for efficient use of materials. To meet this new request, materials and process databases, and materials selection tools have been developed in the last 20 years, allowing both for a better use of materials, and for a guidance of "materials by design". The case of materials associated with a prescribed geometry, so-called "architectured materials", are a striking example of this evolution from "materials by chance", via "materials in competition", to "materials by design". Recent developments in AI to generate new materials open new opportunities and raise new challenges for this general trend toward materials by design.

Plenary Talk PLV VII Wed 14:00 HSZ/0002

Stronger yet weaker: Long-range orientational order in 2D active matter — •Hugues Chaté — CEA - Saclay, France

The Mermin-Wagner-Hohenberg theorem tells us that, in a 2D system in equilibrium, the spontaneous breaking of a continuous symmetry cannot lead to true long-range order. Out of equilibrium, and in particular in active matter systems, it is now well known that 2D true long-range orientational order is possible.

I will first give an updated view of our knowledge of polarly ordered phases in 2D active matter systems. I will then proceed to show that many of these phases are metastable to the nucleation of droplets which, opposite to the Peierls argument at play in equilibrium, grow and eventually destroy order. Order is thus both stronger (truly long-range) and weaker (metastable) in 2D active systems.

Plenary Talk PLV VIII Thu 8:30 HSZ/AUDI

Insights into aqueous solution oxide interfaces from ab initio neural network potential molecular dynamics — •Annabella Selloni — Princeton University, Department of Chemistry, Princeton, NJ, United States

Aqueous solution-oxide interfaces play a critical role in many environmental, biological, and energy-relevant processes. Molecular dynamics (MD) simulations employing ab initio based deep neural network potentials (DPs) have recently emerged as a valuable approach to complement experimental observations and obtain detailed molecular scale insights. In this talk, I shall discuss recent applications of DP-MD to understand the structure and properties of aqueous solution-oxide interfaces. Focusing on titanium dioxide, a prototypical metal oxide with a prominent role in energy applications, specific topics will include characterization of the electrified TiO2-electrolyte interface, and the effects of organic compounds such as formic acid and methanol on the structure and chemistry of water at the interface.

Plenary Talk PLV IX Thu 14:00 HSZ/AUDI

On the sunny side - polymer-based organic solar cells — •Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany

Polymer-based organic solar cells open up new fields of application compared to conventional silicon-based solar cells, as they are flexible, lightweight, color-adjustable, and potentially very cost-effective. In addition, they also function in low-light conditions and have a high power density, which makes them very attractive for space applications, in addition to their classic terrestrial applications. Since 2025, single-junction organic solar cells have surpassed the magic 20% efficiency rate. Moreover, organic solar cells are also successfully combined with other solar technologies in tandem devices as recently demonstrated with an efficient near-infrared harvesting in perovskite-organic tandem solar cells [1]. Current research questions focus on the aging mechanisms of organic solar cells and the feasibility of converting solar cell production to highly scalable manufacturing methods. The Müller-Buschbaum Group is investigating both issues using advanced X-ray and neutron scattering methods in situ and operando during production [2] and solar cell operation [3]. In addition, the Müller-Buschbaum Group has conducted pioneering work in investigating organic solar cells in space, demonstrating that organic solar cells function equally well in space as they do in the laboratory [4]. [1] Nature 643, 104-110 (2025); [2] Adv. Energy Mater. 15, 2404724 (2025); [3] Nano Energy 140, 111043 (2025); [4] Joule 4, 1880-1892 (2020)

Plenary Talk PLV X Thu 14:00 HSZ/0002

Towards a Science of Cities: A Complex Systems Approach — •Marta Gonzalez — UC Berkeley, USA

Cities are complex systems whose dynamics emerge from the interactions of millions of individuals, institutions, and infrastructures. In this talk, I present a framework that applies the principles of complex systems science to urban environments, aiming to uncover unifying patterns and mechanisms that govern urban behavior. Drawing on large-scale mobility, traffic, emissions, and financial transaction data, I show how cities can be studied as living laboratories of collective behavior. First, I examine the macroscopic dynamics of urban traffic, identifying critical thresholds that mark the onset and collapse of mobility systems across different cities, and framing these collapses as nonequilibrium phase transitions. I then explore the environmental consequences of these dynamics, introducing a scalable model that links real-world mobility patterns to vehicular CO* emissions, highlighting the pivotal role of vehicle kilometers traveled. Shifting focus to spatial structure, I illustrate how mobility data reveals the transformation of urban form in response to disruptive events, such as pandemics, and offer novel metrics to quantify home-based travel and structural shifts. Finally, I demonstrate how behavioral regularities in credit card transaction sequences encode individual lifestyles and social structures, showing how economic activity reflects deeper patterns of urban life. Together, these studies underscore the value of a data-driven, systems-oriented approach to understanding and shaping the future of cities.

Plenary Talk PLV XI Fri 8:30 HSZ/AUDI

Phase separation in Cell Physiology and Disease — •Anthony Hyman — Pfotenhauerstraße 108

Cells organize many of their biochemical reactions by formation and dissolution of non-membrane-bound compartments. Recent experiments show that a common mechanism for such biochemical organization is phase separation of unstructured proteins to form liquid-like compartments. These liquid-like compartments can be described by principles elucidated from condensed-matter physics and are therefore termed biomolecular condensates. I will discuss the relationship between the formation of liquid like compartments, quality control mechanisms that preserve the liquid-like state, and the onset of aggregated-protein pathology that is commonly observed in neurodegenerative diseases.

Prize Talks

Prize Talk PRV I Mon 13:00 HSZ/0002

Driven Quantum Materials: Controlling Emergent Phenomena away from Equilibrium — •Andrea Cavalleri — Max Planck Institute for the Structure and Dynamics of Matter — Laureate of the Stern-Gerlach-Medal 2026

I will discuss how coherent electromagnetic radiation, when tuned to collective modes in quantum materials, can be used to induce unexpected dynamical phenomena. The core idea is that when uncoupled normal modes are driven nonlinearly, complex correlations are created that are absent in equilibrium. Emergent dynamical orders, which include superconductivity, magnetism, ferroelectricity and other functional phenomena, are created in this way, with both fundamental and applied ramifications. I will touch on the crucial importance of modern ultrafast X-Ray Free Electron Lasers, and novel THz sources that are matched to these.

Prize Talk PRV II Tue 13:00 HSZ/0002

Polymers / Soft Matter as Model Systems for Physics — •Kurt Kremer — MPI für Polymerforschung, Mainz, Deutschland — Laureate of the Max-Planck-Medal 2026

Polymers, long chain molecules, comprise important materials of our daily life, being it simple commodities with all their advantages and disadvantages or high-tech materials in electronics or medicine, etc. Furthermore, bio-polymers such as cellulose or DNA are central constituents of living organisms. Thus, polymers have been subject of applied physics since their discovery. That, however, changed with de Gennes' n->0 theorem, showing that the inverse chain length 1/N can be mapped onto the distance |T-Tc|/Tc from the critical point in a n-vector spin model. At about the same time computer simulations became powerful tools to study critical phenomena, complemented by experiment, most notably neutron scattering for polymers. All this marked the start of polymers becoming versatile systems to study critical phenomena.

Polymers/Soft Matter are susceptible to small molecular stimuli. Thus, minute shifts in local interactions easily turn into macroscopic property changes. Here generic physical concepts meet chemical details, making polymers so versatile. The talk will review a few examples, where such effects lead to physically interesting phenomena (active systems, glass transition, nanoporous materials). Finally, new challenges imposed by soft matter will shortly be discussed.

Prize Talk PRV III Tue 13:00 HSZ/0004

Optics of single molecules explored with sub-nm precision — •Anna Rosławska — Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany — Laureate of the Gaede-Prize 2026

Light-matter interaction is essential for mechanisms such as luminescence, photosynthesis, and energy harvesting, defining the emission characteristics of molecular systems and governing the conversion of energy between photons and electrons. While these processes are intensively studied and employed, little is known about their dependence on atomic-scale properties since reaching such precision in optics is extremely demanding. This challenge is nowadays overcome thanks to the combination of optical spectroscopy approaches with scanning probe microscopy, which profit from the extreme field enhancement provided by the tip that enables atomic-scale optics [1]. In my talk, I will discuss how this approach can be applied to gate fluorescence by individual charges [2], used to induce photochemical reactions with sub-nm precision [3], and enables probing optical properties of individual biological pigments.

Prize Talk PRV IV Wed 13:00 HSZ/0003

Fractionalisation, fractals and strong coupling QED in spin liquids — •Roderich Moessner — MPI-PKS Dresden — Laureate of the Max-Born-Prize 2026

After a long and sustained research effort, the quest for an experimental realisation of a quantum spin liquid shows encouraging signs of nearing conclusion. This talk recalls some basic background on the nature of spin liquids and their place in what has become known as topological condensed matter physics. It then covers particularly notable properties which have been experimentally discovered in the magnetisation dynamics, namely the existence of a dynamical fractal and of disorder-free subdiffusion in three dimensions. It concludes with a discussion of the promise of realising an experimental platform for strong coupling quantum electrodynamics in the present work on pyrochlore materials.

Prize Talk PRV V Thu 13:00 HSZ/0002

Observation of Floquet states in graphene — •Marcel Reutzel — Philipps-Universität Marburg, Fachbereich Physik and mar.quest, Germany — Georg-August-Universität Göttingen, I. Physikalisches Institut, Germany — Laureate of the Walter-Schottky-Prize 2026

Material phases are traditionally controlled by parameters such as temperature or doping. Newer efforts employ ultrashort light pulses and correlated - but incoherent - interactions of the electron-lattice-spin systems to create non-thermal phases. While such on-demand material engineering has been established in the last years, more recent efforts strive for the coherent counterpart: By using time-periodic light fields (a.k.a Floquet engineering), new electronic band structures and correlated or even topological phases can be created. Importantly, these phases can then be coherently controlled by the properties of the light field. Therefore, fundamental research on Floquet engineering promises the realization of emergent material phases without any counterpart in thermal equilibrium.

Here, we will outline how the development of time-resolved momentum microscopy - a new variant of time- and angle-resolved photoelectron spectroscopy - has enabled the direct observation of Floquet states in monolayer graphene [1]. These proof-of-principle experiments on semi-metallic graphene open up a new pathway for testing the many theoretical proposals of light-induced phase transitions that have so far remained elusive.

[1] Merboldt *et al.*, Nature Physics 21, 1093 (2025).

Prize Talk PRV VI Thu 13:00 HSZ/0003

Knots and Links in Magnetism — •Maria Azhar — Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany — Laureate of the Hertha-Sponer-Prize 2026

Magnetic materials can host remarkably stable, intertwined structures that behave like knots, links, and braids; discrete objects that can be counted and, in principle, used to store information. This talk explains why such complex patterns can exist, ranging from magnetic whirls (Skyrmions) to knots and links (Hopfions), and three-dimensional objects that have only recently been observed, such as screw dislocations of spiral magnetic order.

In some magnets, the far-field is non-uniform, which fundamentally changes which knots or links are possible. Stability is then no longer described by a single number: new states emerge with fractional character, smoothly connecting configurations that would otherwise appear distinct.

At a deeper level, these phenomena follow a simple yet profound geometric idea: magnetic configurations map one sphere onto another, and their winding determines stability. Understanding the underlying principles turns knots and links into practical building blocks for robust and controllable magnetic matter.

Ceremonial, Lunch, Evening Talks and Discussions

Discussion PSV I Mon 13:00 HSZ/AUDI

Sustainability! And now? – Opportunities for young researchers — •Roxana Scharpegge[1,10,11], Hiroki Sayama[2,3], Thomas Schubatzky[4], Birte Höcker[5], Uwe Riedel[6], John Plane[7], Pauleo Nimtz[8,10], and Stefanie Falk[9,11] — [1]Bielefeld University — [2]Binghampton University, State University NY, USA — [3]The University of Tokyo, Japan — [4]Universität Innsbruck, Austria — [5]University of Bayreuth, Germany — [6]DLR Institute für CO2-arme Industrieprozesse, Cottbus, Germany — [7]University of Leeds — [8]Potsdam University, Germany — [9]Karlsruher Institut für Technologie — [10]Working Group Young DPG (AKjDPG) — [11]Working Group Climate (AGK)

Did you miss learning about sustainability during your studies? Does the flood of news about the climate crisis make you feel hopeless? Are you interested in having a societal impact through your day-to-day work? Your skills and experiences from diverse areas can be valuable in developing innovative solutions to sustainability challenges, as collaboration between different disciplines and sectors is crucial to creating a more sustainable future. In this panel discussion, we want to encourage you to consider a career in this future-shaping field.

Inspired by experiences and insights from experts who were once in the same position as you, we aim to offer you a glimpse into the opportunities available and discuss different career pathways. Feel free to contribute your own questions. We hope this discussion helps you in your decision to transform both your future and ours.

Lunch Talk PSV II Mon 13:00 HSZ/0004

Physics Meets Statistics: Advancing Data Analytics in Semiconductor Manufacturing — •Sarah Fischbach — Robert Bosch Semiconductor Manufacturing Dresden GmbH

After earning her Ph.D. in semiconductor physics, Sarah Fischbach transitioned to an industry career. In 2018, she joined the newly established semiconductor plant of Bosch in Dresden, where she began developing concepts and methodologies for data analytics and exploring applications of machine learning. Since 2022, she has been responsible for analytics and digitalization within the technology department of the 300 mm wafer fab. In this session, she will discuss the exciting challenges the semiconductor industry presents to physicists and share insights on how machine learning can support production processes.

Discussion PSV III Tue 13:00 HSZ/AUDI

Soft Science Skills - Self-branding for Scientists — •Lucas Kreuzer[1], •Christian Kuttner[2], and •Alexander Schlaich[3] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), TUM, Garching, Germany — [2]Nature Communications, Berlin, Germany — [3]Technische Universität Hamburg, Hamburg, Germany

This session explores communication and self-branding strategies designed for scientists, helping them to effectively communicate their expertise and build a recognizable professional identity. Our invited speakers will share insights on how science communication can be used as a tool to position oneself strategically within a research or industry field and how to benefit from the multiple opportunities of digital and social media platforms. Thereby, attendees will obtain a specific action plan on how they can enhance their visibility, credibility, and career opportunities in academia and industry.

Lunch Talk PSV IV Tue 13:00 HSZ/0003

Funding Opportunities for International Collaborations at the German Research Foundation — •Joanna Kowalska, Mario Bomers, Christian Hahn, and Michael Mössle — Deutsche Forschungsgemeinschaft e.V., Bonn; Germany

The German Research Foundation (Deutsche Forschungsgemeinschaft, DFG) is Germany's largest organisation for funding fundamental research. As a self-governing body that supports and promotes research, it offers a wide range of funding opportunities, from individual grants to large coordinated programmes. This talk will focus on the DFG's opportunities for supporting international collaborations. It will cover the ways in which international research partners can be included in individual grants and coordinated programmes, as well as outline dedicated funding opportunities for bi- and multilateral projects. It will also introduce the Walter Benjamin Programme, which supports researchers in their early career phase in gaining experience at a research institution, either abroad or in Germany.

PSV V: Ceremonial Session with Award Ceremony

Time: Tuesday 16:00–18:00 Location: HSZ/AUDI

Ceremonial Talk PSV V HSZ/AUDI

Quantum computers as large research instruments - what can we expect and how do we develop them? — •Frank Wilhelm-Mauch — Institute for Quantum Computing Analytics, Forschungszentrum Jülich, Wilhelm-Johnen-Straße, 52428 Jülich, Germany — Theoretical Physics, Saarland University, 66123 Saarbrücken, Germany

Quantum computing is currently a ubiquitous topic in the science and technology media. This has good reasons: The progress has been remarkable, quantum computers promise enhanced computational reach without relying on Moore's law - on the other hand, some promises are also far beyond what can be seriously justified. This talk will give a review of the status of the field and argue that they curretly should be viewed as large research instruments. This means that they should be developed with open access and leave room for creative uses and solutions. This opens great opportunities for physicist to co-develop, understand, and use these machines.

Discussion PSV VI Wed 13:00 HSZ/AUDI

Career Paths: Academia or Industry? — •Joanna Kowalska[1], •Elisabeth Trommer[2], •Jonas Schubert[3], •Annegret Rössler[4], Pauleo Nimtz[4], Aisha Aqeel[5], Lucas Kreuzer[5], and Hans-Georg Grothues[6] — [1]German Research Foundation (DFG), Bonn — [2]Attocube systems AG, Munich — [3]DermaPurge, Dresden — [4]Working Group Young DPG (AKjDPG) — [5]AG young Leaders in Physics (AG youLeaP) — [6]Working Group on Industry and Business (AIW)

After completing your undergraduate studies, your PhD, or, at the latest, your first postdoc, you may ask yourself: Do I want to stay at a research institution or work in industry? In this panel discussion, we would like to talk about this question with experts from different areas of science and industry representing different career paths and stages.

There will be further time for questions and personal discussions at 15:00 to 16:30 in room BEY/0117.

Lunch Talk PSV VII Wed 13:00 HSZ/0002

The French Research Landscape in Physics — •Elisabeth Giacobino — Laboratoire Kastler Brossel, Sorbonne Université, ENS, CNRS, 75005 Paris, France

France has a strong scientific community in physics, with many centers located in several large cities, especially in Paris and in the Ile de France region (the Paris region). In the past years there was an effort to reinforce activities like higher education and research outside the Paris region. The French research is operated by the Universities and by large organisations like CNRS or CEA. Most of the laboratories and institutes in physics are managed jointly by a university and an organisation like CNRS. The large instruments are also mostly operated by research organisations. There is a long tradition of international cooperation in France, especially with Germany. In particular Germany and France are quite successful in the European projects, and Germany is the most frequent partner of France in these collaborative projects. In this presentation we will show more details on the geographic location and on the organization of the French research institutes and laboratories in physics, and on the international and European collaborations, in particular with Germany.

Evening Talk PSV VIII Wed 19:00 HSZ/AUDI

Gravitationswellenastronomie – quo vadis? — •Michèle Heurs — Leibniz Universität Hannover, Hannover, Germany — Deutsches Zentrum für Astrophysik (DZA), Görlitz, Germany — Deutsches Elektronen-Synchrotron DESY, Zeuthen, Germany

Seit der ersten direkten Detektion von Gravitationswellen (GWn) im Jahr 2015 haben wir ein völlig neues Beobachtungsfenster zum Universum aufgestoßen (komplementär zu elektromagnetischem Spektrum, Neutrinos und kosmischer Strahlung) und damit das Zeitalter der Multi-Messenger-Astronomie mit GWn eingeläutet. Eine Fülle wissenschaftlicher Erkenntnisse wurde bereits gewonnen – aber es gibt noch so viel mehr zu entdecken!

Die Empfindlichkeit aktueller laserinterferometrischer GW-Detektoren ist so aberwitzig hoch, dass das durch die Quantenmechanik gegebene Rauschen des verwendeten ultrastabilen Laserlichts die Messungen limitieren würde. Dies erfordert die Verwendung von nichtklassischem (sog. „gequetschtem") Licht, das bereits routinemäßig in der aktuellen (zweiten) Generation von GW-Detektoren, z. B. aLIGO und AdVirgo, eingesetzt wird. Viele zusätzliche Rauschquellen, wie seismisches und thermisches Rauschen, stellen weitere Herausforderungen für die Detektoren der nächsten (dritten) Generation dar, z. B. für das Einstein-Teleskop, ein geplantes unterirdisches GW-Observatorium in Europa.

Um mehr über unser Universum zu lernen, benötigen wir höhere Detektionsraten für eine aussagekräftige Gravitationswellenastronomie; dafür benötigen wir höhere Detektionsempfindlichkeit und größere Detektionsbandbreite. In meinem Vortrag werde ich das Prinzip der interferometrischen GW-Detektion einführen, einige der fortschrittlichen Technologien (bereits eingesetzt oder in Entwicklung) erläutern und die Pläne für zukünftige interferometrische Gravitationswellenobservatorien wie das Einstein-Teleskop beleuchten.

Lunch Talk PSV IX Thu 13:00 HSZ/0004

The organic development and growth story of aSpect Systems GmbH — •Marcus Verhoeven — aSpect Systems GmbH

The talk will present the organic development and growth story of aSpect Systems GmbH, a Dresden-based technology company at the intersection of semiconductor engineering and applied physics. Starting from a small team dedicated to advancing semiconductor test and automation technologies, aSpect has continuously evolved by leveraging deep technical expertise in hardware, software, mechanics and optics to solve real-world industrial challenges. Today, the company supports development services, supply chain solutions, test and automation equipment for imaging, optoelectronics and semiconductor manufacturing, helping to bridge the gap between cutting-edge research and industrial application.

Invited Talks, Tutorials, and Contributed Talks

TUT 1: Hands-on Tutorial: HyperSpy – Multidimensional data analysis using Python (joint session FM/TUT)

HyperSpy is a community-developed, open-source library providing a framework to facilitate interactive analyses of multidimensional datasets – in particular spectrum images – in an easy and reproducible fashion. It facilitates the application of analytical procedures operating on individual spectra/images to a multi-dimensional dataset and gives easy access to tools that exploit the multi-dimensionality of the dataset. Born out of the electron microscopy scientific community and building on the extensive scientific Python environment, HyperSpy provides tools to efficiently explore, manipulate, and visualize complex datasets of arbitrary dimensionality, including those larger than a system's memory. The HyperSpy ecosystem includes Python packages that provide dedicated routines for many electron microscopy-based measurement techniques, but also for luminescence spectroscopy and other fields. Through the library RosettaSciIO, the reading and writing of a large range of file formats is supported.

Please bring your laptop. There will be limited power outlets in the room, so come with a fully charged battery.

Materials will be made available from 01.03.2026 via a dedicated GitHub repository. Participants are encouraged to download them ahead of time, set-up Python on their computer following the instructions and run the jupyter notebooks presented during the tutorials on their laptops:

https://github.com/LumiSpy/DPG2026-Tutorial

Organized by Jonas Lähnemann (PDI Berlin), Benedikt Haas (HU Berlin), Aidan Campbell (PDI Berlin), Hannah C. Nerl (HU Berlin) and Magnus Nord (NTNU Trondheim).

Time: Sunday 16:00–18:15 Location: HSZ/0002

TUT 1.1 Sun 16:00 HSZ/0002

Introduction to HyperSpy — •Jonas Lähnemann[1], Aidan F. Campbell[1], Hannah C. Nerl[2], Magnus Nord[3], and Benedikt Haas[2] — [1]Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany — [2]Department of Physics, Humboldt Universität, Berlin, Germany — [3]Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway

The session begins with a brief introduction to HyperSpy that with its 2.0 release has grown to an ecosystem of Python packages that provide dedicated routines for electron microscopy-based measurement techniques such as EELS, EDX, 4DSTEM, holography, tomography and CL, but also for luminescence spectroscopy. In general, it can be useful for any measurement, where a signal is mapped over multiple dimensions (position, time, angle, ...).

Tutorial TUT 1.2 Sun 16:15 HSZ/0002

Hands-On Session 1: General usage HyperSpy/RosettaSciIO — •Jonas Lähnemann — Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany

In the initial tutorial, we will show how to easily read in data from a variety of formats and introduce the basic data structure of HyperSpy. General data operations, artefact removal and plotting functionalities as a basis of reproducible data analysis workflows will be covered as well.

Tutorial TUT 1.3 Sun 16:45 HSZ/0002

lumiSpy for luminescence spectroscopy — •Aidan Campbell — Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany

This session will focus on tools ideal for analysing data recorded with cathodoluminescence, photoluminescence or related spectroscopy techniques. We will demonstrate convenience functions for rapid spectroscopy data analysis, model fitting, and visualisation. Luminescence spectroscopy may also lead to more complicated data sets with spectral, spatial and time dimensions for which we showcase interactive tools for navigating and understanding this data.

Tutorial TUT 1.4 Sun 17:15 HSZ/0002

Hyperspy for Electron Energy-loss Spectroscopy — •Hannah Nerl — Humboldt Universität zu Berlin, Berlin, Germany

This hands-on session demonstrates a complete electron energy-loss spectroscopy (EELS) analysis workflow using HyperSpy and its exSpy extension. Participants will work through practical examples covering essential preprocessing steps including spectral alignment and drift correction, followed by quantitative analysis techniques such as model-based peak fitting and automated peak tracking across multidimensional datasets. The tutorial emphasizes reproducible analysis pipelines, showcasing how to leverage principal component analysis (PCA) for noise reduction in low-signal regimes. All examples use real EELS datasets and focus on practical workflows applicable to both core-loss and low-loss spectroscopy of 2D materials and nanostructures. Participants will gain hands-on experience with Jupyter notebooks that can be directly adapted to their own research data.

Tutorial TUT 1.5 Sun 17:45 HSZ/0002

Using pyXem for magnetic and structural analysis of 4D-STEM data — •Magnus Nord — Norwegian University of Science and Technology, Trondheim, Norway

pyXem is an extension of HyperSpy with a focus on data processing of 4D-STEM data: from crystallographic analysis using Scanning Precession Electron Microscopy (SPED), to magnetic imaging with Scanning Transmission Electron Microscopy - Differential Phase Contrast (STEM-DPC). In this tutorial, we will show how one can study the crystal structure and domain structure in a nanostructured magnetic material.

TUT 2: Tutorial des Fachverbands Didaktik der Physik (joint session DD/TUT)

Physics teaching at universities can be significantly enriched by moving beyond traditional lecture formats and embracing interactive, learner-centered approaches that foster deep and sustainable understanding. Drawing on successful practices from universities in Germany and abroad, this workshop highlights how insights from learning psychology and proven teaching innovations can be translated into effective physics education. It invites participants to explore how evidence-based, interactive methods can transform learning experiences and support lasting learning outcomes in everyday teaching practice.

Time: Sunday 16:00–18:15 Location: BEY/0137

Tutorial TUT 2.1 Sun 16:00 BEY/0137

Rethinking University Teaching: Creating interactive and sustainable learning environments in lectures — •Susanne Heinicke[1], Christian Kautz[2], Peter Riegler[3], Claudia Schäfle[4], Silke Stanzel[4], and Micol Alemani[5] — [1]Institute for Physics Education, University of Muenster — [2]Hamburg University of Technology — [3]Ostfalia University of Applied Sciences — [4]Technische Hochschule Rosenheim — [5]University of Potsdam

The workshop bridges current findings from learning psychology with experience and research findings on practical teaching formats to enhance effective learning in university physics education. We will give an overview of key principles from educational psychology concerning how we learn to provide a foundation for understanding learning effectiveness. Participants will explore and critically reflect on evidence-based interactive methods like peer instruction, interactive formats, and problem-based learning that can be transferred to their own teaching. The workshop concludes with a discussion on implementation strategies and evaluation approaches to support sustainable integration into everyday teaching practice.

TUT 3: Tutorial: Machine Learning Use Cases in Materials Science (joint session AKPIK/TUT)

Artificial intelligence (AI) tools are increasingly shaping research in materials science and physics by enabling advanced data analysis, modeling, and predictive capabilities.

This tutorial presents three practical use cases that demonstrate how machine learning methods can support materials science research.

Time: Sunday 16:00–18:15 Location: HSZ/0003

Tutorial TUT 3.1 Sun 16:00 HSZ/0003

Welcome Remarks Arbeitskreis Physik, moderne Informationstechnologie und Künstliche Intelligenz — DPG AKPIK and •Arash Rahimi-Iman — Deutsche Physikalische Gesellschaft e.V.

Inspired by last year's meeting program in Regensburg, March 2025, our interdisciplinary Working Group on Physics, Modern IT and Artificial Intelligence, the AKPIK, again offers a research-focused "AKPIK Day" on Tuesday during the upcoming conference. Together with the practical use cases of machine learning presented in this tutorial session, as well as the presentations and poster session planned for Thursday, we hope to encourage many conference attendees to engange scientifically in the areas of the AKPIK.

Tutorial TUT 3.2 Sun 16:05 HSZ/0003

A practical machine learning case study in materials science: Stumbling blocks, lucky breaks, and helpful colleagues — •Max Grossmann, •Malte Grunert, and Erich Runge — Institute of Physics and Institute of Micro- and Nanotechnologies, Technische Universität Ilmenau, 98693 Ilmenau, German

Machine learning projects in materials science are often exciting at first, but quickly encounter practical challenges. In this tutorial, we present a hands-on case study from our group and walk through the entire process, from the initial idea to building a dataset to training a working model. Rather than focusing solely on technical details, we highlight the stumbling blocks, unexpected insights, helpful colleagues, and lucky coincidences that shaped the project. We discuss the most important aspects of starting a machine learning project in physics or materials science, such as choosing a meaningful target property, designing a reliable dataset, avoiding common pitfalls, and identifying situations where simple approaches are as effective as advanced ones. Our goal is to provide an honest, accessible, and experience-driven introduction and guidance to researchers considering venturing into machine learning for the first time – the kind of guidance we wish we had when we started.

5 min. break

Tutorial TUT 3.3 Sun 16:50 HSZ/0003

Machine Learning-based Analysis of Electron Microscopy Images: Preprocessing and Synthetic Data Generation — •Amir Omidvarnia — Forschungszentrum Jülich, Jülich, Germany

In this tutorial session, participants will learn how to prepare electron microscopy (EM) images for machine learning (ML) analysis using a series of Jupyter Notebook demonstrations. The tutorial illustrates essential preprocessing steps such as denoising, normalization, and contrast enhancement using Python. The session then transitions to synthetic EM data generation, showing how classical augmentation and modern generative models can create controlled datasets that mimic real data. By observing these live examples, attendees will gain a conceptual understanding of how preprocessing pipelines and synthetic data strategies can be used for ML-based EM analysis.

5 min. break

Tutorial TUT 3.4 Sun 17:35 HSZ/0003

Machine Learning-based Analysis of Electron Microscopy Images: Segmentation — •Amir Omidvarnia — Forschungszentrum Jülich, Jülich, Germany

The second session focuses on segmentation of EM images using modern deep-learning architectures. Through a step-by-step Jupyter Notebook demonstration, the tutorial walks through the training and evaluation of a U-Net style segmentation model. Participants will see real examples of common challenges in EM segmentation, such as low contrast, overlapping nanoscale structures, and label ambiguity. By the end of the session, attendees will have an implementation-oriented understanding of how segmentation pipelines are built and validated in practice.

TUT 4: Tutorium: Physics of Behavior (joint session SOE/TUT/DY)

The emerging field of the physics of behavior seeks to quantitatively characterize complex behavior in biological agents under naturalistic conditions, using tools from dynamical systems theory and statistical physics. Even in simple organisms, behavioral richness demands new methods of measurement and analysis, as well as new theoretical frameworks. In the absence of a first-principles theory, data-driven approaches are essential, and the many interacting degrees of freedom call for descriptions capable of handling high-dimensional systems.

This tutorial introduces how concepts from dynamical systems theory and statistical physics can be applied to quantify behavior across biological scales and to develop simple yet predictive models. It is intended for physicists at all levels, beginning with graduate students, who are interested in computational approaches to modeling animal behavior. The tutorial is accompanied by an openly accessible code repository to support hands-on exploration of selected topics.

Time: Sunday 16:00–18:15 Location: HSZ/0004

Tutorial TUT 4.1 Sun 16:00 HSZ/0004

Physics of Behavior — •Greg Stephens — Vrije Universiteit Amsterdam, Amsterdam NL — OIST Graduate University, Tancha, JP

In these tutorials we view behavior as a complex dynamical system and we incorporate insights from dynamical systems theory and statistical physics to quantitatively capture what animals do. Of course, such theory was not historically developed to understand animal behavior, and there are particular challenges associated with the modeling of living systems. Of these, the most important is a lack of first-principles theory necessitating a data-driven approach.

In the first half of our session we will introduce two primary concepts. (1) Posture Space Analysis via Dimensionality Reduction. We explore posture space analysis by demonstrating how to decompose high-dimensional postural data into a few meaningful eigenpostures using Principal Component Analysis (PCA). The dataset used comes from C. elegans posture tracking. (2) Posture Space Dynamics via State Space Reconstruction. We review the concepts of state space and chaotic systems through a toy model. We then introduce a modern data-driven technique for state space reconstruction.

15 min. break

Tutorial TUT 4.2 Sun 17:15 HSZ/0004

Physics of Behavior — •Antonio Carlos Costa — Paris Brain Institute, Paris, France

Animal behavior is inherently nonlinear and multiscale, spanning millisecond movements to hour-long strategies. In the second half of our session, we will complement first-principles approaches with data-driven methods to identify multiscale dynamics in behavioral data.

We will present three key techniques: (1) state space reconstruction combined with transfer operators to extract long-timescale modes from partial observations, (2) coarse-grained modeling to infer slowly-varying behavioral dynamics and explain heavy-tailed statistics, and (3) a multiscale distance metric for reconstructing behavioral phenotypes from dynamic observations.

We will review the theoretical foundations of slow mode identification using transfer operators (illustrated with stochastic and chaotic toy models), and then demonstrate their applicability to real-world data, including posture dynamics in C. elegans and zebrafish.

TUT 5: Hands-On Tutorial: Magnetic Structure Determination Using Fullprof and SARAh Representation Analysis (joint session MA/TUT)

The functionalities of many materials of contemporary interest are related to complex types of magnetic ordering. Accurate magnetic structure determination is thus crucial for understanding and optimizing such materials.

After an introduction into the subject, participants of the tutorial will gain hands-on experience on the methods for magnetic structure determination.

Time: Sunday 16:00–18:15 Location: TRE/PHYS

Invited Talk TUT 5.1 Sun 16:00 TRE/PHYS

Recent advances and challenges in magnetic structure determination — •Dmytro Inosov — Institut für Festkörper- und Materialphysik, TU Dresden, Germany

In this introductory tutorial talk, I will provide an overview of magnetic structure determination in the context of recent advances in magnetic materials. I will focus on the limitations and challenges of magnetic structure refinement, and explain why it is important to use the full range of complementary experimental methods alongside conventional diffraction in order to develop a consistent understanding of magnetic structures. This is particularly important when dealing with complex types of magnetic order, such as noncollinear and multi-Q spin textures, altermagnets, and systems with multiple magnetic sublattices or very weak and/or fluctuating magnetic moments.

Tutorial TUT 5.2 Sun 16:30 TRE/PHYS

Hands-On Tutorial: Magnetic Structure Determination Using Fullprof and SARAh Representation Analysis — •Matthias Frontzek — Oak Ridge National Laboratory, Neutron Scattering Division, One Bethel Valley Road, 37831 Oak Ridge, TN, USA

The determination of magnetic structures is a crucial aspect of materials science, particularly for understanding the magnetic properties of novel materials. Given the limited availability of neutrons with the closure of smaller sources, competitive access to beam time, and the high hurdles associated with software usage, there is an increasing need for training in the analysis of magnetic structures. This tutorial aims to provide participants with practical skills in magnetic structure determination using SARAh and Fullprof, two powerful tools frequently utilized in this field.

Participants will:

-Gain hands-on experience with the tools and techniques necessary for magnetic structure determination.

-Refine nuclear and magnetic structures using real data sets.

-Understand key concepts in diffraction techniques and steps involved in the magnetic structure determination process.

Important: for Hands-on participation, please bring a laptop with a working installation of Fullprof (https://www.ill.eu/sites/fullprof/).

For links to Fullprof, SARAh stand-alone and tutorial data visit: https://neutrons.ornl.gov/wand/users

TUT 6: Hands on tutorial: Linking large language models with digital workflows for materials science simulations (joint session MM/TUT)

Advanced computational simulations often require chaining several models and software packages together, a process that demands careful workflow management. In this tutorial you can gain hands-on experience with the Python based workflow environment pyiron (www.pyiron.org). Participants in the tutorial will be able to run all the examples shown in the presentation interactively on their own laptops. There is no need to install any code, just a standard web browser to explore the applications interactively.

Time: Sunday 16:00–18:15 Location: TRE/MATH

Tutorial TUT 6.1 Sun 16:00 TRE/MATH

Hands on tutorial: Linking large language models with digital workflows for materials science simulations — •Jörg Neugebauer[1], Tilmann Hickel[1,2], and Ralf Drautz[3] — [1]Max Planck Institute for Sustainable Materials — [2]Bundesanstalt für Materialforschung und -prüfung — [3]ICAMS, Ruhr Universität Bochum

Advanced computational simulations now reliably predict material properties, but they often require chaining several models and software packages together, a process that demands expert knowledge and careful workflow management. Efficient, reproducible research therefore hinges on automated workflow tools that can handle this complexity. In this tutorial we introduce pyiron (www.pyiron.org), a Python based workflow environment for building and executing fully automated simulation pipelines. We show how complex simulations workflows can be constructed programmatically via Python code as well as via a flow-based graphical user interface. We further introduce how large language models (LLMs) can be embedded to streamline the ”human in the loop” tasks. After a brief overview of pyiron’s core concepts, we construct workflows for computing ab initio thermodynamic bulk phase diagrams. The necessary steps, such as density functional theory calculations, training ACE-based machine learning potentials, and exploring phase stability using foundational models like GRACE, are all performed within pyiron workflows. Participants will learn how to develop and integrate such workflows into their own materials science simulations, thereby enabling faster, more transparent, and more reproducible research.

Symposium AI and Data Challenges behind Emerging Self-Driving Laboratories (SYAI)

jointly organised by
the Surface Science Division (O),
the Biological Physics Division (BP),
the Metal and Material Physics Division (MM),
the Environmental Physics Division (UP),
the Working Group "Young DPG" (AKjDPG), and
the Working Group on Physics, Modern IT and Artificial Intelligence (AKPIK)

Jörg Neugebauer
MPI für Nachhaltige Materialien
Max-Planck-Straße 1
40237 Düsseldorf
neugebauer@mpi-susmat.de

Karsten Reuter
Fritz-Haber-Institut der MPG
Faradayweg 4-6
14195 Berlin
reuter@fhi.mpg.de

So-called Self-driving Laboratories (SDLs) or Materials Acceleration Platforms (MAPs) represent a cutting-edge convergence of artificial intelligence (AI) and machine learning (ML) with lab automation and robotics. SDLs are designed to automate and accelerate experimental processes, addressing inefficiencies and enhancing the precision and safety of lab operations. SDLs operate in active learning loops, in which an ML algorithm selects and plans experiments that are subsequently executed by increasingly automated (robotic) modules. Data from these experiments are fed back into the ML model, refining it and guiding subsequent experiments. This iterative process enhances the efficiency and effectiveness of experimental exploration, and it is the adaptive quality to directly exploit the information gained through the experiments in the past loops that distinguishes modern SDLs from classic approaches in high-throughput experimentation or combinatorial chemistry.

With SDLs emerging in a wide range of application fields from heterogeneous catalysis over optoelectronics to batteries, advances in experiment automation and robotization are obvious drivers for improved throughputs. Complementary to this are, however, multiple IT- and AI/ML- related aspects of SDLs, not least comprising data pipelines and management, workflows, AI- agent platforms, featurization of the experimental data or experiment planning (especially using noisy and multi-fidelity data). This symposium will survey the present state-of-the-art of these aspects and discuss current frontiers.

Overview of Invited Talks and Sessions

(Lecture hall HSZ/AUDI)

Invited Talks

SYAI 1.1	Thu	9:30–10:00	HSZ/AUDI	**Data and Experimental Foundations for Reliable Self-Driving Laboratories** — •Dr. Marcus Tze-Kiat Ng
SYAI 1.2	Thu	10:00–10:30	HSZ/AUDI	**Digital Catalysis - AI for Experiment Planning and Control** — •Christoph Scheurer

SYAI 1: AI and Data Challenges behind Emerging Self-Driving Laboratories

Time: Thursday 9:30–12:15 Location: HSZ/AUDI

Invited Talk SYAI 1.1 Thu 9:30 HSZ/AUDI

Data and Experimental Foundations for Reliable Self-Driving Laboratories — •Dr. Marcus Tze-Kiat Ng — Magnusstr. 11, 12489 Berlin

Self-driving laboratories are increasingly guided by machine learning, yet progress is constrained by the quality, structure, and consistency of experimental data. In this work, autonomous experimental platforms are presented in which high-throughput synthesis, electrochemical testing, and multi-modal characterisation are carried out with high reproducibility. Through these systems, challenges that are rarely captured in benchmark datasets are revealed, including drift, batch effects, measurement noise, and incomplete metadata. Physics-informed representations, uncertainty-aware models, and active-learning strategies are shown to be effective when applied to such real-world data. Case studies in catalyst optimisation and discovery are used to demonstrate how large chemical spaces can be explored once the experimental feedback loop is closed. The experimental and data foundations required for reliable AI-driven materials discovery will be outlined.

Invited Talk SYAI 1.2 Thu 10:00 HSZ/AUDI

Digital Catalysis - AI for Experiment Planning and Control — •Christoph Scheurer — Fritz-Haber-Institut der MPG, Berlin

Self-driving laboratories (SDLs) epitomize a cutting-edge integration of machine learning with laboratory automation. Operating in active learning loops, SDLs use machine learning algorithms to plan experiments that are then executed by increasingly automated (robotic) modules. Here, I will present our perspective on emerging SDLs for accelerated discovery and process optimization in heterogeneous catalysis. Drawing on recent work in catalyst discovery, kinetic modelling, and catalyst degradation studies, I will argue against the paradigm of full automation and the objective of keeping the human out of the loop. Analysis of the associated workflows indicates that crucial advances will stem from establishing fast proxy experiments, re-engineering existing apparatuses and measurement protocols, and developing modelling approaches with real-time capabilities. Industrially relevant use cases will also require humans to remain in the loop for continuous decision-making, mandating explainable AI. In turn, active learning algorithms must be advanced to flexibly accommodate adaptations of the design space and variations in information content and noise in the acquired data.

Invited Talk SYAI 1.3 Thu 10:30 HSZ/AUDI

Autonomous, Data-Driven Workflows for Materials Acceleration Platforms with pyiron — •Jan Janssen and Joerg Neugebauer — Max Planck Institute for Sustainable Materials, Düsseldorf, Germany

The hierarchical nature of materials – spanning electronic, atomistic, microstructural, and macroscopic scales – necessitates an integrated multiscale strategy for accelerating materials discovery. Realizing such a strategy requires close coordination across chemistry, materials science, and physics, and an equally tight coupling of simulation and experiment. Materials Acceleration Platforms (MAPs) address this need by embedding both theoretical and experimental data streams into a unified active-learning loop. A central challenge is ensuring that information can be meaningfully transferred across scales. We approach this by propagating uncertainties throughout the entire multiscale workflow, enabling quantitative comparison from ab-initio predictions to experimental measurements. This uncertainty-aware integration makes it possible to reduce the number of required experiments by several orders of magnitude. The resulting hierarchy of simulations is powered by machine-learning models – including ML interatomic potentials, Bayesian optimization, and large-language-model (LLM) agents – each contributing to decision-making within the MAP. The pyiron workflow framework provides the digital backbone for this integration. By encoding domain expertise into modular, machine-actionable workflows, pyiron enables simulation specialists to formalize their methods in a way that is both reproducible and interoperable.

Invited Talk SYAI 1.4 Thu 11:15 HSZ/AUDI

Machine Learning for Autonomous Optimization and Discovery of Materials — •Pascal Friederich — Karlsruhe Institute of Technology, Karlsruhe, Germany

Machine learning can accelerate the screening, design, and discovery of new molecules and materials in multiple ways, e.g. by virtually predicting properties of molecules and materials, by extracting hidden relations from large amounts of simulated or experimental data, or even by interfacing machine learning algorithms for autonomous decision-making directly with automated high-throughput experiments. In this talk, I will focus on our research activities on the use of machine learning for automated data analysis and autonomous decision-making in self-driving labs [1,2]. I will discuss extensions of Bayesian optimization to extend the autonomous decision-making process to more complex experimental and computational self-driving labs, as well as possibilities to include machine learning based recommendations already in the process of designing the experiments [3].

Transforming Our View on Transformers in the Sciences — •Kevin Maik Jablonka — Friedrich-Schiller Universität Jena, Jena, Germany — HPOLE Jena, Jena, Germany

The sciences face a fundamental challenge: much of the data we need for building models is not currently reported or usable in any structured form. Large language models (LLMs) have shown promise in addressing this through text-to-data conversion and direct predictive capabilities, attracting tremendous attention across scientific applications. In my contribution, I will present a roadmap based on comprehensive benchmarks of language models, multimodal models, and autonomous agents in chemistry and beyond. We have developed specialized evaluation benchmarks to assess scientific knowledge, reasoning abilities, and autonomous tool use across frontier models. Our results reveal a striking paradox: these models can exceed the performance of experts with decades of experience on certain tasks, while simultaneously failing worse than novices on other seemingly basic problems. I will discuss what these benchmark findings mean for the future of LLMs in scientific research, which applications are ready for deployment, where critical gaps remain, and how the field should prioritize development efforts. Finally, I will present the advances in models, systems, and infrastructure we have developed to enable practical impact across the sciences.

Symposium Fluids with Broken Time-Reversal Symmetry: Odd/Hall Viscosity between Active Matter and Electron Flows (SYBS)

Viscosity is a fundamental property of fluids and an important physical quantity characterizing resistance to flow and energy dissipation. While time-reversal symmetry holds in conventional fluids, its violation can lead to striking phenomena, one of which is the emergence of a dissipationless transport coefficient called odd viscosity. Odd viscosity, also known as Hall viscosity, was originally proposed by Avron et al., as a quantized observable in electron fluids with a magnetic field. Since this seminal work, odd viscosity has been studied in various systems, such as 2D electron fluids, fractional Hall fluids, and ionic crystals. Although odd viscosity was also known in plasma physics, it was largely overlooked in fluid dynamics, mainly due to the technical challenges involved in its experimental realization. In recent years, however experiments in driven colloidal systems led to a surge of interest in odd viscosity in the active matter community. In parallel, our understanding of odd phenomena was advanced by continuum theories with many novel exact solutions. Major open questions in the field include the microscopic mechanisms that lead to odd viscosity, its experimental manifestations, the transition from two- to three-dimensional systems, and the effect of odd viscosity on hydrodynamic phenomena at different length scales, ranging from microrheology to turbulent flows. This Symposium will connect the wider condensed matter and active matter physics communities with recent theoretical advances in odd viscosity.

SYBS 1: Fluids with broken time-reversal symmetry: Odd/Hall viscosity between active matter and electron flows

Time: Tuesday 9:30–11:45 Location: HSZ/AUDI

Invited Talk SYBS 1.1 Tue 9:30 HSZ/AUDI

Odd viscosity in three-dimensional fluids: flows, wakes, and eddies — •Tali Khain — Harvard University, Cambridge, MA, USA

Systems composed of spinning particles or driven by a magnetic field break mirror symmetry at the microscopic level. These chiral fluids can be described by adding so-called "odd" viscosities, which do not dissipate energy, in the Navier-Stokes equations. In this talk, I will discuss a theoretical fluid mechanics framework to describe the consequences of these broken symmetries on fluid flow [1]. Using a combination of analytical and numerical methods, we show how these odd viscosity coefficients modify flow across a range of Reynolds numbers. In the low Reynolds number limit, sedimenting objects in a chiral fluid generate a rotating flow that is absent in usual fluids; in turn, this flow affects how immersed objects respond to forces and torques [2]. At intermediate Reynolds numbers, odd viscosity reshapes the vortex structure of the wake of a sphere, which affects the onset and nature of the periodic vortex shedding state. At high Reynolds numbers, the non-dissipative nature of odd viscosity disrupts the energy cascade that occurs in fully developed turbulent flows, leading to pattern formation with a tunable scale [3].

Odd viscosity in two-dimensional hydrodynamic electron transport — •Igor Gornyi and Dmitry Polyakov — Karlsruhe Institute of Technology, Karlsruhe, Germany

We discuss the role of odd (Hall) viscosity in two-dimensional hydrodynamic electron transport in two spatial dimensions. We formulate a general framework to study the flow of the electron fluid past a random array of impenetrable obstacles in the presence of a magnetic field and derive a linear-response resistivity tensor. For the no-slip boundary condition on the obstacles, the resistivity tensor does not depend on the Hall viscosity. By contrast, for the specular boundary condition, the total electric field is rotated by Hall viscosity, which means the emergence of a Hall-viscosity-induced effective magnetic field that leads to a deviation of the Hall constant from its universal value, as well as to a modification of the longitudinal resistivity. We combine the hydrodynamic and electrostatic perspectives by addressing the distribution of charges that create the flow-induced electric fields around obstacles and provide a connection between the resistivity tensor and the disorder-averaged electric dipole induced by viscosity at the obstacle. This establishes a conceptual link between the resistivity in hydrodynamics and the notion of the Landauer dipole.

Invited Talk SYBS 1.3 Tue 10:30 HSZ/AUDI

Odd slip on chiral active surfaces — •Andrej Vilfan[1] and Yuto Hosaka[2] — [1]Jožef Stefan Institute, Ljubljana, Slovenia — [2]Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

Chiral active surfaces are characterized by persistent energy input with a defined sense of chirality, for example by a carpet of symmetrically rotating biological or artificial cilia. We demonstrate that when subjected to a shear flow, such a surface can lead to an effective odd slip velocity, in addition to classical Navier slip. Odd Navier slip represents a novel category of odd responses beyond the established concepts of odd viscosity and elasticity, which occur in bulk fluids or solids, and odd diffusivity of point particles. We show that a suspension of particles with odd slip can exhibit odd viscosity, providing a new mechanism for its emergence.

Invited Talk SYBS 1.4 Tue 11:15 HSZ/AUDI

Parity-odd transport in electron fluids — •Johanna Erdmenger — Institut für Theoretische Physik und Astrophysik, Julius-Maximilians-Universität Würzburg, 97074 Würzburg

Parity-odd transport in two-dimensional electron systems reveals an interplay between geometry, topology, and hydrodynamics. In channel geometries, the Hall viscous force competes with the Lorentz force, leading to nonlinear Hall voltage profiles and, at a critical magnetic field, a complete cancellation of the total Hall response [1,2]. Channel voltage measurements provide a direct experimental probe. Similar effects arise for the hydrodynamic inverse Nernst signal [2].

For hydrodynamic spin transport, non-dissipative parity-breaking transport phenomena are generated by torsion. The torsional Hall viscosity has interesting connections to recent developments in general relativity. We analyse the impact of magnetic fields and quadratic band-structure corrections on the torsional transport coefficient, showing that torsional response can reverse direction relative to conventional Hall viscous forces, while still distinguishing topologically trivial and nontrivial regimes [3].

Invited Talk SYBS 1.5 Tue 11:30 HSZ/AUDI

Curved Odd Elasticity — Lazaros Tsaloukidis[2], Yuan Zhou[3], Jack Binysh[3], Nikta Fakhri[4], Corentin Coulais[3], and •Piotr Surówka[1] — [1]Institute of Theoretical Physics, Wrocław University of Science and Technology, 50-370 Wrocław, Poland — [2]Max Planck Institute for the Physics of Complex Systems, Noethnitzer Str. 38, 01187, Dresden, Germany — [3]Institute of Physics, University of Amsterdam, Science Park 904, 1098 XH, Amsterdam, The Netherlands — [4]Department of Physics, Massachusetts Institute of Technology, Cambridge, MA, USA

Living materials such as membranes, cytoskeletal assemblies, cell collective and tissues can often be de- scribed as active solids materials with a elastic response about a well defined reference configuration and energized from within. These materials often live in complex and curved manifolds, yet most descriptions of active solids are flat. Here, we explore the interplay between curvature and non-reciprocal elasticity by a co- variant effective theory on curved manifolds in combination with numerical simulations. We find that curvature spatially patterns activity, gaps the spectrum, modifies exceptional points and introduces non-Hermitian de- fect modes. Together these results establish a foundation for hydrodynamic and rheological models on curved manifolds, with direct implications for living matter and active metamaterials.

Symposium Beyond Transistors: Material-Based Edge Computing Paradigms (SYBT)

jointly organised by
the Magnetism Division (MA) and
the Functional Materials Division (FM)

Atreya Majumdar
Universität Duisburg-Essen
atreya.majumdar@uni-due.de

Karin Everschor-Sitte
Universität Duisburg-Essen
karin.everschor-sitte@uni-due.de

Dennis Meier
Universität Duisburg-Essen
dennis.meier@uni-due.de

The rapid progress of artificial intelligence has led to unprecedented computational capabilities, but also to growing energy and resource demands that challenge edge computing applications such as autonomous systems and smart sensors. These resource limitations are rooted in the conventional von Neumann architectures and silicon-based transistors of the current technology. This symposium explores alternative paradigms in which computation emerges directly from the intrinsic properties and dynamics of materials. Bringing together experts primarily from condensed matter physics and optics, the focus lies on material-based platforms, including spintronics, ferroelectrics, ionic and phase-change materials, as well as photonic and hybrid ligh-matter platforms. These systems enable complementary functionalities, including non-volatile, analog, and high-speed information processing, naturally supporting concepts such as neural networks and physical reservoir computing. By focusing on material-intrinsic physical effects for computing, the symposium aims to highlight conceptually new, energy-efficient pathways toward scalable edge AI beyond traditional transistor-based technologies.

Finding Neuromorphic Advantage with Magnetism — •Johan Mentink — Radboud University, Nijmegen, Netherlands

Neuromorphic computing promises much faster and much more energy-efficient computations with applications domains spanning the whole compute continuum. Nevertheless, rather little is known about applications of neuromorphic computing in computational physics such as the simulation of magnetic materials. In this talk we present our results on exploring and benchmarking neuromorphic computing for probabilistic simulations of quantum magnetism. Our explorations include hardware paradigms such as in-memory computing [1], probabilistic bits [2,3] and large-scale simulations with spiking-based systems electronic systems. We find that the massively parallel nature of neuromorphic hardware offers important scaling advantages over existing digital hardware and enables orders of magnitude faster and more energy-efficient variational quantum Monte Carlo simulations. Moreover, beyond existing neuromorphic paradigms, we show that even better scaling is in reach by adopting new magnetic device concepts, such as those harnessing Brownian skyrmion dynamics [4]. Our results open a path to find neuromorphic computational advantage in probabilistic quantum simulation and suggest high potential to break existing computational barriers for selected computational problems in general.

Accelerating Neural Networks Computation with Ferroelectric Oxides — •Laura Bégon-Lours, Nikhil Garg, Alexandre Baigol, Anwesha Panda, Nathan Savoia, and Alexander Flasby — Integrated Systems Laboratory, D-ITET, ETH Zürich

On conventional computers, the performance of AI models is limited by the data transfer between the memory and the processor. Compute-in-Memory architectures offer a new paradigm: Vector-Matrix Multiplications may be performed by a voltage drop through a matrix of programmable resistances, the *synaptic weights*. Ferroelectric materials are excellent candidates for their realization: the conductance is programmed by controlling the configuration of the ferroelectric domains. The mechanisms governing the resistive switching in WOx / HZO-SL (5 nm) bilayers are discussed. The effect of the programming pulse duration and amplitude on the polarization switching are investigated, from milliseconds to nanoseconds timescales. Devices of different sizes and shapes are measured down to 500 nm in dimension. For an device size of 1 micrometer square, an On/Off ratio as high as 4 is obtained for 20 ns pulses, a 4-fold improvement compared to 40 um devices. The relatively low crystallization temperature of polycrystalline hafnium oxide / zirconium oxide superlattices (HZO-SL) is compatible with the Back-End-Of-Line (BEOL) of CMOS transistors. These results not only demonstrate the functionalization of the BEOL with synaptic weights, but also pave the way for the integration of ferroelectric field-effect transistors with Beyond CMOS semiconductors.

Invited Talk SYBT 1.3 Wed 10:30 HSZ/AUDI

a photonic approach to probabilistic computing — •Wolfram Pernice — Heidelberg University, Kirchhoff-Institute for Physics, Heidelberg, Germany

Unlike artificial neural networks (ANNs), which focus on maximizing accuracy, biological systems excel at handling uncertainty. This ability is believed to be essential for adaptability and efficiency, yet traditional ANNs, implemented on deterministic hardware, struggle with capturing the full probabilistic nature of inference. To address this limitation, Bayesian neural networks (BNNs) replace deterministic parameters with probability distributions, allowing us to distinguish between epistemic uncertainty (due to limited data) and aleatoric uncertainty (arising from noise). By incorporating Bayesian inference, BNNs enable uncertainty quantification and allow for out-of-distribution detection in cases of incomplete data. However, processing probabilistic models remains a challenge for conventional digital hardware, which relies on deterministic von Neumann architectures that separate memory from computation. In electronic crossbar arrays, memristors exhibit inherent stochasticity, making them suitable for probabilistic inference. Yet, sequential sampling and variability in memristive materials present obstacles. To address these challenges, I will outline recent progress in photonic computing architectures that harness hardware noise as a computational resource rather than a constraint.

Invited Talk SYBT 1.4 Wed 11:15 HSZ/AUDI

Tackling Reliability and Scalability in Neuromorphic Computing via Noise-aware Learning — •Eleni Vasilaki — Computer Science, The University of Sheffield, 211 Portobello, Sheffield, S1 4DP, UK

Neuromorphic computing has evolved into a broad label covering technologies ranging from biologically inspired systems to machine-learning-style architectures. Computing with materials is often promoted as a potentially energy-efficient alternative to conventional hardware, but some of these claims lack robust empirical support. In this talk I will outline key challenges in the field, with a focus on variability and scalability. I will present concrete examples from my recent work showing how noise-aware learning in systems with stochastic, device-level behaviour can help mitigate variability and improve robustness. These results suggest that while variability poses real constraints, it can be addressed through appropriate learning strategies.

Invited Talk SYBT 1.5 Wed 11:45 HSZ/AUDI

Bayesian nanodevices for trustworthy artificial intelligence — •Damien Querlioz — Univ Paris-Saclay, CNRS, Palaiseau, France.

Artificial intelligence (AI) increasingly powers safety-critical systems that demand robust, energy-efficient computation, often under conditions of data scarcity and uncertainty. Traditional AI approaches are limited in their ability to quantify confidence, leaving them vulnerable to unreliable predictions. In this talk, we introduce Bayesian electronics, which harnesses the intrinsic randomness of emerging nanodevices for on-device Bayesian computations. By encoding probability distributions at the hardware level, these devices naturally estimate uncertainty and reduce overhead compared with purely deterministic designs. We examine how Bayesian networks and Bayesian neural networks can be implemented in this framework to enhance sensor fusion and out-of-distribution detection. We also describe how hardware training via Markov chain Monte Carlo or Langevin dynamics yields energy-frugal sampling-based learning. Finally, we draw parallels with biological systems that are hypothesized to similarly exploit noise for probabilistic computation. By integrating device physics, algorithmic design and system-level optimization, Bayesian electronics offers a path towards more trustworthy and adaptive AI hardware.

Symposium Designing Quantum Materials with Light: From Floquet to Cavity Engineering (SYFC)

jointly organised by
the Semiconductor Physics Division (HL),
the Surface Science Division (O), and
the Low Temperature Physics Division (TT)

Marcel Reutzel
Universität Marburg
Renthof 5
35032 Marburg
marcel.reutzel@uni-marburg.de

Michael Sentef
Universität Bremen
Otto-Hahn-Allee 1
28359 Bremen
sentef@uni-bremen.de

This symposium focuses on how tailored light fields and optical cavities can be used to design and control novel phases of quantum matter far from thermal equilibrium or even in the dark. Building on rapid progress in ultrafast experiments – including time-resolved momentum microscopy and high-quality 2D/3D materials – Floquet and cavity engineering now enable the creation of engineered band structures, correlated and topological phases, and emergent "polaritonic quantum matter." In parallel, ab initio and advanced many-body theory have matured to the point of providing quantitative guidance and interpretation for these experiments. The symposium will bring together leading international experts from theory and experiment to discuss current breakthroughs and future directions towards optoelectronic and quantum-information devices based on light-designed quantum materials.

SYFC 1: Designing Quantum Materials With Light: from Floquet to Cavity Engineering

Time: Monday 9:30–12:15 Location: HSZ/AUDI

Invited Talk SYFC 1.1 Mon 9:30 HSZ/AUDI

Subcycle videography of strong-field controlled band structures — •Rupert Huber[1], Manuel Meierhofer[1], and Ulrich Höfer[1,2] — [1]Department of Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, Germany — [2]Department of Physics, Marburg University, Germany

In lightwave electronics, the oscillating carrier field of intense light pulses has been utilized as an alternating bias to coherently accelerate electrons through solids [1]. Lightwave-driven closed quantum trajectories can lead to new eigenstates and tailored Floquet-Bloch band structures. We will first report how all-optical measurements can uniquely identify the presence of Floquet-Bloch states using high-order sideband generation [2]. A direct momentum-resolved observation of the formation and decay of Floquet-Bloch band structures on subcycle time scales has become available with ARPES-based band-structure videography [3]. While our lead-off experiments were limited to subcycle dynamics at small electron momenta, a novel approach using momentum microscopy with few-fs XUV pulses affords a panoramic view of strong-field dynamics throughout the first Brillouin zone. We will illustrate how this approach allows us to reveal the anatomy of strong-field light-matter interaction in quantum materials ranging from graphene to novel flat-band materials.

Invited Talk SYFC 1.2 Mon 10:00 HSZ/AUDI

Engineering Quantum Materials through Structured Cavity Vacuum Fluctuations — •Angel Rubio — Max Planck Insttitue for the Structure and Dynamics of Matter

Structuring the photon density of states in optical cavities enables control of material properties through strong light*matter coupling. Quantum Electrodynamical Density Functional Theory (QEDFT) extends TDDFT by incorporating quantized electromagnetic fields into electronic structure theory, providing an ab initio framework for predicting cavity-induced phenomena. Experiments such as photon-mediated superconductivity and optically engineered topological phases show that vacuum fluctuations, rather than classical light, can reshape material ground states and drive new quantum phases.

We present an ab initio approach to study cavity effects in two-dimensional materials. Using QEDFT, we show how vacuum fields modify van der Waals systems, inducing charge localization, tunable band gaps, and interlayer spacing that alter ferroelectric and optical responses. A non-perturbative Hartree*Fock framework further reveals cavity-mediated electron interactions in graphene and dichalcogenides, where anisotropic photon modes open Dirac gaps while isotropic ones renormalize the Fermi velocity. Cavity photons thus emerge as a new control parameter for correlated quantum states.

Invited Talk SYFC 1.3 Mon 10:30 HSZ/AUDI

Floquet engineering of quantum materials: from semiconductors to semimetals — •Shuyun Zhou — Department of Physics, Tsinghua University

Time-periodic light-field can dress the electronic states of quantum materials, providing a fascinating controlling knob for transient modifications of the electronic structure with versatile light-induced emergent phenomena. In this talk, I will present our recent experimental progress on the Floquet engineering of quantum materials using time- and angle-resolved photoemission spectroscopy (TrARPES). In particular, experimental progress on the Floquet engineering of semiconductors and semimetals. Experimental insights on Floquet engineering and light-matter interactions in quantum materials will also be discussed.

15 min. break

(Quantum) Light Control of Materials — •Dante Kennes — RWTH Aachen University, Germany — MPSD Hamburg, Germany

Light offers a versatile handle for tailoring quantum materials. I will outline two complementary examples focusing on their theoretical and computational nonequilibrium quantum many-body descriptions: (i) Ultrafast optical drives can transiently reshape a solid's symmetry and electronic structure, where for the latter Floquet engineering provides the framework for accessing and stabilizing novel non-equilibrium phases [1]. (ii) Embedding a material in an optical cavity couples it to quantized photon modes, unlocking new many-body phenomena in the realm of cavity quantum electrodynamics [2]. I will close with an outlook on merging these strategies with the flexibility of two-dimensional heterostructures to enable on-demand design of quantum functionalities [3].

Invited Talk SYFC 1.5 Mon 11:45 HSZ/AUDI

Lightwave-driven electrons in a Floquet topological insulator — Daniel Lesko[1,2], Tobias Weitz[1,2], Weizhe Li[1], Selina Nöcker[1,2], Celina Hüttner[1], Tamara Pröbster[1], Simon Wittigschlager[1], Christian Heide[1,3], Ofer Neufeld[4], and •Peter Hommelhoff[1,2] — [1]Department Physik, Friedrich-Alexander-Universität, Erlangen — [2]Fakultät für Physik, Ludwig-Maxilians-Universität, München — [3]University of Central Florida, Orlando, Fl, USA — [4]Technion, Haifa, Israel

Topological insulators enable novel quantum and electronic phenomena but are limited by material constraints. Floquet topological insulators (FTIs), created by time-periodic driving, promise tunable topological properties and petahertz operation. We demonstrate optical control of photocurrents in light-dressed graphene, where circularly polarized pulses induce an FTI state and phase-locked second-harmonic pulses drive electron dynamics. This enables measurement of all-optical anomalous Hall and valley-polarized photocurrents, revealing sub-cycle phase sensitivity and dynamical symmetry selection rules. Supported by ab-initio and analytical theory, our results establish a bridge between Floquet and topological physics, attosecond science, and valleytronics, advancing ultrafast topotronic control beyond static band engineering.

Biological systems are composed of molecular components similar to those found in soft matter, yet they exhibit extraordinary and often extreme material properties that are essential for the robustness of living cells, tissues, and populations. These remarkable properties frequently emerge from the multiple hierarchical levels of organization intrinsic to living matter. This guest country symposium with speakers from France and Germany discusses the active and hierarchical principles that apply across diverse biological scales, from molecular assemblies to cells, tissues and even swarms of animals, and their role in biology's unique emergent properties.

SYGF 1: Guest Country Symposium France: Soft, Active and Alive: Emergent Properties in Living Matter (SYGF)

Time: Wednesday 15:00–18:15 Location: HSZ/AUDI

Invited Talk SYGF 1.1 Wed 15:00 HSZ/AUDI

Liquid crystal geometries in type I collagen-based tissues — •Nadine Nassif — Sorbonne Université/CNRS, UMR7574, Paris, France

Many biological tissues exhibit hierarchical fibrillar architectures that resemble the geometry of liquid crystalline phases. Such ordering occurs in matrices composed of collagen, chitin, cellulose, or DNA, and governs essential structure/property relationships. Bone and cornea are two emblematic examples: bone exhibits a twisted-plywood architecture, whereas the cornea displays a highly organized orthogonal plywood arrangement that ensures transparency and mechanical integrity. In bone, collagen confinement creates supersaturation of proteins and ions, with major consequences for mineral formation. Our research aims to reproduce the collagen-based building blocks underlying these tissues to better understand morphogenesis and develop advanced biomaterials. Type I collagen shows lyotropic behavior, forming successive ordered phases and retaining liquid-crystal organization during fibrillogenesis. Using a bioinspired continuous-injection process mimicking cellular secretion, we scale up collagen assemblies from droplets to 3D bulk materials. Their biomimetic mineralization produces collagen/apatite composites with strong structural and functional similarity to bone, as demonstrated by in vitro and in vivo investigations. Overall, our results demonstrate the importance of physico-chemical processes in biomineralization, which are usually discussed from a biological perspective.

Invited Talk SYGF 1.2 Wed 15:30 HSZ/AUDI

Self-organization of the cytoplasm by physical instabilities — •Jan Brugues — Cluster of Excellence Physics of Life, TU-Dresden, Dresden, Germany

Early development across vertebrates and insects critically relies on robustly reorganizing the cytoplasm of fertilized eggs into individualized cells. This intricate process is orchestrated by large microtubule structures that traverse the embryo, partitioning the cytoplasm into physically distinct and stable compartments. Despite the robustness of embryonic development, here we uncover an intrinsic instability in cytoplasmic partitioning driven by the microtubule cytoskeleton. We reveal that embryos circumvent this instability through two distinct mechanisms: either by matching the cell cycle duration to the time needed for the instability to unfold or by limiting microtubule nucleation. These regulatory mechanisms give rise to two possible strategies to fill the cytoplasm, which we experimentally demonstrate in vitro and in zebrafish and Drosophila embryos. Our results indicate that the temporal control of microtubule dynamics could have driven the evolutionary emergence of species-specific mechanisms for effective cytoplasmic organization. Furthermore, our study unveils a fundamental synergy between physical instabilities and biological clocks, uncovering universal strategies for rapid, robust, and efficient spatial ordering in biological systems.

Invited Talk SYGF 1.3 Wed 16:00 HSZ/AUDI

From morphogenesis to space partitioning by microtubules and molecular motors. — •Manuel Thery — ESPCI, Paris, France

Microtubules are not just tracks for transport; they can also be moved by the forces exerted by molecular motors. In this presentation, we will first demonstrate how the interplay between moving microtubules and transported motors can result in the emergence of shapes from random mixtures (morphogenesis). We will explain how these shapes are maintained in dynamic steady-states by active and polar boundaries. Then, we will explore the plasticity and adaptation of these boundaries to geometric constraints, as well as their ability to polarise or bipolarise a confined space (space partitioning). Finally, we will discuss the relevance of this process to various forms of intracellular organisation.

15 min. break

Invited Talk SYGF 1.4 Wed 16:45 HSZ/AUDI

More than the sum: how composite interfaces govern function — •Alba Diz-Muñoz — European Molecular Biology Laboratory, Heidelberg, Germany

The cell surface of animal cells is a composite interface with several layers, the plasma membrane, the actomyosin cortex and a membrane-to-cortex attachment protein layer that binds them together. Biochemically and mechanically each of these layers differs. My group is taking an engineering-inspired approach, combined with traditional cell biology methods, to quantitatively measure and predict how the various mechanical layers at the surface of animal cells govern function. Together, our work identifies membrane-to-cortex attachment as a critical mechanotransducer in cells, and the membrane-to-cortex distance as a key geometrical parameter that regulates protein activity at the cell surface.

Invited Talk SYGF 1.5 Wed 17:15 HSZ/AUDI

Swimming and Swarming of Intelligent Active Particles — Segun Goh[1,2], Priyanka Iyer[1], Rajendra Singh Negi[1], and •Gerhard Gompper[1] — [1]Institute for Advanced Simulation, Forschungszentrum Juelich, Germany — [2]Sejong University, Seoul, South Korea

The collective behavior of motile active matter displays many emergent self-organization, like flocking and swarming [1]. For living systems, as well as microrobotic systems, activity and locomotion is combined with sensing of the environment and adaption of motion. We study such system by considering models of 'intelligent' active particles with visual perception and self-steering in both dry [2,3] and wet systems [4,5].

Here, we focus on wet systems, where hydrodynamic interactions contribute significantly or dominate the self-organization [4,5]. Pusher- and puller-type squirmers display very different emergent behaviors. Pusher-pursuers may not be able to catch up with pusher-targets even at larger pursuer speeds [4]. Also, aligning pushers can form stable pairs only with speed adjustment of the pursuer . In large ensembles, pushers display active turbulence, while pullers form unstable clusters, vortices, and jets [5].

Invited Talk SYGF 1.6 Wed 17:45 HSZ/AUDI

Perturbing the collective motion of fish with challenging environments — •Aurélie Dupont — LIPhy, CNRS Univ. Grenoble Alpes, Grenoble France

Collective movements can be observed across species and on various scales: from bacteria to mammals. We are interested in the collective behavior of small fish when confronted with external physical perturbations. When forced to escape through a narrow opening, most animals behave like granular materials and clogging events decrease the efficiency of evacuation. In this emergency exit scenario, we challenged the gregarious behavior of a group of macroscopic aquatic agents, neon fish, by forcing the school to pass through a small opening[Larrieu, Sci. Rep. 2023]. Using a statistical analysis developed for granular material and applied to crowd evacuation, our results clearly show that, unlike human crowds or herds of sheep, no clogging forms at the bottleneck. The fish do not collide and wait by respecting their social distance and a minimum delay between two successive exits. In a second experiment, we perturbed the schooling behavior of a group of zebrafish by adding an array of pillars to the observation tank[Ventejou Phys. Rev. E 2024]. We observed a behavioral transition from a polarized group when the density of pillars is low to independent fish aligned with the array of pillars. The abrupt transition from natural to artificial orientation occurs when the distance between pillars is comparable to the social distance of the fish. We developed a stochastic model of relative orientation between pairs of fish that captures the behavioral transition and provides information on the evolution of cognitive parameters.

Symposium Interacting Degrees of Freedom in Ultrathin Quantum Films (SYQF)

jointly organised by

Understanding the interactions between different degrees of freedom and their associated low-energy excitations is crucial for comprehending the physical behavior of condensed matter systems. In atomically thin quantum films, reduced dimensionality and enhanced confinement lead to amplified or modified interactions, resulting in novel physical phenomena. This symposium provides an interdisciplinary platform to discuss recent advances in the field of coupled degrees of freedom in ultrathin materials, with contributions from both experimental and theoretical perspectives. Exploring these effects not only deepens our understanding of quantum nanomaterials but also paves the way for integrating systems with interacting degrees of freedom into next-generation electronic, optoelectronic, and quantum technologies.

Invited Talk SYQF 1.1 Fri 9:30 HSZ/AUDI

Exciton dressing by extreme nonlinear magnons in a layered semiconductor — •Geoffrey M. Diederich — University of Maryland Baltimore County, 1000 Hilltop Circle, Baltimore MD, USA

Collective excitations presenting nonlinear dynamics are fundamental phenomena with broad applications. A prime example is nonlinear optics, where diverse frequency-mixing processes are central to communication and attosecond science, and extreme (>sixth-order) harmonic generation provides broad wavelength conversion. Leveraging recent progress in van der Waals magnetic semiconductors, we demonstrate nonlinear optomagnonic coupling. In the layered antiferromagnetic semiconductor CrSBr, we observe exciton states dressed by up to 20 harmonics of magnons, resulting from their extreme nonlinearities. We also create tunable optical sidebands via sum- and difference-frequency generation between two optically bright magnon modes under symmetry-breaking magnetic fields. Moreover, we can tune the observed difference-frequency generation mode into resonance with one of the fundamental magnons, which results in parametric amplification of magnons. Our findings realize the modulation of the optical-frequency exciton with the extreme nonlinearity of magnons at microwave frequencies, which could find applications in magnonics and hybrid quantum systems, and provide a method for optomagnonic neuromorphic computing devices.

Invited Talk SYQF 1.2 Fri 10:00 HSZ/AUDI

A tale of demons and decay in two-dimensional (alter)magnets — •Alexander Mook — Universität Münster

Altermagnets are a newly discovered class of magnetic materials that combine broken time-reversal symmetry with zero net magnetization, offering promising opportunities for spintronics. I will introduce the basic principles of altermagnetism and discuss two recent advances in understanding their collective excitations. First, electron-electron interactions create a new type of low-energy mode: spin-polarized acoustic plasmons ("spin demons"). Second, I will show how the splitting of magnon bands enables spontaneous magnon decay driven purely by quantum many-body fluctuations, setting an intrinsic limit on magnon lifetimes. These findings highlight the unconventional excitation physics of altermagnets and their potential for future functional materials.

Invited Talk SYQF 1.3 Fri 10:30 HSZ/AUDI

Magnetism, light and matter - Role of excitons in two-dimensional magnets — •Florian Dirnberger — Zentrum für QuantumEngineering (ZQE), Technical University of Munich, Garching, Germany — Department of Physics, TUM School of Natural Sciences, Technical University of Munich, Munich, Germany

Studies on van der Waals magnetic materials have recently unveiled a rare type of optical quasiparticle formed by spin-polarized electronic states in magnets. With properties that have no analogue among excitons in conventional semiconductors, these so-called magnetic excitons offer a compelling playground to explore the interplay between magnetism, light and matter.

In this talk, I will review the magneto-optical properties of excitonic van der Waals magnets, with a particular focus on recent work on the antiferromagnetic insulator CrSBr. This archetypal layered magnet provides key insights into how magnetic order alters excitonic responses, and how excitons in turn influence magnetic dynamics. It further enables experiments to probe magnetic excitons in the regime of strong light-matter coupling, bringing concepts from photonics into the picture. Optical spectroscopy reveals pronounced exciton responses to applied magnetic fields, dynamic coupling between excitons and both coherent and incoherent magnons, and magnon-induced excitonic correlations. Together, these results open new directions for magneto-optics and highlight opportunities to control magnetically correlated quantum materials through strong light-matter interactions.

Invited Talk SYQF 1.4 Fri 11:15 HSZ/AUDI

Advantages and challanges of resonance Raman scattering with infrared excitation energy — •Leonetta Baldassarre — Department of Physics, Sapienza University of Rome, I-00185 Rome Italy

Resonance Raman scattering is a valuable spectroscopic technique, providing a probe into the intertwined electronic and vibrational properties of materials. The main strength of resonance Raman lies in its ability to selectively map distinct regions of the electron and phonon dispersion simply by tuning the excitation laser energy.

I will introduce our experimental approach of performing resonance Raman by lowering the excitation energy deep into the Near-Infrared. This frequency shift is strategic, enabling us to probe scattering processes resonant with the bottom of the conduction band in narrow-band semiconductors or close to the Dirac points. I will provide an overview of the custom-built experimental setup and present the results from its application to diverse materials such as layered semiconductors like $MoSe_2$ and $MoTe_2$ or graphene.

Our measurements are compared to *ab-initio* calculations so to identify the phonons involved in the resonant processes and, in the case of graphene, introduce the existence of a momentum-dependent electron-phonon coupling between low-energy carriers and zone-boundary optical phonons. Resonance Raman scattering with infrared excitation can be thus viewed as an indispensable tool for exploring and understanding the essential, often-hidden, charge-carrier and lattice dynamics that define the physics of low-dimensional quantum matter.

Invited Talk SYQF 1.5 Fri 11:45 HSZ/AUDI

Shining light on 2D antiferromagnets — •Dmytro Afanasiev — Radboud University

Ultrafast optical control of antiferromagnetic order is a key goal in spintronics and magnonics. Resonant excitation of local orbital degrees of freedom, such as dd transitions in transition-metal ions, offers a direct route to modify magnetic exchange and anisotropy on femtosecond timescales. However, orbitally driven photomagnetism has been demonstrated in only a few materials, and the factors governing its efficiency remain unclear.

Here, we study ultrafast spin dynamics induced by resonant pumping of dd transitions in layered antiferromagnetic thiophosphates XPS3. We first establish the photomagnetic response in single magnetic-ion compounds, where local orbital excitation triggers coherent spin precession via ultrafast anisotropy modulation. We then extend this approach to binary compounds containing two distinct transition-metal ions, demonstrating that selective excitation of specific orbital resonances strongly enhances the efficiency and controllability of magnon generation.

These results identify general design principles for orbitally driven photomagnetism in collinear antiferromagnets and establish transition-metal substitution as a powerful strategy for achieving efficient ultrafast control of antiferromagnetic spin dynamics.

The UN Sustainable Development Goals call for transformative action across all sectors. Physics, as a foundational science, plays a key role - from understanding complex natural and socio-economic systems to developing sustainable technologies, fostering responsible resource use, and advancing sustainability-oriented education and public outreach. This symposium brings together diverse perspectives from within the physics community to explore interdisciplinary contributions to sustainability, including earth system modeling, energy systems, transport, molecular recycling and circularity as well as science education. Through five expert talks from various fields, we aim to highlight the relevance of physics and physics education for future-oriented transformation and inspire early-career researchers to engage with pressing global challenges in meaningful, scientifically grounded ways.

Time: Monday 15:00–17:45 Location: HSZ/AUDI

Invited Talk SYSC 1.1 Mon 15:00 HSZ/AUDI

Open-Endedness and Community-Based Approaches to Sustainability Challenges — •Hiroki Sayama — Binghamton University, State University of New York, Binghamton, NY, USA — Waseda University, Tokyo, Japan

The sustainability of our natural and social environments is of utmost importance in today's complex world. Achieving this goal is challenging because of: the complexity of interconnected networks involving numerous variables, factors, and stakeholders; the uncertainty and unpredictability in the dynamics of these components and their interactions; the possibility of unexpected outcomes resulting from well-planned solutions; and the fundamental lack of cooperative incentives for stakeholders to participate in actions that are collectively beneficial yet individually detrimental. To address these difficult sustainability challenges, one can benefit from insights into complex systems, especially the open-endedness of complex dynamical/evolutionary systems and the active involvement of community members in participatory solution development. In this talk, I will provide a birds-eye view of the recent open-endedness literature being developed in complexity science, artificial life, and AI, and discuss its relevance to sustainability issues. I will also report on a concrete example of community-based approaches to sustainability implemented in the Greater Binghamton area (called the "Binghamton Two Degrees" project). These approaches are becoming increasingly relevant in our sustainability efforts, as we now face irreversible environmental changes arising in a world that may have already passed the critical transition point.

Invited Talk SYSC 1.2 Mon 15:30 HSZ/AUDI

Education as a Social Tipping Element: Evidence from Climate and Physics Education Research — •Thomas Schubatzky — University of Innsbruck, Innsbruck, Austria

The concept of social tipping elements draws attention to societal leverage points that may accelerate transitions towards sustainability. Education is frequently named as one of these leverage points. In this talk, I outline key findings from recent meta-analyses and review studies in climate and physics education research and discuss the conditions under which educational processes may exert transformative effects. The evidence thereby consistently shows substantial gains in climate-related knowledge, while effects on attitudes and behavioural outcomes are smaller but reliably detectable. The pronounced heterogeneity across studies, however, indicates that the underlying mechanisms of effective climate education are still insufficiently understood. The talk addresses this challenge by drawing on selected empirical studies that illustrate how educational interventions can initiate reinforcing feedbacks at both the individual and collective level. These studies are intended to highlight concrete pathways through which education may operate as a social tipping element, and how micro-level learning processes could scale up to support broader societal transformation.

Invited Talk SYSC 1.3 Mon 16:00 HSZ/AUDI

Mechanistic and Material Perspectives on Enzymatic Hydrolysis of Semicrystalline Polyesters — •Birte Höcker — Biochemie, Universität Bayreuth, Germany

Enzymatic degradation of polyethylene terephthalate (PET) provides a sustainable route for polyester recycling, yet efficiency remains limited by both enzyme diversity and substrate properties. To address this, we developed a tunable degradation platform incorporating realistic substrates and adaptable to various polyesters, enabling parallelized purification and high-throughput characterization of novel enzymes and engineered variants. Using this system, we identified halophilic PETases from the marine Halopseudomonas lineage. High-resolution crystallography of one candidate revealed a unique active-site architecture lacking the canonical π-stacking clamp and exhibiting altered loop conformations, prompting an extension of the PETase classification to include type III enzymes. These enzymes demonstrated remarkable salt tolerance and improved PET hydrolysis at elevated temperatures. Complementary studies on polybutylene terephthalate (PBT) highlight the critical role of semicrystalline morphology: reducing crystallinity and optimizing incubation near the glass transition significantly enhance hydrolysis. By expanding the structural and sequence space of PET-degrading enzymes, combined with material-specific insights, we aim to establish a foundation for efficient enzymatic recycling of semicrystalline polyesters and support the development of next-generation biocatalysts for sustainable plastic management.

Decarbonization Options for Industry — •Uwe Riedel — DLR Institut für CO2-arme Industrieprozesse, 03046 Cottbus, Deutschland

Industrial decarbonization is pivotal to achieving emission targets. In 2024, CO2-emissions from the industrial sector amounted to approximately 153 million tons, accounting for around 25% of Germanys total CO2-emissions.

However, decarbonizing this sector is challenging due to the wide variety of processes involved. In some cases, electrification is a viable solution, but often, sector-specific approaches are necessary. The presentation will show examples from various sectors and explain the options available for different process temperatures.

Invited Talk SYSC 1.5 Mon 17:15 HSZ/AUDI

Impacts of Cosmic Dust and Space Debris in the Terrestrial Atmosphere — •John Plane — School of Chemistry, University of Leeds, UK

Cosmic dust particles are produced from sublimating comets and collisions between asteroids. Because the particles enter the atmosphere at hypersonic velocities, collisional heating with air molecules leads to vaporization of their metallic constituents. The injection of these elements causes a wide variety of atmospheric phenomena: global layers of metal atoms between 80 and 105 km; airglow emissions; metallic ions (sporadic E layers) which affect radio communications; and meteoric smoke particles which enable the nucleation of mesospheric ice clouds and the freezing of polar stratospheric clouds. Certain metal atoms can be observed by ground-based lidar and from satellites, providing excellent tracers of dynamics and chemistry at the edge of space.

The global mass input rate of cosmic dust to the atmosphere is estimated to be around 27 tonnes per day. This estimate was obtained using an astronomical dust model to provide the size and velocity distributions of dust in the inner solar system, combined with a chemical ablation model to determine the rates of metal injection and deposition of cosmic spherules in the polar ice-caps. The re-entry of spacecraft from low Earth orbit currently produces influxes of metals such as aluminium and lithium which already exceed natural background levels. The atmospheric implications of the expected significant increase in these anthropogenic fluxes during the next decade will be discussed.

Symposium SKM Dissertation Prize 2026 (SYSD)

jointly organised by
all divisions of the Condensed Matter Section of the DPG

Elke Scheer
Department of Physics, University of Konstanz
Universitätsstraße 10
78464 Konstanz
elke.scheer@uni-konstanz.de

The divisions belonging to the Condensed Matter Section (SKM) of the DPG annually award the SKM Dissertation Prize. The prize acknowledges outstanding research during the doctoral studies in the research areas of the SKM completed between October 2023 and 2025, and its excellent oral presentation. Based on nominations, a jury consisting of the chair persons of all SKM divisions has selected five finalists to present their work in this symposium. The winner will be selected after the symposium and publicly announced Tuesday, March 10, 2026 in the afternoon during the ceremonial session (Lecture hall HSZ/AUDI starting at 16:00).

Stochastic-Calculus Approach to Non-equilibrium Statistical Physics — •Cai Dieball — Max Planck Institute of Multidisciplinary Sciences, Göttingen, Germany

Truly understanding living matter requires understanding physical processes far from thermodynamic equilibrium on the level of individual molecules. While single-molecule experiments can probe individual stochastic trajectories, the strong influence of thermal noise and limited number of repetitions pose significant challenges. Here, we address these challenges using the mathematical framework of stochastic calculus. This approach yields important insights into fluctuations of time-averaged densities and currents, which are central observables in non-equilibrium stochastic thermodynamics [1]. Building on these methodological advances, we provide a new route to derive thermodynamic uncertainty relations that link observed currents to the distance to equilibrium, quantified via entropy production [2]. Strikingly, this new derivation generalizes to trade-off relations beyond thermodynamic uncertainty relations, enabling thermodynamic inequalities for bulk observables and dynamics with inertia [3]. Furthermore, we employ the stochastic framework to theoretically predict and experimentally confirm an asymmetry between heating and cooling dynamics far from equilibrium [4].

Nonuniform magnetic spin textures for sensing, storage and computing applications — •Sabri Koraltan — Insitute of Applied Physics, TU Wien, Vienna, Austria

Spintronic materials underpin many modern technologies, from hard-disk drives to magnetic sensors. While these applications traditionally rely on uniform magnetization states, recent advances focus on nonuniform magnetic textures such as vortices, and skyrmions. In my doctoral thesis, I explored such textures for sensing, storage, and computing applications [1].

The first part of my talk covers the discovery and characterization of spin textures with arbitrary topological charge in ferromagnetic [Co/Ni] multilayers [2]. Using simulations and experiments, we demonstrate coexisting higher-order skyrmions and antiskyrmions and uncover their distinct dynamics under spin-transfer torques.

The second part presents a three-dimensional magnetic-field sensor with a wide linear range and intrinsic offset cancellation, enabled by spin-orbit torque symmetry in a [W/CoFeB/MgO]*10 multilayer that stabilizes stripe domains and skyrmions [3]. I will show, through experiment and micromagnetics, how spin-orbit torques reshape the magnetic state at high current densities to achieve full 3D sensing, with topological transitions detected electrically via the anomalous Hall effect.

Invited Talk SYSD 1.3 Mon 10:30 HSZ/0002

Anomalous Quantum Oscillations beyond Onsager's Fermi Surface Paradigm — •Valentin Leeb — University of Zurich — Technical University of Munich

Quantum oscillation measurements are the most precise method for determining Fermi surface properties in bulk three-dimensional metals, owing to Onsager's relation, which connects the oscillation frequency to an extremal cross-section of the Fermi surface. This canonical, semiclassical theory of quantum oscillations has been remarkably successful in unearthing electronic properties of metals for over 75 years. However, with the emergence of modern quantum materials and advancements in experimental sensitivity, breakdowns of the semiclassical theory have recently come to light. In this talk, I demonstrate that additional quantum oscillation frequencies - breaking Onsager's relation - emerge generically in multiband metals. These anomalous frequencies, referred to as non-Onsager oscillations, are induced by impurities, scattering from fluctuations, or weak and strong electronic interactions. Using a combination of analytic theory, numeric modeling, and experimental verification, I establish them as fundamental features of quantum oscillation spectra. Properly identifying non-Onsager oscillations is essential for accurately reconstructing the Fermi surface. Moreover, these frequencies encode rich information about underlying material properties beyond the scope of the semiclassical theory. The results, presented here, refine our understanding of quantum oscillations in complex materials and open new avenues for probing electronic correlations, emergent phenomena, and unconventional metallic states.

Invited Talk SYSD 1.4 Mon 11:00 HSZ/0002

Coherent Control Schemes for Semiconductor Quantum Systems — •Eva Schöll — PhoQS Institute, CeOPP, and Department of Physics, Paderborn University, Paderborn, Germany — Institute of Semiconductor and Solid State Physics, Johannes Kepler University, Linz, Austria — Institute for Integrated Circuits and Quantum Computing, Johannes Kepler University, Linz, Austria

Single photons are fundamental building blocks for advancing quantum technologies. Therefore, quantum light sources that simultaneously exhibit properties such as high single-photon purity, indistinguishability, and entanglement fidelity are essential. Semiconductor quantum dots (QDs) are promising candidates that already meet many of these requirements. In this talk, I will provide a deeper understanding of the underlying quantum-level schemes and reveal an intrinsic limit on indistinguishability for photons arising from a radiative cascade. To address this, we studied QDs under s-shell resonant excitation and two-photon excitation (TPE), and introduced a novel excitation technique combining TPE with stimulation of the first transition. This method can overcome the previously mentioned limit on indistinguishability.

Invited Talk SYSD 1.5 Mon 11:30 HSZ/0002

On stochastic thermodynamics under incomplete information: Thermodynamic inference from Markovian events — •Jann van der Meer — Department of Physics No. 1, Graduate School of Science, Kyoto University, Kyoto 606-8502, Japan

Stochastic thermodynamics provides the framework for analyzing thermodynamic quantities along individual trajectories of small but fully observable systems. If, however, the observable dynamics is coarse-grained, i.e., does not capture all relevant degrees of freedom, the principles of stochastic thermodynamics generally cannot be applied directly. With access to some observables, preeminent results in the field (e.g. the thermodynamic uncertainty relation) often establish lower bounds on the average entropy production in terms of such observables.

However, there is no reason why attention should be limited to bounds on the averaged entropy production only. In my talk, I present the concept of a fluctuating entropy production on the coarse-grained level, which contains more information than about averages only, thereby allowing us to, e.g., estimate the strength of driving forces and localize entropy production spatially and temporally. From a theoretical point of view, these results rely on the identification of Markovian events, a systematic way of describing the dynamics and thermodynamics of a variety of possible coarse-grained dynamics in terms of semi-Markov processes.

Symposium Tipping Points in Social and Climate Systems (SYTP)

jointly organised by
the Physics of Socio-economic Systems Division (SOE),
the Dynamics and Statistical Physics Division (DY),
the Environmental Physics Division (UP),
the Thin Films Division (DS), and
the Working Group "Young DPG" (AKjDPG).

The concept of tipping points has become central to understanding both climate dynamics and social transformations. This symposium brings together physicists and interdisciplinary researchers to explore the mechanisms underpinning tipping behavior in complex systems. Topics include nonlinear dynamics of the Earth system, early warning signals of climate tipping points, and the emergence of social tipping cascades in response to policy, technology, and behavioral shifts.

Overview of Invited Talks and Sessions

SYTP 1: Tipping Points in Social and Climate Systems

Time: Thursday 15:00–17:45 Location: HSZ/AUDI

Invited Talk SYTP 1.1 Thu 15:00 HSZ/AUDI

Social Tipping in Heterogeneous and Polarized Populations — •Sara Constantino[1], Sonke Ehret[2], Elke Weber[3], Sonja Vogt[2], and Charles Efferson[2] — [1]Stanford University, Stanford, USA — [2]University of Lausanne — [3]Princeton University

Leveraging social norms to create widespread social change through circumscribed interventions has been hailed as an effective mechanism for addressing climate change. Lab experiments find that a small fraction of a population - a committed minority - can tip a population to an alternative stable state. However, the feasibility of social tipping interventions to incite widespread change depend on specific conditions. In two online experiments, we test (1) the role of group identities in facilitating and interrupting the emergence of social norms, and (2) how heterogeneous preferences impact whether an intervention is effective or not. In the first study, we ran an online experiment in which participants faced consistent incentives to coordinate their choices. We found that while the control groups developed norms slowly before intervention, they transitioned to new norms rapidly after intervention. In contrast, the identity groups developed norms rapidly before intervention but persisted in a state of costly disagreement after an intervention. In a second study, we ran a group experiment where we tested the effects of prior preferences and the magnitude and targeting of tipping interventions. Our results show that pre-intervention heterogeneity significantly moderated the effects of tipping interventions. These findings suggest social tipping success depends on mundane features of the environment.

Invited Talk SYTP 1.2 Thu 15:30 HSZ/AUDI

Tipping points and regime shifts in coupled social-climate systems — •Chris Bauch — Department of Applied Mathematics, University of Waterloo, Canada

Coupled social-climate interactions are important, yet the modelling of such systems is in its infancy, including the study of their tipping points. In this talk, I will touch briefly on two coupled social-climate models*a simpler model intended to study potential interactions between climate and social tipping points, and a more realistic model with regional structure that is parametrised with geophysical, economic, demographic and social data. Among other findings, I will highlight some unexpected predictions that emerge from the nonlinear interactions in the models. I will also touch upon data-driven dynamical systems approaches to predicting tipping points in climate and social-climate systems.

Invited Talk SYTP 1.3 Thu 16:00 HSZ/AUDI

How to tune Earth system models toward tipping? — •Sebastian Bathiany[1,2] and Niklas Boers[1,2] — [1]Technical University of Munich — [2]Potsdam Institute for Climate Impact Research

Models of complex dynamical systems like the Earth's climate often involve large numbers of uncertain parameters. Comprehensive exploration of the parameter space is typically prohibitive due to excessive computational costs. Systematic gradient-based parameter optimization is not feasible because such models are typically not differentiable. This is especially problematic in cases where the models describe highly nonlinear and possibly abrupt dynamics, where sensitivity to parameter changes is high. Components of Earth's climate system, such as the North Atlantic Overturning Circulation or the polar ice sheets, are at risk of undergoing critical transitions in response to anthropogenic climate change. Concerns have been raised that these Earth system components are too stable in state-of-the-art models. In my presentation, we will see examples how new scenario simulations allow studying the possibility and the consequences of tipping events in Earth system models. Also, we will discuss a method for efficient, systematic, and objective calibration of dynamical complex system models, targeted at adjusting system stability. Given a number of physical or observational constraints, the method can efficiently adjust stability biases in a range of complex system models and help reveal potentially hidden instabilities, with important implications for Earth system modelling.

15 min. break

Invited Talk SYTP 1.4 Thu 16:45 HSZ/AUDI

Algorithmic amplification and contextual sensitivity in political information exposure — Iris Damião, Ana Vranic, Paulo Almeida, Lília Perfeito, and •Joana Gonçalves de Sá — LIP, Lisbon, Portugal

Understanding criticality and tipping points is key to analyzing how small changes can cascade into large-scale effects. In information ecosystems, these dynamics emerge in both social media and algorithmically mediated platforms, where recommendation systems interact with user behavior to produce disproportionate societal impacts.

Misinformation on platforms like Twitter (X) is often assumed to spread faster than the truth. Yet, empirical evidence varies. Analyzing three large datasets - Vosoughi News, Global Claims, and Truth Seeker- we find that cascade size distributions are very dependent on sampling choices and this sensitivity can lead to opposite results when studying information diffusion.

Beyond social media, search engines (SEs) and large language models (LLMs) increasingly shape access to information. Using a privacy-preserving bot system, we conducted synchronized searches prior to the 2024 European Parliament. Results varied by location and query type; however, SEs and LLMs consistently emphasized right-leaning entities, revealing systematic algorithmic bias.

Together, these findings illustrate that algorithmically driven platforms can reflect and amplify political biases, creating fragmented informational realities.

Invited Talk SYTP 1.5 Thu 17:15 HSZ/AUDI

The complex interplay between democracy and platform power — •Philipp Lorenz-Spreen — Center Synergy of Systems, TU Dresden, Germany

Information and communication technology has undergone dramatic developments over the last two decades. Increasing interconnectedness has led to more self-organized public debates, platforms and their algorithms have gained new power over discourse, and generative AI has made content fabrication easier than ever. But it has also given research new tools to quantify precisely these systemic changes. Detailed data from social media allows us to measure and model their network structures and dynamics. Against this background, we ask: What is really changing, what does science know about the connection between the crises of democracy and the worldwide use of digital and social media? A number of political behaviors appear to be influenced by the use of digital media, such as increasing polarization or declining trust in institutions. Our findings show that while there is agreement in the literature on some of the relationships, these vary across the world and, above all, the underlying mechanisms by which these dimensions are linked are still unknown. A better understanding of these systems is critical for civil society in democracies worldwide, and I will conclude with a methodological outlook on how we are currently trying to explore these missing puzzle pieces.

BP 1: Active Matter I (joint session BP/CPP/DY)

Time: Monday 9:30–12:45 Location: BAR/SCHÖ

BP 1.1 Mon 9:30 BAR/SCHÖ

Bayesian inference of magnetosensing in a magnetotactic bacterium — •Sascha Lambert[1], Emilie Gachon[2], Damien Faivre[2], and Stefan Klumpp[1] — [1]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany. — [2]Aix Marseille Université, CEA, CNRS, BIAM, 13115 Saint-Paul-Lez-Durance, France.

Magnetotactic bacteria are often assumed to align only passively with external magnetic fields, yet recent observations of the magnetotactic bacterium SS-5 reveal a pronounced increase in swimming speed under geomagnetic conditions. Because flagellated microorganisms typically follow helical paths, magnetic torques could, in principle, straighten their trajectories and create an apparent increase in speed, offering a purely mechanical explanation. We test this hypothesis using a physical swimming model based on Active Brownian Particles that incorporates magnetic torques, rotational propulsion, and helical motion, and we explore the relevant parameter space using Bayesian inference constrained by three-dimensional trajectory data. Posterior predictive simulations demonstrate that the mechanically induced increase in apparent speed is far too small to account for the experimental observations, even under extreme parameter choices. The results quantitatively rule out swaying as a sufficient explanation for the behaviour of SS-5 and instead support the presence of an active magnetic sensing mechanism.

BP 1.2 Mon 9:45 BAR/SCHÖ

Vorticity-induced surfing and trapping in porous media — •Pallabi Das[1], Mirko Residori[1], Axel Voigt[2,3,4], Suvendu Mandal[5], and Christina Kurzthaler[1,3,4] — [1]Max Planck Institute for the Physics of Complex Systems, Germany — [2]Institute of Scientific Computing, TU Dresden, Germany — [3]Center for Systems Biology Dresden, Germany — [4]Cluster of Excellence, Physics of Life, TU Dresden, Germany — [5]TU Darmstadt, Germany

Microorganisms often encounter strong confinement and complex hydrodynamic flows while navigating their habitats. Combining finite-element methods and stochastic simulations, we study the interplay of active transport and heterogeneous flows in dense porous channels. We find that swimming always slows down the traversal of agents across the channel, giving rise to robust power-law tails of their exit-time distributions. These exit-time distributions collapse onto a universal master curve with a scaling exponent of $\approx 3/2$ across a wide range of packing fractions and motility parameters, which can be rationalized by a scaling relation. We further identify a new motility pattern where agents alternate between *trapping* along fast streams and extended *surfing* phases, the latter determining the power-law exponent. Unexpectedly, trapping occurs in the flow backbone itself – not only at obstacle boundaries – due to vorticity-induced reorientation in the highly-heterogeneous flow environment. These findings provide a fundamentally new active transport mechanism with direct implications for biofilm clogging and the design of novel microrobots capable of operating in heterogeneous media.

BP 1.3 Mon 10:00 BAR/SCHÖ

Adhesion Patterns in Gliding Filamentous Cyanobacteria — •Elias Fischer[1], Paul Nieschwitz[2], Stefan Karpitschka[2], and Holger Stark[1] — [1]Institute of Physics and Astronomy, TU Berlin, Germany — [2]Department of Physics, Universität Konstanz, Germany

Filamentous cyanobacteria play an important role in many ecosystems and the carbon cycle of our planet. They exhibit gliding motility when in contact with solid surfaces or each other. Despite their ecological relevance and increased use in biotech applications, the exact nature of the force-generating process remains not fully understood.

Our recent measurements of filamentous cyanobacteria gliding across flat surfaces and visualized in kymographs show spatio-temporal adhesion regions along the filament, indicating an intrinsic helical shape. Based on our a novel approach for modeling the mechanical aspects of individual cyanobacteria filaments, we are able to interpret the complex kymograph patterns. Each filament is modeled as a helical chain of thin cylindrical segments in 3D with bending and twisting elasticity. The filaments interact with nearby surfaces and filaments via a hard-core repulsion and an exponentially decaying adhesion force. Importantly, the propulsion forces that push the filament forward are only applied locally at surface-contacting segments.

Our simulated kymographs reveal how both the helical shape and the adhesion strength strongly influence the filament's gliding speed and the dynamics of the surface-attachment regions. Thereby, we crucially contribute to the understanding of how real filamentous cyanobacteria generate their propulsion forces.

BP 1.4 Mon 10:15 BAR/SCHÖ

The 3D chirality of malaria parasites determines their motion patterns in 2D and originates at the apical pole — •Leon Lettermann[1], Mirko Singer[2], Smilla Steinbrück[2,3], Falko Ziebert[1], Sachie Kanatani[3], Photini Sinnis[3], Friedrich Frischknecht[2], and Ulrich Schwarz[1] — [1]Institute for Theoretical Physics & BioQuant, Heidelberg University — [2]Parasitology, Center for Infectious Diseases, Heidelberg University — [3]School of Public Health and Malaria Research Institute, Johns Hopkins University

Plasmodium sporozoites, the slender forms of the malaria parasite injected by mosquitoes into the skins of their vertebrate hosts, provide a medically highly relevant model system for active chiral particles. Using 3D tracking in synthetic hydrogels, we show that sporozoites consistently move on right-handed helical trajectories. When they encounter a two-dimensional substrate, they switch to clockwise circular motion, whereas circling on glass in medium occurs with the opposite sense of rotation, suggesting on glass they try to invade the medium above. Using a sandwich assay, we demonstrate that chirality also determines the reverse transition from two-dimensional to three-dimensional motion. Combining these measurements with a theory for gliding motility allows us to identify the likely origin of chirality, namely an asymmetric distribution of adhesins. After confirming this via two-sided traction force microscopy, we finally use STED super-resolution microscopy to reveal a corresponding tilt in the apical ring complex. In summary, our analysis thus uncovers both the biological relevance and the molecular basis of chirality in the movement of malaria parasites.

BP 1.5 Mon 10:30 BAR/SCHÖ

Squirmer dynamics in porous environments — •Mirko Residori[1], Christina Kurzthaler[1], and Sebastian Aland[2] — [1]Max Planck Institute for the Physics of Complex Systems — [2]TU Freiberg

We introduce a computational framework for simulating the dynamics of microswimmers in complex porous environments. Specifically, we adopt a diffusive domain approach to represent the surface of a micro-swimmer, modeled as a squirmer. This method ensures accurate and stable finite-element simulations, even in highly confined geometries. Validation against analytical and numerical benchmarks confirms the model*s accuracy and robustness. We then apply it to explore squirmer motion in heterogeneous porous media, revealing how hydrodynamic interactions lead to behaviors such as dynamic trapping due to hydro-dynamically induced re-orientations. Moreover, we demonstrate that the squirmer parameter and the repulsive potential critically influence a squirmer's ability to navigate and escape confinement. The proposed framework offers a versatile and efficient tool for studying active motion in complex fluids and provides new insights into micro-swimmer transport and control in natural and engineered systems.

BP 1.6 Mon 10:45 BAR/SCHÖ

Dynamics of passive tracers in active dumbbell suspension — •Chandranshu Tiwari and Sunil P. Singh — Department of Physics, Indian Institute of Science Education and Research, Bhopal 462066, India.

The transport of passive tracers in active fluids exhibits rich dynamics arising from persistent interactions between active agents and the tracer. In our work, we employ Brownian dynamics simulations to investigate the dynamical behaviour of both isotropic(circular) and anisotropic(elliptical) tracers in active dumbbell suspension, considering only steric interactions. For circular tracers, we find that the speed shows a crossover from monotonically decreasing to increasing with tracer size as the dumbbells' speed is increased. The tracer's effective diffusion also displays a non-monotonic dependence on area fraction: the diffusivity first increases and then decreases at higher area fractions.

For anisotropic tracers, the characteristic non-monotonic trend persists. Moreover, their motion along the major and minor axes differs significantly. Anisotropic accumulation of active particles around the tracer generates direction-dependent forces and fluctuations, favouring motion along the major axis. Consequently, both the speed and diffusivity along the major axis exceed those along the minor axis.

Invited Talk BP 1.7 Mon 11:15 BAR/SCHÖ

Modeling and inference of magnetotactic motility in complex environments — •Stefan Klumpp — Institute for the Dynamics of Complex Systems, University of Göttingen, Göttingen, Germany

Magnetotactic bacteria orient themselves and swim along field lines of the geomagnetic field. Their magnetically directed self-propelled motion makes them an instance of dipolar active matter. Here we focus on the interaction of these bacteria with walls or obstacles. Experiments in microfluidic systems show that interactions with walls result in (possibly transient) alignment parallel to the wall, which may compete with the alignment with the magnetic field. The dynamic behavior arising from the competition of the two alignments includes U-turn trajectories in circular chambers and trapping and escape dynamics in channels with overlapping cylindrical obstacles. In a phenomenological picture, the resulting motion can be described in an Active Brownian Particle model by introducing a wall torque that competes with the magnetic torque, which results in good agreement with experimental observations. Systematic Bayesian inference of the wall torque from observations shows that only a part of the torque function (dependence on incident angle) can be learned reliably from the data.

BP 1.8 Mon 11:45 BAR/SCHÖ

Quantifying aggregation behaviour of filamentous cyanobacteria — •Elias Illing and Stefan Karpitschka — Fachbereich Physik, Universität Konstanz

Cyanobacteria are ubiquitous in nature, frequently causing ecological and economic harm by explosive growth, so called blooms.

We investigate the collective dynamics of entangled filamentous cyanobacteria in open liquid media, reminiscent of their aggregates found during later stages of blooms. We investigate the impact of illumination on the clustering and spreading of the bacteria and quantify the morphology of the bacterial aggregates by image analysis. We determine the critical density necessary for initial clustering and track the evolution of the subsequent stages, ranging from stable clusters to spreading mats. These states can be modulated by light intensity variations, potentially allowing for control of the morphological evolution of cyanobacterial aggregates.

BP 1.9 Mon 12:00 BAR/SCHÖ

Dynamically Induced Spatial Segregation in Multi-Species Bacterial Bioconvection — •Mingqi Yan[1,2], Chenxi Wang[3], Oscar Gallardo-Navarro[4], Rinat Arbel-Goren[4], Joel Stavans[4], and Erwin Frey[1,2] — [1]Department of Physics, Ludwig-Maximilians-Universität München, Theresienstraße 37, 80333 München, Germany — [2]Max Planck School Matter to Life, Hofgartenstraße 8, 80539, München, Germany — [3]School of Science, Harbin Institute of Technology, 518055, Shenzhen, China — [4]Department of Physics of Complex Systems, Weizmann Institute of Science, 7610001, Rehovot, Israel

Bacterial bioconvection is a classic example of collective behavior in active matter, where upward-swimming bacteria create density instabilities leading to large-scale fluid flows. While this phenomenon is well-studied in single-species suspensions, natural environments are typically inhabited by diverse microbial communities. Here, we investigate the collective dynamics of multi-species bacterial suspensions. Combining experiments with a continum model, we show that different bacterial species can spontaneously segregate into stable, spatially interlocked domains. Our theoretical analysis reveals that this segregation is not driven by biochemical antagonism but rather by the interplay between species-specific motility characteristics and the self-generated hydrodynamic flows. This work provides new insights into how physical interactions alone can drive the spatial organization of complex microbial communities.

BP 1.10 Mon 12:15 BAR/SCHÖ

Light-switchable microbial rafts at air-liquid interfaces — •Gustav F. Nolte, Alexandros A. Fragkopoulos, Timo Völkl, Mechthild Rappold, and Oliver Bäumchen — University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany

In biological active matter, clustering occurs across a wide range of time and length scales, from molecular assemblies such as actomyosin networks to macroscopic systems like fire ant rafts. Here, we report on a fast, light-switchable, and fully reversible clustering phenotype on the microscale, observed at air-liquid interfaces: the raft formation of the biciliated microalga *Chlamydomonas noctigama*.

C. noctigama is a relative of the model organism *Chlamydomonas reinhardtii*, which exhibits light-switchable adhesion and subsequent clustering at solid-liquid interfaces [1,2]. We show how the cluster morphology depends on cell density and discuss potential growth mechanisms by analyzing dynamics of individual clusters. Furthermore, we characterize the dependence of raft formation on the light spectrum and interfacial free energy. Using micropipette force spectroscopy [3], we show that single cells exploit capillary forces for light-switchable ciliary adhesion to the air-liquid interface, enabling raft formation. In their natural habitats, reversible clustering may provide an advantage by allowing cells to accumulate in locations optimal for photosynthesis while increasing resilience to environmental stress.

BP 1.11 Mon 12:30 BAR/SCHÖ

Circadian gravitaxis: Photosynthetic microswimmers remodel local pH to actively tune vertical migration — Arkajyoti Ghoshal[1], Soumitree Mishra[1], Jayabrata Dhar[2], Hans-Peter Grossart[3,4], and •Anupam Sengupta[1,5] — [1]Physics of Living Matter, Department of Physics and Materials Science, University of Luxembourg, Luxembourg — [2]Department of Mechanical Engineering, National Institute of Technology Durgapur, India — [3]Department of Plankton and Microbial Ecology, Leibniz Institute of Freshwater Ecology and Inland Fisheries, Stechlin, Germany — [4]Institute of Biochemistry and Biology, Potsdam University, Germany — [5]Institute for Advanced Studies, University of Luxembourg, Luxembourg

Motile phytoplankton shuttle between bright surface waters and deeper nutrient rich layers, usually controlled by internal circadian clocks. Yet many species show irregular movements, defying the expected circadian rhythm. Studying a bloom forming photosynthetic species, we found that cells adjust their vertical migration by altering local pH, mediated by a shift in their gravitactic behavior. This self-modulation of pH generates sub-populations which are physiologically similar but swim differently, remaining vertically separated even under uniform conditions. Supported by a cell-level analysis and mathematical model, we confirm that the pH-mediated circadian shift is underpinned by morphological adjustments. Our results support a circadian gravitactic model in which diurnal pH control drives diversified migration, enhancing fitness particularly in acidifying oceans.

BP 2: Computational Biophysics I

Time: Monday 9:30–12:45 Location: BAR/0106

BP 2.1 Mon 9:30 BAR/0106

Topology driven spatial organization of DNA-polymers in geometric confinement — •Debarshi Mitra[1], Shreerang Pande[2], and Apratim Chatterji[2] — [1]Leibniz Institute of Polymer Research Dresden, Hohe Strasse 6, 01069 Dresden, Germany — [2]Dept. of Physics, Indian Institute of Science, Education and Research-Pune (IISER-Pune), India-411008

The mechanism of chromosome segregation and organization in the bacterial cell cycle is one of its least understood aspects. The bacterial chromosome is often modeled as a bead spring ring polymer. We introduce cross-links in the DNA-ring polymer, resulting in the formation of loops within each replicating bacterial chromosome. We use simulations to show that the chosen polymer-topology ensures its self-organization along the cell long-axis, such that various chromosomal loci get spatially localized as seen in-vivo, in various growth conditions [1,2]. The organization arises only due to entropic repulsion between polymer loops of each daughter chromosome. We also reconcile observations from complementary experimental techniques probing the organization of the chromosome [1]. We further establish organizational principles for topologically modified polymers in various kinds of geometric confinement and discuss possible relevance to eukaryotic chromosomes.

BP 2.2 Mon 9:45 BAR/0106

An extended boundary integral method for viscoelastic cells — •Thomas Mayr and Stephan Gekle — University Bayreuth, Bayreuth, Germany

The boundary integral method is a powerful method for modeling soft objects such as capsules, vesicles or red blood cells in flows at low Reynolds numbers. The beauty of this method lies in its effective two-dimensional description of the boundaries making fluid-structure interaction simple in comparison to other methods. So far, the boundary integral method is restricted to cells with a viscoelastic membrane and a purely viscous interior, whereas most biological cells contain a complex cytoskeleton and a nucleus in addition to their membrane. Here, we develop an extended three-dimensional boundary integral method, that can handle such cells, which are treated as a homogeneous viscoelastic material surrounded by a viscoelastic membrane. We use our method to study systematically the influence of bulk and membrane viscoelasticity on the dynamics of a cell in shear flow closely corresponding to recent experiments [1].

BP 2.3 Mon 10:00 BAR/0106

Synchronization of both microtubule ends facilitates robust spindle length control — •Shane Fiorenza[1], Sheba Cheeran[2], Elena Doria[2], Iva Tolić[3], Patrick Meraldi[2], and Nenad Pavin[1] — [1]Faculty of Science, University of

Zagreb — [2]Faculty of Medicine, University of Geneva — [3]Rudjer Bošković Institute, Zagreb

The mitotic spindle is a biomechanical structure that relies on a well-controlled geometry to accurately segregate genetic material, and so the mechanisms responsible for setting spindle length have been extensively studied both in vivo and in vitro. One of these myriad mechanisms, microtubule poleward flux, has proven difficult to characterize, with experiments showing that decreasing poleward flux can lead to spindle length increasing, decreasing, or remaining constant. How the spindle regulates its length and the role of poleward flux in this process remains unclear. Here we show that length-dependent regulation at both microtubule ends constitutes a fundamental mechanism of spindle length control through poleward flux. Our model demonstrates that length-dependent mechanisms at both microtubule ends allow plus- and minus-end dynamics to synchronize with one another, resulting in perturbations at either end having opposite effects on poleward flux for increasing spindle size. We predict that spindle length and poleward flux can be uncoupled via simultaneous perturbations, which we confirm with in vivo depletion experiments of KIF18A, KIF2A, and KATNB1 proteins. Our results provide a new way of understanding spindle length control and resolve a long-standing paradox of how poleward flux relates to spindle length.

BP 2.4 Mon 10:15 BAR/0106

A coarse-grained model for investigating the ejection of dsDNA from a viral capsid — •Adrian John Pinto[1], Klara Strobl[2], Carmen San Martin[3], Mar Alcazar Hutardo[2], Paul van der Schoot[4], Pedro J. de Pablo[2], Horacio V. Guzman[5], and Peter Virnau[1] — [1]Institute of Physics, JGU, Mainz, Germany — [2]Autonomous University of Madrid, Madrid, Spain — [3]Spanish National Center for Biotechnology, Madrid, Spain — [4]Eindhoven University of Technology, Eindhoven, Netherlands — [5]Institute of Material Science of Barcelona, Barcelona, Spain

Viruses are microscopic infectious agents that hijack the metabolic machinery of their hosts to replicate. They consist of genetic material, DNA for adenovirus, enclosed within a protein shell called a capsid. Adenoviruses are associated with respiratory diseases, gastroenteritis, conjunctivitis, and urinary tract infections. In this work, we investigate the denaturation of the viral capsid in the presence of urea as a chemical denaturant and analyze how increasing urea concentration affects capsid stability. To model the experimental system in simulations, we propose a coarse-grained representation of viral DNA based on a Kratky-Porod chain, which allows us to incorporate solvent conditions and obtain realistic length scales. Additionally, we model the capsid as a spherical confinement composed of discrete beads and introduce openings of various sizes to map changes in urea concentration to the simulation environment. Our findings indicate that the lag time observed in intensity curves can be explained by differences between partial and complete capsid opening.

BP 2.5 Mon 10:30 BAR/0106

Multi-Scale Computational Framework for Modeling Metabolic Pathways — •Miljan Dašić, Ashwathi Poolamanna, Mehrnoosh Khodam Hazrati, and Štěpán Timr — J. Heyrovský Institute of Physical Chemistry of the Czech Academy of Sciences, Dolejškova 2155/3, 182 00 Prague 8, Czech Republic

Spatial organization of enzymes (clustering, assemblies, and substrate channeling) has been increasingly recognized as a key determinant of metabolic efficiency. Recent studies suggest that non-specific enzyme-substrate interactions and molecular crowding can further impact the performance of metabolic pathways. However, the combined effect of these factors remains insufficiently quantified.

To address this gap, we developed a multi-scale computational framework connecting molecular-level enzyme-substrate interactions with emergent pathway-level kinetics. We first perform extensive coarse-grained Molecular Dynamics (MD) simulations with LAMMPS to quantify substrate transition kinetics at varying crowding levels. Resulting trajectories are analyzed using Markov State Models (MSMs) to extract the relevant states and transition rates. These kinetic parameters are then used to parameterize stochastic Reaction-Diffusion (RD) simulations in Smoldyn, enabling the study of large enzyme assemblies, different reaction orders, and multi-step metabolic pathways.

Our results reveal how molecular interaction strengths, crowding conditions as well as enzyme spatial organization impact pathway efficiency across scales: from nanometers and nanoseconds (MD) to micrometers and seconds (RD).

BP 2.6 Mon 10:45 BAR/0106

Coexistence in competition for shared resources with fluctuating fitness — •Angelique Burdinski and Dirk Brockmann — Center Synergy of Systems (Synosys), TUD Dresden University of Technology, 01069, Dresden, Germany

Understanding how species coexist in competitive scenarios has long been a central question in ecology and evolution. The contradiction between the competitive exclusion principle and the observed diversity of species has puzzled researchers for decades. Fluctuating environmental factors that selectively change species fitness have been proposed to stabilize coexistence, but theoretical results remain inconclusive. How competitive forces and temporal variability shape evolutionary outcomes remains debated, with model-specific results and few universal insights. We compare species dynamics under two generic but qualitatively different mechanisms. One model captures direct competition via the standard replicator equation; the other represents a consumer-resource system, yielding the adjusted replicator model. Under uniform fitness, both show identical asymptotics, diverging sharply when fitness fluctuates. The standard replicator leads to quasi-fixation of a single species, whereas the adjusted replicator exhibits stable coexistence below a critical timescale. We derive coexistence bounds based on the mean and variance of fitness, showing that higher mean and lower variability favor fixation, while coexistence may persist even in disadvantaged situations. This contrast reflects direct versus indirect competition and supports coexistence as a generic outcome of shared-resource interactions in temporally varying environments.

BP 2.7 Mon 11:15 BAR/0106

Dielectric response of graphene and MoS_2 nanopores in the detection of single amino acids — •Longlong Li and Maria Fyta — Computational Biotechnology, RWTH Aachen University, Germany

Recent advances in two-dimensional (2D) material nanopores have opened new opportunities for biosensing with single-molecule precision. In this work, we investigate the interaction of single amino acids with graphene and MoS_2 nanopores using density-functional theory (DFT), combined with dielectric response calculations and non-equilibrium Green's function (NEGF) transport simulations. After identifying the most stable conformations of selected amino acids residing inside the nanopores, we calculate both the electronic transport and optical response of the nanopores in the absence and presence of these biomolecules. While electronic current-voltage characteristics reveal only modest amino-acid-dependent variations, the optical response, characterized by frequency-dependent dielectric functions and optical absorption spectra, exhibits distinct material-specific signatures. In particular, MoS_2 nanopores exhibit strong and broadband optical sensitivities, which are significantly larger than those of graphene and thus enable more distinct discrimination of single amino acids across multiple photon energies. Our simulations reveal an enhancement in the optical read-out of nanopores and an even stronger signals in the case of MoS_2 nanopores highlighting the possibility of a broadband optical detection for protein detection platforms and biosensors.

BP 2.8 Mon 11:30 BAR/0106

From Bioanalytics to Neuromorphic Computing: Graphite-Based Nanopores for Protein Sequencing and Iontronic Memristors — •Chandan K. Das and Maria Fyta — Computational Biotechnology, RWTH Aachen University, Worringerweg 3, 52074 Aachen, Germany

Protein sequencing with single amino acid resolution using ionic current signatures is a rapidly advancing technique, yet challenges persist in maintaining protein linearity and controlling their translocation through solid state nanopores. We introduce a graphite-based nanopore featuring a constriction inspired by alpha-hemolysin. All atom MD simulations show that the positively charged pore lumen promotes strong anion selectivity and drives electro-osmotic flow (EOF), which generates hydrodynamic drag opposing the electrophoretic force (EPF). Balancing these forces straightens proteins during translocation and increases their residence time within the constriction, substantially improving sequencing accuracy. This design enables detection of all 20 proteinogenic amino acids and their post-translational modifications. Beyond sequencing, the graphite-based architecture supports diverse iontronic applications. In a graphite-hydrogel-graphite nanofluidic memristor, a neutral hydrogel selectively traps cations, inducing ion concentration polarization. Simulations reveal characteristic memristive behavior, including a hysteretic current-voltage response. Overall, graphite nanopores offer a versatile platform for sequencing and neuromorphic computing.

BP 2.9 Mon 11:45 BAR/0106

Protein Translocation in Two Dimensional Nanopores from Molecular Dynamics and Free Energy Calculations — •Peijia Wei, Mayukh Kansari, Santiago López Páramo, and Maria Fyta — Computational Biotechnology, RWTH Aachen University, Worringerweg 3, 52074 Aachen, Germany

Nanopores, nanometer scale openings in materials, offer strong potential for ultra fast, cost effective and real time next generation sequencing technologies. These pores can electrophoretically drive charged biomolecules through and detect them. Using computer simulations, we compare two dimensional nanopores, graphene and MoS_2, to evaluate their effectiveness in protein detection. Protein translocation and dynamics are being controlled by varying the surrounding solvent, using both a typical monovalent salt solution and a molecular solution. Atomistic simulations assess the ability of each nanopore to thread proteins, on the basis of the ionic current signals through the pore. We also perform free energy calculations to quantify the thermodynamic factors that influence protein entry and passage through the pores. Our results show that graphene nanopores interact strongly with proteins, which hinders transloca-

tion under physiological conditions. This can be overcome by adding a denaturant that forms a hydrophilic and cation rich layer on the surface and enables linearized threading. In contrast, MoS_2 nanopores allow protein passage even in physiological solutions and offer inherent control of the translocation. By combining molecular dynamics with free energy analysis, we reveal how the complex interactions among all components shape translocation behavior.

BP 2.10 Mon 12:00 BAR/0106

Extending quantum-mechanical benchmark accuracy to biological ligand-pocket interactions — •Mirela Puleva[1], Leonardo Medrano Sandonas[2], Balázs D. Lorincz[3], Jorge Charry[4], David M. Rogers[5], Péter R. Nagy[3], and Alexandre Tkatchenko[1] — [1]University of Luxembourg, Luxembourg — [2]TUD Dresden University of Technology, Germany — [3]Budapest University of Technology and Economics, Hungary — [4]Luxembourg Researchers Hub asbl, Luxembourg — [5]Oak Ridge National Laboratory, USA

Predicting the binding affinity of ligands to protein pockets is key in the drug design pipeline, yet accurate capture of interactions in the flex- ible ligand-pocket motifs requires robust quantum-mechanical (QM) benchmarks, which are scarce. Disagreement between "gold standard" Coupled Cluster (CC) and Quantum Monte Carlo (QMC) methods further challenges large non-covalent benchmarks. We introduce the QUantum Interacting Dimer (QUID) benchmark framework modeling diverse ligand-pocket motifs. CC and QMC agree within 0.5 kcal/mol for QUID, which spans key non-covalent binding motifs and energetic contributions from symmetry-adapted perturbation theory. Benchmark results shows several dispersion-inclusive density functional ap- proximations predict energies accurately but differ in atomic van der Waals forces, while semiempirical and empirical methods need im- provements for non-covalent interactions (NCIs) in out-of-equilibrium geometries. With a wide span of NCIs, highly accurate interaction en- ergies, and further molecular properties, QUID goes beyond the "gold benchmark" QM benchmark of ligand-protein systems.

BP 2.11 Mon 12:15 BAR/0106

Insights into Quantum Decoherence in Biological Light Harvesting from First-Principles Simulations — Thomas Trepl, •Ingo Schelter, Johannes M. Foerster, and Stephan Kümmel — University of Bayreuth, Bayreuth, Germany

Photosynthesis is a fascinating process of outstanding importance since it provides the energy for most life on Earth. Considering the remarkable quantum efficiency with which the energy of absorbed photons is transferred in the initial light-harvesting step, there exists a long-standing speculation about the role of quantum coherence.

In this talk, I show the decoherence and localization of excitation energy that evolves from the coupled electron and nuclear dynamics in the B850 ring at room temperature after an initial Laser excitation as typically used in an experiment. The electron dynamics of the whole multichromophoric system is described by the real-time formulation of time-dependent density functional theory. The nuclear dynamics is treated by Ehrenfest dynamics, allowing for a non-adiabatic coupling between electrons and nuclei. The simulations show that nuclear dynamics starts to trigger quantum decoherence after only a few tens of femtoseconds.

BP 2.12 Mon 12:30 BAR/0106

Human breathing pattern dominates the effective diffusivity of droplets emitted while speaking — •Lars Natusch and Roland Netz — Fachbereich Physik, Forschungsgruppe Roland Netz, Freie Universität Berlin, Berlin, Germany

For understanding airborne viral infection pathways, the prediction of the effective diffusivity of saliva droplets emitted from a person while speaking and breathing is crucial.

In enclosed non-ventilated indoor spaces the diffusivity of tracer particles or molecules emitted by a person is governed by the complex interplay of various physical transport mechanisms. By comparison of lattice-based simulations of the three-dimensional compressible Navier-Stokes equation with experiments measuring the spreading of carbon-dioxide emitted from a person, we demonstrate that molecular diffusion and convection due to body heat and temperature gradients at walls and windows are present, but that the main spreading mechanism is related to the periodic breathing pattern of a person, which induces long-range advection.

Our results identify breathing as the dominant mechanism for particle transport in stagnant indoor air.

BP 3: Tissue Mechanics I

Time: Monday 9:30–12:45 Location: BAR/0205

Invited Talk BP 3.1 Mon 9:30 BAR/0205

The unreasonable effectiveness of computational models in biological patterning and morphogenesis — •Michel Milinkovitch — Dept. of Genetics & Evolution, University of Geneva, Geneva, Switzerland

I will discuss how vertebrate skin colours and skin appendages (scales, feathers, hairs) are spatially patterned through Turing and mechanical instabilities. First, I will show that Reaction-diffusion (RD) models are particularly effective for understanding skin colour patterning at the macroscopic scale, without the need to parametrise the profusion of variables at the microscopic scales. I suggest that the efficiency of RD is due to its intrinsic ability to exploit continuous colour states and the relations among growth, skin-scale geometries, and the (Turing) pattern intrinsic length scale. Second, I will show how drug treatments can permanently trigger transitions between scale appendage types or even between chemical and mechanical self-organisation. Third, I will show that a three-dimensional mechanical model, integrating growth and material properties of embryonic skin layers, captures most of the dynamics and steady-state pattern of head scales in crocodiles and tortoises. Fourth, I will show that the spectacular morphogenesis of the strongly overlapping snake scales can be recapitulated with a mechanical model integrating tissue plasticity and active material properties. These studies indicate that Biology, despite its 'messy' nature (with its unmanageable profusion of cellular and molecular variables) can be efficiently and quantitatively investigated mathematically, including with simple phenomenological models.

BP 3.2 Mon 10:00 BAR/0205

Mechano-chemical stabilisation of topological defects in an elasto-nematic sheet — •Suganthan Senthilkumar[1], Kinneret Keren[2], and Marko Popović[1,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Technion-Israel Institute of Technology, Haifa, Israel — [3]Ruder Bošković Institute, Zagreb, Croatia

Self-organisation of patterns during animal development involves a complex interplay of various biophysical and biochemical mechanisms. A striking example is *Hydra*, where ordered arrays of nematic actin fibers give rise to orientational order on animal-scale with +1 topological defects at the head and foot of an adult animal. To study the nematic patterns observed during *Hydra* regeneration we recently proposed a mechano-chemical feedback loop that involves orientational order, tissue strain and morphogen gradients[1]. Here we develop a continuum formulation of the same feedback loop in 2d and show that it can stabilise aster shaped +1 topological defects in a self organised manner. We obtain a phase diagram for +1 defect stability using analytical calculations and compare it with vertex model simulations that employ the feedback loop. Finally, we calculate the correction to the mobility coefficient of the +1 defect due to the morphogen field associated with it.

BP 3.3 Mon 10:15 BAR/0205

What jellyfish teach us about tissue mechanics and shape programming — •Anne Materne[1,2], Zhiqi Shen[1,2,3], Daniel Font-Martín[4], Vladislav Koren[5], Ulyana Shimanovich[5], Chiara Sinigaglia[4], and Carl D. Modes[1,2] — [1]MPI of Molecular Cell Biology and Genetics, Dresden, Germany — [2]Center for Systems Biology Dresden, Germany — [3]Southern University of Science and Technilogy, Shenzhen, China — [4]CNRS Languedoc-Roussillon, France — [5]Weizmann Institute of Science, Israel

Jellyfish are little-studied marine organisms with astounding regenerative capacities. Their rapid wound closure has been implicated to rely, at least partially, on the mechanical properties of the individual tissues in the jellyfish umbrella. In particular, this includes the mesoglea, a thick extracellular matrix structure essential for jellyfish shape and body function. Here, we model the mesoglea's role in wound closure using a coarse-grained spring lattice approach. In this way, we can capture essential material processes without knowledge of all molecular- and cellular-scale underpinnings. Our work shows that simple mesoglea pre-strain is sufficient to initiate closure in a broad spectrum of wound shapes. This finding is in line with previous experimental work in the hydrozoan jellyfish *Clytia hemisphaerica* and confirms the essential role of tissue mechanics in the life history of marine invertebrates. It will be interesting to explore this role more systematically in the future. Furthermore, our results presented here also provide unexpected insights for the field of 3D shape-programmable materials.

BP 3.4 Mon 10:30 BAR/0205

Apical extracellular matrix regulates fold morphogenesis in the Drosophila wing disc — •Vincenzo Maria Schimmenti[1], Jana F. Fuhrmann[2], Natalie A. Dye[3,4], and Marko Popovic[1] — [1]Max Planck Institute for Physics of Complex Systems, Dresden, Germany — [2]Aix Marseille Univ, CNRS, IBDM, Marseille, France — [3]Mechanobiology Institute, National University of Singapore,

Singapore — [4]Biomedical Engineering Department, National University of Singapore, Singapore

Tissue folding is a fundamental process in animal organ development. We investigate how fold shape and mechanics change during Drosophila wing disc morphogenesis, from larval stages (when folds deepen and grow) to early pupa, when the tissue unfolds into a bilayer. Using 3D apical surface segmentation, we introduce quantitative metrics for fold depth and width on a curved surface. We also identify a fibrous apical extracellular matrix (aECM) that physically links the two sides of each fold. A lateral vertex model with an adhesive aECM layer predicts that unfolding requires aECM removal. Genetic perturbations confirm that aECM adhesion stabilizes folds: its loss distorts fold shape and dynamics, while failure to remove it prevents unfolding. These perturbations produce adult wing defects, demonstrating that larval fold morphology influences adult wing shape. Together, our work highlights a central mechanical role for aECM in stabilizing epithelial folds during animal development.

BP 3.5 Mon 10:45 BAR/0205

Elastic coupling between nucleus and cell shape drives a mechanical transition in epithelial architecture — •Ian D. Estabrook[1], Anne Rosfelter[2], Yu-Chiun Wang[2], and Anna Erzberger[1] — [1]European Molecular Biology Laboratory (EMBL), Heidelberg, Germany — [2]RIKEN Center for Biosystems Dynamics Research, Kobe, Japan

As the largest organelle, the cell nucleus can affect the shape, spatial organisation and mechanics of cells in a variety of tissue contexts. Despite extensive studies on the molecular mechanisms underlying nuclear positioning and mechanics, it remains unclear whether the nucleus actively controls tissue architecture.

Here, we combine elasticity theory and the Drosophila blastoderm stage embryo as a generic experimental model to investigate the mechanical role of nuclei on epithelial organisation.

By developing a general method that integrates mechanical and geometrical properties extracted from imaging data, we show that from elastic coupling between nuclei and the cell surface, a mechanically driven phase transition emerges between simple columnar and pseudostratified tissue architectures. Genetic and optogenetic experimental perturbations provide evidence supporting such coupling and confirm the predicted transitions following changes in mechanical and geometric parameters.

Our work identifies a novel mechanical role of nuclear elasticity, independent of specialised machineries and may represent a general, generic mechanism controlling emergence of tissue level structures.

BP 3.6 Mon 11:15 BAR/0205

Mechanical regulation of neuroepithelial development — •Niklas Gampl[1,2], Alex Kingston[3], Caren Norden[4], and Kristian Franze[1,2,5] — [1]Max-Planck-Zentrum für Physik und Medizin, Erlangen, DE — [2]Medical Institute of Biophysics, FAU Erlangen-Nürnberg, DE — [3]Cambridge Stem Cell Institute, University of Cambridge, UK — [4]Gulbenkian Institute for Molecular Medicine, Oeiras, PT — [5]Department of PDN, University of Cambridge, UK

During embryonic development, initially flat neuroepithelial tissues remodel themselves into complex 3D structures such as the brain or retina. This process is driven by intrinsically generated forces that depend on the cells' mechanical environment. However, how accumulated tension in the tissue feeds back on individual cells to influence their fate or migration patterns is not well understood. To address this, we downregulated the cellular force sensor Piezo1 in zebrafish and *Xenopus laevis* embryos, thereby reducing local mechanosensing capabilities. Piezo1 downregulation led to impaired retinal lamination, deformed retinae and nuclear rounding. Additionally, live imaging of Piezo1-deficient zebrafish eye primordia revealed defects in retinal progenitor migration during optic cup morphogenesis. These finding suggest that Piezo1 activity contributes to coordinating force generation and tissue level tension in the developing neuroepithelium, thus leading to nuclear and tissue shape changes. Combining laser ablation to locally perturb force propagation with direct measurement of tissue tension will clarify how Piezo1-dependent mechanical feedback links nuclear shape, cell fate decisions and tissue morphogenesis.

BP 3.7 Mon 11:30 BAR/0205

Emergence of hyperuniform tiling in the developing retina — •Mehmet Can Ucar[1] and Sandra Siegert[2] — [1]University of Sheffield, Sheffield, UK — [2]Institute of Science and Technology Austria, Klosterneuburg, Austria

Efficient tiling and space-filling are fundamental design principles of living systems: from neurons and immune cells to vascular networks, these structures must optimize spatial coverage for proper function. Yet how cells collectively achieve non-redundant coverage during growth remains largely unexplored. Here, we combine a theoretical model of growing, branched cells with tunable local interactions and experimental analysis of developing retinal microglia. Our model shows that simple neighbor repulsion during growth is sufficient to drive non-redundant tiling, yielding a substantial increase in coverage with minimal territory overlap. Strikingly, this mechanism also leads to the emergence of a hyperuniform organization, where density fluctuations are progressively suppressed. Consistent with these predictions, microglia in the developing retina exhibit both efficient tiling and suppressed fluctuations, supporting the proposed mechanism for retinal patterning. Together, these findings reveal how local interactions can generate both efficient tiling and hyperuniform order, suggesting a general principle for tissue-wide optimization.

BP 3.8 Mon 11:45 BAR/0205

Reshaping morphogen gradients through porous tissue architecture — •Diana Khoromskaia[1,2], Mohit Dalwadi[4], and Zena Hadjivasiliou[2,3] — [1]Universität Münster, Germany — [2]Francis Crick Institute, London, UK — [3]University College London, UK — [4]University of Oxford, UK

The morphogenesis of tissues during embryonic development is controlled by concentration gradients of morphogens – signalling molecules whose readout determines cell fate decisions. How the spread of morphogens is affected in tissues with complex geometry and spatially heterogeneous architecture is not well understood. To address this question, we introduce a porous vertex model, by explicitly considering the network of extracellular spaces between the cells. Morphogens produced by source cells disperse through the tissue via three modes of transport: extracellular diffusion, membrane-bound diffusion, and cell-based transport through recycling. With this model we investigate how cell-scale geometry, such as cell size, cell shape anisotropy, and cell distance, influences effective diffusion and degradation of morphogens at tissue-scale, employing numerical and semi-analytical upscaling methods. A non-linear coupling between cell packing and morphogen concentration renders the morphogen gradient robust to perturbations by locally buffering fluctuations in the production. Our characterisation of tissues as active porous materials provides new insights into how morphogenesis and cell fate determination may interact during embryonic development.

BP 3.9 Mon 12:00 BAR/0205

Mechanics and hydraulics of the *C. elegans* germ line — •Chandraniva Guha Ray[1,2,3], Jonathan Jackson[2], Jonas Neipel[1,2,3], Julia Pfanzelter[2], Stephan W. Grill[2,3,4], and Pierre A. Haas[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems — [2]Max Planck Institute of Molecular Cell Biology and Genetics — [3]Center for Systems Biology Dresden — [4]Cluster of Excellence Physics of Life, TU Dresden

In the cylindrical germ line of the nematode *Caenorhabditis elegans*, germ cells surround a tube called the rachis, to which all germ cells are connected via openings in the cells called rachis bridges. These rachis bridges allow exchange of cytoplasm between the rachis and the germ cells, which mature as they move towards the proximal end of the germ line where a hydraulic instability decides germ cell fate [1]. However, cortical contractility would collapse static germ cells by releasing their cytoplasm into the rachis through the rachis bridges. Here, we explain how the hydraulic flows in the germ line prevent this collapse and thus stabilise the germ line mechanically: We present a coarse-grained vertex model of a steady-state germ line that couples these hydraulic effects to cell mechanics. We compare the model to experimental observations and thus show how the interplay of fluid pumping and cell contractility can build a dynamically stable germ line.

BP 3.10 Mon 12:15 BAR/0205

Hydrodynamic theory of two-dimensional human gastruloid development — •Oliver M. Drozdowski[1], Chloé Roffay[2], Sarah Jay[2], Diana Pinheiro[2], and Edouard Hannezo[1] — [1]Institute of Science and Technology Austria, Klosterneuburg, Austria — [2]Research Institute of Molecular Pathology, Vienna, Austria

Gastrulation is a crucial stage of embryonic development, as it entails the formation of the three germ layers. Two-dimensional in-vitro systems derived from human embryonic stem cells, so-called gastruloid discs, recapitulate the underlying patterning mechanisms, resulting in the formation of concentric rings of extraembryonic amnion-like cells at the edge and the three germ layers. Starting from experimental data of flattening amnion-like cells at the gastruloid edge, we developed a cross-sectional bubbly vertex model to describe the observed columnar to squamous transition. In agreement with experimentally measured morphometrics and mechanical properties, cell flattening is shown to be driven by local active wetting. Since gastruloids display fluid-like tissue properties, we developed a hydrodynamic description of the tissue-scale dynamics derived from the vertex model. This model predicts a gastruloid morphology consistent with experimental observations, suggesting that local cellular mechanics contribute to human gastruloid shape dynamics.

BP 3.11 Mon 12:30 BAR/0205

A mechanical origin for implantation defects in embryos from aged females — Kate E. Cavanaugh[1,2], •Maria-Jose Franco-Oñate[3,4], Diana J. Laird[5], Patrick W. Oakes[6], Ricard Alert[3,4,7], and Orion D. Weiner[1,2] — [1]Cardiovascular Research Institute, University of California, San Francisco, USA — [2]Department of Biochemistry and Biophysics, University of California, San Francisco, USA — [3]Max Planck Institute for the Physics of Complex Sys-

tems, Dresden, Germany — [4]Center for Systems Biology Dresden, Germany — [5]Department of Obstetrics, Gynecology, and Reproductive Sciences, University of California, San Francisco, USA — [6]Department of Cell and Molecular Physiology, Loyola University Chicago Stritch School of Medicine, IL USA — [7]Cluster of Excellence Physics of Life, TU Dresden, Germany

Women over 35 experience reduced fertility, linked to impaired embryo implantation. In mouse embryos from aged mothers, we observe defective spreading of the extra-embryonic tissue. To uncover the mechanism, we use a continuum model that treats the tissue as a droplet of active polar fluid. Fitting the model to experimental data shows that increased tissue surface tension and viscosity in aged embryos account for the impaired spreading. Experimental measurements of forces and spreading dynamics confirm that these mechanical changes are sufficient to explain the implantation defect. This work shows how physical modeling of embryo mechanics can quantitatively predict implantation success and guide embryo selection in Assisted Reproductive Technologies.

The Multi-faceted Role of Cholesterol in Cellular Membranes and Lipid Nanoparticles — •Rainer Böckmann — Computational Biology - Theoretical & Computational Membrane Biophysics, Friedrich-Alexander-Universität Erlangen-Nürnberg

Cellular membranes serve as dynamic interfaces regulating numerous biological processes, with cholesterol playing a central role in shaping their structure, dynamics, and function. Likewise, cholesterol is crucial for stabilizing lipid nanoparticles (LNPs) in pharmaceutical applications and for enhancing their therapeutic efficacy. Here, we elucidate the multifaceted functions of cholesterol in both biological membranes and LNPs using atomistic molecular dynamics simulations, including constant-pH approaches.

Our findings challenge conventional views of membrane organization by revealing that thermal membrane bending and local cholesterol distribution can collaborate to soften membranes [1], even though cholesterol is widely associated with membrane thickening and reduced permeability. Turning to lipid nanoparticles, we demonstrate that cholesterol is significantly enriched in the LNP shell [2], resulting in shifts of the pK_a of aminolipids by 2-4 units, contingent on the specific lipid composition [3]. This insight underscores the importance of cholesterol-lipid interactions in modulating the physicochemical properties of LNPs, with direct implications for the design and optimization of cholesterol-containing nanocarriers in drug delivery. [1] Pöhnl et al. Nat.Commun. 14, 8038 (2023) [2] Trollmann, Böckmann. Biophys.J. 121, 3927 (2022) [3] Trollmann, Böckmann. Small (2026)

BP 4.2 Mon 15:30 BAR/SCHÖ

Transient interactions between cationic ionizable lipids and anionic lipids foster lamellar to hexagonal phase transition — •David Noel Zimmer[1,2], Friederike Schmid[1], and Giovanni Settanni[1,2] — [1]Physics Department Johannes-Gutenberg University Mainz — [2]Faculty of Physics and Astronomy Ruhr University Bochum

RNA-based therapeutics have demonstrated remarkable efficacy and hold great promise for future applications. The most common delivery systems for these drugs are lipid-based nanoparticles (LNPs), which incorporate ionizable cationic lipids (ICLs) as key components. ICLs are believed to facilitate endosomal escape of the cargo by interacting with anionic lipids in the endosomal membrane, although the underlying molecular mechanism remains unclear. One proposed model suggests that the membrane is destabilized by cone-shaped complexes formed between ICLs and endosomal anionic lipids; clear evidence of stable complexes is still missing. Here[1], we re-examine the problem through equilibrium and nonequilibrium simulations of model membrane systems containing DODMA (ICL), DOPS (anionic lipid) and DOPE (helper lipid). Our results confirm absence of co-localization at equilibrium, but reveal a transient formation of cone-shaped complexes during lamellar-to-inverted-hexagonal phase transitions, which considerably accelerates the transition process. These findings may open new ways for controlling endosomal escape through the rational design of ICLs optimized to interact with cell- or stage-specific endosomal anionic lipids. Osmolyte Effects on Protein Stability: Charge-Regulation is Essential — •Julia Keil and Nico F. A. van der Vegt — Technische Universität Darmstadt, Germany

Osmolytes such as glycine modulate protein stability through differences in their preferential interactions with folded and unfolded states. In this work, we revisit glycine's influence on protein stability by explicitly incorporating charge-regulation effects - protonation and deprotonation of titratable groups - into our study of glycine-protein interactions. Using constant-pH molecular dynamics simulations[1], we develop a titratable glycine model. This pH-dependent model predicts that at pH 7 glycine is depleted from nonpolar elastin-like polypeptides (ELPs) but enriched near acidic and basic ELP residues. It also shows a pH-dependent accumulation of glycine around ELPs and the mini-proteins Trp-cage and GB1, both consistent with prior experimental and computational observations[2-4]. Notably, charge regulation produces systematically stronger preferential binding of glycine to ELPs and mini-proteins at neutral pH than predicted by fixed-charge models. Although glycine is zwitterionic in bulk solution at pH 7, acid-base interactions with NH_3^+ and COO^- protein groups alter its protonation state within biomolecular hydration shells. The corresponding shifts in apparent pKa values promote electrostatically favorable combinations of protonation states, providing a mechanistic explanation for the enhanced preferential binding. [1] J. Chem. Theory Comput. 2022, 18, 10,6148-6160 [2] PNAS 2017, 114, 10, 2479-2484 [3] J. Phys. Chem. B 2020, 124, 30, 6565-6574 [4] Biochem. 1987, 26, 16, 5147-5153

Is helicity cooperative? Mechanistic insights from IM30 folding-unfolding dynamics — •Tika Ram Bhandari[1,2], Kurt Kremer[1], Friederike Schmid[2], and Martin Girard[1] — [1]Polymer Theory, Max Planck Institute for Polymer Research, Mainz, Germany — [2]Institute of Physics, Johannes Gutenberg University, Mainz, Germany

Helical transitions help regulate protein behavior, but how different chain segments influence each other's helicity is not well understood. Using coarse-grained molecular dynamics with Hamiltonian Replica Exchange, we examine the disordered-to-helical transition of IM30, the bacterial homolog of ESCRT-III. By tuning hydrogen-bond strengths, we show that the coiled-coil region is more helical than other domains, while overall helicity stays stable due to secondary-structure interactions. Fragments behave differently inside the full chain, revealing cooperative coupling without changing total helicity. Analysis shows both positive and negative links between helicity and chain extension, and identifies four main conformational states. These results clarify how segment interactions control helical transitions and maintain global helicity stability.

BP 4.5 Mon 16:15 BAR/SCHÖ

Grand canonical simulations of micellization in intrinsically disordered proteins — •Rodrigo F. Dillenburg[1,2], Martin Girard[1,5], Friederike Schmid[2], and Edward A. Lemke[3,4] — [1]Max Planck Institute for Polymer Research, Mainz, Germany — [2]Institute of Physics, Johannes Gutenberg University, Mainz, Germany — [3]Biocenter, Johannes Gutenberg University, Mainz, Germany — [4]Institute of Molecular Biology, Mainz, Germany — [5]Institute for quantitative and computational biosciences, Mainz, Germany

Molecular dynamics (MD) simulations with coarse-grained force fields have been the gold standard in the computational modeling of liquid-liquid phase separation (LLPS) and biomolecular condensates. While much attention has been focused on large droplets, very little is known about the formation of microphases, such as micelles, in such systems. There is evidence that such assemblies arise from intrinsically disordered proteins (IDPs) with a block co-polymer architecture. However, due to their finite size they are highly sensitive to the periodic boundary conditions of the simulation box. The commonly implemented slab geometry is thus unfit to tackle such systems. To overcome this we have implemented a semi-grand canonical monte carlo (SGCMC) algorithm that significantly speeds-up MD simulations. Our implementation is compatible with implicit solvent 1-bead-per-amino acid force fields such as Calvados and HPS. We show that such approach allows one to run simulations efficiently in a cubic box, at very low densities typical of biological systems. We also highlight the advantages of SGCMC in simulating micelles compared to regular MD.

Toward programmable microrobots: DNA-based molecular communication between hydrogel microbeads — •Alexandra Bienau, Alexander Wietfeld, Wolfgang Kellerer, and Friedrich C. Simmel — Technical University Munich, Germany

Emerging applications in biomonitoring and smart therapeutics require materials that can sense biochemical cues, process and transfer information, and respond accordingly. In nature, such capabilities are often achieved through chemical communication, for example in bacterial quorum sensing or immune-cell signaling, where diffusing molecules enable coordinated behavior across many units.

DNA-based hydrogels offer a programmable platform for engineering similar functions, supporting sensing, logic operations, and responsive cargo release. Their porous structure enables molecular diffusion and biochemical exchange. Here, we establish DNA-based molecular communication between hydrogel microbeads. Using emulsion-based droplet microfluidics, we fabricate uniformly sized microbeads that can be modularly loaded with molecular cargo. We immobilize photo-initiated transmitter (TX) and fluorescence-based receiver (RX) systems within them. Communication occurs through diffusing DNA strands, and we characterize signal propagation using experiments and a comprehensive modeling framework.

Looking ahead, this platform enables the design of more sophisticated communication protocols and provides a step toward programmable hydrogel microrobots capable of collective information processing and dynamic interaction with biological environments.

BP 5.2 Mon 15:15 BAR/0205

Microfluidic Micropipettes: A Chip-Based Platform for Membrane Mechanics at Scale — •Sebastian W. Krauss[1], Megan Wong[2], Sepideh Razavi[3], Lorenzo Di Michele[1], and Pietro Cicuta[2] — [1]Department of Chemical Engineering and Biotechnology, University of Cambridge, UK — [2]Cavendish Laboratory, University of Cambridge, UK — [3]School of Sustainable Chemical, Biological and Materials Engineering, University of Oklahoma, USA

The mechanical properties of lipid membranes play an important role in diverse processes, from cell interactions to diseases. Established techniques, however, often suffer from low throughput or provide only bulk mechanical readouts, such as overall stiffness, making it challenging to obtain statistically robust measurements of membrane mechanics. Here, we present a microfluidic platform incorporating hundreds of micropipette like confinements on a single chip, enabling parallel mechanical characterisation of giant unilamellar vesicles (GUVs) in a single experiment. The forces acting on the membrane can be precisely tuned via the applied flow rates and the custom channel geometries, allowing well-defined, controllable mechanical testing. The platform also enables in situ exposure of GUVs to membrane-active compounds, such as surfactants, facilitating direct observation of their impact on membrane mechanics, including the dynamics and reversibility of these effects. This high-throughput approach opens the possibility for systematic screening of compound libraries, providing a quantitative framework to study the interactions between solutes and their impact on membranes.

BP 5.3 Mon 15:30 BAR/0205

Supported DPPC/DPPG Bilayers on Oxide Substrates as a Versatile Platform for Protein*Membrane Studies and Future FRET-Based Sensing — •Daniel Saavedra[1], Benjamin Ruz[1], Marcelo Cisternas[2], Susana Rojas[2], and Ulrich Volkmann[1] — [1]Institute of Physics, Pontificia Universidad Católica de Chile, Santiago, Chile — [2]School of Industrial Engineering, University of Valparaíso, Santiago, Chile

We develop a dry-processed supported lipid platform to study how membrane composition and substrate chemistry modulate protein-lipid interactions. Following the dry two-step self-assembly method for DPPC on silicon [1], we prepare DPPC bilayers with gramicidin A on SiO2 and characterize them by temperature ramps using very-high-resolution ellipsometry, AFM, FTIR, and SERS. Ellipsometry resolves DPPC pre- and main-phase transitions and peptide-induced shifts in thermal stability, which correlate with AFM domain morphology and FTIR amide I changes. In parallel, DPPC/DPPG bilayers are deposited on SiO2 and TiO2 and probed by AFM, FTIR, and ellipsometry to disentangle the influence of lipid charge and oxide surface on bilayer continuity and phase behavior, consistent with previous studies on lipid oxide interfaces [2]. Together, these results establish a solvent-free, thermally robust lipid architecture compatible with multimodal read-out and future integration of carbon quantum dots for FRET-based sensing. Hexagonal and Lamellar Superstructure in DSPE-PEG1000 Monolayers at the Air/Water Interface — •Issam Assi, Heiko Aherns, and Christiane A. Helm — Institute of Physics, University of Greifswald, Germany

Inspired by diblock copolymer self-assembly, we investigate lipopolymer monolayers at the air/water interface. We studied DSPE-PEG1000 monolayers with alkyl chains in the liquid-condensed phase in dependence of the molecular area. Due to its conformational entropy, the moderately hydrophilic PEG has a larger area requirement than the alkyl chains in all-trans conformation. Small-angle grazing incidence X-ray diffraction (GID) measurements identified a hexagonal superstructure. The ordered alkyl chains form hydrophobic domains that are embedded in dissolved PEG. These domains consist of the alkyl chains of ca. 200 PEGylated lipid molecules. During monolayer compression, the number of alkyl chains in a domain remains constant, while their area fraction increases. At an area fraction of 50%, a transition to a lamellar superstructure occurs. During this transition, the alkyl chain domains merge. This transition is attributed to the entropy loss of the laterally compressed PEG chains. Wide-angle GID reveals that the alkyl chains in the liquid-condensed phase possess the same small cross-sectional area, as those in DSPE monolayers, indicating that PEG has little influence on the liquid-condensed phase. The hexagonal superstructure was confirmed with AFM images.

BP 5.5 Mon 16:00 BAR/0205

Numerical simulation of wetting of biomembranes — •Mokbel Marcel and Aland Sebastian — TU Bergakademie Freiberg

Biological cells utilize membranes and liquid-like droplets, known as biomolecular condensates, to structure their interior. The interaction of droplets and membranes, despite being involved in several key biological processes, is so far little understood. Here, we present a first numerical method to simulate the continuum dynamics of droplets interacting with deformable membranes via wetting. The method combines the advantages of the phase-field method for multiphase flow simulation and the arbitrary Lagrangian-Eulerian method for an explicit description of the elastic surface. The model is thermodynamically consistent, coupling bulk hydrodynamics with capillary forces, as well as bending, tension, and stretching of a thin membrane. Its capabilities are illustrated in several two- and three-dimensional axisymmetric scenarios.

BP 5.6 Mon 16:15 BAR/0205

Theory of Michaelis-Menten kinetics in phase-separated systems — •Gaetano Granatelli[1], Samuel S. Gomez[1], Sudarshana Laha[2], and Christoph A. Weber[1] — [1]Faculty of Mathematics, Natural Science, and Materials Engineering, Institute of Physics, University of Augsburg, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Phase-separated systems can regulate chemical reactions through spatial organization. Motivated by their biological relevance, we develop a mean-field theoretical framework for enzymatic kinetics within liquid condensates formed by phase separation. Building on a model that decouples the phase separation dynamics of scaffold components from the chemical kinetics of dilute clients, we generalize the classical Michaelis-Menten theory of enzyme kinetics to spatially heterogeneous systems with coexisting phases. In our framework, the dynamics of client concentrations are governed by scaffold-controlled parameters such as condensate size, partitioning, relative kinetic coefficients, and diffusion. We explore how they modulate the initial reaction rate across regimes set by the interplay of diffusive and reactive timescales, and we derive explicit expressions for the local reaction rate constants in each phase, allowing direct experimental measurement of how condensates modulate reaction kinetics. We find that, compared to homogeneous conditions, phase-separated liquid condensates can mediate either optimal enhancement or suppression of the initial rate. Our results provide experimentally testable predictions to quantify how phase separation modulates enzymatic activity in living and synthetic systems.

Eco-Friendly PEGylated Iron Oxide Nanoparticles for In Vitro Targeted Delivery and Controlled Release of Docetaxel in SK-OV-3 Ovarian Cancer Cells — •Romesa Soomro[1], Che Azurahanim Che Abdullah[1,2], and Halima Alem Marchand[3] — [1]1Biophysics Lab, Department of Physics, Faculty of Science, Universiti Putra Malaysia, 43300, Selangor, Malaysia — [2]2Cancer Research Lab, Institute of Bioscience, Universiti Putra Malaysia, 43300, Selangor, Malaysia — [3]3Department of Matériaux, Métallurgie, Nanosciences, Université de Lorraine, Nancy, France

Iron oxide nanoparticles were green-synthesized using oolong tea extract as a natural reducing and stabilizing agent. A Taguchi L9 design was applied to optimize reaction parameters and obtain stable nanoparticles with reduced hydrodynamic size. The optimized particles were PEG-coated to improve biocompatibility and subsequently loaded with docetaxel for targeted cancer therapy. Characterization using spectroscopy, diffraction, magnetic measurements, and electron microscopy confirmed successful synthesis and coating, with superparamagnetic behavior and particle sizes below twenty nanometers. Drug release studies showed sustained, pH-responsive release under acidic conditions. Cytotoxicity evaluation using SK-OV-3 ovarian cancer cells demonstrated high biocompatibility of PEG-coated nanoparticles and strong anticancer activity of the docetaxel-loaded system. The results indicate that green-synthesized PEGylated iron oxide nanoparticles provide a promising and sustainable platform for controlled anticancer drug delivery.

BP 7.2 Mon 15:00 P5

The Potential Impact of a Novel Chitosan-Titanium dioxide Nanoparticles against Hepatocellular Carcinoma in Rat Model — Omnia Ahmed Mohamed Elbakary[1], Eman Ibrahim Kandil[1], Sawsan Mohamed Elsonbaty[2], Shaimaa El-saied Mohamed[1], and •Nermeen Mohamed Elbakary[3] — [1]Faculty of Science, Biochemistry department, Ain Shams University, Cairo, Egypt — [2]Radiation microbiology department, National center for radiation research and technology, Egyptian Atomic Energy Authority, Cairo, Egypt — [3]Radiation biology department, National center for radiation research and technology, Egyptian Atomic Energy Authority, Cairo, Egypt

Hepatocellular carcinoma (HCC) the most common type of liver cancer, is the fifth most common malignant tumor type worldwide and the second leading cause of cancer-related death. This study investigates the potential therapeutic effects of novel chitosan-titanium dioxide nanoparticles (Cs-Ti NPs) against hepatocellular carcinoma (HCC) in a rat model. The experimental design included five groups: a healthy control group, a group administered with diethylnitrosamine (DEN) to induce liver carcinogenesis, a group treated with Cs-Ti NPs, a DEN group subsequently treated with 5-Fluorouracil (5-FU), and a DEN group treated with Cs-Ti NPs. DEN was administered orally at 20 mg/kg body weight five times weekly for six weeks to induce tumor formation. Therapeutic interventions with Cs-Ti NPs and 5-FU were applied post-induction. The study evaluated apoptotic markers (Bcl-2, Bax, p53, Caspase-3, Cytochrome C), signaling pathways (MAPK, ULK1, mTOR), and serum tumor markers (AFP, NF-κB, COX-2) via ELISA. Results are expected to elucidate the molecular mechanisms involved and assess the efficacy of Cs-Ti NPs in mitigating HCC progression, potentially offering a new nanotherapeutic avenue for liver cancer treatment.

BP 7.3 Mon 15:00 P5

Viscous and Plastic Energy Dissipation Processes of Native Collagen Fibrils in AFM-based Nanoindentation Measurements under Controlled Humidity — •Martin Dehnert, Paul Zech, Mario Zerson, and Robert Magerle — Fakultät für Naturwissenschaften, Technische Universität Chemnitz, Germany

Collagens, lipids, and water are among the major molecular components of connective tissue, yet surprisingly little is known about their interactions in vivo. Here, we use AFM-based nanoindentation experiments to measure the mechanical response of collagen fibrils to deformation under constant strain (relaxation) or constant stress (creep) at different humidity levels and at different deformation speeds. The measured data are evaluated using a power-law analysis, in which the detailed indentation history, including the different indentation velocities, is taken into account. An in-depth analysis reveals that the phenomena of stress relaxation and creep compliance can be described by a time-scaled power law. Furthermore, we show that energy dissipation is primarily caused by plastic deformation during tip indentation and can be quantified with the ductility index. This parameter can also be used for high-resolution imaging of connective tissues. The ductility index provides additional information about the nanomechanical changes in collagen fibrils during development, aging, and disease.

BP 7.4 Mon 15:00 P5

Cyanobacteria as biological actuators — •Paul Nieschwitz and Stefan Karpitschka — Department of Physics, Universität Konstanz, Germany

Filamentous cyanobacteria are highly resilient, light-responsive organisms whose robustness and availability makes them ideal candidates for building engineered living materials (ELMs), that can adapt to or be controlled by external cues.

Here, we present a simple actuator composed of entangled filament assemblies wrapped around elastic PDMS-pillars. Contraction of the network generates a net resultant force that deflects the pillars. By calibrating the compliance of the pillars, we quantify this force. Varying the actuator geometry, filament density and illumination conditions, allows us to characterize the force output and dynamic response of the actuator.

Without requiring the need for genetic modification or sophisticated culture conditions, this platform offers a simple and robust approach to create light-controlled biological machines.

LactiFilm: Hydrogel supported co-culture biofilms of lactobacilli and phytoplankton for sustainable production of lactic acid — •Carina Schneider and Regine von Klitzing — TU Darmstadt, 64289 Darmstadt, Germany

Lactic acid is an essential bulk chemical used across the food, pharma, and cosmetics industry. Recently, its demand has been rising as the monomer for synthesizing polylactic acid, a major biodegradable alternative to conventional plastic. Hence, biological synthesis of lactic acid offers a greener production option. In this work, we develop a biofilm-inspired strategy by immobilizing lactobacilli and algae in smart hydrogels.

The algae immobilization matrix is formed from cross-linkable PNIPAM (Poly N-Isopropylacrylamide) microgels containing the UV-sensitive comonomer HMABP (2-Hydroxy-4-(methacryloyloxy)benzophenone), enabling microgel crosslinking into a stable hydrogel film. Due to the volume phase transition temperature of PNIPAM, the matrix exhibits controllable swelling and deswelling behavior. This responsiveness allows for regulated partial lysis of the algae to release nutrients that support lactic-acid production. To assess the mechanical strength of the hydrogel, we perform atomic force microscopy (AFM) indentation measurements.

Multi-phase coexistence of charged condensates — •Chengjie Luo, Yicheng Qiang, and David Zwicker — MPI-DS, Göttingen, Germany

Biomolecular condensates are complex droplets whose formation is believed to be primarily driven by short-range attractive interactions between diverse molecules. However, charges that mediate long-range interactions can also strongly affect phase separation. Using a mean-field theory, we demonstrate that electrostatic interactions can drive rich phase separation behavior. In a simple system of three charged components, these interactions can lead to the coexistence of multiple phases, including homogeneous phases with different compositions and patterned phases with finite-sized droplets. Furthermore, applying an external electric field can dramatically alter these coexistence states: weak fields cause charged droplets to move like colloidal particles, while stronger fields stretch droplets, leading to the formation of striped patterns. Our work establishes electrostatics and electric fields as potent controllers of phase coexistence, with implications for understanding biological condensates and designing synthetic patterned materials.

Density and viscosity Measurements of the cytosol of human red blood cells — •Thomas John, Karin Kretsch, and Christian Wagner — Experimental Physics, Saarland University

We present a method to determine the viscosity of the intracellular liquid - the cytosol - of human red blood cells (RBCs). Our method combines the measurement of the mass density distribution of RBCs and the viscosity of the cytosol as a function of the water content. The density distribution is measured through buoyant density centrifugation combined with cell counting. By correlating this distribution of cell population densities with the viscosity-density relation of the cytosol, we obtain a log-normal distribution of the cytosol viscosity of healthy RBCs. The viscosity contrast λ, defined as the ratio of viscosities between the RBC cytosol and the blood plasma under physiological conditions, is determined to have a log-normal distribution with a mean value of $\bar{\lambda} = 10$. This value is significantly larger than those used in the literature for numerical simulations. The wide distribution of the viscosity values results from the loss of a small amount

of water from the RBCs over their 120-day lifespan. We find that the viscosity of the cytosol in older cells is more than twice as high as in younger cells, a fact that should be taken into account in future theoretical investigations.

Model particles to study interaction of microplastic particles — •Kai Gossen, Andreas Fery, and Günter Auernhammer — IPF Dresden, Dresden, Germany

Microplastic in the environment is typically coated by natural organic matter forming an ecocorona. We present an approach to model ecocorona on particles with well-defined polymers, synthetic and derived from natural polymers. Polystyrene particles were coated with fluorescent polyelectrolyte multilayer systems, PS(Chitosan/Hyaluronic acid) and PS(Poly(dimethyldiallylammonium chloride) /Polystyrene sulfonate) by the layer-by-layer method. Systems with 2, 4 and 6 bilayers were synthesized. The second layers were fluorescently labelled with SNARF conjugated dextran. It was found that zeta potentials of the PS(Chi/HS)2/4/6 systems assume val- ues (-20 mV to -35 mV) that are similar to those of PS-ecocorona particles (-40 mV to -5 mV). The pH-dependent fluorescence of particle suspensions and indi- vidual particles were measured at pH values between pH 3 and pH 8. A well mea- surable pH dependence between pH 4.5 and 8 for the PS(Chi/HS) systems and the PS(PDADMAC/PSS) system could be measured. Automating particle synthesis via cross-flow filtration produces particle batches of up to 5 g. The system could serve to selectively study effects of surface properties of ecocorona coated particles such as surface stiffness or zeta potential.

Controlled Spray coating of Bacterial Nanocellulose Thin films revealed by Surface-Sensitive X-ray Scattering — •Joanne Neumann[1], LI Li[2], Edina Klein[1,3], Jan Rubeck[1], Ute Römling[2], Holger Sonderrmann[1,3], and Matthias Schwartzkopf[1] — [1]DESY, Photon Science, Notkestr. 85, D-22607 Hamburg — [2]Department of Microbiology, Tumor and Cell Biology, Biomedicum, KI, Karolinska Institutet, Nobels väg 6, S-17177 Stockholm — [3]CSSB, Center for Structural Systems Biology, Notkestr. 85, D-22607 Hamburg

Bacterial nanocellulose (BNC) is a sustainable biomaterial valued for its purity, nanoscale fibrillar structure, and biocompatibility. Its properties can be tailored through genetic engineering, growth conditions, and processing. Here, we fabricate thin films from BNC produced by *S. typhimurium*, *Komagataeibacter*, and *Klebsiella* using airbrush spray deposition of aqueous dispersions as a green, reproducible method. We examine how different extraction procedures (acidic, alkaline, surfactant-based) affect nanoscale organization and film adaptability. High-resolution X-ray scattering (μGIUSAXS/μGIWAXS) is used to probe fibril orientation, aggregation, and hierarchical ordering. Our results show extraction-dependent structural variations that influence film homogeneity and functional performance. By refining spray-coating and scattering protocols, this work links chemical treatment history to structural adaptability and supports sustainable strategies for controlled BNC thin-film fabrication in materials science and bioengineering.

Engineering Shear-Thinning Hydrogels: A Dynamic Scaffold for 3D Tissue Culture — •Bruno Schmelz[1], Fen Li[2], Kai Zhang[2], and Timo Betz[1] — [1]Third Institute of Physics, University Göttingen — [2]Sustainable Materials and Chemistry, University Göttingen

Extracellular matrix scaffolds are essential for advanced 3D cell culture systems, providing structures for cell movement as well as physical and chemical cues that promote migration, proliferation, and differentiation. Hence, the extracellular matrix is crucial for functional tissue formation. However, natural extracellular matrix materials used in vitro, such as collagen and elastin, are difficult to control regarding elastic properties, polymer mesh size, and homogeneity. Our objective is to design a dynamic hydrogel, tailored to meet the specific requirements of 3D tissue culture, such as viscoelastic properties and cell-binding sites, that initially supports tissue formation but can be dissolved and replaced by cell-generated extracellular matrix. We propose a hydrogel with dynamic cross-links that allows for reorganization by embedded cells, resembling processes in physiological tissues. We present the rheological properties of the hydrogel and the initial findings of cellular migration and reorganization of cell-gel systems. When subjected to stress, the hydrogel exhibits a transition to a more liquid-like state, with the potential to solidify again upon stress relaxation. This behavior allows cells to remodel their surrounding matrix and shape their environment, as evidenced by experiments with cells cultured in the hydrogels.

Atomic-Scale Probing of Aluminum Distribution in Catalysts and Peptide COM Fidelity — •Sakshi Sinha — Department of Materials Physics, Institute of Material Science, University of Stuttgart, Heisenbergstr. 3, 70569 Stuttgart

Atom Probe Tomography (APT) enables three-dimensional, atomic-scale mapping of inorganic and biomolecular materials. Using conventional lift-out specimen preparation, we study aluminum distribution in microporous aluminosilicate catalysts with varying Al content. The frequency distribution with considering different sphere sizes N in order to investigate size-dependent effects for segregating or clustering behavior of the Al atoms. APT reveals atomic-scale clustering and uniformity of Al, providing direct insight into acid site density and strength, and complements bulk techniques such as ICP-OES by resolving localized compositional variations. For biomaterials, cryogenic quench-freezing is used to prepare aqueous specimens. Mass spectra indicate that fragmentation behavior is concentration-dependent and influenced by hydration shell disruption during field evaporation. Experimental interfragment distances closely match theoretical center-of-mass distances within 1 Å, demonstrating that APT can preserve biomolecular subunit spatial relationships with sub-angstrom fidelity. These studies demonstrate the versatility of APT in probing both inorganic and biomolecular systems with unprecedented atomic precision, opening pathways for understanding structure*function relationships across material classes.

BP 7.12 Mon 15:00 P5

Decoupling Crosslink Stability and Network Connectivity in Coiled Coil Crosslinked Hydrogels — Stefanie Lenzeder[1], Geonho Song[1,2], Isabell Tunn[2], Alberto Sanz de Leon[2], Tanja D. Singewald[1], and •Kerstin G. Blank[1,2] — [1]Johannes Kepler University, Linz, Austria — [2]Max Planck Institute of Colloids and Interfaces, Potsdam, Germany

Biomimetic hydrogels serve as a powerful platform for investigating how cells sense and respond to the mechanical cues in their environment. Despite significant progress, the precise mechanisms how cells evaluate the elastic and viscoelastic properties of their surroundings remain incompletely understood. While hydrogels are typically characterized based on their bulk material properties, cells probe these materials on the molecular scale through receptor-ligand interactions. Bridging the gap between molecular-scale interactions and macroscopic material behavior is thus essential for advancing our understanding of cell-material interactions. Inspired by proteins found in the extracellular matrix, we are investigating biomimetic hydrogels crosslinked with coiled coil forming peptides. These modular building blocks enable precise control over their molecular characteristics, such as thermodynamic, kinetic and mechanical stability as well as oligomerization state. Our findings show that the bulk material properties are governed more strongly by network connectivity than crosslink stability. These insights deepen our understanding of how molecular design impacts the macroscopic behavior of hydrogels, opening new avenues for tailoring materials for specific biological applications.

BP 7.13 Mon 15:00 P5

Development and investigation of coarse-grained particle models for alginates. — •Hensi Gandhi, Rudolf Weeber, and Christian Holm — Institute for Computational Physics, University of Stuttgart, Stuttgart, Germany

Alginates form ion-mediated gel networks whose mesoscale structure and mechanical properties depend on monomer sequence, charge distribution, and environmental conditions. We aim to develop coarse-grained models that capture these molecular features while remaining computationally efficient. Our ongoing work combines all-atom molecular dynamics with systematic coarse-graining to derive bonded interactions, electrostatics, and ion-mediated cross-linking rules. The models will be implemented in ESPResSo [1] using implicit solvent, with extensions for multivalent ions and shear via Lees Edwards or lattice Boltzmann coupling. We will study how monomer sequence, salt concentration, and pH influence chain flexibility, persistence length, gelation kinetics, and network topology, and compare structural and mechanical observables with experiments to assess model transferability. This framework is intended to support mesoscale predictions within the GRK SusGel program [https://www.susgel.kit.edu/24.php] and link molecular design to macroscopic gel properties.

BP 7.14 Mon 15:00 P5

Cytoskeletal Networks in 3D Cysts Under Strain — •Greta Höhndorf[1], Ruth Meyer[1], Ruben Haag[1], Ulrike Rölleke[1], Ulla Unkelbach[2], Nicole Schwarz[3], Andreas Janshoff[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen — [2]Institute of Physical Chemistry, University of Göttingen — [3]Institute of Molecular and Cellular Anatomy RWTH Aachen University

The cytoskeleton of eukaryotic cells mainly consists of actin filaments, microtubules and intermediate filaments (IFs). Unlike actin and microtubules, IFs are cell-type specific. Epithelial cells express keratin IFs, which form a layer close to the membrane in certain cell types. This layer is referred to as the "IF-cortex" and is hypothesized to adopt a "rim-and-spokes" structure with radial spokes supporting mechanotransduction properties of the cell. This structure raises questions about how the actin and IF cortices complement each other and how the mechanical properties of keratin influence force transmission in cells under high strain. To address these questions, we show a 3D approach where epithelial cells form polarized cysts and are stretched by injecting mineral oil into the

lumen. When comparing wild-type (WT) and keratin knock-out (KO) cysts, we find that KO cysts deform more easily at low strains and respond more sensitively at high strains than WT cysts, indicating a stabilizing role of keratin under increased mechanical load. Furthermore, by staining actin, keratin, and the nuclei and performing fluorescence imaging pre and post stretching, we investigate strain dependent network changes and deformations.

BP 7.15 Mon 15:00 P5

Interactions between single actin and vimentin filaments — •Pallavi Kumari[1], Kristian Pajanonot[1,2], Komal Bhattacharyya[2], Stefan Klumpp[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

The cytoskeleton plays a crucial role in maintaining cellular structure, mechanics, and function. Recent advances suggest that the diverse tasks of the eukaryotic cytoskeleton depend on the interactions between its filamentous components–microtubules, actin filaments, and intermediate filaments. Despite a growing number of studies aimed at a better understanding of these interactions, it remains unclear whether actin and intermediate filaments interact directly in the absence of an auxiliary protein. Previous *in vitro* studies on reconstituted mixed filament networks have reported inconclusive results. To clearly resolve this inconclusiveness, it is essential to further simplify the system down to the single filament level. Here, we present a study on the direct interactions between actin and vimentin intermediate filaments at the single filament level. Using quadruple optical tweezers combined with confocal microscopy and microfluidics, we precisely control the interaction conditions, visualize the interactions in real time, and measure the forces involved. Our research provides direct evidence of actin-vimentin interactions, together with a quantification of the interaction forces they exert on each other.

BP 7.16 Mon 15:00 P5

Mechanical Properties of Intermediate Filament Networks — •Jonas Penning, Komal Bhattacharyya, and Stefan Klumpp — Institut für Dynamik komplexer Systeme, Georg-August-Universität Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

The mechanical strength and dynamics of cells are essential for sustaining life. For instance, during simple activities such as breathing or walking, cells experience significant tensile stresses as they are stretched, sheared, or compressed. The cytoskeleton - a cross-linked composite network of actin, microtubules, and intermediate filaments - plays a central role in determining the cells' mechanical properties. This work focuses primarily on intermediate filaments, with particular emphasis on vimentin. Compared to actin, intermediate filaments exhibit much smaller persistence lengths, but are much more stretchable with highly nonlinear elasticity. A simplified, lattice-based model of fibrous networks with variable connectivity has been developed to investigate the mechanical and physical properties of such vimentin filament networks, as the model allows for the corresponding nonlinear behavior of individual vimentin filaments under strain. Analogous to experimental approaches, the mechanical properties of the model are tested by applying normal and shear strains or stresses and analyzing the resulting responses. Stretching the networks isotropically and comparing linear and nonlinear strain-behavior of individual filaments, the model shows an internal energy decrease for nonlinear elasticity and a strain-softening quantified by a turning point in the bulk modulus with increasing network-strain.

BP 7.17 Mon 15:00 P5

Phosphorylation-induced softening of vimentin networks revealed by optical tweezers microrheology — •Yuzhen Feng, Shanay Zafari, and Sarah Köster — Institute for X-Ray Physics, University of Göttingen, Germany

Phosphorylation is a key post-translational modification regulating intermediate filament (IF) organization and cell mechanics. While phosphorylation-induced softening of single vimentin filaments has been reported, its impact on network-level mechanics remains unclear. Here, we employ optical tweezers-based active microrheology to quantify the mechanical properties of vimentin IF networks containing defined fractions of the phosphomimetic vimentin mutant S72E. Both unmodified and phosphomimetic vimentin networks exhibit a viscoelastic response with partial stress relaxation after deformation. Increasing the phosphomimetic content reduces the overall stiffness, indicating phosphorylation-induced softening at the network level. These findings extend the understanding of how biochemical regulation at the molecular level translates into mechanical remodeling of IF across scales from the single-filament to the network level.

BP 7.18 Mon 15:00 P5

Microtubule networks exhibit amorphous material behavior — •Claudia Marcelli[1], Raffaele Mendozza[2], Shanay Zafari[1], Ruben Haag[1], Peter Sollich[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen, Germany — [2]Institute for Theoretical Physics, University of Göttingen, Germany

Microtubules (MTs), together with intermediate filaments and actin, are the main components of the cytoskeleton. Among these filaments, MTs are the stiffest. They can form a rigid cellular scaffold and transmit forces across the cell while remaining extremely dynamic and able to assemble into specific cell structures (e.g. mitotic spindles). While MTs have been extensively characterized at the single-filament level, it is still not fully resolved how they collectively behave at the network-scale level. Here, we present a comprehensive characterization of the linear and nonlinear mechanical responses of stabilized MT networks at the microscale by using optical tweezers. To this aim, we employ both strain-ramp and large-amplitude oscillatory strain protocols, applying a range of deformations that allows us to probe both regimes. Our results show that MTs can withstand high stress and behave as an amorphous material, exhibiting a yielding transition from an elastic response at small strains to a viscous response at large strains. These findings provide us with a deeper understanding of the mechanics of MT networks while setting the stage for future studies in which dynamic or active elements can be incorporated into the network to understand how activity modifies material mechanical properties.

BP 7.19 Mon 15:00 P5

MatrixModel: Building a Computational Model of the HSPC niche — •Julia Käsehagen and Sophia Rudorf — Institute for Cell Biology and Biophysics, Leibniz Universität Hannover, Germany

Haematopoietic stem and progenitor cells (HSPCs) rely on finely tuned adhesion to extracellular matrix (ECM) proteins within the bone marrow niche to balance quiescence, self-renewal, and differentiation. As part of the research consortium Matrix Evolution [1], MatrixModel develops a multiscale computational framework to predict how ECM composition, architecture, and mechanics regulate HSPC behavior, including adhesion and motility. We implemented two pipelines to use and adapt models by other goups: (i) a mechanochemical ODE model of integrin-talin-vinculin adhesion dynamics (by Honasoge et al. [2]) and (ii) a hybrid Cellular-Potts-Bead-Spring model of ECM fiber networks (by Tsingos et al. [3]).

For (i), we will parameterize the ODE model for HSPCs to predict adhesion lifetimes and tractions per adhesion. In (ii), the Cellular-Potts-Model (CPM) governs HSPC shape and contract energies, while a nonlinear fiber network captures density, crosslinking, and anisotropy. Cell-fiber links inherit rate laws from results of the ODE model.

[1] https://www.cell.uni-hannover.de/en/research/main-research-areas/matrix-evolution

BP 7.20 Mon 15:00 P5

Stiffness Characterization of Microtentacles: an optical tweezers study — •Kirill Korneev[1], Thomas John[1], Franziska Lautenschläger[1,2], and Christian Wagner[1,2] — [1]Department of Experimental Physics, Saarland University, Saarbrücken, Germany — [2]Center of Biophysics, Saarland University, Saarbrücken, Germany

Laser tweezers (LT) are devices used for manipulating, trapping, and measuring forces on particles within optical traps, and they are commonly used in biophysics. Microtentacles (McTNs) are membrane protrusions supported by bundles of microtubules produced inside cells. These McTNs appear in circulating tumor cells and are thought to play a key role in facilitating the cells adhesion and extravasation process from the blood vessel. Although the biological mechanisms underlying McTN formation have been partially characterized, their characterization by physical material parameters is still lacking. The objective of this work is to study the deformation of McTNs using optical trap force measurements. We will show how McTNs behave under the action of external forces in the piconewton range and suggest a method to extract their Young's moduli

BP 7.21 Mon 15:00 P5

Determination of the Human Red Blood Cell Mass Density Distribution — •Luca Hastenteufel[1], Thomas John[1], Karin Kretsch[1], and Christian Wagner[1,2] — [1]Dynamics of Fluids, Experimental Physics, Saarland University, 66123 Saarbrücken, Germany — [2]Physics and Materials Science Research Unit, University of Luxembourg, L-1511 Luxembourg, Luxembourg

Red blood cells (RBCs) survive in circulation for approximately 120 days, during which their mass density increases, leading to the formation of a density distribution (DD). This distribution is commonly used as a diagnostic marker and as an indicator of individual cell age. However, few studies have examined the detailed form of the DD, with only few datapoints. In this study, the DD of erythrocytes was quantitatively derived using microscopic imaging approaches in controlled linear density gradients. Linear gradients were created using Percoll and Optiprep, common density media used for the density separation of cells or subcellular compounds. A custom microscopic scanning setup was developed to image RBC distributions along the gradient with a micrometre spatial resolution over several cm. Through image analysis, the vertical positions of individual cells were detected and by single cell counting, the DD was constructed in high resolution. The measured DD revealed significant deviations from Gaussian behaviour.

BP 7.22 Mon 15:00 P5

Integration of environmental stimuli into the contraction dynamics of *Physarum polycephalum* — •Nora Deiringer and Karen Alim — School of Natural Sciences, Technical University of Munich, Garching, Germany

In many organisms, behaviour and decision-making are guided by environmental stimuli. However, the internal dynamics linking stimuli to behaviour are often complex and not fully understood. Additionally, an organism's response to a stimulus can depend on its past stimulus history. In the unicellular, network-shaped organism *Physarum polycephalum*, migration results from the redistribution of cell mass driven by self-organised rhythmic tube contractions. In this study, we mimic environmental stimuli by exposing the cell's contraction dynamics to patterns of harmful blue light. Through live recordings, we observe the imprints of these patterns in the cell's dynamics and investigate how dynamic stimulus memories arise and decay. By varying the time span between two consecutive stimuli, we aim to elucidate how past stimulus history influences responses to future ones. Our findings provide insight into the mechanisms by which simple, non-neural organisms can organise adaptive behaviour.

BP 7.23 Mon 15:00 P5

Coordination of Migration by Adaptive Mechanics — •Diana Lenski, Lucas Troeger, and Karen Alim — School of Natural Sciences, Technical University of Munich, Germany

Unicellular organisms navigate and adapt to their environment using characteristic migration strategies, among them chemotaxis, the ability to detect and respond to chemical gradients. Although numerous models exist for amoeboid migration, the mechanisms governing directional sensing and movement in dynamical systems with complex morphologies across various size scales remain partially characterised. Besides continuous locomotion, migration strategies can involve dynamic regulatory phases that modulate the migratory behaviour. One such example in the slime mould *Physarum polycephalum* are stationary oscillations that repeatedly interrupt persistent migration.

This project involves the analysis and modelling of experimentally observed stationary oscillations in *P. polycephalum* across macroscopic and intermediate scales. These oscillations manifest as the periodic, opposing formation of protrusions that define the direction of migration, making them a key observable across spatial and temporal scales. First, we will statistically evaluate the chemotactic efficiency of large and small plasmodia on the macroscopic scale. Subsequently, we will examine oscillation dynamics by tracking contraction patterns to evaluate their contribution to migration phases and energy efficiency.

Integrating both perspectives will provide a deeper understanding of oscillatory migration phases as a fundamental element of amoeboid migration strategies.

BP 7.24 Mon 15:00 P5

Deep learning architecture combining Vision Transformers and U-Nets for robust traction force microscopy — •Yunfei Huang[1], Elena Van der Vorst[2,3], and Benedikt Sabass[1,2,3] — [1]Faculty of Physics, Technical University Dortmund, Dortmund, 44227, Germany — [2]Faculty of Physics and Center for NanoScience, Ludwig Maximilian University of Munich, Munich, 80752, Germany — [3]Department of Veterinary Science, Ludwig Maximilian University of Munich, Munich, 80752, Germany

Traction force microscopy (TFM) quantifies cellular forces on the extracellular matrix. Although deep learning has advanced TFM analysis, challenges remain in achieving reliable inference across spatial scales, estimating uncertainty, and integrating biological information such as cell type. In this study, we propose a robust deep learning architecture, ViT+UNet, which integrates a U-Net with a Vision Transformer. Our results show that this hybrid model outperforms either U-Net or ViT alone in predicting traction force fields. In addition, ViT+UNet achieves superior generalization across a wide range of scales, which allows one to use the algorithm for TFM with different setups and equipment. We extend the model with an uncertainty estimation module that enables simultaneous prediction of traction forces and confidence levels. Incorporating cell-type information further improves accuracy. Simulated results show that the algorithm effectively reconstructs 3D traction fields in non-linear elastic matrices.

BP 7.25 Mon 15:00 P5

Identifying the proteins controlling the intracellular active mechanics — •Noemie Veyret, Till Muenker, and Timo Betz — Third institute of Physics, University of Göttingen, Germany

Over the past few years, the study of cell mechanical properties has allowed new insights on the understanding of biological processes and life complexity. According to previous work, intracellular mechanical properties can be narrowed down to a fingerprinting of only 6 parameters. Through the use of active and passive microrheology measurements via optical tweezers, frequency dependent viscoelastic properties and intracellular activity were found to vary for different cell types. The aim of this project is to find a correlation between changes in protein expressions and mechanical fingerprint of cells. To do so optical tweezers measurements will be performed during the differentiation process of induced Pluripotent Stem Cells (iPSC) into different cell types such as skeletal muscles or cardiac fibroblasts. This measurement allows the characterization of the mechanics during the iPSC differentiation process. In parallel, the cell proteome will be studied using mass spectroscopy. Combining both, we hope to find the connection between proteins and their mechanical role, the intracellular "mechanome".

BP 7.26 Mon 15:00 P5

Characterization of filamentous cyanobacteria using force-sensing micropipettes — •Paul Dufke and Stefan Karpitschka — Fachbereich Physik, Universtität Konstanz

Filamentous cyanobacteria strongly influence nearly all ecosystems, sometimes with harmful impacts. It is believed that their dominance is based on collective traits such as aggregation, entanglement and dispersal, but the details remain elusive. To understand the collective behaviour that arises in ensembles of many filaments, it is necessary to quantify the mechanical properties of individual filaments. We characterize their bending stiffness using force-sensing micropipettes with nanonewton resolution, quantifying three different species across various growth stages, which affect the filament diameter and thus their bending stiffness. The observed diameter dependence of the bending modulus suggests that most of the structural rigidity emerges from a thin region near the cell wall. The connection between culture age and mechanical properties indicates that modulations of flexural rigidity may also influence the collective behaviour at different stages in the life cycle of a colony.

BP 7.27 Mon 15:00 P5

Passive vs active shells: from spectrin to actin cortex — •Tim Kutz[1], Bart Vos[1], Bart Jan Ravoo[2], Andreas Janshoff[3], and Timo Betz[1] — [1]Third Institute of Physics, Georg August Universität Göttingen, Göttingen, Germany — [2]Institute of Physical Chemistry, Georg August Universität Göttingen, Göttingen, Germany — [3]Organic Chemistry Institute and Center for Soft Nanoscience, University of Münster

The viscoelastic and tensile properties of the cell surface are key regulators of processes such as migration, division, and shape control, yet the respective roles of membrane and cortex remain only partially understood. Here, we use a combined experimental approach integrating atomic force microscopy (AFM) and micropipette (MPA) aspiration to dissect surface mechanics in two paradigmatic systems: red blood cells (RBCs) and Xenopus tadpole cells (XTCs). RBCs provide a membrane-dominated reference state with a passive spectrin network, while XTCs feature an active actomyosin cortex coupled to the plasma membrane. AFM-based tether pulling and creep compliance measurements yield local effective tension and viscoelastic response, whereas MPA reports global surface tension and large-scale deformation behaviour. From the combined data, we identify clear differences in relaxation behavior and tension build-up between RBCs and XTCs, reflecting the presence of active contractile elements in the cortex. Our results demonstrate how multi-modal micromechanical probing can disentangle membrane- versus cortex-dominated contributions to cell surface tension.

BP 7.28 Mon 15:00 P5

Deciphering the role of flagellar membrane glycoproteins in ciliary adhesion of *Chlamydomonas reinhardtii* — •Lea Rupprecht[1], Adrian Nievergelt[2], Rodrigo Catalan[1], Lara Hoepfner[3], and Oliver Bäumchen[1] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]Max Planck Institute of Molecular Plant Physiology, 14476 Potsdam, Germany — [3]Human Technopole, 20157 Milan, Italy

Elucidating the physical mechanisms of microbe-surface interactions is essential for developing novel technologies to control the formation of microbial biofilms. While most studies focus on bacteria as model systems, the adhesion of eukaryotic photosynthetic microorganisms to surfaces remains rather elusive. *Chlamydomonas reinhardtii* has been shown to adhere to surfaces with its two cilia under blue light [1], yet the underlying molecular mechanism remains unclear. For decades, the N-glycosylated proteins FMG1-B were considered the main adhesive components of the ciliary glycocalyx, with FMG1-A also contributing to its organization and function. We performed *in vivo* single-cell micropipette force spectroscopy [2] and adsorption/desorption [3] experiments on CRISPR/Cas9-generated FMG1-B-, FMG1-A-, and double-knockouts of *C. reinhardtii*. Thereby we examine how the absence of specific glycocalyx components affects ciliary adhesion forces in different light conditions.

BP 7.29 Mon 15:00 P5

Probing the micromechanics and fluidity of cellular spheroids — •Tom Sosniok[1], Antoine Girot[1], Gabriel de Barros Righes[2], Rodrigo Catalán[1], Ada Cavalcanti-Adam[2], and Oliver Bäumchen[1] — [1]University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — [2]University of Bayreuth, Cellular Biomechanics, 95447 Bayreuth, Germany

Characterizing the mechanical properties of multicellular spheroids is crucial to elucidate the dynamics of biophysical processes such as pathological tissue development, tumor metastasis and disease progression. Spherical cellular aggregates

often serve as valuable tissue models, yet, they cannot be readily characterized with conventional techniques that are optimized for single cells. By combining micropipette force spectroscopy [1] with optical shape tracking, we provide an experimental approach to measure the mechanical properties of spheroids. Here, we first applied this technique to the model organism *Volvox globator*, a photosynthetic microbe that naturally forms spherical aggregates. We show that the compression and relaxation dynamics of *Volvox* can be described by a viscoelastic model, with the viscous component exhibiting a shear-thinning behaviour that is accurately described by a power-law fluid. We find that the viscoelasticity of the aggregates as well as their elastic modulus depend on their life stage. Finally, we applied the same methodology and modelling to aggregates of human colorectal adenocarcinoma cells with epithelial morphology and analysed their mechanical properties.

BP 7.30 Mon 15:00 P5

Intracellular mechanics in migrating cells — •Jannis Fischer[1], Mohammad Amin Eskandari[1], Sarah Louisa Lädke[1], Till Moritz Münker[1], Matthias Krüger[2], and Timo Betz[1] — [1]Third Institute of Physics, Göttingen, Germany — [2]Institute for Theoretical Physics, Göttingen, Germany

To fulfill their incredibly large number of different tasks, biological cells have developed mechanisms to adapt their physical properties and appearance, for example cell shape variation or cell migration. It is still not clear whether the changes in these mechanical properties are due to passive or active processes. Investigating and understanding these processes is the core of this work. For this, I will analyze the behavior of migrating cells, which are induced to move alternately on adhesive patterns. To connect the observed dynamics with the underlying mechanical properties and activities, I will use the new quantity of mean back relaxation (MBR). This can not only overcome the low throughput of optical tweezers, but also determine activity and mechanical properties through purely passive observations. With the MBR, we want to answer the question of how cellular shape influences mechanical properties.

BP 7.31 Mon 15:00 P5

Passive microrheology reveals anisotropic intracellular activity — •Sarah Louisa Lädke[1], Till Moritz Münker[1], Matthias Krüger[2], and Timo Betz[1] — [1]Third Institute of Physics - Biophysics, Georg August Universität Göttingen — [2]Institute for Theoretical Physics, Georg August Universität Göttingen

To investigate intracellular activity and the associated deviations from thermodynamic equilibrium, we study the fluctuations of endogenous vesicles and phagocytosed beads in various cell types and conditions. Experimentally, we combine darkfield microscopy with high-speed imaging and advanced image post-processing techniques, enabling the acquisition of trajectories with spatial and temporal resolution in the order of nanometers and milliseconds, respectively. We apply a novel observable, termed Mean Back Relaxation (MBR) [Münker et al., Nature Materials, 2024], to these trajectories. The MBR quantifies non-equilibrium in confined systems and establishes a link between intracellular particle fluctuations and their effective energies. In doing so, we aim to extend the principles of passive microrheology to non-equilibrium environments. The MBR derived from our trajectories breaks time-reversal symmetry and exhibits pronounced anisotropies, indicating not only heterogeneous cellular structures but also anisotropic activity.

BP 7.32 Mon 15:00 P5

Forces in oocyte deformation analyzed via shear flow deformability cytometry — •Merle Duchêne[1], Bart Vos[1], Jordan Dieter Groh[1], Pratima Sawant[2], and Timo Betz[1] — [1]Third Institute of Physics - Biophysics, Georg August University Göttingen — [2]Institute for X-Ray Physics, Georg-August-Universität Göttingen

Oocytes form the origin of many developing organisms and display distinct mechanical responses compared to smaller somatic cells. Their nuclei are unusually deformable, mimicking whole-cell shape during external compression. Apart from chemical signaling, mechanosensing in the nucleus plays a central role in gene expression. However, the forces involved in oocyte deformation are not quantified and still poorly understood.

Here, we aim to employ microfluidic methods to investigate deformations of cells and nuclei in a well-controlled, high-throughput method via shear flow deformability cytometry, commonly referred to as real-time deformability cytometry (RT-DC). We modified this method for oocytes, by first generating a preliminary channel design using COMSOL simulations. To evaluate device performance after fabrication, polyacrylamide beads are studied and provide a reference for estimating oocyte behavior in the same geometry. Finally, oocyte deformation is recorded to obtain mechanical properties. This helps us to better understand forces involved oocyte development and migration on its journey from the ovaries to an embryo.

BP 7.33 Mon 15:00 P5

Linking Theory and Experiment: RBC Deformation in a Cross-Shaped Microfluidic Channel — •Clara Gremmelspacher[1], Stephan Gekle[1], and Manouk Abkarian[2] — [1]Universität Bayreuth — [2]Centre de Biologie Structurale, Montpellier

Red blood cells (RBCs) must deform significantly to pass through narrow capillaries, a process governed by membrane mechanics such as shear elasticity and membrane viscosity. We use a combined experimental and computational approach to study RBC stretching under extensional flow. The investigated setup consists of two opposing inflow channels and two perpendicular outflow channels arranged in a cross shaped geometry creating a stagnation point at the intersection. By comparing deformation patterns and timescales between microfluidic experiments and Bounday-Integral-Simulations, we extract key mechanical properties of the RBC membrane. This approach links theoretical descriptions to observed dynamics, providing insights into microcirculatory behavior.

BP 7.34 Mon 15:00 P5

Mechanistic Insights into PFAS Interactions with Biological Membranes — •Samuel Türken[1], Doreen Biedenweg[2], Janet Krüger[1], Stefanie Spiegler[2], Bob Fregin[2], Wibke Busch[1], and Oliver Otto[2] — [1]Helmholtz Centre for Environmental Research - UFZ, Leipzig, Germany — [2]Institute of Physics - University of Greifswald, Greifswald, Germany

Per- and polyfluoroalkyl substances (PFAS) are widely used, highly persistent organic chemicals that accumulate in humans and the environment. PFAS exposure is associated with a range of adverse health and environmental effects, yet their mechanisms of action in human cells remain poorly understood. Molecular simulation studies show that PFAS integrate into phospholipid membranes and alter membrane fluidity in a structure-dependent manner.

To investigate how PFAS influence whole-cell mechanics, we used real-time deformability cytometry (RT-DC), which provides single-cell, millisecond-scale measurements of deformation and cell elasticity, i.e., the Young's modulus. This approach captures the mechanical response of HL60 cells after 1 minute PFAS exposures, reducing the contribution of slower cellular adaptive processes. Complementing this, we quantified PFAS-induced changes in membrane order using a Laurdan-based assay. We found that PFAS exposure decreased cell deformability and increased cell stiffness, detectable even at environmentally relevant concentrations in a dose- and structure-dependent manner. Combined membrane-order and RT-DC results show that PFAS alter membrane physical state and thereby modulate whole-cell mechanics.

BP 7.35 Mon 15:00 P5

Bat thermomechanics of red and white blood cells as a blueprint for human hibernation — •Bob Fregin[1,2], Doreen Biedenweg[1], Gerald Kerth[3], and Oliver Otto[1,2] — [1]Institute of Physics, University of Greifswald, Greifswald, Germany — [2]German Center for Cardiovascular Research, Greifswald, Germany — [3]Applied Zoology and Nature Conservation, Zoological Institute and Museum, University of Greifswald, Greifswald, Germany

Hibernation lets mammals conserve energy by sharply slowing metabolism during cold or resource-poor periods. A key challenge is sustaining blood flow at low body temperatures ($\leq 10\,^{\circ}$C). Here, the mechanical properties of red (RBCs) and white blood cells (WBCs) could play a crucial role, which we studied for the hibernating common noctule bat, the non-hibernating Egyptian fruit bat, and humans. Using dynamic real-time deformability cytometry, RBC and WBC elasticity and viscosity were measured at physiologically-relevant time scales (Milliseconds) and temperatures (37 $^{\circ}$C, 23 $^{\circ}$C, and 10 $^{\circ}$C).

Our analysis revealed a temperature-driven increase in RBC elasticity and viscosity, which is mainly influenced by membrane properties and not the cytosol. This effect is significantly enhanced in bats. Finally, our data demonstrate that RBC membranes of both bat species display a transition to a viscous-like state at lower temperatures, which is not explained by seasonal variations of environmental factors but seems to originate from physical properties of the cell membrane. Our results suggest blood cell thermomechanics as a target for future research on human hibernation.

BP 7.36 Mon 15:00 P5

Enhancing optical parameters of platelets in real-time deformability cytometry — •Tristan Franke, Bob Fregin, Doreen Biedenweg, Lucia Wegbünder, and Oliver Otto — Institute of Physics, University of Greifswald, Greifswald, Germany

Real-time deformability cytometry (RT-DC) is a high-speed, label-free cytometric method for imaging and analyzing cell mechanical properties. Cells are flushed through a narrow microfluidic channel and deform by hydrodynamic stresses, while being illuminated by a stroboscopic high-power LED and imaged by a high-speed CMOS camera.

Using RT-DC allows for investigating platelet mechanics, which are key to blood coagulation and may help explain underlying causes of, e.g., coagulopathy and thrombosis. However, with a cell size of only a few micrometers, platelets appear to be difficult to analyze optically, resulting in low image quality, often

characterized by motion blurring, low brightness, and a low level of morphological detail.

We investigated the interplay between various parameters, including LED exposure time (brightness), hydrodynamic flow rate, objective magnification, numerical aperture, and camera settings, to identify optimal imaging parameters. To further enhance image quality, we inserted a 2.18x intermediate lens in our inverted microscope setup to increase image magnification, previously not possible to achieve, while preserving the depth of focus. In combination with an extended exposure time of 9.3 μs, and a 2x digital gain our results demonstrate a balance between image brightness and motion blurring while achieving improved contrast and resolution in RT-DC.

BP 7.37 Mon 15:00 P5

Microparticle traction force microscopy for DNA microparticles based on experimental and computational advances — •Bastian K. Kraus[1,2], Simon Brauburger[1,2], Tobias Walther[3], Tobias Abele[3], Kerstin Göpfrich[3], and Ulrich S. Schwarz[1,2] — [1]Institute for Theoretical Physics (ITP), Heidelberg University — [2]BioQuant, Heidelberg University — [3]Center for Molecular Biology (ZMBH), Heidelberg University

Traction force microscopy quantifies cellular forces by inferring traction fields from the displacements of fiducial markers embedded in soft elastic substrates. Microparticle traction force microscopy extends this concept by employing elastic spherical microparticles as finite-sized force sensors. Traction fields can be recovered by two methods: the volume method, which tracks nanoparticles inside the microparticle, and the surface method, which only considers the deformed microparticle surface. Here, the two approaches are compared systematically, each as a pipeline combining image processing and elasticity theory. Moreover, they are both implemented in the same experimental system, using soft DNA microparticles with different fluorescent labels, which are held and deformed in micropatterned wells. We find that the two methods can lead to similar results, but have different advantages. While the volume method requires fewer assumptions in the elasticity equations, the surface method is less sensitive to imaging artifacts.

BP 7.38 Mon 15:00 P5

A fast & quantitative method to study membrane elasticity of suspended cells — •Eric Sündermann, Bob Fregin, Doreen Biedenweg, Jan Wilder, Stefanie Spiegler, and Oliver Otto — Institute of Physics, University of Greifswald, Greifswald, Germany

Current research acknowledges the importance of bulk and membrane mechanics for understanding cell state and function under pathophysiological conditions. While microfluidic technologies allow for measuring bulk mechanical properties at rates exceeding 1,000 cells per second, traditional approaches for assessing membrane elasticity lack the throughput required to screen entire cell populations.

Here, we utilise membrane tension cytometry (MTC), a microfluidic method combining shear-induced deformation of cells with the capabilities of Flipper-TR, a fluorophore with fluorescence lifetime proportional to the cell membrane elasticity. We established a calibration procedure using thousands of osmotically stressed red blood cells, and confirmed a quantitative relation between surface area and membrane elasticity introduced earlier for different cell models. Next, we focused on HL60 cells, a myeloid precursor cell line. We disturbed cholesterol and filamentous actin, and demonstrated that MTC is sensitive to changes in lipid composition, while being insensitive to cytoskeletal alterations. Finally, we directly measured the mitochondrial membrane elasticity inside living cells using Mito Flipper-TR. Interestingly, mitochondria seem to respond to an external hydrodynamic stress by an increase in membrane elasticity, which might be relevant to understand fission and fusion processes from a mechanical perspective.

BP 7.39 Mon 15:00 P5

The nature of correlations in the fractional Kelvin-Voigt model — •Dorian Marx[1], Raffaele Mendozza[2], Till Moritz Münker[1], Peter Sollich[2], and Timo Betz[1] — [1]Third Institute of Physics - Biophysics, Georg-August-University Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — [2]Institute for Theoretical Physics, Georg-August-University Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

The inside of cells is a complex, non-equilibrium system. We are interested in the mechanics of this intracellular space, which typically are phenomenologically well described by a complex double-power law (fractional Kelvin-Voigt model). There have been multiple studies on intra- and extracellular systems using different measurement methods that indicated a correlation in the model parameters. We present an analytical and numerical analysis of the complex double-power law model, uncovering the nature of such a correlation and its dependency on measured frequency range. This results in a tool to judge experimental findings and to discern significant, possibly meaningful correlations from those stemming from the nature of the model. As complex double-power law models (or a subclass of them) seem to continue being used in the study of intracellular mechanics, we expect this theoretical investigation to be relevant going forward.

BP 7.40 Mon 15:00 P5

The biophysical response of HL60 cells to a millisecond osmotic stress — •Lucia Wegbünder[1], Eric Sündermann[1], Lea Graichen[1], Doreen Biedenweg[1], Marta Urbanska[2], and Oliver Otto[1] — [1]Institute of Physics, University of Greifswald, Greifswald, Germany — [2]Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, United Kingdom

Local differences in the concentration of osmolytes within the human body require cells to consistently regulate their water in- and efflux. While cells are known to change their volume and mechanical properties on the timescale of seconds to minutes, their millisecond response to an osmotic stress has been, so far, unexplored.

Here, we leverage real-time deformability cytometry to apply osmotic challenges to cells and measure their physical properties including size and elastic modulus 0.5 to 10 milliseconds after exposure. We focus on HL60 cells (a myeloid precursor cell line), which are flushed through a microfluidic channel and in which they are in contact with a sheath fluid of varying osmolality. Similar to longer timescale regimes, we observe swelling under hypoosmotic, and shrinkage under hyperosmotic conditions. Independent of stress direction there is a decrease in the Young's modulus of cells. This is in contrast with long timescale findings, where cells are consistently reported to increase their stiffness under hypertonicity. The ability of cells to physically respond to osmotic stress within milliseconds can be of physiological consequences in situations where cells are exposed to steep osmotic gradients, as is the case for immune cells migrating through changing environments.

BP 7.41 Mon 15:00 P5

Mechanical and Viscoelastic Characterisation of *Giardia duodenalis* Trophozoites Using SCFS and nDMA — •Johannes Mischo[1,2], Maike Derenek[1], Markus Bischoff[1], Karin Jacobs[2], Chistian Klotz[3], Anton Aebischer[3], and Philipp Jung[1] — [1]Institute of Medical Microbiology and Hygiene, Saarland University, Homburg, Germany — [2]Experimental Physics, Saarland University, Saarbrücken, Germany — [3]Department of Infectious Diseases, Unit 16, Robert Koch-Institute, Berlin, Germany

Giardia duodenalis trophozoites use a ligand-independent, mechanically dominated suction or clutching mechanism mediated by the ventral disc to resist intestinal shear [1]. Little is known about the mechanical and viscoelastic properties of the cell. We used single-cell force spectroscopy (SCFS) on individual trophozoites to record detachment force-distance profiles. These datasets provide mechanical information of whole-cell deformation during pull-off, including contributions from the cell body, ventral disc and ventrolateral flange. Complementarily, we measured cell-body elasticity by nano-dynamic mechanical analysis (nDMA). Ventral disc and flange are inaccessible to nDMA because stationary cells keep them in surface contact. We observed single-digit kPa storage and loss moduli with a negative correlation between stiffness and approach speed. Together, SCFS and nDMA provide complementary mechanical information and a framework for understanding how *Giardia* balances elasticity and structural rigidity during its adhesion cycle and survival in the small intestine.

BP 7.42 Mon 15:00 P5

Dynamics of confined immune cell migration — •Santiago Kuhl and Joachim Rädler — Ludwig-Maximilians-Universität, München, Germany

Immune cells must invade tissue to reach their targets, but the dynamics and mechanics of their invasiveness are not well understood at the single cell level. Photolithographically fabricated 3D hydrogel micro-structures provide a promising platform for probing cellular invasiveness. Here we use nonadhesive 3D dumbbell-microcavities to enforce repeated encounters between single cells and pores of varying dimensions, simulating migration in a dense extracellular matrix. This platform enables us to record trajectories of macrophages and dendritic cells and measure dwell times and transmigration probabilities as a function of confinement.

BP 7.43 Mon 15:00 P5

Structural changes of sarcomeres in iPSC-derived 3D engineered skeletal muscle after laser-induced injury — •Lisa-Marie Scharfenstein[1,2], Daniel Härtter[1], Mahboubeh Farajian[2], Mattias Luber[2], Timo Betz[2], Wolfram Zimmermann[1], and Arne Hofemeier[1] — [1]Department of Pharmacology and Toxicology, University Medical Center Göttingen, Göttingen, Germany — [2]Third Institute of Physics, University of Göttingen, Göttingen, Germany

Skeletal muscle injury models are employed to study mechanisms of muscle repair and regeneration. Commonly used muscle injury models such as cryo-injury, crush-injury and cardiotoxin-treatment do not allow for precisely localized muscle damage. Here, we introduce precise laser-based injury in human iPSC-derived 3D engineered skeletal muscle (ESM) tissue grown in a custom-made culture platform. Using high-resolution live microscopy and a sarcomere reporter model (ACTN2-Citrine), we monitor Z-band morphology on timescales of seconds to several days using the previously by our group introduced AI-based Sarcomere Analysis Multi-tool (SarcAsM). In doing so, we

find an average sarcomere elongation of (0.45 +- 0.061) mum (mean +- sem) within 50 mum distance from the injury, that further decays exponentially from the location of injury towards the periphery, suggesting local impaired tensional homeostasis in myofibers surrounding the injury. Taken together, we report first data obtained in a novel human iPSC-based skeletal muscle injury model, which we intend to use for repair and regeneration inducing drugs.

BP 7.44 Mon 15:00 P5

What we learned from 6000 patient blood samples measured with deformability cytometry: age, biomarkers, and disease mechanotypes — •Markéta Kubánková[1,2], Lena Summa[1,2], Maximilian Schlögel[1,2], Martin Kräter[1,2], Manfred Rauh[3], Markus Metzler[3], and Jochen Guck[1,2] — [1]Max Planck Institute for the Science of Light, Erlangen, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [3]Department of Pediatric and Adolescent Medicine,University Hospital Erlangen, Germany

Deformability cytometry is a label-free microfluidic imaging technique that quantifies mechanical and morphological properties of single cells at ~1000 cells/s directly from brightfield images. Here we analyse >6000 whole-blood measurements from a clinical cohort ranging from newborns to adults. We developed an automated analysis pipeline combining feature extraction with clustering and classification of the main blood cell populations, replacing manual gating. Using this framework, we established age-dependent baselines of size and deformation for the major cell classes. We correlated the features with routine biomarkers such as CRP, IL-6 and PCT. Specific mechanotypes, particularly of neutrophils and monocytes, showed associations with these markers and provided information beyond simple cell counts. We also quantified the impact of pre-analytical confounders, such as the time between blood draw and measurement. Finally, by stratifying samples according to clinical information, we identified disease-related patterns in cell mechanotypes, providing a biophysical basis for future diagnostic applications.

BP 7.45 Mon 15:00 P5

Investigating the role of the membrane-associated cytoskeleton in neuronal action potential propagation — •Julia Butzke[1] and Kristian Franze[1,2,3] — [1]Chair of Neuronal Mechanics, Medical Institute of Biophysics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [3]Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK

During maturation, neuronal axons develop submembraneous F-actin rings as a part of the membrane-associated periodic skeleton (MPS). The MPS has been shown to regulate axon diameter, provide mechanical support and contribute to axonal transport. However, the role of the MPS in successful action potential propagation in single axons is not yet fully understood. In this project, we investigate the impact of submembraneous F-actin rings on the mechanical aspects of action potentials. Using super-resolution microscopy, we study the effect of different F-actin-disrupting drugs on the presence and periodicity of F-actin rings in primary hippocampal mouse neurons. We then use atomic force microscopy to measure the mechanical waves that accompany action potentials in axons with different levels of F-actin ring periodicity. By analysing the possible correlation between F-actin ring periodicity and the propagation properties of the mechanical waves, we will contribute to a better understanding of the mechanical aspects of neuronal signal transmission.

BP 7.46 Mon 15:00 P5

Characterizing the Effective Membrane Tension Response to Substrate Stiffness Using AFM and Optical Tweezers — •Tina Borić[1,2], Maria Villamarin[1,2], Julia Butzke[1,2], Eva Kreysing[4], and Kristian Franze[1,2,3] — [1]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [2]Friedrich-Alexander-Universität, Erlangen-Nürnberg, Erlangen, Germany — [3]Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK — [4]University of Warwick, Coventry, UK

Cellular membranes change their physical properties in response to mechanical stimuli, such as changes in tissue stiffness. Membrane tension transduces these mechanical signals into intracellular responses via mechanosensitive ion channels. However, how and if a change in tissue stiffness affects the surface mechanics of the cell, which in turn would contribute to the activation of mechanosensitive ion channels, is not yet known. To investigate the dependence of the effective membrane tension on substrate stiffness, we culture HEK293T cells and hippocampal neurons on custom made compliant substrates, and measure tether forces using optical tweezers and AFM. Furthermore, we use pharmacological treatments that primarily affect the actin cortex and membrane composition to characterize their contributions to the effective membrane tension. Ultimately, our aim is to understand how stiffness induced changes in membrane tension lead to the activation of the mechanosensitive ion channel Piezo1. Our work will contribute to the understanding of how mechanosensitive ion channels are gated, which may have important implications for drug design in the future.

BP 7.47 Mon 15:00 P5

Topologically invariant coordinates for dynamic epithelia undergoing morphogenesis — •Paweł Korzeb[1], Marko Popović[1,4], and Frank Jülicher[1,2,3] — [1]Max Planck Institute for Physics of Complex Systems, Dresden, Germany — [2]Center for Systems Biology, Dresden, Germany — [3]Cluster of Excellence Physics of life, Technische Universität Dresden, Dresden, Germany — [4]Rudjer Bošković Institute, Zagreb, Croatia

Epithelia are two-dimensional tissues, sheets of tightly connected cells that form many structures in organs. Such tissues acquire their shape and function through morphogenesis, a process that involves changes in both their geometry and cellular network topology. A key question in morphogenesis is to understand how cellular processes, such as cell division or T1 transitions, contribute to tissue morphology by changing its geometry and topology. For a curved epithelium, this problem can be formulated in a continuous covariant description on the tissue surface. In this work, we propose two sets of topologically invariant coordinates, describing cellular networks, obtained by embedding a graph representation of the network into $\mathbb{R}^2$ using only its connectivity, without the need to take into account the underlying tissue geometry. We construct these embeddings using the spectrum of the graph Laplacian and a spring-meshwork representation. Local changes of these topologically invariant coordinates allow us to identify the cellular processes occurring during tissue development. This formalism provides a framework to investigate the coupled evolution of epithelial geometry and topology.

BP 7.48 Mon 15:00 P5

BeadBuddy: Multiscale shape analysis of in-vivo stress sensors for force inference — •Alejandro Jurado Jiménez[1], Jonas Isensee[3], Arne Hofemeier[2], Lea Johanna Krüger[4], Raphael Wittkowski[5], Ramin Golestanian[3], Philip Bittihn[3], and Timo Betz[1] — [1]Third Institute of Physics-Biophysics, University of Göttingen — [2]Institute of Pharmacology and Toxicology, University Medical Center Göttingen — [3]Max-Planck-Institute for Dynamics and Self-Organization, Göttingen — [4]Institute of Theoretical Physics, University of Münster — [5]Department of Physics, RWTH Aachen University, DWI - Leibniz Institute for Interactive Materials

The measurement of stresses and forces at the tissue level has proven to be an indispensable tool for the understanding of complex biological phenomena such as cancer invasion, embryo development, or wound healing. One of the most versatile tools for force inference at the cell and tissue level are elastic force sensors, whose biocompatibility and tunable material properties make them suitable for many different experimental scenarios. The evaluation of those forces, however, is still a bottleneck due to the numerical methods seen in the literature until now, which are usually slow and render low experimental yield. Here, we present BeadBuddy, a ready-to-use platform for the evaluation of deformation and stresses from fluorescently labeled sensors within seconds. The strengths of BeadBuddy lie in the precomputed analytical solutions of the elastic problem, the abstraction of data into spherical harmonics, and a simple user interface that creates a smooth workflow for force inference.

BP 7.49 Mon 15:00 P5

Mechanics of reconstituted cardiac microtissues — •Polina Malova, Mattias Luber, Noemie Veyret, Anna Mukhina, Till Münker, and Timo Betz — Georg-August Universität Göttingen

Cardiovascular diseases remain the leading cause of mortality in Western countries [1]. Heart failure, which characterized by reduced cardiac output, myocardial thickening, and diminished contractile strength is among them and is highly prevalent. Human induced pluripotent stem cells (hiPSCs) are widely used for cardiac disease modelling and drug screening due to a preservation of patient-specific genetic backgrounds [2]. hiPSC-derived engineered human myocardium (EHM) microtissues provide an opportunity for *in vitro* research of the cardiac environment in a three-dimensional (3-D) system. Despite extensive characterization of the heart as a complex 3-D system, the mechanics of cellular interactions within the cardiac tissue still require detailed clarification. This work examines how cells within EHM microtissues mechanically interact with neighbouring cells and the extracellular environment to generate observed load curves. We compare contraction profiles of tissues composed of cardiomyocytes with cardiac fibroblasts to those containing cardiomyocytes with human foreskin fibroblasts. In addition, we investigate the contribution of extracellular matrix homeostatic tension to the mechanics of the 3-D system. These findings support the further development of 3-D tissue models for patient-specific drug screening.

Connecting tissue stiffness and glycosylation patterns in the developing brain — •Sarah Fritsche[1,2], Sebastián Vásquez-Sepúlveda[1,2], Leonhard Möckl[3,4], and Kristian Franze[1,2,5] — [1]Medical Institute of Biophysics, FAU Erlangen-Nuremberg, Germany — [2]MPZPM, Erlangen, Germany — [3]Department of Medicine 1/CITABLE, University Hospital Erlangen, FAU

Erlangen-Nuremberg, Germany — [4]MPL, Erlangen, Germany — [5]Department of Physiology, Development and Neuroscience, University of Cambridge, United Kingdom

Mild malformation of cortical development with oligodendroglial hyperplasia and epilepsy (MOGHE) is a pathological entity leading to drug resistant epilepsy that is characterised by increased density of oligodendroglial cells, hypomyelination, and heterotopic neurons in the white matter. This malformation has been linked to mutations of the galactose transporter SLC35A2. At the same time, processes like brain folding involve motion and must therefore be driven by large scale forces. This is why, in order to comprehend this disease to a greater extent, we are investigating the connection between the physical properties of brain tissue and its glycosylation patterns to emulate brain malformations in the Xenopus laevis embryo. The physical properties are measured via atomic force microscopy and the glycosylation patterns via super-resolution microscopy of metabolically labelled galactose, as well as antibody- and lectin stainings. With this approach we aim to understand the relation between the mechanical properties of brain tissue and developmental pathologies.

BP 7.51 Mon 15:00 P5

Cellular shape anisotropy couples to morphogen transport to drive pattern formation — •Stefan Nienhaus[1] and Diana Khoromskaia[1,2] — [1]Institut für Theoretische Physik, Universität Münster, 48149 Münster, Germany — [2]Center for Soft Nanoscience, Universität Münster, 48149 Münster, Germany

To attain their intended structures, many tissues have been shown to rely on morphogens that induce concentration-dependent changes in cell fate and in cellular mechanical properties. These changes can alter the transport properties of the morphogen within the affected tissue. Hence, a feedback loop may arise in which tissue patterning influences morphogen distribution, which in turn influences tissue patterning (bioRxiv:658228). This concept also applies to tissues with nematic order, which has been shown to be crucial to certain morphogenetic processes that predominantly occur at topological defects.

In this work, we explore the complex couplings between morphogens and nematics and aim to investigate the role of topological defects in localising cellular signalling for morphogenesis. Previous work has shown that cellular shape anisotropy may lead to anisotropic diffusion (bioRxiv:683494). Here, through numerical simulations of a reaction-diffusion system coupled to a nematic order parameter, we study how locally anisotropic diffusion affects the observed patterns. Introducing a concentration-dependent nematic alignment as a next step, we will investigate mechanisms of self-organisation that arise from this inherent coupling of morphogens and nematic order in tissues.

Quantifying vascular morphology on a chip — •Leonie Karr — TUM, Munich, Germany

Our human vasculature is dynamic, growing and reorganising not only in development but also continuously adapting its morphology. Yet, what determines vessel formation and branching in healthy and disease states seems complex, given the multitude of contributing factors. Our focus lies in growing a human vasculature within the controlled environment of a chip, with the goal of quantifying the flow properties of self-organised in vitro networks. Employing image analysis techniques in conjunction with flow simulation methods, our objective is to accurately quantify how flow and related properties, such as shear stress and absorption determine network architecture. The results obtained from our analyses will significantly contribute to the development of next-generation therapeutics aimed at targeting vessel development.

BP 7.53 Mon 15:00 P5

Mechanics of spinal cord regeneration in Xenopus laevis — •Maria Tarczewska[1,2] and Kristian Franze[1,2,3] — [1]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [2]Medical Institute of Biophysics, Friedrich-Alexander- Universität Erlangen-Nürnberg, Erlangen, Germany. — [3]Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, UK

In mammals, spinal cord injury (SCI) often leads to paralysis due to the limited regeneration of damaged neurons in the central nervous system (CNS). The African clawed frog (Xenopus laevis) can regenerate CNS neurons during its early life stages - pre-metamorphosis. However, this ability is lost post-metamorphosis, in frogs adult form. Biochemical differences between pre- and post-metamorphosis frog spinal cord tissue identified so far cannot fully explain the differences in their regenerative capacity, suggesting that other signals may contribute to the regeneration. Following SCI, the composition of the extracellular matrix changes, and scar tissue forms. In mammals, this scar tissue, which is softer than healthy tissue, inhibits axon regeneration. In zebrafish, whose CNS neurons regenerate after SCI, tissue stiffens after injury. Mechanical properties of frog spinal cord tissue have not been measured yet. Because mechanosensing of tissue stiffness is critical for axon growth, we test the hypothesis that tissue stiffness is a critical factor in axon regeneration after SCI. We investigate the mechanical differences in the SCI lesion environment in Xenopus. By examining both tissue stiffness and molecular changes, we will illuminate the relationship between these factors and the regenerative capabilities.

BP 7.54 Mon 15:00 P5

Dimensionality and confinement reshape competition in cellular renewing active matter — •Patrick Zimmer[1,2], Philip Bittihn[1,2], and Yoav G. Pollack[1,2] — [1]MPI for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, Göttingen University, Germany

Cellular renewing active matter—assemblies of proliferating and apoptotic cells—underlies tissue homeostasis, morphogenesis, and clonal competition. Previous work in one-dimensional periodic systems identified a fitness advantage associated with rapid dead-cell clearance, an "opportunistic" competition mechanism. Extending this framework, we study two-dimensional cellular aggregates and show that dimensionality modifies the interplay between competition mechanisms for clones with different clearance rates: in 2D, opportunistic and homeostatic-pressure-based competition jointly shape clonal selection. We introduce an explicit circular confinement to probe how boundaries modulate this interplay. While opportunistic competition persists, distinct timescale-dependent behaviors emerge through weakened homeostatic-pressure-based competition near boundaries. Structural analysis reveals that confinement promotes tangential alignment and spatially heterogeneous homeostatic pressure, thereby reshaping competitive outcomes at tissue edges. Our study connects newly discovered competition mechanisms with more realistic biological contexts, highlighting how dimensionality and spatial constraints influence tissue structures and modulate competition in heterogeneous cell populations, with implications for tumor growth dynamics and tissue development.

BP 7.55 Mon 15:00 P5

Remotely Actuated Elastic Meta-Lattices using Bjerknes Forces — •Laurin Sartori[1], Peer Fischer[1,2], and Athanasios G. Athanassiadis[1,2] — [1]Heidelberg University, Heidelberg, Germany — [2]Max-Planck Institute for Medical Research, Heidelberg, Germany

Acoustically-responsive elastic structures have recently gained interest as tools for gentle, wireless manipulation of biological materials. By combining acoustic effects with elastic structures, they can be actuated dynamically to even manipulate single cells in fluidic chambers. However, there is currently a large gap between existing manipulators designed for single cells and larger-scale acoustically-actuatable materials that could be integrated with larger biological tissues or organoids.

Here, we introduce a dynamic acoustic metamaterial that can be change both its geometric configuration and elastic properties in response to sound. The metamaterial consists of an elastic lattice with embedded gas bubbles, and is actuated leveraging the secondary radiation forces between embedded bubbles. By tuning the driving or the microscopic structures the specific response of the material can be tailored. We introduce a numerical model to predict the response of arbitrary lattices, and validate the model experimentally using carefully designed structures that achieve the desired motion.

The engineered lattices shown in this work can be used as building blocks for metamaterials with a remotely tunable stiffness, auxetic properties and memory behavior, providing new interaction paradigms for applications in bio-interfaced soft robotics.

BP 7.56 Mon 15:00 P5

Direct Measurement and Enhancement of Piezoelectric Fields around Microparticles in an Ultrasound Field — •Mareike Stoll[1,2], Honorata Kazimierczak[1,2], Peer Fischer[1,2], and Athanasios Athanassiadis[1,2] — [1]Institute for Molecular Systems Engineering and Advanced Materials, Heidelberg University, Heidelberg, Germany — [2]Max Planck Institute for Medical Research, Heidelberg, Germany

There is growing interest in designing ultrasound-responsive materials that broaden the possibilities for non-invasive, remotely controlled therapies. In this context, piezoelectric micro- and nanoparticles are emerging as promising mediators, generating electric fields and reactive chemical species that can interact with biological tissues. Despite growing evidence suggesting macroscopic effects, a direct measurement of the piezoelectric response of individual particles under an applied ultrasound field has not yet been demonstrated. This knowledge gap presents a hurdle to further design and targeting of piezoelectric particle-mediated therapies. In this work, we introduce a new methodology and provide the first direct measurements of electric potential generated by piezoelectric microparticles during ultrasonication. By mapping the time-varying potential around microparticles we are able to quantify the ultrasound-induced fields and identify enhancement strategies. These results provide a first step to disentangling the contributions of different physical processes involved in sonopiezoelectric therapies, and provide insights into the feasibility and design strategies for therapies based on ultrasound-activated piezoelectric materials.

BP 8: Systems and Networks Biophysics

Origins of the Fittest: Clonal interference in the World Aviation Network — •Adrian Zachariae, Pascal Klamser, and Dirk Brockmann — Technische Universität Dresden, Dresden, Deutschland

Clonal interference, the competition between strains carrying different beneficial mutations, plays a crucial role in shaping evolutionary outcomes in asexual populations. Since the spread of new mutations is critical for CI, it is strongly influenced by the structure of the population. For example, long-range connections can rapidly distribute new mutations, reducing CI. We investigate how this phenomenon unfolds in the the World Aviation Network, which shapes the population structure of microorganisms that use humans as hosts, including pathogens. We developed a novel analytical framework that models the succession of adaptive mutations as a Markov Renewal Process. The process is built by leveraging epidemic modeling methods to model mutation spread in the network. Or approach reveals how the interplay between mutation rate and network topology gives rise to distinct evolutionary regimes: At low mutation rates, strains originating from globally central nodes have higher fixation probabilities, while at higher mutation rates, meso-scale and local properties become more important. Applied to the WAN, affluent, western regions are most likely origins of high-fitness lineages in the low-rate regime, shifting to more populous nations in Asia at high rates. The framework provides valuable insights how spatial structure shapes evolutionary outcome, with particular relevance for pandemic preparedness.

BP 8.2 Mon 17:00 BAR/0106

Polymerization of prebiotic building blocks in a wet-dry cycling system — •Almuth Schmid — LMU, Geschwister-Scholl-Platz 1, München

When it comes to the question on how life could have emerged on an early Earth, not only the setting plays an important role but also the chemistry that helped forming the first building blocks of life. Prebiotic chemistry is limited in multiple ways since many of the common catalysts life uses nowadays are too complex to have been present in such an early stage. In addition, the existing compounds were diluted and only available in low concentration. To overcome these problems, systems like wet-dry cycles can help accumulating molecules while at the same time lowering the reaction activation barrier.[1] In addition, amino acids promote RNA copolymerization more than 100-fold via acid-base catalysis, starting from prebiotically plausible ribonucleoside-2',3'-cyclic phosphates.[2] MD simulations and X-ray crystallography confirmed that water is still present in the dry state, limiting the condensation reaction and hydrolyzing the material. Preliminary experiments showed that by using ammonium salts instead of sodium salts, including nucleotides and hydroxide to adjust the pH, overall longer polymers and yields 5-fold higher than before were obtained. Expanding this adapted wet/dry cycling system with an NH3/CO2 enriched atmosphere [3] would re-create a day and night rhythm on the early Earth, providing a prebiotic way to synthesize RNA.

Invited Talk BP 8.3 Mon 17:15 BAR/0106

Constructing synthetic life-like vesicle systems by integration of artificial metabolic reaction networks — •Laura Heinen — DWI - Leibniz Institut für interaktive Materialien, Aachen, Germany

Life emerges as a systemic property of the interplay of complex chemical reaction networks out of equilibrium. Living cells, for example, need energy to grow, divide, process information and synthesize their own constituent building blocks. In my group we develop minimal metabolic reaction networks to fuel out of equilibrium behavior in synthetic lipid vesicles, to finally, build active cell-like compartments bottom-up, called synthetic cells. In my talk I will demonstrate the construction of autonomous, active behavior in vesicles by the example of cross-feeding in between synthetic vesicles. Key to such sustained out-of-equilibrium behavior is the selective transport of energy molecules across the lipid membrane. One population of vesicles produces and exports adenosine triphosphate (ATP) while a second population of vesicles takes up the ATP and uses this chemical energy to fuel ATP-consuming reactions. The hydrolyzed ATP feeds back into the first vesicle population where it will be recycled, and the interdependent metabolic cycle can be sustained. The vesicles are a platform to enable active behavior in synthetic systems in a continuous, autonomous and adaptive fashion. Fundamentally, they allow us to study non-equilibrium processes in an energy-controlled environment and will promote our understanding of constructing life-like materials and systems.

BP 8.4 Mon 17:45 BAR/0106

Living Network Dynamics: From pH-Stimulated Growth to Resistance Optimization — •Mathieu Le Verge-Serandour, Alexandra Bienau, Karen Alim, and Friedrich Simmel — School of Natural Sciences, Technical University of Munich

In this work, we explore how vascular-like functionality can be integrated into bioelectronic interfaces using the unicellular slime mold Physarum polycephalum. This organism forms a dynamic, self-organized tubular network that exhibits emergent behaviors such as optimization, adaptation, and self-healing, making it an ideal model for studying decentralized, stimulus-responsive growth. By leveraging electrochemically induced pH gradients, we experimentally translate designed network layouts into biological structures and characterize the key dynamics underlying their responses to pH stimuli.

We further analyze Physarum morphological evolution, where the network reorganizes over several hours to evacuate a defined area by sequentially pruning competing parallel veins, ultimately forming a tree-like architecture. Drawing an analogy with power-grid networks, we investigate how sequential pruning depends on the ratio of tube to network resistance. Analytical and numerical results show that regular graphs undergo pruning until the average node degree falls below four, a finding that remains robust in simulations of random networks. Incorporating mass redistribution into this process leads to resistance homogenization, revealing fundamental physical constraints that shape adaptive transport networks.

BP 8.5 Mon 18:00 BAR/0106

Simulation of autoimmune and autoinflammatory diseases: the novel mechanism of psoriasis progression. — •Nadezhda Esenkova[1,2], Lukas Pöschl[1,2], Gerard C. L. Wong[3], and Vasily Zaburdaev[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Germany — [3]University of California, Los Angeles, USA

Autoimmune and autoinflammatory diseases (AIIDs) still remain an unsolved problem. One of the most studied diseases which carries features of both types is psoriasis. In this study, we are focusing on the novel mechanism of disease enhancement, driven by antimicrobial peptides (AMPs) and AMP-like fragments organizing innate immune ligands for enhanced binding to Toll-Like Receptors in immune cells. These fragments have a diverse origin: there is strong recent evidence that serine proteases can digest viral and host proteins into AMP-like fragments. In order to explore the effect of this emerging pathway, we developed a new unified interaction network model for psoriasis, based on the current extant measurements. The model was reduced to a system of nonlinear differential equations, which were studied by using dynamical system theory and numerical methods. Importantly, we find that the proposed model can reproduce the full spectrum of disease progression from healthy response to uncontrolled inflammation and allows comparison of different therapeutic interventions. Finally, by expanding the model to include diffusion, we can successfully predict the geometry of psoriatic plaques, the precise measurements of which may inform modulation of treatment.

BP 8.6 Mon 18:15 BAR/0106

Network-induced control of sustained oscillations in SIRS epidemics — •Samuel Ropert[1,2], Tomas Perez-Acle[2], and Dirk Brockmann[1] — [1]Technische Universität Dresden, Dresden, Germany — [2]Universidad San Sebastián, Santiago, Chile

Sustained oscillations in SIRS epidemic models are well understood in well-mixed populations when infectious and immune periods deviate from exponential waiting times. In contrast, the role of contact network structure in generating or suppressing such oscillations has received little attention. Existing work on small-world networks reports oscillations but does not relate them to effective transition-time distributions. This work investigates how network topology shapes oscillatory SIRS dynamics by simulating a stochastic SIRS process on self-similar modular hierarchical (SSMH) networks. These networks interpolate between random-like graphs and strongly modular, hierarchical structures while preserving system size and mean degree. A single structural parameter controls edge placement across hierarchical levels, reshaping effective distances between communities. Preliminary results show that random-like networks support robust, coherent oscillations in global prevalence, whereas increasing hierarchical modularity desynchronizes outbreaks across communities and gradually destroys the global limit cycle, leading to damped or irregular fluctuations. These findings support an interpretation of epidemic oscillations as a synchronization phenomenon of individual SIRS cycles, where network topology promotes or inhibits global coherence by reshaping the time-to-infection distribution through changes in effective distances.

BP 9: Single Molecule Biophysics

Time: Monday 16:45–18:30 Location: BAR/0205

Invited Talk BP 9.1 Mon 16:45 BAR/0205

Breaking the photobleaching limit in single-molecule FRET with nanophotonic DyeCycling. — Benjamin Vermeer[1], Dong Hoon Shin[2,3], Alexander Vogel[4], Fabian Zundel[1], Sabina Caneva[2], and •Sonja Schmid[1,4] — [1]University of Basel, Basel, Switzerland — [2]Delft University of Technology, Delft, The Netherlands. — [3]Korea University, Sejong, Republic of Korea — [4]Swiss Nanoscience Institute, Basel, Switzerland

Paradoxically, single-molecule FRET studies rely on ensemble averaging during data analysis, because early photo-bleaching prohibits sufficient sampling of single molecules. As a result, the FRET-based study of inter- and intra-molecular heterogeneity in biomolecular function - a specific hallmark of single-molecule techniques - is hardly possible, preventing insights into dynamic disorder, the effects of post-translational and other modifications, of rare but decisive states, etc. Here, we demonstrate hour-long single-molecule FRET observations using DyeCycling in zero-mode waveguides, which circumvents photobleaching through reversible fluorophore binding. We detect the conformational dynamics of single molecules over four orders of magnitude in time (milliseconds-hour), enabling us to directly observe slow kinetic regime changes within individual molecules that were intractable previously. Moreover, we demonstrate the versatility of DyeCycling with DNA and protein molecules. Together, these advances establish DyeCycling/FRET as a powerful new approach that vastly expands the information gain of single-molecule FRET, enabling the study of important biological questions that were previously inaccessible.

BP 9.2 Mon 17:15 BAR/0205

Monitoring the ribosome dynamics at the single molecule level — •Baptiste Bouhet[1], Sandra Blanchet[2], Charles Truong[3], Olivier Namy[2], and Karen Perronet[1] — [1]Light, Matter and Interactions lab, Gif/Yvette, France — [2]Institute for Integrative Biology of the Cell, Gif/Yvette, France — [3]Centre Borelli, Gif/Yvette, France

Protein synthesis is a complex multi-step process involving factors that need to interact in a coordinated manner to properly translate mRNA. As translating ribosomes cannot be synchronized over many elongation cycles, single molecule studies, mainly using total-internal-reflexion fluorescence microscopy, have been introduced to better understand translation dynamics. We decided to monitor the passage of individual, unmodified eukaryotic ribosomes from wheat germ extracts at specific fluorescent primers hybridized along mRNA. Because of the ribosome helicase activity, the double strand formed by the oligonucleotide and the mRNA is opened while the ribosome translates this region of the mRNA. Thus, the consecutive loss of fluorescence signal of two oligonucleotides allows us to measure the translation speed distribution of single ribosomes. We use this system to measure simultaneously the initiation and the elongation kinetics for linear mRNA and during -1 frameshifting, which is induced by a secondary structure on mRNA. We are also currently developing a magnetic tweezers assay to get complementary information on the opening dynamics of these structures. Thanks to its versatility, this method is a valuable tool to investigate translation machinery modifications in human diseases.

BP 9.3 Mon 17:30 BAR/0205

Single-molecule force and torque spectroscopy reveals conformational transitions in DNA and proteins — •Jan Lipfert — Universität Augsburg

Magnetic tweezers are a powerful tool to probe single molecules under precisely controlled forces, down to well below 1 pN, and, in addition can control twist and torque. Here, I highlight recent developments and applications of magnetic tweezers. In particular, I will present how we use magnetic tweezers to probe regulatory conformational changes in protein complexes, including pathogen-cell adhesion and the initiation of primary hemostasis by von Willebrand factor. In addition, I will show how we use the capabilities of magnetic tweezers to precisely measure DNA helicity under changes in environmental conditions and upon small-molecule binding.

BP 9.4 Mon 17:45 BAR/0205

Direct measurement of ultra-weak plant kinesin steps using silicon nanospheres as optical tweezers probes — •Aleksandr Kostarev[1], Shu Yao Leong[1], Anita Jannasch[1], Minoru Fujii[2], Hiroshi Sugimoto[2], and Erik Schäffer[1] — [1]Eberhard Karls Universität Tübingen, Tübingen, Germany — [2]Kobe University, Kobe, Japan

Kinesin motor proteins are essential for transport along cytoskeletal microtubules and cell division. In plants, cytokinesis relies on phragmoplast orienting kinesins (POKs). The kinesin-12 paralog POK2 can generate only about 300 fN of force. This low force is consistent with the idea that POK2 does not transport cargo, similar to weak kinesin-8 motors, the function of which is unknown in plants. To understand the function and mechanochemistry of these ultra-weak motors, it is necessary to detect their individual steps during ATP hydrolysis. However, the spatiotemporal resolution achieved with conventional probes in optical tweezers is insufficient for detecting fast steps at such low forces. To overcome this limitation, we used high refractive-index silicon nanospheres for optical trapping. With these nanospheres, we achieved an unprecedented force resolution of 60 aN at room temperature in liquids with a force sensitivity of 2.7 fN Hz^(-1/2). We bound single POK2 or plant kinesin-8 motors to the nanospheres and were able to detect individual 8-nm steps with 4-nm substeps within a force range of 100-400 fN. These in vitro measurements establish a path toward identifying plant kinesin function and demonstrate the potential of silicon nanospheres for studying ultra-weak molecular machines.

BP 9.5 Mon 18:00 BAR/0205

Ultrafast sensing of single nanoparticles with an optofluidic microcavity — •Shalom Palkhivala[1], Larissa Kohler[1], Christian Ritschel[1], Christoph Pauer[2], Tim Liedl[2], Claus Feldmann[1], and David Hunger[1] — [1]Karlsruhe Institute of Technology, Karlsruhe — [2]Ludwig Maximilian University, Munich

The characterisation of single, unlabelled particles in water is of much interest in biophysics and chemistry, where most processes occur in an aqueous environment. We report measurements of single nanoparticles in aqueous suspension using a fibre-based Fabry-Perot microcavity. For quantitative analysis of the nanoparticles' diffusion dynamics, we developed an analytical autocorrelation function to model diffusion in a standing wave field. This enabled the accurate sizing of nanoparticles having diameters down to 3 nm. [1]

Additionally, the rotational dynamics of anisotropic particles were investigated. Via the polarization modes of the cavity, the orientation of a nanorod was tracked with high temporal resolution (~ 20 ns), orders of magnitude faster than most other current techniques. As an application of our sensor to biosensing, we demonstrate measurements of individual DNA "origami" structures and of few protein molecules, which already enabled their hydrodynamic sizes to be determined.

We further expect our nanosensor to give an insight into the structural properties and conformation of single bioparticles, and to become a powerful tool for diagnosis in biomedicine and for biochemical and environmental assays.

BP 9.6 Mon 18:15 BAR/0205

Indications for Ultrafast Energy Transfer and Subsequent Disulfide Bond Cleavage in Lysozyme upon Ultrafast Excitation of Aromatic Residues — •Philip Wehling[1], Jessica Harich[1], Antonia Freibert[1], Ru-Pan Wang[2], Tae Gyun Woo[3], Junho Lee[3], Seonghyeon Jeong[3], Sungin Yu[3], Haneol Oh[3], Migel Ochmann[1], Victoria Kabanova[4], Emma Beale[4], Philip Johnson[4], Claudio Cirelli[4], Camila Bacellar[4], Briony Yorke[5], Tae Kyu Kim[3], and Nils Huse[1] — [1]University of Hamburg, Hamburg, Germany — [2]DESY, Hamburg, Germany — [3]KAIST, Daejeon, Republik of Korea — [4]Paul Scherrer Institute, Villigen, Switzerland — [5]University of Leeds, Leeds, U.K.

Disulfide bonds play a crucial role in stabilizing the tertiary structure of proteins. Ultraviolet (UV) radiation leads to S-S bond cleavage, possibly compromising the functionality of proteins. Femtosecond X-ray absorption spectroscopy at the sulfur K-edge revealed ultrafast geminate disulfide bond reformation in aliphatic disulfides [1]. These findings raise the question how disulfide bridges behave in proteins upon UV irradiation. Disulfide photochemsitry in Lysozyme by UV excitation across the dominant absorption of the aromatic residues leads to efficient sulfur radical formation which must stem from energy transfer. We discuss yields and possible mechanisms of energy transfer in competition with direct photocleavage of disulfide bridges, and implications for energy dissipation and structural integrity of proteins.

BP 10: Active Matter III (joint session BP/CPP/DY)

Time: Tuesday 9:30–12:45 Location: BAR/SCHÖ

BP 10.1 Tue 9:30 BAR/SCHÖ

inertia-driven re-entrant coil-Globule transition of active ring polymers — •Sunil P Singh[1], Roland G Winkler[2], Rakesh Palariya[1], and Arindam Panda[1] — [1]Indian Institute of Science Education and Research Bhopal, India — [2]Theoretical Physics of Living Matter, Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Germany

The role of inertia in the collective dynamics of active systems has been a subject of increasing interest in recent studies. The present study investigates the inertial effects on active agents. We present the conformational and dynamical characteristics of an active Brownian ring polymer using Langevin dynamics simulations. We show that a long active ring polymer shrinks into globular-like structures even in the absence of attractive interactions. This transition becomes sharper and the structures more compressed as the reduced moment of inertia of the monomers increases, particularly in the intermediate range of activity. We demonstrate that the ring polymer undergoes a coil-globule-coil transition, which is modulated by both activity and rotational inertia. The coil-to-globule transition is mapped in the inertial parameter space (J-M) using the radius of gyration. Additional physical quantities, including bond-bond correlations, scaling behavior in the compressed state, monomer contact probability, geometric distances, coordination number, and effective temperature, further elucidate the physical mechanism driving the collapse. Finally, we show that the effective diffusivity of the ring polymer increases with the reduced moment of inertia as $D_p \sim \sqrt{J}$.

BP 10.2 Tue 9:45 BAR/SCHÖ

Shape selectivity by complex buckling dynamics in poroelastic active gels — •Kinjal Dasbiswas[1], Subhaya Bose[1], Arnab Roy[1], Michael Vennettilli[1], and Anne Bernheim[2] — [1]University of California, Merced, USA — [2]Ben Gurion University, Israel

Shape change in animal cells is prototypically driven by active forces, generated by myosin molecular motors bound to the actin cytoskeleton. Inspired by experiments on disc-shaped extracts of crosslinked actomyosin gels, we aim to show how a family of 3D shapes can arise from buckling caused by non-uniform active stresses. Although synthesized with identical composition of actin, myosin and the crossliker fascin, these gels contract and buckle into different shapes depending on the initial aspect ratio of the disc: thinner gels tend to wrinkle, while thicker gels tend to form domes. By incorporating active stresses, actin alignment, and stress-dependent myosin binding kinetics into a 2D poroelastic gel model, we qualitatively capture trends in gel contraction dynamics observed from quantitative particle image velocimetry (PIV). Next, we carry out numeric simulations of a geometric elastic model for thin sheets to obtain 3D buckled shapes from the strain rates predicted by the poroelastic model. Our results show that the coupling of elasticity to solvent flow, motor binding and fiber alignment play an important role in shape changes in living matter. Our studies have implications for shape changes during tissue morphogenesis and cell migration.

BP 10.3 Tue 10:00 BAR/SCHÖ

The energy cost to build a spindle — •Dongliang Zhang[1], Xingbo Yang[4], Jan Brugués[2,1,3,4], and Frank Jülicher[1,3,4] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [3]Center for Systems Biology Dresden, Dresden, Germany — [4]Physics of Life, Cluster of Excellence, TU Dresden, Dresden, Germany

Spindle is a structure actively build from microtubules (MTs), and plays an important role for chromosome segregation during cell cycle. It's observed in experiments that the spindle size and shape depends on the cell level metabolic rate. In this work, we developed a minimal model that captures the active, energy-consuming processes such as MT turnover and active stress generation, which shows the energy cost for spindle mass maintenance and spindle-shape formation. We show that a spindle can be self-organized through these active processes. We aim to predict how the size and shape of the spindle depends on the energy input, and explain relative experimental phenomena, e.g. spindle shrinkage when the metabolism level is reduced.

BP 10.4 Tue 10:15 BAR/SCHÖ

Cytoskeletal oscillations drive large-scale flows and nuclear organization in early embryonic systems. — •Lara Koehler, Elissavet Sandaltzopoulou, and Jan Brugués — Physics Of Life, TU Dresden

Synchronization drives early embryonic development, enabling simultaneous cell divisions and the spatial organization of nuclei within the embryo. In organisms such as Xenopus, Drosophila, and zebrafish, mitotic waves coordinate cell cycles across distances that exceed diffusion limits, guided by a chemical oscillator. At the same time, global cytoplasmic flows in these syncytial tissues contribute to the large-scale self-organization of nuclei, yet the coupling between biochemical signaling and cytoskeletal mechanics that underlies these directed flows remains poorly understood. Here, we relax the geometric constraints of the embryo and investigate nuclear dynamics in Xenopus egg extracts and complementary simulations. We show that the periodic polymerization and depolymerization of microtubule asters are sufficient to generate robust large-scale directed flows, even though the asters are intrinsically isotropic. Furthermore, we demonstrate that cell division stabilizes short-range order in a global synchronized system. Together, these findings reveal a minimal physical mechanism by which cytoskeletal dynamics and biochemical oscillations jointly organize flows and patterns, with implications for understanding the emergent principles that shape early development across species.

BP 10.5 Tue 10:30 BAR/SCHÖ

Geometric control of cell migration in disordered porous media — •Laeschkir Würthner[1] and Frederik Graw[2] — [1]European Molecular Biology Laboratory, Heidelberg, Germany — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany

Cell migration is a dynamic process that plays a central role in development, wound healing, and immune responses. Active cell movement is controlled by several biochemical and mechanical cues, including chemokine gradients and the mechanical properties of the extracellular matrix (ECM). Although the biochemical pathways underlying directed cell motion are increasingly well understood, the influence of the porous structure of the ECM on active cell motion remains largely unexplored. Using a combination of computational modeling and theory, we investigate how active cells move through 3D disordered porous environments. We show that cell migration in disordered porous media can be understood as a generalized random walk among "traps", with the effective diffusivity determined by the geometry of the microenvironment. A key implication of our work is that spatial heterogeneities in porosity effectively direct cell motion, revealing a guidance mechanism that we refer to as porotaxis. Overall, our work connects geometry with cell motility and underscores the microenvironment as a key regulator of cell migration.

BP 10.6 Tue 10:45 BAR/SCHÖ

Motility-induced mixing transition in exponentially growing multicellular spheroids — •Torben Sunkel[1,2], Lukas Hupe[1,2], and Philip Bittihn[1,2] — [1]MPI for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

Growth drives cellular dynamics in various dense aggregates, but its effects on other relevant activities have only received limited attention. Here, we investigate the interplay of unconstrained growth, steric repulsion and motility in a minimal agent-based model of exponentially growing, three-dimensional spheroids. Our results reveal a diverging mixing time scale at a critical motility threshold, below which mixing of cells is completely suppressed. Above the threshold, large-scale mixing is enabled. Using an effective phenomenological model parameterized from full simulations, we identify two fundamental mechanisms governing this transition: On the cell scale, weak motility-induced active motion is locally suppressed by growth-induced steric repulsion, consistent with an Active Brownian Particle type description of single-cell dynamics. Beyond this, the expanding nature of the system inhibits global mixing purely geometrically by limiting the exploration range of diffusive cell motion. Both mechanisms naturally scale with the growth rate, highlighting the nature of the transition as an interplay between proliferation and motility. The results provide a baseline for identifying additional biological mechanisms in experiments and could be relevant for competition, heterogeneous tumor evolution and other manifestations of motile proliferating active matter.

BP 10.7 Tue 11:15 BAR/SCHÖ

Fluctuation-Response Theory of Non-Equilibrium Complex Fluids — •Ryota Takaki[1] and Frank Jülicher[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Center for Systems Biology Dresden, Dresden, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany

Active soft materials such as cytoplasm and tissues are constantly driven by chemical reactions and often retain long-lived mechanical memory. In this work, we develop a generalized hydrodynamic framework applicable to non-equilibrium fluids with memory at finite wavevectors and frequencies. Our approach is based on exact correlation-function identities, leading to a fluctuation-response relation for steady states, including non-equilibrium. Applying the theory to chemically driven active fluids, we uncover Active Viscoelastic Memory, in which reaction cycles dynamically renormalize the viscous response and can generate negative storage moduli at finite frequency, absent in conventional viscoelastic materials. Our results provide a first-principles basis for modeling memory-dependent dynamics in a broad class of biological and synthetic active

systems, and suggest concrete rheological signatures of chemical driving that can be tested experimentally.

BP 10.8 Tue 11:30 BAR/SCHÖ

Chemically Active Liquid Bridges Generate Repulsive Forces — •Noah Zierthen — DAMTP, University of Cambridge, UK

Intracellular droplets help organize cells by compartmentalizing biomolecules and mediating mechanical interactions. When such droplets bridge two structures, they generate capillary forces that depend on the surface properties and the separation between the structures. While the forces exerted by passive liquid bridges are well understood, the impact of active chemical reactions, ubiquitous in biological condensates, remains unclear.

Here, we investigate a single liquid bridge with continuous chemical turnover, in which the production and degradation of droplet material maintain a non-equilibrium steady state. In this active bridge, the reactions dynamically set the bridge radius, thereby controlling the force-distance relation. In striking contrast to passive systems, we find that activity can generate purely repulsive forces over a broad range of separations. These results show that chemical activity can qualitatively alter capillary forces generated by liquid bridges, suggesting a potential route for cells to actively regulate mechanical coupling via droplets.

BP 10.9 Tue 11:45 BAR/SCHÖ

Shared Laws of Pattern Formation in Reaction-Diffusion and Phase Separation — •Daniel Zhou[1] and Erwin Frey[1,2] — [1]Arnold Sommerfeld Center for Theoretical Physics — [2]Max Planck School Matter to Life

Many nonlinear field theories generate a strikingly similar repertoire of patterns: arrested coarsening, traveling waves, and spatiotemporal chaos appear both in phase-separating systems and in classical reaction-diffusion models. These descriptions have different physical origins, yet recent studies on Turing mixtures and foams in protein systems [1] and on chemotaxis-driven phase separation in cell populations [2] have already highlighted unexpected connections between these ostensibly different mechanisms, linking foam-like, phase-separating, and reaction-diffusion-type patterns. The present work revisits the relation between kinetic and phase-separating descriptions from a more general viewpoint. A unifying perspective is developed that places different modeling frameworks on comparable footing, identifies the conditions under which they yield effectively equivalent patterns, and suggests how stability criteria and design principles can be translated between them. This points toward a more systematic classification of pattern-forming dynamics that cuts across traditional divides between reaction-diffusion, chemotactic, and phase-separating systems.

BP 10.10 Tue 12:00 BAR/SCHÖ

Spatial self-organization of enzymes in complex reaction networks — •Vincent Ouazan-Reboul[1,2], Ramin Golestanian[2,3], and Jaime Agudo-Canalejo[2,4] — [1]LPTMS, CNRS, Université Paris-Sud, 91400, Orsay, France — [2]Max Planck Institute for Dynamics and Self-Organization, Am Fassberg 17, D-37077, Göttingen, Germany — [3]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, OX1 3PU, Oxford, UK — [4]Department of Physics and Astronomy, University College London, WC1E 6BT, London, UK

Living systems contain intricate biochemical networks whose structure is closely related to their function and allows them to exhibit robust behavior in the presence of external stimuli. Such networks typically involve catalytic enzymes, which can have non-trivial transport properties, in particular chemotaxis-like directed motion along gradients of substrates and products. Here, we find that taking into account enzyme chemotaxis in models of catalyzed reaction networks can lead to their spatial self-organization in a process similar to biomolecular condensate formation. We develop a general theory for arbitrary reaction networks, and systematically study all closed unimolecular reaction networks involving up to six chemicals. Importantly, we find that network-wide propagation of concentration perturbations can be key to enabling self-organization, in a manner which is highly sensitive on the global network structure.

BP 10.11 Tue 12:15 BAR/SCHÖ

Spatial organisation of the cell's metabolic power plant via phase separation — •Kathrin S. Laxhuber[1,2] and Frank Jülicher[1,2] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck School Matter to Life

Cell metabolism is the power plant that fuels the active processes essential to life. Recent experimental results show that glycolytic enzymes, central to sugar metabolism, phase-separate to form foci under energetic stress and can localise to sites of demand. To understand this phenomenon, we build and study a minimal theoretical model. We show that droplet formation can act as a metabolic switch that enables the system to maintain energetic homeostasis at higher output power. Notably, the metabolic droplets that emerge from this switch can self-organise to colocalise with demand. We discuss the non-equilibrium features and spatial energetic profiles in this system.

BP 10.12 Tue 12:30 BAR/SCHÖ

Emergent interactions lead to collective frustration in robotic matter — •Onurcan Bektas[1,3], Adolfo Alsina[2,3], and Steffen Rulands[1,3] — [1]Arnold-Sommerfeld-Center for Theoretical Physics and Center for NanoSciences, Ludwig-Maximilians-Universität München, Theresienstr. 37, 80333 München, Germany — [2]GISC, Universidad Rey Juan Carlos, Tulipán, 28933, Móstoles, Spain — [3]Max-Planck-Institute for the Physics of Complex Systems, Noethnitzer Str. 38, 01187 Dresden, Germany

Current artificial intelligence systems show near-human-level capabilities when deployed in isolation. Systems with intelligent agents are deployed to perform tasks collectively. This raises the question of whether robotic matter, where many learning and intelligent agents interact, shows emergence of collective behaviour. And if so, what kind of phenomena would such systems exhibit? Here, we study a paradigmatic model for robotic matter: a system composed of a large collection of stochastic interacting particles where each particle is endowed with a deep neural network that optimizes its transitions based on the particles' environments. For a 1D model, robotic matter exhibits complex phenomena arising from emergent interactions, including transitions between long-lived learning regimes, the emergence of particle species, and frustration. We also find an abrupt, density-dependent change in the behaviour of particles. Using active matter theory, we show that this phenomenon is a reflection of a phase transition with signatures of criticality. Our model captures key phenomena observed in more complex forms of robotic systems.

Time: Tuesday 9:30–12:45 Location: BAR/0106

BP 11.1 Tue 9:30 BAR/0106

Monitoring of biofilms formation using a QCM-D — •Philipp Sievers[1], Andreas Böttcher[1], Günther Räcker[2], Felix Bosch[2], and Diethelm Johannsmann[1] — [1]Institute of Physical Chemistry, Clausthal University of Technology, Arnold-Sommerfeld-Str. 4, 38678 Clausthal-Zellerfeld, Germany — [2]Feindrahtwerk Adolf Edelhoff GmbH & Co. KG, Am großen Teich 33, 58640 Iserlohn, Germany

Biofilms formed by bacteria are a severe problem in many industries. Biofilm formation leads to biofouling, which limits the heat transfer (e.g. in heat exchangers) or contaminates process water. Regular biofilm removal often is necessary. In order to reduce cost, an online detection of biofilm formation is highly desirable.

An instrument is described, which monitors biofilm formation based on a quartz crystal microbalance with dissipation monitoring (QCM-D). In contrast to a conventional gravimetric QCM, which would rely on the shift in the resonance frequency, the most useful parameter to quantify biofouling was found to be the increase in the resonance bandwidth. This is due to the fact that biofilms consist of soft material loosely attached to the resonator, mostly leading to the dissipation of energy. This behavior is recognized based on a specific overtone dependence of the bandwidth, namely increased bandwidth (**) being the same on the different overtones. This feature is best explained with a mechanical equivalent circuit containing a single dashpot coupled to the resonator surface.

BP 11.2 Tue 9:45 BAR/0106

Following bacterial biofilm formation with X-rays: From scanning gradients towards real-life studies. — •Matthias Schwartzkopf[1], Joanne Neumann[1], Edina Klein[1,2], and Holger Sondermann[1,2] — [1]Deutsches Elektronen-Synchrotron (DESY), Notkestr. 85, D-22607 Hamburg, Germany — [2]Centre for Structural Systems Biology (CSSB), Notkestr. 85, D-22607 Hamburg, Germany

Bacterial biofilm formation is a complex multi-step process yielding microbial communities encapsulated in an extracellular matrix of polymeric substances. Biofilms are a significant problem in treating bacterial infections and are one of the main reasons for the persistence of infections. Their increased resistance to classical antibiotics poses a severe threat to global health issues. Therefore, following and understanding the process of biofilm formation are essential for early detection and suppressing biofilm-associated infections. In this context, surface-sensitive X-ray scattering (GI-SAXS) is successfully applied to observe initial thin film growth morphologies and kinetics at various metal/organic in-

terfaces [Schwartzkopf and Roth, Nanomaterials, 6, 239 (2016)]. In this contribution, we present the capabilities and first results of our combinatorial X-ray study on *Pseudomonas aeruginosa* biofilms aiming to provide nanoscale insight into the structure and dynamics of growing biofilms.

Nonlinear rheology of biofilm streamers: An eDNA-driven stress-hardening mechanism — Giovanni Savorana[1,2] and •Eleonora Secchi[1] — [1]ETH Zurich, Switzerland — [2]Princeton University, US

Biofilms are aggregates of microorganisms embedded in a self-secreted polymeric matrix that protects the community from physicochemical insults, enhancing their resilience across environmental, industrial, and medical settings. Because most biofilms develop in moist, flowing environments, they are constantly exposed to hydrodynamic forces. Yet how biofilms withstand strong or fluctuating flow conditions remains poorly understood.

Our work investigates how biofilms assemble under flow and how their morphology and rheology adapt across different flow regimes. Using a microfluidic platform enabling reproducible formation and in situ rheological testing, we show that biofilm streamers-filamentous assemblies that develop within the bulk of the flow-display stress-hardening: under flow-induced axial stress, both the differential elastic modulus and the effective viscosity increase linearly. This non-linear rheological response is conserved across several bacterial species. We develop a physical model showing that extracellular DNA (eDNA) is the key component enabling this stress-hardening behavior, allowing streamers to withstand both rapid and sustained variations in hydrodynamic load. Our work advances the physical understanding of biofilm development, reveals the molecular drivers of their mechanical resilience, and informs strategies for preventing biofilm-induced clogging.

BP 11.4 Tue 10:15 BAR/0106

Matrix-Microbe-Metabolite: Re-thinking transport phenomena in microbially-active soft matrices — •Juan Pablo Carmona Almazán[1] and Anupam Sengupta[1,2] — [1]Physics of Living Matter, Department of Physics and Materials Science, University of Luxembourg, Luxembourg — [2]Institute for Advanced Studies, University of Luxembourg, Luxembourg

The diffusion of biological metabolites through soft matrices is central to microbial biophysics, mediating healthy microbe-host interactions as well as diverse infections and biodegradation. An interplay of mechano-chemical cues, together with the microbe-induced remodeling of the local environments, impacts the metabolite transport in these settings. Yet, currently, we lack a mechanistic model of the Matrix-Microbe-Metabolite interactions. Here, we use a combination of high resolution imaging and quantitative image analysis techniques to study metabolite transport in diverse synthetic matrices with varying mechanical stiffness, composition, and biochemical complexity. Using suitable fluorescent probes as proxies, we quantify the transport kinetics in agarose as well as Matrigel, a model mammalian extracellular matrix. By interfacing atomic force microscopy, we map the results to the matrix structure, focusing on two key metabolites, formate and citrate. Finally, we embed bacterial cells to capture microbe-mediated impact on the diffusion kinetics, which together with the mechano-chemical datasets, provide a biophysical framework for active metabolite distribution in soft environments.

BP 11.5 Tue 10:30 BAR/0106

Differential pili interactions trigger colony eversion and dissemination of bacteria — Stephan Wimmi[1], •Isabelle Wielert[1], Kai Zhou[2], Marc Hennes[1], Benedikt Sabass[2], and Berenike Maier[1] — [1]Institute for Biological Physics, and Center for Molecular Medicine Cologne, University of Cologne, Germany — [2]Institute for Infectious Diseases and Zoonoses, Ludwig-Maximilians-Universitaet Munich, Germany

Attractive forces between cells determine the shape and sorting behaviour of bacterial colonies. During colony development, chemical gradients form within the colony but it is unclear how they affect cohesion. Here, we discover global eversion of colonies formed by Neisseria gonorrhoeae. Like a jet, the inner core flows towards the periphery where it is partially dispersed and partially spreads around the core of the colony. Living dispersed cells leading to fast dissemination. The eversion depends on local oxygen depletion that reduces cellular attraction: prior to eversion the colony consists of a weakly cohesive spherical core surrounded by a strongly cohesive shell. A computational model reveals when the thickness of the strongly interacting shell falls below a critical value a non-linear instability initiates colony-wide eversion. Simulations predict that an increase of cohesion forces among the bacteria suppresses colony eversion. This was confirmed experimentally by a genetic modification that increases attractive forces among bacteria. Overall, we conclude that a gradient of oxygen pushes the colony out of its equilibrium state and that non-linear instabilities trigger cellular fluxes during relaxation to a new stationary state.

BP 11.6 Tue 10:45 BAR/0106

How substrate stiffness and roughness tune early biofilm development: designing platforms for in situ observation of bacterial behavior — •Mathieu Letrou[1], Sofia Gomes[1], Kennedy Chagua Encarnacion[2], Rebecca Matthias[1], Yeraldinne Carrasco Salas[1], Elena Murillo Vilella[1], Lionel Bureau[1], Karin John[1], Delphine Débarre[1], and Sigolène Lecuyer[2] — [1]Université Grenoble Alpes, CNRS, LIPhy, Grenoble, France — [2]Laboratoire de Physique, ENS de Lyon, CNRS, Lyon, France

Biofilm formation begins with bacterial colonization of substrates, a process that occurs across diverse living tissues and abiotic surfaces. Early bacterial exploration of solid-liquid interfaces, governed by adhesion and individual motility, is a known determinant of the subsequent development and persistence of bacterial colonies. Yet, how bacteria integrate environmental cues at these interfaces and adapt their behavior accordingly remains poorly understood. In this talk, I will present recent experimental approaches to generate microenvironments with precisely controlled properties, that also enable the in situ imaging of bacterial behavior within microfluidic channels. Using the pathogen Pseudomonas aeruginosa, I will show how substrate stiffness, rigidity gradients, and the presence of dispersed obstacles can alter surface exploration, thus modifying the onset of colony formation [1]. These results highlight how physical properties of solid-liquid interfaces can regulate early biofilm development and suggest new avenues for controlling surface colonization.

Physics of bacterial adhesion: heterogeneity, patchiness, and surface interactions — •Karin Jacobs — Saarland University, Experimental Physics & Center for Biophysics, Saarbrücken, Germany

Bacterial cells interact with solid interfaces through a heterogeneous cell envelope, giving rise to rich physical behavior at solid-liquid boundaries. From a physics perspective, bacteria can be regarded as soft objects whose adhesion is governed by collective interactions of many fluctuating macromolecules. In this talk, I summarize recent experimental and theoretical work on bacterial adhesion using concepts from soft matter and surface physics.

Using atomic force microscopy-based single-cell force spectroscopy, we determine interaction forces between individual microbial cells and well-defined substrata. These experiments reveal heterogeneity of adhesion across the surface of single bacteria [1,2]. In particular, Gram-positive bacteria such as S. aureus exhibit a patchy adhesion landscape, reminiscent of patchy colloids, where a small number of adhesive regions dominate surface interactions.

We further show how surface properties such as wettability and protein coatings control bacterial adhesion by modulating the accessibility of tethering macromolecules [3]. Overall, these results place bacterial adhesion in the framework of condensed matter physics and illustrate how physical principles can guide the design of bio-interactive materials, ranging from simple functional interfaces to artificial cells. [1] C. Spengler et al., Soft Matter 20 (2024) 484; [2] E. Maikranz et al., Nanoscale 12 (2020) 19267; [3] F. Nolle et al., ACS Omega 10 (2025).

Bacterial motility and chemotaxis in porous media: lophotrichously flagellated *Pseudomonas putida* exhibits run motility with mechanical trapping and active turning events that enable chemotaxis based on a turn-angle bias — •Sönke Beier[1], Agniva Datta[1], Veronika Pfeifer[1], Robert Grossmann[1], and Carsten Beta[1,2] — [1]University of Potsdam, Institute of Physics, Germany — [2]Kanazawa University, Nano Life Science Institute, Japan

Chemotaxis has been extensively studied in bulk liquid, particularly for the peritrichously flagellated *Escherichia coli* with its run-and-tumble motility, where navigation toward chemoattractants relies on a run-time bias, which extends runs when cells swim up nutrient gradients. Less is known about chemotaxis in environments, where confinement limits free swimming and reduces the effectiveness of a run-time bias. Previous studies suggest that *E. coli* also bias its turning angle, adjusting reorientations to favor subsequent runs toward the chemoattractant. By analyzing the soil bacterium *P. putida* in porous media, we identify run phases and active turning events -known from bulk liquid- and additional mechanical trappings caused by the environment[1]. We provide evidence that the bacterium performs chemotaxis by employing a turn-angle bias and show that the resulting directional preference of runs arises from the active, motor-induced turning events, while passive mechanical trapping in the porous matrix weakens the preference[2]. Agent-based simulations indicate that the turn-angle bias is the predominant chemotactic strategy[2]. [1] Datta et al.:Sci Rep 15, 20320 (2025), [2] Beier et al.:arXiv:2503.05286 (2025)

BP 11.9 Tue 12:00 BAR/0106

Patchy Adhesion of Staphylococcus aureus on Structured Surfaces Uncovered via Single Cell Force Spectroscopy — •Samer Alokaidi[1], Hannah Heintz[1], Michael A. Klatt[1], Markus Bischoff[2], and Karin Jacobs[1] — [1]Saarland University, Saarbrücken, Germany — [2]Institute for Microbiologie, Homburg/Saar, Germany

Investigating bacterial adhesion at the single-cell level provides critical insights into bio-film formation and the influence of surface properties on microbial attachment. This study examines the adhesion behavior of Stapylococcus aureus on wrinkled polydimethylsiloxane (PDMS) surfaces using single cell force spectroscopy (SCFS) [1]. While conventional SCFS typically evaluates a single contact point, our approach-utilizing structured surfaces-enables mapping of adhesion across the lower portion of the bacterial cell envelope. This method reveals considerable variation in adhesion strength at different points on the cell surface, supporting the "patchy colloid" model originally proposed for Escherichia coli. Simulations, incorporating angle-dependent molecule-substrate interactions, suggest that localized adhesive "hotspots" on S. aureus may arise from surface roughness, chemical composition, and the clustering of specific adhesive proteins. These findings emphasize the significance of surface structuring in bacterial attachment and provide insights that inform the design of antimicrobial materials.

Drug interactions between translation and transcription-targeting antibiotics result from differences in ribosome regulation — •Natawan Gadjisade and Tobias Bollenbach — Institute for Biological Physics, Cologne, Germany

Combining antibiotics has the potential to improve treatment efficacy and slow the evolution of resistance. When two antibiotics are combined, their effect on bacterial growth may be stronger or weaker than expected. Recent work has shown that such interactions between ribosome-targeting antibiotics can often be predicted using a biophysical model based on bacterial growth laws. Here, we aim to understand the interplay between translation and transcription inhibitors. We identified different types of drug interactions by measuring E. coli growth in two-dimensional concentration gradients of the transcription inhibitor rifampicin and several translation inhibitors. We systematically quantify proteome allocation and individual protein regulation using mass spectrometry-based proteomics measurements. Notably, some translation inhibitors, such as kasugamycin, exhibit signs of disrupted coordination between the two ribosomal subunits. The ribosome concentration does not increase in response, thus violating the usual growth law. The way ribosomes respond to each translation inhibitor influences drug interactions with rifampicin, which itself causes a decrease in ribosome concentration. Based on the quantification of these different responses, we aim to build a biophysical model of antibiotic action that can explain the interaction patterns. Our work has the potential to facilitate quantitative predictions of drug interactions.

BP 11.11 Tue 12:30 BAR/0106

How transformation affects evolution in changing environments — •Ariana Leu, Mona Förster, Melih Yüksel, and Berenike Maier — Institute for Biological Physics, Cologne

Horizontal gene transfer (HGT) is known to play a critical role in bacterial evolution. However, it is still poorly understood under which exact conditions it can confer a fitness advantage and how it affects the dynamics of an evolving bacterial population. We study the effect of transformation on the adaptation of a bacterial population to a new environment depending on cell history.

First, the laboratory strain is adapted to two different environments, exponential growth in liquid and to growth in a structured environment. The pre-adaptation is driven purely by mutation. By selecting one of the two environments for further evolution we compare the adaptation pathways of a well adapted and a poorly adapted strain. We evaluate the fitness of the evolved populations relative to their ancestor, taking into account the effect of HGT. For well-adapted strains growing exponentially in a liquid environment, we see that the distribution of fitness effects broadens for hybrid populations. In a structured environment the adaptation of a poorly adapted strain is accelerated by transformation. We also find that transformation opens up a new genotypic pathway for adaptation that is not available through mutation. In addition, each cell is labeled with a unique genetic barcode at the beginning of evolution. By analyzing the ratio of barcodes at different time points, we gain insight into the evolutionary dynamics within the population.

Tuning the Tracks: Functional Diversity Encoded in Microtubule Lattice States — •Lukas Kapitein — Utrecht University

Microtubules are active polymers that power intracellular transport and signaling. In cells, functionally distinct microtubule subsets are known to coexist, but the underlying mechanisms that specify these subsets have remained unclear. I will show that microtubule lattice conformation, specifically expanded and compacted states, acts as a tunable structural parameter that regulates both motor-driven transport and cytoskeletal signaling. Whereas expanded lattice states define tracks for Kinesin-1 driven transport, compacted states sequester specific signaling factors, both independently of tubulin chemical modification. These findings identify microtubule lattice plasticity as a fundamental mechanism by which active cytoskeletal matter encodes functional diversity.

BP 12.2 Tue 10:00 BAR/0205

Mechanical tension extends the microtubule lattice and modulates kinesin-1 binding in an isoform-dependent manner — Yannic Lurz[1], Benedikt Fischer[1], Laura Muras[2], Antoine Rittaud[3], Hevré Morhbach[4], Igor Kulic[3], E. Michael Ostap[5], Erik Schaffer[1], and •Serapion Pyrpassopoulos[1] — [1]University of Tübingen — [2]University of Uppsala — [3]ICS, Strassburg — [4]ICPM, Metz — [5]University of Pennsylvania

Recent work has shown that the microtubule lattice possesses remarkable structural plasticity, with its conformation modulated by MAPs and motor binding. However, how this plasticity responds to mechanical forces remains poorly understood. We developed assays to measure the effect of tensile forces on single microtubules using optical tweezers and fluorescence microscopy. Decorating microtubules with quantum dots enabled us to measure, with nm-precision, mechanical distortions of ~0.4% under changes in average tensile force <ΔF> = 10.4 pN, within the rage of Fmin = 1.29 pN to Fmax = 20.4 pN, forces comparable to those generated by one to three kinesin-1 motors. Under forces in this range, the average binding rate of KIF5B decreased by ~20%, while its dissociation rate increased by ~10%, reducing its average run length. In extreme cases, run length dropped by up to 46% under tension. By contrast, no statistically significant effects were observed for KIF5C at the same forces. Together, these experiments provide new insights into how microtubules can act as sensors and transducers of mechanical and biochemical cues across the cell.

BP 12.3 Tue 10:15 BAR/0205

Beyond the tip: lattice dynamics, seams, and the mechanism of microtubule fracture — •Amir Zablotsky[1], Subham Biswas[2], Laura Schaedel[2,3], and Karin John[1] — [1]Université Grenoble-Alpes, CNRS, Laboratoire Interdisciplinaire de Physique 38000 Grenoble, France — [2]Experimental Physics and Center for Biophysics, Saarland University, 66123 Saarbrücken, Germany — [3]PharmaScienceHub (PSH), 66123 Saarbrücken, Germany

The structural integrity of microtubules is paramount for cellular function. While tip behavior has been extensively studied, the dynamics of the microtubule lattice remain less explored. We present a theoretical analysis of lattice fracture mechanisms, focusing on the influence of multi-seam structures arising from monomer defects and aiming to provide a more accurate estimation of GDP lattice parameters.

Our findings reveal that seams function as pre-existing pathways that accelerate damage propagation. Consequently, monomer vacancies destabilize the lattice due to the inherent structural loss of tubulin-tubulin contacts and the additive acceleration of fracture through multiple seams. Furthermore, comparison of our simulations with experiments on lattice fracture suggests that the intrinsic ratio of longitudinal to lateral binding energies is bounded at approximately 1.5, challenging previous predictions of lattice anisotropy from tip-growth models.

These results emphasize the urgent need to revise current microtubule growth models to incorporate parameters obtained from lattice dynamics and reassess their implications for overall microtubule stability and tip dynamics.

BP 12.4 Tue 10:30 BAR/0205

Microtubule mechanics in actin network — •Komal Bhattacharyya, Sarah Köster, and Stefan Klumpp — University of Göttingen, Göttingen, Germany

The cytoskeleton provides structural support while enabling dynamic cellular processes such as growth and migration. Actin filaments and microtubules are key cytoskeletal components: actin is semiflexible, whereas microtubules are comparatively stiff and rod-like. The interplay between these two filament systems underlies many biological behaviors. For example, microtubules exhibit increased resistance to compressive forces when embedded within an actin network. In our work, we use the simulation package Cytosim to investigate composite actin-microtubule networks. In particular, we examine the buckling behavior of microtubules subjected to compressive loads and thermal fluctuations,

and how these responses are altered by mechanical coupling to actin. Our results show that the mechanical response of a probe filament such as a microtubule is governed primarily by its immediate local interactions rather than by the bulk properties of the surrounding network. Indicating the actin network can not influence the microtubule dynamics as an uniform elastic medium but only through direct interactions through crosslinkers or molecular motors.

BP 12.5 Tue 10:45 BAR/0205

Polydispersity-Induced Traveling Waves in Microtubule-Motor Mixtures — •Katrina Wharam[1], Ivan Maryshev[1], Filippo De Luca[2], and Erwin Frey[1] — [1]Ludwig-Maximilians Universität München, Germany — [2]University of Cambridge, United Kingdom

Microtubule-motor mixtures are exemplary active systems that self-organize into a variety of non-equilibrium phases, including asters, bilayers, and active foams. While previous theoretical work has largely assumed monodisperse filament lengths, we investigate a mixture with two microtubule populations of distinct lengths and derive a continuum field theory using a Boltzmann-Ginzburg-Landau approach. Analytical and numerical analysis shows that, despite reciprocal microscopic interactions, the system develops emergent asymmetric behaviour at the macroscopic scale. We identify the filament length ratio as a key control parameter: small length ratios yield stationary nematic bands, whereas increasing the disparity leads to traveling waves - a pattern absent in monodisperse models. Our results reveal a generic, collective route to traveling states in non-self-propelling active matter and connect ad-hoc asymmetric-alignment theories with biologically realistic microtubule systems.

Hold on tight no matter what! How cholesterol and cytoskeletal fibers affect microtentacles formation. — •Enrique Colina Araujo[1,2], Lucina Kainka[1,2], and Franziska Lautenschläger[1,2,3] — [1]Department of Experimental Physics, Saarland University, Saarbrücken, 66123, Germany — [2]Center for Biophysics, Saarland University, Saarbrücken, 66123, Germany — [3]Max Planck School, Matter to Life, Heidelberg, 69120, Germany

Following the formation of a primary tumor, cancer cells in the outer areas may detach and undergo an epithelial-to-mesenchymal (EMT) transition, enabling them to migrate and colonize new tissues, ultimately leading to metastasis. Circulating tumor cells (CTCs) play a key role during this invasion. Invasion can only occur after CTCs have attached to the blood vessel wall and extravasated from the bloodstream. Recent work suggests that such adhesion is mediated by microtubule (MT)-based membrane protrusions, known as microtentacles (McTNs). However, it remains unclear how McTNs protrude from the CTC and how they facilitate cell adhesion. In this work, we analyzed McTN formation in MDA-MB-231 cells. Using the actin depolymerizing drug latrunculin A and the cholesterol-depleting drug methyl-β-cyclodextrin (MβCD), we show that McTNs growth results from a reorganization of the actin cortex into areas of high actin concentration as well as from variations in cholesterol distribution in the plasma membrane of CTCs. Furthermore, McTNs' adhesion is integrin-based. Integrin-β-2 is evenly distributed across the surface of McTN, enabling adhesion at every potential contact with the blood vessel walls.

BP 12.7 Tue 11:30 BAR/0205

Coexistence and selection of branched actin networks — •Valentin Wössner[1,2], Falko Ziebert[1,2], and Ulrich S. Schwarz[1,2] — [1]Institute for Theoretical Physics, Heidelberg University, Philosophenweg 19, 69120 Heidelberg, Germany — [2]BioQuant, Heidelberg University, Im Neuenheimer Feld 267, 69120 Heidelberg, Germany

The actin cytoskeleton is crucial for essential cellular processes such as division, migration, and shape regulation. Most cellular actin structures are continuously turned over while keeping similar sizes. However, they are coupled through a shared and finite pool of actin monomers, which begs the question of how they can control their sizes. For branched actin networks, we suggest that local depletion of actin monomers at the leading edge constitutes a generic negative feedback mechanism between the current state of a structure (filament density) and its growth rate (creation of new branches). We derive a single equation capturing this local feedback and the global competition between different networks. Our theory leads to well-defined steady states even in the case of multiple networks sharing the same pool of monomers, without any need for specific molecular processes, in agreement with recent experiments on reconstituted systems. We also present the phase diagram for the transition from coexistence to selection under increased competition.

BP 12.8 Tue 11:45 BAR/0205

Phase Separation Strength Controls Actin Filament Treadmilling — •Beatrice Nettuno[1], Davide Toffenetti[1], Timon Nast-Kolb[2], Moritz Striebel[1], Erwin Frey[1], and Andreas Bausch[2] — [1]Arnold Sommerfeld Center for Theoretical Physics (ASC), Department of Physics, Ludwig-Maximilians-Universität München, Theresienstrasse 37, München, D-80333, Germany — [2]Heinz Nixdorf Chair in Biophysical Engineering of Living Matter, Technical University of Munich, Ernst-Otto-Fischer Str.8, Garching bei München, D-85748, Germany

Actin treadmilling underlies diverse forms of cellular motility, yet the physical principles enabling stable, persistent turnover remain unclear. In our work, we reconstitute a minimal system in which phase-separated condensates of zyxin and VASP balance cofilin-driven severing to produce robust treadmilling and higher-order actin organization. To uncover the mechanistic basis of this emergent behavior, we develop agent-based simulations that quantitatively recapitulate the experimental dynamics. Our modeling reveals that persistent treadmilling requires an optimal condensate cohesion: phase separation must be strong enough to locally concentrate and crosslink filaments, yet sufficiently fluid to permit barbed-end growth and internal rearrangements. Too weak a cohesion fails to stabilize bundles, whereas overly cohesive condensates suppress filament dynamics and prevent sustained turnover. Together, experiments and theory identify a physical mechanism by which the material properties of multivalent protein condensates regulate cytoskeletal turnover.

BP 12.9 Tue 12:00 BAR/0205

Anisotropic stretch biases the self-organization of actin fibers in multicellular Hydra aggregates — •Anais Bailles, Giulia Serafini, Heino Andreas, Christoph Zechner, Carl Modes, and Pavel Tomancak — Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany

Hydra displays a striking planar pattern of actin fibers at the organism scale, and mechanics influence the morphogenesis of biological structures during its prepatterned regeneration. However, how mechanics participate in the formation of an ordered pattern from a totally disordered state remains unknown. To study this, we used cellular aggregates formed from dissociated Hydra cells, which initially lose all actin polarity yet regenerate a long-range actin pattern. We showed quantitatively that the actin meshwork evolves from a disordered symmetric state to an ordered state in which rotational symmetry is broken, and translation symmetry is partially broken, with the nematic and smectic order parameters increasing over days. During the first hours, the actin meshwork displayed spatial heterogeneity in the nematic order parameter, and ordered domains separated by line defects progressively grew and fused. This suggests that local cell-cell interactions drive the transition from disorder to order. To understand the mechanism of ordering, we perturbed the tissue's physical constraints. We showed that while topology and geometry do not have a direct effect, anisotropic stretch biases the emerging orientation of the actin meshwork within hours. This demonstrates the role of tissue mechanics in the alignment of the actin fibers during the disorder-to-order transition.

BP 12.10 Tue 12:15 BAR/0205

Bridging Scales in the Cytoskeleton: Towards a nonperturbative renormalization group framework — •Patrick Jentsch, Thomas Quail, Niccolò Banterle, and Anna Erzberger — European Molecular Biology Laboratory, Heidelberg, Germany

Microtubules (MTs) and their interactions are microscopically well characterized, yet the connection between these interactions and the emergent, functionally relevant collective behavior of the cytoskeleton remains incomplete. To develop an analytic framework that links these scales, we aim to explore the use of nonperturbative renormalization group (NPRG) methods to derive large-scale effective theories of MT networks from a microscopic model of interacting MTs. Using *Xenopus laevis* egg extract as a model system, we have begun inferring a phenomenological theory of interacting MTs at the micrometer scale based on TIRF microscopy data. In the next stage, this model will be coarse-grained using NPRG methods to obtain an effective description at the millimeter scale, enabling us to track the scale dependence of interaction couplings and the emergence of new dynamical processes. Ultimately, the resulting effective theory will be evaluated by comparing predicted correlation functions with experimental measurements of spontaneously formed MT asters which we are currently imaging using millimeter-scale widefield and confocal techniques.

BP 12.11 Tue 12:30 BAR/0205

Bayesian inference of bond parameters from interactions between single filaments — •Kristian Angeli Pajanonot[1,2], Sascha Lambert[1,2], Pallavi Kumari[1], Stefan Klumpp[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

Interactions among cytoskeletal filaments-actin, microtubules, and intermediate filaments-regulate cell structure, movement, and transport. Single-filament direct interactions can be measured using a quadruple optical tweezers setup. In this approach, filaments are attached to two separate bead pairs held in optical traps and positioned in a cross configuration. As the vertical filament is pulled across the other one, the bond that forms between these filaments experiences increasing mechanical load until it breaks. Previous analysis using Kolmogorov-Smirnov (KS) tests allows for the estimation of bond parameters but lacks a probabilistic interpretation. Here, we present a Bayesian inference framework to estimate bond parameters from the interaction data. Using published data on

the interaction between two vimentin filaments, we show that Bayesian inference provides consistent results with the KS test and with narrower parameter estimates. We then investigate how the pulling velocity influences the bond parameters and find that probing different pulling velocities improves inference compared to using a single velocity. Finally, we apply the method to other cytoskeletal filament interactions demonstrating broader applicability and offering guidance for future experimental optimization

Controlling Cell Motility and Morphology by Microscale Stripe Patterns — •Henrik Groh and Matthias Weiss — University of Bayreuth, Experimental Physics I, 95447 Bayreuth, Germany

Cells are highly responsive to the architecture of the substrate on which they adhere. In particular, cell morphology and motility can be influenced by providing microstructured adhesion patterns, e.g. fibronectin-coated lanes of varying width, as this determines how cellular adhesion sites form and organize. To study this in more detail, we generated fibronectin-coated lanes through the Primo technique with widths ranging from 2.5 μm to 40 μm on which highly migratory breast cancer cells (MDA-MB-231) adhered. As the lane width was changed, cells exhibited significant changes in their morphology, including alterations in aspect ratio and orientation angle relative to the lanes. In addition, the cells' motility, specifically velocity and migration mode composition, underwent pronounced changes as the lane width decreased. Our findings provide important insights into how cell migration might be guided with simple physico-chemical cues and highlight the potential of micro-patterned substrates as a tool for cancer cell migration analyses, possibly providing a core mechanism that underlies cell migration in development and disease.

BP 14.2 Tue 18:00 P2

Computational Modelling of Active-Polymer Dynamics in Gliding Filamentous Cyanobacteria — •Krishna Iyer Vadakkeputhanmadom Subramanian[1], Stefan Karpitschka[2], and Stefan Klumpp[1] — [1]Georg-August University, Göttingen, Germany — [2]University of Konstanz, Konstanz, Germany

Filamentous cyanobacteria such as *Oscillatoria lutea*, *Kamptonema animale* and *Nostoc commune* constitute a natural realization of active polymers: long, flexible filaments that self-propel by gliding motility and whose activity can be tuned with light. Dense colonies display a rich repertoire of collective phenomena—nematic lanes, topologicaldefects, spirals, clusters etc.—yet the physical mechanisms that connect single-filament properties (bending rigidity, propulsion force, reversal rates) to these emergent states remain largely unexplored. We develop a Browinan-dynamics framework, each filament represented as a chain of active particles with tangential self-propulsion and stochastic direction-reversal events, and explore the collective-state phase diagram in the space of activity, rigidity and length of filaments. Through comparisons with experiments, we seek to understand the mechanisms behind reversal events, both at collective and filament levels.

BP 14.3 Tue 18:00 P2

Filamentous cyanobacteria in model complex environments — •Jakob Gönnenwein, Elias Illing, and Stefan Karpitschka — Fachbereich Physik, Universität Konstanz

Cyanobacteria are pervasive throughout most ecosystems, ranging from open water bodies to porous media like soil or sandstone. Their accelerated growth in a warming climate constitutes rising ecologic and economic threats. Besides harmful blooms in natural water bodies, their degrading effect on buildings and sculptures has been identified as a threat to cultural heritage sites.

In our work we investigate the motility, individual behaviour and collective mechanics of filamentous cyanobacteria. We use well-controlled quasi-two-dimensional model porous media that mimic properties of natural habitats like soil or sandstone, while allowing direct observation of their dispersal characteristics. Using this system, we derive characteristic persistence scales of orientational order and density fluctuations in relation to the porosity parameters of the model medium.

Characterizing their collective behaviour in porous media allows us to understand and potentially mitigate their adverse effects on porous structural materials.

BP 14.4 Tue 18:00 P2

Motility Modes and Deformation Dynamics in *Trypanosoma brucei* — •Hannes Wunderlich[1], Marinus Thein[2], Lucas Brehm[2], Geena Eglmeier[2], Klaus Ersfeld[2], and Matthias Weiss[1] — [1]Experimental Physics I, University of Bayreuth, Germany — [2]Laboratory of Molecular Parasitology, University of Bayreuth, Germany

Trypanosoma brucei is a unicellular parasitic microswimmer whose flagellum-driven motion and cell-body elasticity are essential for navigating host environments and maintaining immune evasion.

Although run-and-tumble dynamics have been described for both the procyclic and bloodstream forms of T. brucei, details of motility changes and cell deformation during locomotion remain poorly understood. To address this gap, we performed a comparative analysis of the motility of bloodstream- and procyclic-form trypanosomes in controlled microfluidic environments. Using high-resolution recordings in bulk and in confining single-emulsion droplets (allowing tracking over extended periods), we extracted and analyzed positional trajectories and cell-shape time series. As a result, we reveal marked differences in swimming efficiency and overall motion patterns between the two trypanosome forms. Our findings indicate that cell-body elasticity and deformation play a crucial role in motility and may be directly relevant for biological processes such as surface-protein exchange.

BP 14.5 Tue 18:00 P2

A microfluidic device for probing microbial adhesion phenotypes in light and flow gradients — •Florian Böhme and Oliver Bäumchen — University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany

The unicellular photosynthetic microbe *Chlamydomonas reinhardtii* has naturally evolved the ability to unspecifically adhere to surfaces under sufficient illumination with blue light [1]. Their natural habitats are porous, liquid-infused soil and temporary pools. Thus, the cells regularly experience spatiotemporal light variations as well as external flows. *Chlamydomonas* employs its two cilia to firmly attach to surfaces, a mechanism which is hypothesized to sustain a stable photosynthetic yield while providing protection from external flows at low energetic costs.

We mimic such complex natural habitats by creating artificial microscale flow systems with tailored light and fluid flow conditions. Our microfluidic devices entail sections featuring continuous light-intensity gradients of certain wavelengths. At the same time the cells may experience external flows through precise pressure control in the channels. This allows for quantifying population statistics of microbial adhesion phenotypes in terms of threshold intensities of individual light switches and adhesion strengths during exposure to external flows. Our microfluidic devices can be employed for the high-throughput screening of adhesion phenotypes of wild-type and genetically modified photosynthetic microorganisms.

BP 14.6 Tue 18:00 P2

Active stresses induce bending instabilities and oscillatory dynamics in semiflexible filaments — •Sreehari Choorikkat, Jonas Bosche, Ludger Santen, and Reza Shaebani — Theoretical Physics and Center for Biophysics, Saarland University, 66123 Saarbrücken, Germany

Despite their high structural rigidity, cytoskeletal filaments can undergo large deformations driven by active stresses generated by motor proteins. We investigate

this phenomenon by developing a two-dimensional model in which a discretized filament interacts with an underlying array of molecular motors. Using Monte Carlo simulations, we show that stochastic motor binding and unbinding events can produce a wide range of deformation patterns, including bending, buckling, knot formation, and oscillatory motion. We characterize these dynamical regimes by analyzing the time-resolved mean curvature and by determining how the frequency and amplitude of oscillations depend on key physical parameters such as filament length, bending stiffness, and motor density. Our results delineate the parameter space that supports robust, sustained oscillations and clarify how the coupling between motor activity and filament mechanics generates dynamical instabilities.

Modeling host-pathogen interactions via stochastic simulations and neural network-driven Bayesian inference — •Soham Mukhopadhyay[1], Jonathan Pollock[2], David Voehringer[2], and Vasily Zaburdaev[1] — [1]MPZPM, Erlangen, Germany — [2]Department of Infection Biology, University Hospital Erlangen, Friedrich-Alexander University Erlangen, Germany

Helminth infections affect a large proportion of the world's population and cause significant morbidity. There are no vaccines against helminths, and the mechanisms of anti-helminth immune responses are often not well-understood. Taking the murine hookworm *N. brasiliensis* as our experimental system, we develop a mechanistic model that describes the parasite load in different host organs — which the parasite migrates through over the course of its lifecycle — as a function of time. We abstract infection progression as a state-transition process and simulate it via kinetic Monte Carlo, thereby linking the infective dose of larvae to the number of eggs shed to the environment by adult worms from the host intestines, which can then be compared to experimental data. To infer model parameters — the various transition rates — from experimental data, we employ emerging techniques from the domain of neural network-driven Bayesian inference to infer the posterior probability distribution of parameters conditioned on data. Using this model and inference framework, we plan to compare the population dynamics for different immune perturbations.

BP 14.8 Tue 18:00 P2

Structural Analysis of Cyanobacterial Monolayers — •Rodewald Lars and Karpitschka Stefan — Department of Physics, University of Konstanz, Germany

Cyanobacteria are interesting organisms from several perspectives e.g., due to their ecological importance and biotechnical potential but also as model active matter systems as they constitute active polymers that exhibit a wide variety of collective behavior.

Here we investigate dense quasi-2-dimensional layers of filaments and analyze the patterns that emerge from their motility and mutual interactions. In contrast to molecular systems here the complete microstate of the system can be accessed by optical microscopy, which allows for a more complete understanding and description of the global dynamics and structures including nematic and polar order parameters and defect formation.

In this contribution we discuss the design of a confining structure to generate monolayers while providing a healthy environment allowing for long term experiments. Using this structure we investigate the impact of light intensity on the behavior of the individual cyanobacteria and therefore the structures present the associated emerging order in the monolayer.

BP 14.9 Tue 18:00 P2

Mathematical modeling of larvae motility in complex environments — •Sreya Chatterjee[1], Jhanvi H. Patel[2], David Voehringer[2], and Vasily Zaburdaev[1] — [1]MPZPM, Erlangen,Germany — [2]Department of Infection Biology,University Hospital Erlangen,Friedrich-Alexander University,Erlangen.Germany

N. brasiliensis is one of the most widely-studied helminth parasites due to the relatively simple life cycle for parasite production and its ability to be used in animal models, especially rodents. The larvae mature into adult worms in the lumen of the small intestine, which is composed of mucus produced by goblet cells. Studying their interactions with the surrounding host tissue will help us understand how helminths trigger and modulate immune responses. The mucus layer of the extracellular matrix is viscoelastic which influence their motility. We model these adult worms as active agents exhibiting persistent motion within this viscoelastic environment. To capture their dynamics, we formulate the problem using the well-established framework of Active Brownian Particles (ABPs). As a first step, we study the behavior of a simple system of two ABPs connected by a spring through analytical approaches as well as numerical simulations. Next we will extend this model to simulate N-particles connected by springs to capture a more realistic model of the movement of the worm in viscoelastic environment.

BP 14.10 Tue 18:00 P2

Modeling the aging dynamics of confluent endothelial cells — •Anselm Hohlstamm, Andreas Deussen, Stephan Speier, and Peter Dieterich — Institut für Physiologie, TU Dresden

Coordinated movements of endothelial cells are essential for maintaining the barrier function of blood vessels while adapting to disturbances. Understanding the underlying dynamics of these movements can provide valuable insights into the complex biological processes and help to detect changes under pathophysiological conditions. Therefore, we cultured human umbilical vein endothelial cells and stained their nuclei to enable cell tracking. We obtained several tens of thousands of cell paths with durations of up to 48 hours (dt=10 min). Bayesian inference was applied to estimate model parameters and probabilities. Our analysis revealed an age-dependent reduction of mean cell velocities, with cells never coming to a complete standstill. Furthermore, the velocity autocorrelation function indicated correlated movement patterns that persist for approximately 1-2 hours and may be linked to the movements of neighboring cells. The active motion is further influenced by strong repulsive cell-cell interactions, which become particularly relevant shortly after cell division. By combining elements of generalized stochastic processes and cell-cell-interactions, we constructed models that integrate these characteristics and generate collective dynamics in simulations similar to those observed in experiments. In summary, our study provides a comprehensive characterization of endothelial cell movement dynamics and develops a stochastic model that can be used for future simulations and predictions.

BP 14.11 Tue 18:00 P2

Mechanosensing by active singularities — •Fabian Knüpfer[1], Jonas Neipel[1,2], and Frank Jülicher[1] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck Institute for Molecular Cell Biology and Genetics, Dresden, Germany

During the development of an animal, the self-organized formation of chemical patterns establishes the body plan, defining body axes as well as the midline. However, the overall symmetry of an embryo is typically broken before, in particular due to environmental cues. Here we investigate how mechanical cues can control pattern formation. Motivated by the egg-shell that confines various embryos, we consider a rigid heterogenous substrate coupling to an active fluid surface. We focus on localized centers of mechanical activity, i.e. multipoles and topological defects of the active stress field. We ask how variations in friction and substrate curvature impact on the movement of such active singularities. We show that monopoles of isotropic active tension are advected towards maxima in friction. We then discuss how on a curved surface gradients in Gaussian curvature map to friction gradients to explain the localization of stress multipoles in anisotropic geometries. Finally, we explore how in an active nematic, topological defects move along gradients in friction and substrate curvature.

BP 14.12 Tue 18:00 P2

Swimming With and Against Confined Microscale Flows — •Vishu Saini and Marisol Ripoll — Theoretical Physics of Living Matter (IAS-2), Institute for Advanced Simulation, Forschungszentrum Jülich , Germany

Bacteria in real-world settings are typically navigating heterogeneous porous media, such as soil [1]. Such environments involve a complex interplay between geometric confinement and fluid flow [2], which can be understood as networks of channels with varying cross sections [3]. By means of Brownian Dynamics simulations, we investigate the properties of microswimmers in the presence of both confinement and flow to identify universal mechanisms that microorganisms employ to traverse complex environments. Since self-propelled particles tend to accumulate at the walls, the strength of the flow will determine the upstream or downstream nature of swimming. This will be importantly modified by the intrinsic rotational noise of the self-propelled and the channel width, which is known to vary together with the geometric characteristics of the media. The interaction between self-propelled particles will also importantly affect the dynamics with the formation of percolating clusters. We systematically characterize these dynamics for varying flow strengths and channel sizes, as often encountered in soil-like porous environments.

BP 14.13 Tue 18:00 P2

Synthesis and characterization of platinum (pt)-decorated se-tio2@fcnts nanocomposite and their photocatalytic antibacterial mechanism — •Asif kamal[1], Akhtar munir[2], Jinguang yang[3], and Yingwen wang[4] — [1]Department of Plant Sciences Quaid-i-Azam University Islamabad, 45320 Islamabad, Pakistan. — [2]Department of Chemistry, Quaid-i-Azam University Islamabad, 45320 Islamabad, Pakistan. — [3]Key Laboratory of Tobacco Pest Monitoring, Controlling and Integrated Management, Tobacco Research Institute of Chinese Academy of Agricultural Sciences, Qingdao 266101, China: — [4]Key Laboratory of Tobacco Pest Monitoring, Controlling and Integrated Management, Tobacco Research Institute of Chinese Academy of Agricultural Sciences, Qingdao 266101, China:

The development of efficient and sustainable antibacterial agents is crucial to address the growing threat of multidrug-resistant pathogens. In this study, we report the synthesis and characterization of a novel nanocomposite Pt-decorated

selenium-doped titanium dioxide supported on functionalized carbon nanotubes (Pt/Se-TiO2@FCNTs) with enhanced photocatalytic antibacterial performance under visible light. This new material was synthesized through sol gel method by in situ pt NPs decoration to achieved uniform dispersion and strong interfacial coupling between the components. Comprehensive characterization using XRD, TEM, SEM-EDS, FTIR, Raman, XPS and UV confirmed successful Se doping, Pt decoration, and improved optical absorption in the visible range. The photocatalytic antibacterial activity was evaluated against E. coli and Ralstonia solanacearum.

Laser-cell interactions in a microorganism model: Influence of irradiation with 1064 nm on *E. coli* — •Katja Schmitz and Beatrix Konermann — Trier University of Applied Sciences, Trier, Germany

Lasers are being used more and more in sensor technology, including in biotechnological applications such as fermentation monitoring. However, the biological impact of laser radiation on microorganisms is not clarify understood. Depending on the wavelength, the radiation can induce DNA damage, protein denaturation, or thermal effects, which can inhibit growth or kill cells. Additional parameters, such as irradiation duration and intensity, also influence these interactions.

This study investigates the effects of a 1064 nm laser on the growth and metabolism of *E. coli* under different irradiation conditions. An *E. coli* culture was exposed to a 100 mW laser radiation with variable irradiation times. After treatment, the samples were either cultivated immediately or returned to the culture medium. Growth behavior was evaluated by determining total and viable cell counts, which were then compared to those of untreated reference samples.

Initial results showed no detectable influence of 1064 nm irradiation on cell growth or metabolic processes. A literature review was conducted to contextualize these findings and summarize the reported positive, negative, and neutral effects of laser exposure on microorganisms. These results contribute to a more detailed understanding of laser-cell interactions and highlight the need for further research, particularly regarding wavelength- and organism-specific effects.

BP 14.15 Tue 18:00 P2

Agent-based modeling of short range cell-cell communication — •Ricardo Santander[1,3], Noam Golan[2], Lior Kreindler[2], Avigdor Eldar[2], and Vasily Zaburdaev[1,3] — [1]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [2]School of Molecular Cell Biology & Biotechnology Tel Aviv University, Israel — [3]Friedrich-Alexander-Universität, Erlangen, Germany

We use agent-based simulations to model synthetic gene regulatory networks that mediate short-range cell-cell communication in bacterial monolayers. These circuits couple intracellular dynamics of transcription factors and inhibitors with extracellular concentration fields driven by diffusion, secretion, and uptake of signaling peptides. Individual bacteria are represented as elongating, dividing capsules that act as point-like sources and sinks shaping the extracellular concentration field. The model is nondimensionalized to expose key parameter groups that govern the balance between secretion, import, diffusion, and dilution. Simulations reproduce the influence of nearby inhibitor-producing cells on their neighbors observed in microfluidic experiments and provide detailed insight into how spatial organization and transporter-driven accumulation control signaling range, spatial patterns, and circuit behavior in dense bacterial populations

BP 14.16 Tue 18:00 P2

Effects of extracellular DNA on material properties of bacterial biofilms — •Mandus Aldag, Isabelle Wielert, Stephan Wimmi, and Berenike Maier — Institute for Biological Physics, University of Cologne

Many bacterial species form spatially structured biofilms that protect the bacteria from external stresses. In *Neisseria gonorrhoeae*, a human pathogen, early biofilms are characterized by the formation of spherical colonies with liquid-like local order via active attractions between single cells. An important component of biofilms is extracellular DNA (eDNA), that is predominantly released from lysed cells and is proposed to have biofilm-stabilizing properties. Here, we use a combination of confocal microscopy, laser tweezers and tolerance assays to explore the spatial distribution of eDNA and how it affects structure, dynamics and attractive forces in gonococcal colonies. We find that after 16h of growth, *N. gonorrhoeae* colonies show filamentous, network-like eDNA structures, that can span over large parts of the colony and often interconnect lysed cells. Treatment with DNase prevents the formation of the eDNA network while the spherical colony shape is maintained. Furthermore, we find that the presence of eDNA is associated with a lower bacterial within-colony motility, compared to DNase-treated colonies. The results suggest that even though gonococcal colonies can still form in DNase presence, eDNA affects the cohesive properties of cells within biofilms which potentially influences the biofilm's susceptibility to antibiotics.

BP 14.17 Tue 18:00 P2

Probing Bacterial Adhesion on Functionalized Silicon Surfaces Using AFM-Based Single-Cell Force Spectroscopy — •Hannah Heintz, Hendrik Hähl, and Karin Jacobs — Experimental Physics & Center for Biophysics, Campus E2 9, 66123 Saarbrücken, Germany

Understanding bacterial adhesion to solid surfaces is crucial for biomedical as well as technical applications ranging from implants to antifouling strategies. In this study, we investigate how chemical functionalization and nanoscale roughness influence microbial attachment. We employed silicon surfaces that were modified by (i) coating with octadecyltrichlorosilane (OTS) to render them hydrophobic, (ii) pre-conditioning with a protein film of the hydrophobin HFBI from *Trichoderma reesei*, and (iii) controlled etching with hydrofluoric acid to introduce varying roughness levels. Adhesion forces of *Staphylococcus aureus* and *Shewanella oneidensis* were quantified using Atomic Force Microscopy (AFM)-based Single-Cell Force Spectroscopy (SCFS), employing both polydopamine-mediated and FluidFM vacuum-based cell immobilization. Complementary AFM and confocal microscopy enabled simultaneous characterization of topography, elasticity, and cell wall architecture. Our results reveal distinct adhesion profiles depending on surface chemistry and bacterial species, highlighting the interplay between hydrophobicity and roughness. These findings provide mechanistic insights into biointerface design and pave the way for tailored surface engineering to control microbial colonization.

BP 14.18 Tue 18:00 P2

Exploring Chemotaxis in Magnetotactic Bacteria: A Biophysical Approach — •Diego Roesch — nstitut de Biosciences et Biotechnologies d'Aix-Marseille, Aix en Provence, France

Magnetotactic bacteria (MTB) navigate complex microenvironments by integrating magnetic, chemical, and physical cues. Although magnetotaxis and aerotaxis have been extensively studied, the mechanisms governing chemotaxis in MTB remain largely unexplored, particularly at the level of the bacterial flagellar motor. This work aims to establish a quantitative steady-state model of motor dynamics in Magnetospirillum gryphiswaldense (MSR-1) as a foundation for studying how the motor adapts to and integrates chemical stimuli.

Using tethered-cell assays, high-speed recording, and a custom Python analysis pipeline, individual MSR-1 motors were characterized, revealing three well-defined rotational states: counterclockwise (CCW), clockwise (CW), and pausing. MSR-1 motors exhibited frequent directional reversals and extensive time spent in transient failed-switch pauses, whereas genuine long pauses formed rare but highly persistent states following lognormal distributions, likely reflecting regulatory or mechanistic resets of the motor.

Switching intervals, long pauses, and most run durations follow non-Poissonian, lognormal-like statistics, suggesting structured rather than memoryless regulation. Since MSR-1 possesses two polar flagella, this framework also opens the way to investigate the synchronicity and coordinated behavior of both motors under chemical stimulation.

BP 14.19 Tue 18:00 P2

Controlling transport for RNA enrichment in alkaline hydrothermal vents at the emergence of life — •Mona B. Michelsen[1], Almuth Schmid[2], Dieter Braun[2], and Karen Alim[1] — [1]Theory of Biological Networks, School of Natural Sciences, Technical University of Munich, Garching, Germany — [2]Systems Biophysics, Ludwig Maximilians University, Munich, Germany

Reactive mineral surfaces within alkaline hydrothermal vents (AHVs) at the prebiotic ocean floor are compelling candidates for mediating the accumulation and stabilization of early biomolecules such as RNA. The intricate hierarchical architecture of AHVs, featuring central conduits branching into finely ramified networks, creates dynamic microenvironments that may promote selective adsorption of RNA onto mineral surfaces and enhance local concentrations through flow-driven accumulation. These mineral-RNA interactions could have influenced both the persistence and the catalytic potential of primitive RNA species, potentially facilitating steps toward replication and evolution.

In this project, we apply microfluidics to construct quasi-2D analogues of hydrothermal vents in the laboratory, enabling direct observation of mineral precipitation, flow patterns, and RNA transport under controlled chemical and physical conditions. This approach allows us to investigate how mineral surfaces and flow dynamics influence RNA accumulation and the potential for mineral-assisted RNA catalysis and replication in prebiotic environments.

BP 14.20 Tue 18:00 P2

Molecular Dynamics Simulations as a tool to investigate the impact of novel imidazole-based cholesterol analogs in lipid bilayers — •Clara Rickhoff and Andreas Heuer — Institut für Physikalische Chemie, Universität Münster, Münster, Germany

In biological membrane systems of eukaryotic cells, the cholesterol plays an important role, impacting for example the fluidity and structure of the membrane. To gain a deeper understanding of the behaviour of cholesterol a range of analogs were developed to add functionalities required for lab experiments such as fluorescence to the sterol. In order to investigate cholesterol via these tools, it is es-

sential that the anaolgs show a similar behaviour to that of the wildtype molecule. In a previous study a similar behaviour was observed between a non-charged imidazole-based cholesterol analog (CHIM-N) and cholesterol itself [1].

The present study focuses on a novel group of imidazole-based cholesterol analogs with a more flexible linker between imidazolium and cholesterol and a fully retained cholesterol backbone. Via Molecular Dynamics (MD) Simulations it can be assessed how accurate these new analogs mimic cholesterol in terms of order parameter, tilt angle and position within the membrane. Furthermore, a comparison of the different new analogs as well as with the molecules already applied in cells can be made.

Modelling genome condensation and membrane bending in SARS-CoV-2 — •Nils O. Winkler, Sarah M. Seibert, Falko Ziebert, and Ulrich S. Schwarz — Institut Theoretische Physik & BioQuant, Uni Heidelberg

While many enveloped RNA-viruses use a rigid protein capsid to package and protect their genome, SARS-CoV-2 uses a high density of the transmembrane protein M to structurally reinforce its membrane, which then bends around the viral genome condensed by the cytosolic protein N. Interestingly, the RNA-genome seems to be further subdivided into smaller subunits, leading to a nested egg structure. We theoretically study the energetics of this situation by miminizing appropriate energy functions for genome condensation, membrane bending, droplet wetting and wrapping. In particular, we investigate which of these energy contributions can explain the nested egg structure as observed experimentally.

BP 14.22 Tue 18:00 P2

Modelling Wave Propagation on Monolayers — •Philipp Zolthoff and Jan Kierfeld — TU Dortmund University, Dortmund, Germany

Recent experimental advances have enabled precise studies of pressure wave propagation through monolayers at the air-water interface, triggered by light-induced conformation changes of embedded azobenzenes. We model wave generation and propagation using a fractional Lucassen-type wave equation and compare experimental results on pulse shape and pulse propagation in detail with numerical simulations in order to describe experiments quantitatively and unravel the influence of possible non-linearities and different rheological monolayer models. Particular attention is paid to the question how the influence of non-linearities and rheology changes for different states of the monolayer, i.e., in different regions along its Langmuir isotherm.

BP 14.23 Tue 18:00 P2

A synthetic flow system for modelling the vascular margination effect using microbeads — •Teresa M. Maunz, Alexandra Bienau, Friedrich Simmel, and Karen Alim — School of Natural Sciences, Technical University of Munich, Germany

The margination effect in the blood vasculature causes particles to migrate toward the blood vessel walls due to interactions with red blood cells (RBCs). Margination plays an important role in particle-based drug delivery targeted at the vascular endothelium, which requires contact with the endothelium for delivery. While margination has been studied with simulations and (some) experiments, how to control margination for synthetic particles is underexplored and requires thorough experimental testing of multiple variable parameters. Here, we present a synthetic microfluidic system dedicated to investigating the margination effect. The base system consists of a microfluidic channel carrying a binary suspension of beads, mimicking RBCs and marginating particles. Physiological conditions are emulated by tuning parameters that have been predicted to be crucial for the emergence and prominence of the margination effect, such as vessel diameter, RBC volume fraction, RBC deformability, the size ratio between RBCs and particles, and flow characteristics. We anticipate that our system will contribute to identifying key parameters that enable the margination effect, thereby improving our understanding of blood flow and facilitating the development of future drug delivery testing models.

BP 14.24 Tue 18:00 P2

Effects of perfluorocarbons on lipid monolayers and protein adsorption — •Jaqueline Savelkouls[1], Michael Paulus[1], Christian Thiering[1], Michelle Dargasz[2], Lena Friedrich[1], Mike George[1], Prashant Hitaishi[3], Svenja Hövelmann[3,4], Oleg Konovalov[5], Eric Schneider[1], Gordon Scholz[1], Chen Shen[4], and Metin Tolan[1] — [1]Technische Universität Dortmund, Germany — [2]Universität Siegen, Germany — [3]Christian-Albrechts-Universität zu Kiel, Germany — [4]DESY, Hamburg, Germany — [5]ESRF, Grenoble, France

Lipid monolayers serve as biomimetic models to study structural and functional aspects of protein-membrane interactions, which are essential for understanding physiological functions. Investigating how perfluorocarbon (PFC) effects on these interactions may aid new therapeutic strategies. This study examines the influence of various PFCs on structural changes of lung-surfactant-like DPPA and DPPC monolayers at different initial surface pressures, as well as on the adsorption behavior of surface-active proteins. Experiments were conducted at beamlines ID10 (ESRF, Grenoble) and P08 (PETRA III, Hamburg) under ambient conditions using a combined grazing incidence X-ray diffraction and X-ray reflectivity study. The results demonstrate that the effect of the PFCs on the lipid structure and protein adsorption depends on the chemical characteristics of the PFCs, the lipid type, and the lipid phase. This work will discuss how the adsorption of PFCs at the membrane promotes protein association.

BP 14.25 Tue 18:00 P2

Local dynamical properties of lipid bilayers using Scanning Ion Conductance Microscopy (SICM) — •Eric Lieberwirth[1], Franziska Dorn[1], Regina Lange[1], Una Janke[2], Mihaela Delcea[2], Ingo Barke[1], and Sylvia Speller[1] — [1]Physics of Surfaces and Interfaces, Institute of Physics & LLM, University of Rostock, Germany — [2]Biophysical Chemistry, Institute of Biochemistry, University of Greifswald, Germany

To determine dynamical properties of lipid bilayers, various experimental methods have been established, e. g. contour analysis and fluctuation spectroscopy. Based on Helfrichs theory from 1973 [1], bending rigidity and membrane tension of lipid bilayers can be derived. We demonstrate a local measurement approach by Scanning Ion Conductance Microscopy (SICM) on Giant Unilamellar Vesicles (GUVs) for evaluation of dynamic lipid bilayer properties. Using a nanopipette controlled via a feedback loop to maintain constant membrane-tip distance, we record time traces of local membrane height fluctuations with nanometer precision. In a contour analysis like approach [2], we obtain a bending rigidity of a few $k_B T$ and membrane tension of a few $\mu\mathrm{Nm}^{-1}$. Computation of the power spectral density (PSD) based on [3] combined with a global-local fit provides a second evaluation route with same data set, yielding in similar results. Differences and limitations of both methods are discussed.

Influence of PLIN5 and Lipid Composition on Lipid Droplet Contact Sites with other Organelles — •Mahsa Mohammadian, Shima Asfia, and Ralf Seemann — Department of Experimental Physics and Center for Biophysics, Saarland University, Saarbrücken, Germany

Lipid droplets (LDs) maintain cellular lipid homeostasis through dynamic interactions with other organelles. Understanding how these contact sites form is crucial for uncovering the mechanisms of lipid exchange and signaling. In this study, we used an in vitro model to investigate how lipid composition and the LD-associated protein perilipin 5 (PLIN5) influence contact formation between an LD monolayer and a bilayer membrane. Artificial LDs consisting of triolein and coated with either a DOPE or DOPC monolayer containing PLIN5 or not were incubated with large unilamellar vesicles (LUVs) that mimic the bilayer membrane of the organelle. Using double fluorescence labeling of the LUV bilayer and the core, we can distinguish between fusion of the LUV bilayer with the LDs and stable attachment of LUVs to the LD's surface. Our results show that the probability of fusion between LDs and LUVs is greatly increased for DOPE-coated LDs, while PLIN5 promotes the stable attachment of LUVs to the LD's surface and prevents fusion. These observations illustrate how certain lipid and protein components can modulate contact formation between LDs and membranes in a controlled in vitro system, and provide a basis for future studies on the molecular mechanisms of organelle communication.

BP 14.27 Tue 18:00 P2

Elucidating the dynamics of DNA-based Transmembrane Receptors through Molecular Dynamics Simulations — •Cyrille Ngueldjou Tahabo[1], Doruk Baykal[2], Lorena Baranda Pellejero[2], Andreas Walther[2], and Lukas Stelzl[3,4] — [1]Institute of Physics,University of Johannes Gutenberg,Mainz,Germany — [2]Department of Chemistry,University of Johannes Gutenberg,Mainz,Germany — [3]Institute of Molecular Physiology, University of Johannes Gutenberg, Mainz, Germany — [4]Institut of Molecular Biology, Mainz (IMB), Germany

Building an artificial cell is an essential step to creating artificial life-like systems and a critical step in this endeavour is to design molecular systems which enable the communication of an artificial cell with its environment. Such artificial life-like systems hold great promise for biomedical engineering. By mimicking biological mechanisms to enable the transmission of information from the exterior of artificial cells across membranes to their interior, we will contribute to creating new artificial life-like systems and gain insights to essential biological information processing mechanisms and advance simulation method development, using an atomistic molecular dynamics and Coarse Grained simulations approaches, who can be synthesized to function as receptors in artificial life-like systems. we study DNA attached to an anchor insert in lipid membranes. In the simulations we investigate how Anchor interacts with the membranes and how DNA-Anchor changes local membrane structure.

Ray-based simulation and experimental analysis of red blood cell imaging in brightfield microscopy

— •Aaron Kreis, Sarah Tabea Hermes, Thomas John, and Christian Wagner — Experimental Physics, Saarland University

The interpretation of brightfield microscopy images of red blood cells (RBCs) requires a quantitative understanding of how light propagates through their biconcave geometry. We present a numerical ray-tracing framework that models refraction and reflection at the cell–medium interface according to Snell's and Fresnel's laws, explicitly reproducing the optical configuration of a brightfield microscope. The simulated intensity distributions show excellent quantitative agreement with experimentally measured axial intensity profiles acquired using a conventional inverted microscope. This confirms that geometrical optics adequately describe light propagation through RBCs, as diffraction effects remain negligible for micrometer-scale objects. The approach enables label-free prediction of contrast and focus-dependent image formation, paving the way for future quantitative assays of single-cell oxygenation and advanced label-free imaging.

BP 14.29 Tue 18:00 P2

Photothermal imaging of autofluorescent retinal pigment epithelium (RPE) granules — •Sicheng Tian[1,2], Maryam Ali[1,2], Hanan Alderzy[1,3], Christoph Krafft[1,2], Martin Hammer[1,3], and Daniela Täuber[1,2] — [1]Friedrich Schiller University Jena — [2]Leibniz Institute of Photonic Technology, Jena — [3]Jena University Hospital, Jena, Germany

The retinal pigment epithelium (RPE) plays an important role in the photocycle. RPE cells contain varied amounts of micrometer-sized autofluorescent granules, including melanosomes (M), lipofuscin (L) and melanolipofuscin (ML), whose distribution varies throughout the RPE layer and with increasing age. Non-invasive fundus autofluorescence is used for clinically monitoring the distribution of L and ML. Specific alterations in the distribution of L, ML and M are linked to age-related macular degeneration (AMD)[Bermond et al., IOVS, 2020, 61, 35]. In spite of their importance, their chemical composition is not fully understood. Mid-IR Photo-induced Force Microscopy (PiF-IR) can provide a chemical evaluation of cell and organelle surfaces with less than 5 nm spatial resolution [Ali et al., Anal. Chem., 2025, 97, 23914] by combining powerful infrared illumination with mechanical detection using atomic force microscopy (AFM-IR). We utilized PiF-IR for the investigation of isolated M in a dried droplet. We complemented our study by sub-micron photothermal images using Optical Photothermal Infrared spectroscopy (O-PTIR) under illumination at visible wavelengths. We compare the results to PiF-IR spectra and conventional Fourier-transform IR spectra obtained on membrane phospholipids.

BP 14.30 Tue 18:00 P2

Multimodal imaging with light microscopes and scanning small angle X-ray scattering — •Boram Yu[1], Mangalika Sinha[1], Rita Mendes da Silva[1,2], Ulrike Rölleke[1], Manfred Burghammer[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen, Germany — [2]The European Synchrotron, Grenoble, France

Imaging biological cells using X-rays is a complementary approach to electron and fluorescence microscopy due to their high penetration depth and the possibility for label-free imaging. One such technique is scanning small angle X-ray scattering (SAXS), which enables the acquisition of a real-space overview image with moderate resolution and reciprocal-space information with high resolution of cells in aqueous environment. However, intracellular structures in aqueous environment are very sensitive to radiation; therefore, the investigation of such damage requires additional imaging techniques beyond scanning SAXS. We present a scanning SAXS configuration, which integrates a mobile fluorescence microscope and an on-axis bright field microscope with a microfluidic sample chamber. The microfluidic sample chamber is compatible with X-ray measurement, as well as two microscopes, owing to its very thin design. While the fluorescence microscope enables obtaining correlative images before and after X-ray scanning within a short time span, the bright field microscope produces bright field images simultaneously during the scan. Our approach provides complementary information on specimens to X-ray measurements, thereby demonstrating its applicability in various fields.

BP 14.31 Tue 18:00 P2

Receptor-Mediated Binding Kinetics of Ligand-Functionalized Lipid Nanoparticles for Targeted mRNA Delivery — •Tianyi Cao — Faculty of Physics and Center for NanoScience, Ludwig Maximilians University, Munich 80539, Germany

For targeted mRNA delivery, lipid nanoparticles (LNPs) are functionalized with PEG-lipid tethers that display affinity ligands–such as full antibodies, Fab fragments, or peptides–to enable receptor-specific cell binding.

We establish a quantitative single-cell binding assay to characterize these receptor-mediated interactions using functionalized LNPs. Using time-lapse live-cell imaging on single-cell arrays (LISCA), we track individual particles via fluorophore-labeled lipid components incorporated directly into the LNP membrane. We systematically vary the molar fraction of functionalized PEG-lipids to quantify how ligand density influences binding probability and saturation behavior.

From these trajectories we extract apparent on-rates, binding capacities, and cell-to-cell variability arising from heterogeneous receptor expression. Under controlled shear flow, we distinguish diffusion-limited from reaction-limited binding and quantify how hydrodynamic forces modulate bond formation and stability.

We further extend the framework to multivalent LNPs carrying mixtures of different ligands that target distinct receptors on the same cell. This assay provides a mechanistic, single-cell-resolved readout of receptor-mediated LNP binding, enabling rational optimization of selective mRNA delivery formulations.

BP 14.32 Tue 18:00 P2

Optical properties of red blood cells and refractive index of hemoglobin — •Sarah Tabea Hermes, Agatha Belén Pinto Pino, Thomas John, and Christian Wagner — Experimental Physics, Saarland University

As the determination of the oxygen saturation of whole blood is common practice in medicine, the research of the oxygenation state of individual red blood cells (RBCs) remains challenging. When observing RBCs under a light microscope, the image is a composition of absorption as well as refraction (since the refractive index inside the RBC is higher than in the medium) and further depends on the focal plane, see Poster Aaron Kreis. This is important both for determining the composition of the cell via absorption as well as for edge detection because the refraction leads to "ghost edges". It is thus relevant to research the optical properties of RBCs and in particular the refractive index of the hemoglobin inside the RBCs. This allows for better comparison with numerical simulations and enables to precisely match the refractive index of the medium and the RBCs. We will present a detailed measurements about the refractive index of hemoglobin solutions in comparison with literature values.

BP 14.33 Tue 18:00 P2

Time resolved fluorescence anisotropy of single phalloidin-dye complexed F-Actin fibrils: MD simulation and experiments. — Phillip Seeber[1], •Shangjun Cheng[1,2], Lukas Spantzel[1,3], Rainer Heintzmann[1,2], and Daniela Täuber[1,2] — [1]Friedrich Schiller University Jena — [2]Leibniz Institute of Photonic Technology, Jena — [3]Jena University Hospital, Jena

Phalloidin conjugates are widely used to visualize actin filaments (F-Actin) due to their high binding affinity [1]. Fluorescence polarization imaging adds information on cellular structures known from other approaches [2, 3]. Moreover, super-resolution techniques such as STED and SIM often employ polarization optics. For aligned samples, such as actin filaments, insights in fluorophore orientation and wobbling dynamics will improve the interpretation of experimental results. Here, we apply quantum chemical methods including DFT, TD-DFT and ADC(2) to study the trajectory of the dye*s transition dipole moments during thermal fluctuations. We correlate the MD simulations with fluorescence anisotropy measurements acquired using time-resolved fluorescence lifetime imaging (FLIM) and 2D polarization fluorescence imaging (2D-POLIM) [3]. [1] Melak M., Plessner M., et al. Journal of cell science, 2017, 130, 525. [2] Rimoli, C. V., Valades-Cruz C.A., et al. Nat Commun 2022, 13, 301. [3] Camacho R., Täuber D., et al. Communications Biology, 2018, 1, 157.

Nanomechanical ultrastructure of native skin — •Mario Zerson[1], Martin Dehnert[1], Paul Zech[1], Melanie Knaak[2], Korinna Jöhrens[2], Martin Kaatz[3], and Robert Magerle[1] — [1]Fakultät für Naturwissenschaften, TU Chemnitz — [2]Institut für Pathologie, Klinikum Chemnitz gGmbH — [3]Hautklinik, DRK Krankenhaus Chemnitz-Rabenstein

Native skin has a complex, layered structure across the epidermis and dermis. In this study, we explore the use of atomic force microscopy (AFM) to examine the nanomechanical morphology of skin under controlled relative humidity conditions that maintain water content close to physiological levels. We examined cryosections of native, unfixed rabbit skin with tapping mode AFM and AFM-based nanoindentation measurements. This enables imaging the nanomechanical ultrastructure of the stratum basale in the epidermis and of collagen fibrils in the dermis with 20 nm spatial resolution. The results are compared with optical micrographs of adjacent stained sections of the same specimen and with scanning electron micrographs reported in the literature.

BP 14.35 Tue 18:00 P2

Red Blood Cell shape classification using curvature flow and spherical harmonics — •Nikolas Lerch, Felix Maurer, Diana Örüm, and Thomas John — Universität des Saarlandes

The morphological characterization of erythrocytes deformed due to pathology or disease has traditionally relied on manual assessment, which introduces subjective sources of error and hampers the differentiation of closely related morphologies such as echinocytes and acanthocytes. We present an automated method for the objective classification of deformed erythrocytes. The approach employs a bijective mapping of surface curvature onto a reference sphere via curvature flow and decomposes the resulting features into spherical harmonics. The

resulting spectral signatures enable the assignment of cells to morphologically distinct clusters. The method is quantitative and reproducible, explicitly identifies transient shapes and transition regions between morphologies, recognizing them as such and distinguishing them from clearly defined class expressions, and thereby opens new perspectives for computer-assisted hematology.

BP 14.36 Tue 18:00 P2

Diffusion and deoxygenation/oxygenation of hemoglobin solutions in microfluidics — •Agatha Belén Pinto-Pino, Sarah Tabea Hermes, Thomas John, and Christian Wagner — Experimental Physics, Saarland University

The observation of red blood cells (RBCs) under bright field microscopy allows the study of how absorption and refraction combine to form image contrast. In this work, we use the absorption of light to investigate the diffusion of hemoglobin in water in microfluidic channels. By analyzing how intensity profiles evolve over time, we characterize the diffusion behavior of hemoglobin in water. The setup will also be used to study the transition from deoxygenated to oxygenated hemoglobin, because the absorptions differ strongly for those states, in particular for different wave length of the light. This study helps for a better understanding of the mechanisms that govern oxygen transport in blood.

BP 14.37 Tue 18:00 P2

Implementation of NIR excitation and detection in 2D-POLIM setup — Shangjun Cheng[1,2], •Zilong Huang[1], Rainer Heintzmann[1,2], and Daniela Täuber[1,2] — [1]Friedrich Schiller University Jena — [2]Leibniz Institute of Photonic Technology, Jena

Two-dimensional polarization fluorescence imaging (2D-POLIM) has been used to probe the orientation/rotation of molecules and the Förster resonance energy transfer between closely located chromophores [Camacho et al., Adv. Mat. 2019, 31, 1805671; Camacho et al., Commun. Biol. 2018, 1, 157]. 2D-POLIM can provide full in-plane information on the polarization state of the sample through synchronized control of the excitation and detection polarizations. Near-infrared (NIR) excitation reduces the background from intrinsic autofluorescence in cells and tissue samples. Here, we show a stable, precisely controllable excitation polarization of a 785 nm laser. We also demonstrate the potential of 2D-POLIM in imaging and analysis of molecular orientation in the NIR range.

BP 14.38 Tue 18:00 P2

Metasurfaces for Oblique Plane Microscopy — •Maike Kreutz[1,2], Martijn Moorlag[1], Ibnun Nur Akash[3], Stephan Daetwyler[4], Sara Lelek-Greskovic[5], Ibnun Nur Akash[3], Yijun Wang[3], Chih-Yao Hsu[6], Yu-Chuan Chang[6], Yao-Wei Huang[6], Reto Fiolka[4], Florian Engert[1], Maryna L. Meretska[3], and Fabian F. Voigt[1] — [1]MCB, Harvard University — [2]RWTH Aachen University — [3]INT, Karlsruhe Institute of Technology (KIT) — [4]UT Southwestern Medical Center — [5]SCRB, Harvard University — [6]Department of Photonics, National Yang Ming Chiao Tung University

A promising emerging bioimaging technique is oblique plane light-sheet microscopy (OPM), which allows volumetric imaging using a single scan mirror but suffers from significant losses due to its complex optical path. To enhance the light-collection efficiency of OPMs, we propose to integrate optical metasurfaces into the optical path of an OPM. Metasurfaces utilize sub-wavelength nanostructures for manipulation of electromagnetic fields and can be produced with CMOS-compatible technology. By implementing tailored metagrating designs, we aim to reduce losses in single-objective light-sheet setups.

BP 14.39 Tue 18:00 P2

Lens-free lab-on-chip fluorescence microscopy using angle-stable polariton filters — •Anja Lindenau[1], Andreas Mischok[1], and Malte Gather[1,2] — [1]Humboldt Centre for Nano- and Biophotonics, Department of Chemistry, University of Cologne, Germany — [2]School of Physics and Astronomy, University of St Andrews, Scotland

Fluorescence microscopy is an essential tool in biomedical research but typically relies on complex optical setups with high-numerical-aperture objectives and specialised colour filters, which results in a large footprint and high acquisition costs. Here, we present a modified commercial CMOS image sensor for lens-free fluorescence microscopy. Lens-free imaging enables compact, low-cost systems with a large field-of-view (> 20 mm) and pixel-limited resolution (1.4 micrometer). To overcome the limitations of conventional colour filters, in particular their strong angular dispersion, we integrate a polariton-based filter directly on the sensor. This novel filter design exploits ultra-strong light-matter coupling between photons and material excitons, maintaining a stable long-pass cut-off below 540 nm over a broad range of incidence angles and thereby drastically improving the signal-to-noise ratio. Initial results highlight the potential for high-resolution on-chip lens-free fluorescence microscopy with significantly enhanced image quality.

BP 14.40 Tue 18:00 P2

Construction of Mueller Matrix Polarimeter with a Polarization Camera — •Kathrin Rott — Georg August Universität, Göttingen, Deutschland

A Mueller matrix polarimeter based on a division-of-focal-plane polarization camera has been developed for microscopy. The setup enables spatially resolved measurements of Mueller matrix elements in a single image acquisition, allowing the extraction of polarization parameters such as retardance, diattenuation and depolarization. The setup includes a polarization state generator (PSG) consisting of a linear polarizer and a rotating compensator, and a polarization state analyzer (PSA) implemented through the micro-polarizer array of the camera. This design allows fast measurement of Mueller matrix images with micrometer-scale resolution. Initial work focused on characterizing the camera, including calibration of nonlinear response, sensor homogeneity, polarization angle accuracy and pixelwise extinction ratio. The aim is to enable label-free imaging of biological cell cultures and to investigate whether polarization-based contrast can provide information about microstructures such as the cytoskeleton or nucleus. Unlike tissue samples, which typically exhibit polarization effects, the focus here lies on exploring polarization contrast in single cells. The project combines optical component development with a potential biophysical application and forms the basis for further studies on polarization contrast in cell culture imaging.

BP 14.41 Tue 18:00 P2

Quantification of in vivo flow of blood cells - adhesion cascade — •Khadija Larhrissi[1], Felix Maurer[1], Selina Wrublewsky[2], Alexis Darras[3], and Christian Wagner[1] — [1]Department of Experimental Physics, University Campus, Saarland University, 66123 Saarbrucken, Germany. — [2]Institute for Clinical and Experimental Surgery, Saarland University, 66421 Homburg, Germany — [3]School of Physics, University of Bristol, Bristol, United Kingdom)

Red blood cells (RBCs) constitute the majority of cells in the blood and play a key role in transporting oxygen to tissues and organs. On the other hand, leukocytes, also known as white blood cells (WBCs), make up approximately 1% of the total blood volume in most mammals. The flow of these cells ensures the body's defense against various viral and bacterial infections. The WBCs exhibit two modes of motion: a fast flow mode where they move with the surrounding fluid, and a slower rolling mode where they partly adhere to the wall, whereas RBCs simply flow with the surrounding fluid. In this study, our objective is to examine the influence of geometry and distribution on the flow of WBCs. To achieve this, we used Golden Syrian Hamsters as a model system to quantify the flow of cells by fluorescence microscopy and compare their behavior in different networks of vessels. Additionally, since some WBCs are larger in size than the capillaries they pass through, we will examine the impact of this size difference on their flow.

BP 14.42 Tue 18:00 P2

Visualizing Immune Cell Behaviour in 3D: An Ex Vivo Lattice Lighsheet Microscopy and Analysis Framework — •Anna Schepers[1], Joannah Fergusson[1], Edward Wheeler[1], Jacky Ko[1], Robert Kochl[2], and Marco Fritzsche[1] — [1]Kennedy Institute of Rheumatology, University of Oxford, UK — [2]King's College London, UK

The inherently multiscale immune response is regulated by diverse cell interactions, relying on cues from tissues down to single cells and subcellular structures. The intricate dynamics of the immune system present challenges for the observation of the immune response. A technological advance has been achieved with the introduction of lattice light sheet microscopy (LLSM), allowing fast and gentle imaging of live samples while achieving subcellular resolution. By complementing LLSM-based volumetric imaging with advanced sample handling of ex vivo tissue samples and perfusion imaging chambers, we provide a system that preserves critical physiological complexity. We present a complex data processing and analysis framework for robust 3D segmentation and tracking cells in the complex tissue environment allowing cell profiling from live cell behaviour. We show that in our setup, we can follow single cells and their interactions in volumes several cell layers deep in living samples within their environment, providing nuanced insights into the immune response.

BP 14.43 Tue 18:00 P2

Large-area AFM SmartMapping for contact lens characterization and mechanobiological tissue analysis — •Jörg Barner, Andre Körnig, Joan-Carles Escolano, and Thomas Henze — BioAFM, Bruker Nano Surfaces, Am Studio 2D, 12489 Berlin, Germany

Atomic force microscopy (AFM) provides quantitative nanoscale characterization of soft materials and biological systems, enabling analysis of surface topography, elasticity, and viscoelasticity under physiologically relevant conditions. We applied AFM to two distinct systems: ophthalmic contact lenses and highly corrugated tissues. For lenses, SmartMapping was used to acquire large-area curvature maps (up to several millimeters) combined with localized high-resolution measurements of nanomechanical properties. Silicone hydrogel lenses were analyzed, revealing heterogeneities in elasticity critical for balancing oxygen permeability and comfort. For biological samples, SmartMapping enabled automated imaging of rough, heterogeneous specimens such as 3D tumor spheroids (>100 um) and brain tissue sections (>300 um), capturing stiffness gradients relevant to mechanotransduction and transport. The synchronized XYZ-piezo and AFM head movement ensured reproducible mapping across extended areas without manual intervention, overcoming limitations of conventional AFM in lateral range and throughput. These results demonstrate that SmartMapping in-

tegrates large-scale imaging with nanoscale precision, establishing AFM as a robust platform for material optimization in ophthalmology and spatially resolved mechanobiological studies.

BP 14.44 Tue 18:00 P2

X-ray holo-tomography reveals 3D structure of protein networks and lipid globules in heat-treated egg yolk — •Felix Wittwer[1,2], Nimmi Das Anthuparambil[2], Frederik Unger[2], Randeer Pratap Gautam[2], Silja Flenner[3], Imke Greving[3], Christian Gutt[2], and Peter Modregger[1,2] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Universität Siegen, Siegen, Germany — [3]Helmholtz-Zentrum Hereon, Geesthacht, Germany

Egg yolk is a versatile ingredient for cooking and food processing. As a natural emulsifier, it allows to bind fats and water. Under heating, the texture and consistency of egg yolk changes due to denaturation, aggregation, coagulation and gelation. By using X-ray holo-tomography, we could study the heat-induced changes in egg yolk on the micron to sub-micron length scale. In contrast to other techniques such as electron microscopy, X-ray holography can be used without sample staining, fixation, or drying, which potentially alter or damage the sample. Our results reveal a developing separation between proteins and lipids with fatty components rapidly aggregating into large globules around 40 micrometer in size.

BP 14.45 Tue 18:00 P2

Realignment and realization of polarization-resolved confocal FLIM — •Lizhong Mou[1], Shangjun Cheng[1,2], Subham Adak[1,2], Maryam Ali[1,2], Daniela Täuber[1,2], and Rainer Heintzmann[1,2] — [1]Friedrich Schiller University Jena — [2]Leibniz Institute of Photonic Technology, Jena

Fluorescence lifetime imaging microscopy (FLIM) is an attractive technique in the life sciences that enables quantitative mapping of excited-state lifetimes in the regime of nanoseconds within microscopic images [Le Marois et al., J. Biophot. 2017, 10,1124]. Conventional fluorescence polarization is widely used to assess the orientation and rotation of molecules but typically relies on millisecond acquisition times [Camacho et al., Adv. Mat. 2019, 31, 1805671]. Here, we present an alignment protocol for polarization-resolved confocal FLIM that delivers nanosecond temporal resolution and high-quality imaging. We further investigate time-resolved polarization states of dye molecules from cell and tissue samples.

BP 14.46 Tue 18:00 P2

Physics Informed Neural Networks for Microbial Interaction Network Inference — •Luca Battiston[1,2] and Frank Cichos[1] — [1]Universität Leipzig, Linnestr. 5, 04103, Leipzig, Germany — [2]Helmholtz Centre for Environmental Research GmbH (UFZ), Permoserst. 15, 04318, Leipzig, Germany

Recent advances in machine learning have enabled data-driven modeling of complex dynamical systems, with growing interest in methods that extract meaningful information about the underlying physical laws. Among these, Physics-Informed Neural Networks (PINNs) have emerged as a powerful tool for system identification, particularly in settings where data are scarce or noisy. On the other hand, generalized Lotka-Volterra (gLV) equations are widely used to model microbial community dynamics, provided that the underlying interaction matrix is known. In this work, we aim to reconstruct these interactions by combining PINNs with Least Squares Regression for inference of the interaction network. We evaluate our method using extensive gLV simulations covering a range of interaction matrix complexities and noise levels. Our results demonstrate high accuracy in network recovery and show that the approach retains robustness under measurement noise. This provides a step toward developing a robust and flexible framework for identification of complex interaction patterns in microbial communities.

BP 14.47 Tue 18:00 P2

Experimental Setup for the Irradiation of Organoids with High-Energy Electron Beams — •Laura Andrea Pastor Luque[1], Natascha Thomas[2], Victor Empe[2], Carla Sprengel[1], Antonio Tarzikhan[2], Constantin Aniculaesei[2], Thomas Heinemann[2], Mirela Cerchez[2], and Thomas Heinzel[1] — [1]Condensed Matter Physics Laboratory, Heinrich Heine University, Düsseldorf, Germany — [2]Institut für Laser- und Plasmaphysik, Heinrich Heine University, Düsseldorf, Germany

Organoids are three-dimensional cell systems that mimic key physiological and structural characteristics of human tissues, making them highly relevant models for studying biological responses to ionizing radiation. However, experimental platforms for irradiating organoids with high-energy electron beams remain limited, particularly regarding precise dose control and sample handling. In this work, we present the design and development of an experimental irradiation setup specifically adapted for organoid cultures. The system integrates a high-energy electron beam source with a setup to irradiate organoids samples at different energy ranges (MeV).

Evolution-inspired exploration of pattern formation in reaction diffusion systems — •Ming Hong Lui[1,2] and Erwin Frey[1,2] — [1]Faculty of Physics, Ludwig Maximilian University of Munich, Germany — [2]Max Planck Schools Matter to Life, Max Planck Institute for Medical Research, Heidelberg, Germany

Protein reaction networks often contain complex network topology. Modelling them involves numerous variables such as concentrations, diffusion rates and kinetic coefficients. Each variable adds an additional dimension to the phase space that made sweeping parameters challenging and impedes comprehensive understanding of the full dynamics by demanding assumptions or simplifications of biological systems.

Here, we present an alternative pipeline to full parameter sweeps, to characterize pattern-forming regimes, by applying an evolutionary algorithm. We iteratively bootstrapped parameter combinations that demonstrated instability using linear stability analysis. Together with applying mutations, represented by random displacements on the high-dimensional phase space, we could focus our attention in the vicinity of instabilities to reconstruct a heuristic phase diagram more effective than evenly-spaced parameter sweeps.

We shall demonstrate how this algorithm can be applied to various reaction-diffusion models, where it provided more informed choices of diverse systems to run full numerical simulations on, bridging the gap bewteen analytical and numerical solutions.

BP 14.49 Tue 18:00 P2

Pancreatic Network Morphogenesis — •Yasmin Abdelghaffar[1], Coline Schewin[2], Szabolcs Horvát[3], Monalisa Mishra[2], Lydie Flasse[2], Carl Modes[2,4], Anne Grapin-Botton[2], and Benjamin M. Friedrich[1,4] — [1]Cluster of Excellence Physics of Life, Technical University Dresden, Dresden, Germany — [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [3]Reykjavik University, Reykjavik, Iceland — [4]Center for Systems Biology Dresden, Dresden, Germany

During the course of development, the mammalian pancreatic ductal network remodels from a fully connected plexus to a tree-like branched network optimized for fluid transport. Previous in silico modeling suggested that this remodeling could be guided by flow through the network [1]. However, the physical mechanism of flow sensing in the developing pancreas remains open.

We quantitatively analyze duct network morphology at subsequent developmental time-points, to reverse-engineer putative physical mechanisms of network remodeling. This includes a spatial zonation of statistical network properties and an empirical Murray's law relating duct diameter to hierarchy level (Strahler number). We put forward theoretical descriptions, e.g., of cilia-based flow sensing, which reproduce distinct variants of Murray's law, which could be distinguished by future experiments.

BP 14.50 Tue 18:00 P2

A Mathematical Model of Microlesion-Driven Calcium Signalling in Fibroblast Networks — •Kara Nachtnebel[1,2,3,5], Eric Greto[1,2,3], Anna Möller[1,2,3,6], Christian Maueröder[1,2,3], David B. Blumenthal[6], Vasily Zaburdaev[4,5], and Stefan Uderhardt[1,2,3] — [1]Department of Medicine 3 - Rheumatology and Immunology, FAU und Universitätsklinikum Erlangen — [2]Deutsches Zentrum für Immuntherapie, FAU — [3]Exploratory Research Unit, Optical Imaging Centre Erlangen, FAU — [4]Department of Biology, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU) — [5]Max-Planck-Zentrum für Physik und Medizin, Erlangen — [6]Department of Artificial Intelligence in Biomedical Engineering, FAU, Erlangen, Germany

Resident tissue macrophages (RTMs) maintain tissue homeostasis by continuously sensing and integrating local environmental signals. The interstitial fibroblast network, an omnipresent, self-interconnected system capable of generating intracellular calcium signals and transmitting them to neighbouring cells, provides signals that RTMs can detect and respond to. For example, in response to calcium elevations associated with tissue lesions, macrophages initiate rapid cloaking behaviour. Disruption of fibroblast networks can amplify unwanted immune activation and may contribute to the development of autoimmune diseases. We present a mathematical model of microlesion-induced calcium signalling in gap-junction-coupled fibroblast networks. It shows how microlesions drive signal propagation via intra- and extracellular pathways and quantifies the factors that shape this process.

BP 14.51 Tue 18:00 P2

Equal Partitioning of the Min Proteins at Cell Division — •Natan Dominko Kobilica[1], Nora Deiringer[2], Vitalii Grigorev[3], Antonia Winter[1], Robin Köhler[4], Sean Murray[5], Viktor Sourjik[3], Henrik Weyer[6], and Erwin Frey[1] — [1]ASC, LMU München, Munich, Germany — [2]Technical University of Munich, Garching, Germany — [3]Max Planck Institute for Terrestrial Microbiology, Marburg, Germany — [4]Geomagic, Leipzig, Germany — [5]IMESO-IT, Giessen, Germany — [6]Kavli Institute for Theoretical Physics, University of California, Santa Barbara, Santa Barbara, USA

The pole-to-pole oscillation of the Min proteins in Escherichia coli plays a crucial role in the process of cell division. The oscillation facilitates the formation of the

FtsZ ring, which determines the division site. It is essential that the Min proteins are distributed equally between daughter cells to ensure precise determination of the division site in subsequent divisions. Previously, experiments and stochastic particle-based simulations have linked protein equipartition to the splitting of the pole-to-pole oscillation. Importantly, the splitting is already triggered before the division is fully completed. The goal of this study is to explain the mechanism underlying the splitting of oscillations using the well-known reaction-diffusion equations for the Min System. We model the constriction during cell division as a reduced diffusion rate between the two parts of the mother cell. This already captures the oscillation splitting and agrees well with realistic simulations of the constricting cell. Additionally, we conduct high-throughput microfluidic experiments which align well with the predicted protein dynamics.

BP 14.52 Tue 18:00 P2

Information Processing and Scaling of Spatially Coupled Complex Networks — •Ambar Neel[1,2,3] and Carl Modes[1,2,3] — [1]Max Planck Institute for Molecular Cell Biology and Genetics (MPI-CBG), Dresden 01307, Germany — [2]Center for Systems Biology Dresden (CSBD), Dresden 01307, Germany — [3]Cluster of Excellence, Physics of Life, TU Dresden, Dresden 01307, Germany

Biological adaptive spatial networks are constantly grappling with increasing the efficiency of the network while minimising the metabolic costs. Simulations demonstrate that incorporating fluctuations in a system's sinks/sources leads to the onset of topological complexity in the network. Additionally, it has recently been shown that coupling two spatial networks also results in topological complexity categorised by the existence of loops. This framework is very well suited to investigating information processing in such spatially coupled networks and is thus the focus of this presentation. Along with organ systems such as the pancreas, kidney and bone marrow, the liver is a prime candidate for this analysis as it consists of bile and blood capillary systems that are interwoven. Another challenge is to understand the packing limit of these complex spatial networks by scaling them until a critical point is reached. This provides a meaningful length-scale for the system, allowing for further investigation into fundamental questions regarding geometrical aspects of these spatially embedded complex networks as well as setting up the template to compare these results to experimentally acquired datasets of sinusoids in the liver lobules of mice.

BP 14.53 Tue 18:00 P2

Chimeric RNA-DNA Oligomers Overcome Template-Product Inhibition in Prebiotic Ligation — •Lena Mühlschlegel, Ludwig Burger, and Ulrich Gerland — Physics of Complex Biosystems, School of Natural Sciences, Department of Bioscience, Technical University of Munich, Garching, Germany

The RNA world hypothesis proposes that DNA-based life evolved from a precursor living system that used RNA alone to store genetic information. However, it is unclear how the transition from a system purely based on RNA to one incorporating DNA could have occurred. At the transition, a lack of specificity in the synthesis of genetic polymers in prebiotic systems likely led to the simultaneous emergence of RNA and DNA, involving molecules comprising RNA-DNA nucleotides, which we refer to as chimeric RDNA strands. Because homogeneous RNA-RNA and DNA-DNA duplexes are highly stable, template-product inhibition can impede template-directed ligation. Experimental data show that RDNA-DNA or RDNA-RNA duplexes tend to be less stable than RNA-RNA and DNA-DNA duplexes, suggesting that RDNA strands might overcome template-product inhibition. We developed a nearest neighbor model parametrized by experimental data to predict RDNA hybridization energies as a function of sequence and used it to simulate template-directed ligation of RNA and DNA in the presence and absence of RDNA strands. We found a hybridization free energy regime in which RDNA strands enable the efficient replication of RNA and DNA, providing a potential pathway for the early evolutionary transition from RNA to DNA.

BP 14.54 Tue 18:00 P2

FRET-guided selection of RNA 3D structures — •Mirko Weber[1], Felix Erichson[1], Maciej Antczak[2,3], Vanessa Schumann[1], Josephine Meitzner[1], Tomasz Zok[3], Fabio D. Steffen[4], Marta Szachniuk[2,3], and Richard Börner[1] — [1]Laserinstitut Hochschule Mittweida, University of Applied Sciences Mittweida, Mittweida, Germany — [2]Institute of Bioorganic Chemistry, Polish Academy of Sciences, Poznan, Poland — [3]Institute of Computing Science, Poznan University of Technology, Poznan, Poland — [4]Department of Oncology, University of Zurich, Zurich, Switzerland

Integrative RNA modeling requires structurally validated ensembles and experimental data that reflect binding and folding behavior. However, predicting such structure collections remains challenging due to rugged energy landscapes and extensive conformational heterogeneity. We address these limitations with a FRET-guided selection strategy that identifies RNA conformational states consistent with single-molecule FRET (smFRET) data. We predicted 3D structures of a ribosomal RNA tertiary contact containing a GAAA tetraloop and a kissing loop using RNAComposer, FARFAR2, and AlphaFold3, and validated them based on Watson-Crick base pairing and an eRMSD threshold. For all retained models, we computed accessible contact volumes of the sCy3/sCy5 dye pair using FRETraj and derived FRET distributions, which were weighted against experimental smFRET data. Our results demonstrate that in silico predicted structures can reproduce the experimental transfer efficiencies, and that our selection reliably identifies RNA conformations consistent with the smFRET data.

Intrinsically disordered regulators of endocytosis - an integrated NMR/single molecule fluorescence approach — •Sigrid Milles — Leibniz-Forschungsinstitut für Molekulare Pharmakologie (FMP), Berlin, Germany

Intrinsically disordered proteins (IDPs) lack clearly defined structure and are therefore highly flexible and easily adaptable to different binding partners. This makes them important players in many biological processes, often with vital regulatory functions. Their dynamic features and broad range of interaction modes, however, render them difficult to study and analyzing their complexes often requires integrated approaches. Integrating complementary parameters from of nuclear magnetic resonance (NMR) and single molecule fluorescence approaches allowed us to describe the conformational landscape of IDPs at molecular resolution and promises to shed new light onto various biological processes. Among those counts clathrin mediated endocytosis. The early phases of clathrin mediated endocytosis are organized through a highly complex interaction network mediated by clathrin associated sorting proteins (CLASPs) that comprise long intrinsically disordered regions (IDRs). We characterize the IDRs of those CLASPs in their entirety and at molecular resolution, uncovering a plethora of interactions of various strengths and dynamic features with their endocytic interaction partners, proposing a rationale for how first interactions and dynamic rearrangement of partners take place during the uptake of a coated vesicle.

Adaptive NK cell analysis by t-SNE — •Andrea Schneider[1], Wiebke Moskorz[2], Jörg Timm[2], and Thomas Heinzel[1] — [1]Heinrich-Heine University Duesseldorf — [2]University Hospital od Duesseldorf

High-dimensional flow cytometry data from Natural Killer (NK) cells, collected using a comprehensive panel of typical and adaptive NK cell markers, poses a challenge for the characterization of complex cell subsets. To visualize the complete receptor expression profile in a two-dimensional cellular plot, we applied t-distributed Stochastic Neighbor Embedding (t-SNE) to the multi-parameter dataset. The resulting t-SNE projection successfully resolved distinct immune subpopulations regarding NK cell development and adaptive NK cells. Crucially, the map enabled the simultaneous visualization and comparison of different definitions of adaptive NK cells (including NKG2C+ and FceRIg- subsets within mature NK cells), visually confirming their close relatedness. Furthermore, while CD95 is known to be increased in adaptive NK cells, the t-SNE visualization clearly confirmed that this high expression level is consistently shared across all defined adaptive cell clusters, which were tightly localized within the embedding. This methodology demonstrates the power of non-linear embedding techniques for validating complex immunological phenotypes. Moreover, it establishes a visual framework for comparative studies of NK cells across different patient groups, including Hepatitis C Virus (HCV) seronegative, chronically HCV infected, and HCV resolved donors, with each cohort further stratified by Cytomegalovirus serostatus.

BP 14.57 Tue 18:00 P2

Exploring coarse graining RNA force fields via Machine Learning — •Anton Emil Dorn[1], Emile de Bruyn[1], Fabrice von der Lehr[3], Stefan Kesselheim[1,4], Philipp Knechtges[3], and Alexander Schug[2] — [1]Forschungszentrum Jülich — [2]KIT — [3]DLR Köln — [4]Universität zu Köln

In Protein structure prediction there have been massive improvements recently with the help of machine learning. In RNA structure prediction however the situation is less ideal due too much sparser experimental data. Here we attempt to solve a modified version of the problem by determining a coarse-grained RNA force field for Molecular Dynamics simulations. The data sparsity can here be alleviated by atomistic RNA simulations using proven and established force fields. In a first step we show the viability of this approach with a limited scenario of only small RNA molecules. We also explore different bead numbers for the coarse graining to determine the best approximation.

BP 14.58 Tue 18:00 P2

Segmentation and classification of retinal pigment organelles in fluorescence lifetime imaging microscopy (FLIM) data — •Maryam Ali[1,2], Hala Alhaj Ahmed[3,4], Martin Hammer[4], Rainer Heintzmann[1,2,5], and Ondrej Stranik[1,2] — [1]Leibniz Institute of Photonic Technology, Jena, Germany — [2]Friedrich Schiller University, Jena, Germany — [3]Ernst-Abbe University of Applied Sciences, Jena, Germany — [4]Jena University Hospital, Jena, Germany — [5]Abbe Centre of Photonics, Jena, Germany

Retinal Pigment Epithelium (RPE) granules can be categorized based on their autofluorescence and morphology like Lipofuscin (L), Melanolipofuscin (ML), and Melanin(M)[1]. Fluorescence lifetime measurements reveal another discriminative feature; however, identifying individual granules remain challenging by human eye. Here, we present a computational analysis pipeline for seg-

menting and classifying RPE granules from fluorescence lifetime imaging microscopy (FLIM) data. The analysis was implemented in a custom Python script employing seeded watershed segmentation to isolate individual granules and discriminate hyperfluorescent lipofuscins, characterized by longer lifetimes. Granules with shorter lifetimes were further analyzed by examining their lifetime distribution across their surfaces, allowing MLs to be distinguished from other melanin-rich granules. The proposed approach achieved high performance, with mean sensitivity 87% and mean specificity 98% compared to manually classified ground truth data. [1] K. Bermond et al., IOVS 2020, 61, 35

BP 14.59 Tue 18:00 P2

Modeling the Clustering of Pma1 in the Yeast Plasma Membrane under Starvation — •Annemarie Quas[1], Roland Wedlich-Söldner[2], and Andreas Heuer[1] — [1]Institut für Physikalische Chemie, Universität Münster — [2]Institut für Zelldynamik und Bildgebung, Universität Münster

Starvation of yeast cells leads to the internalization of most plasma membrane (PM) proteins via endocytosis, strongly reducing the overall protein content of the PM. However, the level of the H^+-ATPase Pma1 is hardly affected by starvation. Instead, clustering of Pma1 is observed under these conditions. FF-EM images reveal 2D crystals composed of hexagonal units corresponding to Pma1 hexamers. Interestingly, deletion of Mrh1 blocks the clustering of Pma1. An interplay between the positively charged C-terminus of Mrh1 and the negatively charged phosphatidylserine (PS) is proposed, as Mrh1 is not required for clustering in the absence of PS. Because experimental insight into the mechanism of cluster formation is limited, we employ a coarse-grained Monte-Carlo model to investigate how interactions between Pma1 hexamers can drive large-scale organization. In our 2D model, Pma1 is represented as hexamers with attractive corner-to-corner interactions. By systematically varying particle density and interaction strength, we explore the system's phase behavior and identify conditions under which extended cluster formation emerges. We analyze cluster sizes, time-dependent growth, and characteristic cluster shapes to gain mechanistic insight into how molecular interactions could stabilize the observed protein crystals.

BP 14.60 Tue 18:00 P2

Refining Coarse-Grained Models for Accurate Protein Folding and Mechanics — •Yi-Chen Tsai and Chi-cheng Chiu — National Cheng Kung University, Tainan, Taiwan

Accurately modeling protein folding and mechanical behavior in coarse-grained (CG) simulations requires balancing structural fidelity with physical realism. We develop a mesoscale modeling framework that advances CG protein simulations by integrating refined structure-based and hybrid physics-based approaches. The Gō-type structure-based model is refined by incorporating overlaid native-specific potentials, backbone dihedrals, improper torsions, and sidechain interactions. These additions improve folding accuracy, suppress chiral inversion, and yield more realistic mechanical responses across diverse proteins[1]. Building on this, a hybrid CG approach denoted as GōSPICA is developed by combining native-contact potentials with the physics-based SPICA CG force field. The hybrid model enables spontaneous folding, reproduces native fluctuation patterns and force-extension behavior, and remains fully compatible with membrane environments without relying on elastic network restraints. Together, these developments establish a versatile CG modeling framework for simulating protein behavior in biologically relevant environments.

PINNs based inference in reaction-diffusion systems — •Lukas Pöschl[1,2] and Vasily Zaburdaev[1,2] — [1]Friedrich-Alexander Universität Erlangen-Nürnberg — [2]Max Planck Zentrum für Physik und Medizin

Physics-informed neural networks (PINNs) promise to serve as universal function approximators that embed governing equations and biophysical constraints to operate under noisy, low data conditions. However, PINNs exhibit various training pathologies that limit broad practical application beyond simple benchmarking problems. We identify situations in biophysical models where PINNs fail, including stiff kinetics, sharp gradients and chaotic dynamics and map these to corresponding failure modes in the standard PINN formulation, together with the respective mitigations. We assess this improved formulation on four problems with synthetically generated experimental data. These tasks include the classical forward and inverse problems for parameter estimation and inference of experimentally inacessible species. Furthermore, we address the issue of discovering chaotic and pattern forming dynamics and thus the optimization of experimental parameters to explore these biophysically relevant regimes. Across selected problems, the modified PINNs suggest promising performance in handling the tested systems and the ability to operate with sparse measurements and noisy data.

BP 14.62 Tue 18:00 P2

Self-assembly of sarcomeres by pairwise interactions in muscle fibers — •Amirali Zandieh, Abhinav Kumar, Francine Kolley-Köchel, and Benjamin M. Friedrich — Cluster of Excellence "Physics of Life", Dresden University of Technology

Walking, flying, and heartbeat are powered by the contraction of sarcomeres, the elementary contractile units of striated muscle, which are arranged in series into periodic myofibrils extending across the length of a muscle cell [1]. While the physical principles underlying sarcomere self-assembly remain unclear, recent work on Drosophila indirect flight muscle revealed that myosin motor filaments, Z-disk proteins, and titin/Sallimus form an initial periodic pattern, with actin filaments becoming polarity-sorted only later, motivating 1D minimal models [2].

To develop more realistic 3D descriptions of myofibrillogenesis and capture their cross-sectional organization, we employ ESPResSo [3] for agent-based simulations. With only pairwise interactions, sarcomere-like periodic patterns emerge and become registered in-phase along the transverse direction, as quantified by Kuramoto order parameters. Additionally, the catch-bond behavior of actin crosslinkers enhances and stabilizes this order. Together, these results show that pairwise interactions between sarcomeric components are sufficient to drive the emergence of order, marking a key step toward understanding the physical basis of sarcomere self-assembly.

BP 14.63 Tue 18:00 P2

Assessing the performance of quantum-mechanical descriptorsin physicochemical and biological property prediction — •Alejandra Hinostroza Caldas[1], Artem Kokorin[2], Alexandre Tkatchenko[2], and Leonardo Medrano Sandonas[1] — [1]TUD Dresden University of Technology, 01069 Dresden, Germany — [2]University of Luxembourg, L-1511 Luxembourg City, Luxembourg

Understanding how molecular structure relates to physicochemical and biological properties is essential for computer-aided drug design. A major challenge in applying machine learning (ML) to this problem is defining numerical representations that capture both geometric and electronic information. We introduce the QUantum Electronic Descriptor (QUED) framework [ChemRxiv, doi:10.26434/chemrxiv-2025-hj4dc], which integrates geometric descriptors (BOB, SLATM) with a quantum-mechanical descriptor (D_{QM}) that encodes global and local electronic properties computed efficiently with the DFTB method. We validate QUED on the QM7-X dataset of small drug-like molecules and show that incorporating electronic structure information substantially improves ML predictions of physicochemical properties. For biological endpoints, QUED also demonstrates predictive value for acute toxicity (LD50) in TDCommons-LD50 and for lipophilicity in the MoleculeNet benchmark. Our findings underscore the benefits of integrating electronic structure information with geometric descriptors and highlight the role of conformational diversity in improving the robustness of molecular property prediction.

Modelling neuron growth dynamics and role of extra-cellular matrix — •Mathar Kravikass, Federica Furlanetto, Lars Bischof, Pritha Dolay, Ben Fabry, Sven Falk, Marisa Karow, and Vasily Zaburdaev — Friedrich-Alexander-Universität (FAU)

Biological tissues are composed of cells embedded in extracellular matrix (ECM) and extracellular fluid. We study the role of cell-matrix interactions in the context of brain tissues and the mechanism of neurite growth through this matrix. We consider two modes for the neurite growth: linear growth by tip extension and growth by the traction force at the tip of the neurite with the modeled ECM particles. In a liquid-like ECM model, we demonstrate how growth is influenced by the ECM interactions when the matrix is freely deformable. These growth patterns were also shown to fit to a run-and-tumble process, which describes how the interaction parameters relate to the persistence and speed of the growth. Additionally, solid-like ECMs were considered in which the ECM particles are connected by springs, thus forming a lattice. In this scheme, we were able to study more closely how lattice stiffness affects neurite growth patterns. These simulations recapitulated growth patterns of neurites in organoids models of neurodevelopmental disease and neurite growth in artificial ECMs with controlled properties. Finally, we present how this model could be used in the future to describe more complex systems, such as neuronal network formation.

BP 14.65 Tue 18:00 P2

Motion or Player? Identifying Structural Drivers of Rare Transitions — •Ali Sharifian and Alexander Schug — Scientific Computing Centre, Karlsruhe Institute of Technology, Karlsruhe, Germany

Rare transitions in complex molecular and soft-matter systems are often described by low-dimensional collective variables (CVs) that track progress between long-lived states. Here we distinguish between the motion -pathway in high-dimensional space- and the players -specific atoms, residues, or coarse-grained units- that most strongly drive that motion. With accurate structure

prediction now routine for many proteins, the central challenge is to move from static models to a mechanistic view of functional dynamics based on full ensembles. We present an ensemble-based framework that takes high-dimensional structural data from simulations or experiments and, for any chosen CVs, identifies these structural players. From a structural ensemble and user-defined CVs, we construct the free-energy landscape, determine a minimum-barrier path between metastable states, and define a transition tube that isolates barrier-crossing configurations. Within this tube, a path-conditioned principal component analysis captures transition-specific fluctuations, while time-lagged independent component analysis resolves the associated slow modes. Combining each feature's contribution to variance and slowness into a single importance score yields a ranked map of transition hotspots. These hotspots can guide mutations, targeted coarse-graining, and allosteric drug design across biomolecular and synthetic systems.

Electronic and structural properties of (doped) bilayer systems of graphene and molybdenene — •Sabrina Smid — RWTH Aachen, Worringer Weg 3, 52074 Aachen

Two-dimensional (2D) materials have attracted intense interest since the discovery of semi-metallic graphene in 2004. Owing to its exceptional electronic, thermal, and mechanical properties, graphene has become a key platform for exploring van der Waals (vdW) heterostructures. Stacking different 2D crystals enables emergent phenomena absent in the isolated layers, as exemplified by graphene encapsulated in hexagonal boron nitride, where interfacial screening enhances carrier mobility. The introduction of twist angles in such heterostructures has further unlocked new electronic behavior, including flat-band correlated states in twisted bilayer graphene.

Recently, the emergence of metallic molybdenene, synthesized via microwave-assisted exfoliation of MoS_2, has further expanded the 2D materials landscape. Its intrinsic metallic character and tunable properties in vdW architectures suggest promising opportunities for heterostructure engineering. Motivated by this, we additionally perform density-functional theory calculations on a vdW bilayer composed of semi-metallic graphene and metallic molybdenene, examining how twist angle and carrier doping modify its structural and electronic properties.

BP 14.67 Tue 18:00 P2

Dynamic Generation of Rigidity and Curvature during Clathrin-mediated Endocytosis — •Johannes Dreckhoff, Leon Lettermann, and Ulrich Schwarz — University of Heidelberg, Germany

Clathrin-mediated endocytosis is a main transport pathway across cell membranes, yet the physical mechanisms by which the clathrin coat assembles to drive generation of membrane curvature are not understood well. In particular, it has been argued that bending would not be possible if the coat attained its high stiffness already at the initial stages. Here we address this crucial issue using agent-based kinetic Monte Carlo simulations for coat assembly in spherical geometries with variable curvature. By formulating a microscopic Hamiltonian governing individual clathrin legs, we elucidate the interplay between lattice growth, topological defects, effective membrane stiffness and macroscopic curvature generation. Our simulations reveal that the effective bending rigidity of the coat increases by approximately two orders of magnitude during assembly, driving the curvature generation. We also observed the growth curvature imprinting itself onto the system, resulting in a "curvature memory" effect. Crucially, our simulations capture the distinct dynamical regimes observed in experiments: we successfully reproduce the flat-to-curved transition, while also predicting stalled, flat growth events, potentially driven by premature lattice stiffening. This unifying description demonstrates that clathrin-mediated endocytosis is a multi-facetted process during which rigidity and curvature are generated in a cooperative manner.

BP 14.68 Tue 18:00 P2

Revealing Temporal Hierachy in Larval Zebrafish Behaviour and Its Neuronal Representation — •Leonard Constien[1], Gautam Sridhar[2], Joao C. Marques[3], Drew N. Robson[3], Jennifer M. Li[3], Antonio C. Costa[1], and Claire Wyart[1] — [1]Paris Brain Institute (Institut du Cerveau), Sorbonne University, INSERM U1127, CNRS UMR 7225, Paris, France — [2]Okinawa Institute of Science and Technology 1919-1 Tancha, Onna-son, Kunigami-gun Okinawa, Japan 904-0495 — [3]Max-Planck-Institut für biologische Kybernetik, Tubingen, Germany.

On a given timescale, animal behaviour can be structured into behavioural states, each defined by a similarity of kinematics, immediate goals and physiological states. Further, coarse behavioural state divide into substates, unfolding on faster timescales. How are these states represented in the brain and which structures control their dynamics across timescales? To address these questions, we apply a Markov chain analysis framework to a dataset of larval zebrafish behaviour with parallel recording of whole-brain activity at cellular resolution. The approach identifies behavioural states in a principled and unbiased manner and reveals a hierarchical organization of hunting behaviour from the seconds to minutes timescale. Further, by applying the framework independently on neuronal activity, we reveal a similar structure of the dynamics, identify representing brain regions and investigate the links to behaviour. This work will motivate further studies to determine the circuits and mechanisms behind the regulation of behavioural dynamics.

BP 14.69 Tue 18:00 P2

Dynamic Health Monitoring: Predicting COVID-19 with Wearable Sensor Data and catch22 Features — •Paul Buttkus and Dirk Brockmann — Technical University Dresden (SynoSys), Dresden, Germany

In the initial stages of a pandemic, when intervention leverage is highest, controlling infectious-disease spread hinges on timely detection of emerging cases. The rapid, global transmission of COVID-19 highlighted the need for scalable sensing tools that can pick up early physiological signatures of infection. Using data from the Corona Data Donation Project, which provides resting heart rate, step count, and sleep duration time series from over 120,000 voluntary participants in uncontrolled, real-world settings, we trained regression models to classify COVID-19 test results. Based solely on daily aggregated features, this model achieved an above random guessing success rate, revealing a non-trivial signal despite coarse temporal resolution and strong noise. To better highlight the underlying dynamics, we employ the catch22 (22 CAnonical Time-series Characteristics) feature set to map raw sensor data to a compact set of interpretable descriptors, and additionally extend our framework to higher-temporal-resolution data to incorporate periodicity metrics (e.g., circadian modulation of heart rate and activity) that are lost under daily aggregation. We show which dynamical features are most informative for distinguishing COVID-19-positive from negative individuals and discuss how this framework could turn large-scale wearable data into a real-time surveillance tool for public health.

BP 14.70 Tue 18:00 P2

A Computational Approach to Drug Screening for the Sphingosine-1-Phosphate Receptor Family for Therapeutic Use against Autoimmune Diseases — •Janos Hintze, Tim Bennet Hausmann, Jonathan Hungerland, and Ilia Solov'yov — Institute of Physics, Carl von Ossietzky Universität, Carl-von-Ossietzky-Str. 9-11, 26129 Oldenburg, Germany

Current drugs used in the treatment of multiple sclerosis (MS) often lead to a variety of unwanted side effects. Some of the target proteins in MS treatment are sphingosine-1-phosphate receptors (S1PRs), which form a family of five structurally similar G protein-coupled receptors (GPCRs) that are found in various tissues throughout the human body. In this work, a generative diffusion model was used to design a broad spectrum of novel ligand candidates. To account for receptor flexibility, molecular docking was performed on different protein conformations obtained through molecular dynamics (MD) simulations. Analysis of the generated ligand candidates showed a consistently low similarity to existing S1PR-targeting drugs. Approximately 2000 candidates show a favorable binding affinity and subtype-specific selectivity based on their docking scores. This dataset can be further investigated based on other criteria such as toxicity, synthesizability, and stability, aiming to identify selective ligands for S1PRs, relevant for MS therapy.

BP 14.71 Tue 18:00 P2

Applying a topology sensitive metric for RNA contact prediction — •Christian Faber[1], Utkarsh Upadhyay[1], Oskar Taubert[2], and Alexander Schug[1,2] — [1]Jülich Supercomputing Centre, Forschungszentrum Jülich, 52428, Jülich, — [2]Scientific Computing Centre, Karlsruhe Institute of Technology, 76344, Eggenstein-Leopoldshafen

Predicting the spatial structure of non-coding RNA (*ncRNA*) is an important task for understanding fundamental processes in living nature. Physical force fields are used to infer the structure from a sequence using simulations on high-performance computers. However, the best results are obtained by incorporating probable contacts as additional restraints. These can be derived from evolutionary data using statistical methods or from more recent artificial intelligence (AI) algorithms.

In the past, the focus was on achieving the highest possible proportion of correctly predicted contacts, while the distribution of these contacts on the contact map was overlooked. We have demonstrated the importance of this distribution for structure prediction and have therefore introduced a measure of it.

In our current work, we apply our new metric to a state-of-the-art algorithm *Barnacle*. To achieve this, the algorithms must undergo complete retraining and a new dataset must be generated that avoids data leakage. While our results demonstrate the practical application of such a procedure, they also underscore the challenges posed by the limited availability of data for RNA molecules, a problem which becomes particularly apparent when modelling AI networks.

BP 14.72 Tue 18:00 P2

Structure and Dynamics of Network-Forming Protein Solutions using SAXS and megahertz XPCS — •Adrian Maximilian Roda Lentz[1], Michael Paulus[1], Michelle Dargasz[2], Florian Wieland[3], and Christian Gutt[2] — [1]Department Physics/DELTA, TU Dortmund, Dortmund, Germany — [2]Department of Physics, University of Siegen, Siegen, Germany — [3]Institute of Metallic Biomaterials, Helmholtz-Zentrum Hereon, Geesthacht, Germany

This study explores the structure of networks formed by the biopolymer hyaluronic acid, together with the dynamics of embedded proteins, in this framework ferritin and apoferritin. Hyaluronic acid is a major constituent of synovial fluid and a key component in tissue dynamics and repair; therefore, characterization is essential for advancing biomedical applications. Static Small-Angle X-ray Scattering (SAXS) conducted at P10 (DESY) and BL2 (DELTA) was employed for structural characterization, complemented by megahertz Xray Photon Correlation Spectroscopy (XPCS) at MID (EuXFEL) to quantify the dynamics. First results indicate a pronounced impact of hyaluronic acid on the collective diffusion behavior of proteins.

BP 14.73 Tue 18:00 P2

Quantum mechanical/molecular mechanics (QM/MM) calculations for absorption spectra of photoactive proteins, including many-body screening contributions — •Jelena Schmitz[1,2], Maximilian Graml[1,2], Till Rudack[1,3], and Jan Wilhelm[1,2] — [1]Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, Germany — [2]Institute of Theoretical Physics, University of Regensburg, Germany — [3]Structural Bioinformatics, Regensburg Center for Biochemistry, University of Regensburg, Germany

The GW method and the Bethe-Salpeter equation (BSE) capture many-body screening effects, important for the full quantum mechanical description of excitations in large biological structures. Spectral shifts in photoactive proteins resulting from conformational changes can be described using a hybrid quantum mechanics/molecular mechanics (QM/MM) framework [1]. Our work investigates the impact of incorporating GW+BSE in QM/MM calculations, and examines how larger QM regions influence the accuracy of predicted shifts. We aim to compare to experimental results and QM/MM calculations using different ab initio approaches [1]. In order to perform calculations on larger, non-periodic systems, we are implementing RI-DFT as a pre-calculation method within the CP2K software package, prior to GW. This could provide us with access significantly larger system sizes, even full electrostatic protein surroundings, and therefore even higher accuracies.

BP 14.74 Tue 18:00 P2

Investigating molecular mechanisms of signaling in the multistep phosphorelay system of Magnaporthe oryzae via All-Atom Molecular Dynamics Simulations — •Jonas Paulus[1], Dennis Martin[1], Antonia Preuss[1], Milena Runge[2], Stefan Jacob[2], and Lukas Stelzl[1] — [1]Institut für molekulare Physiologie, Mainz, Germany — [2]Institut für Biotechnologie und Wirkstoff-Forschung, Mainz, Germany

Pathogenic fungi cause an annual loss of 15% of the world's major crops and the phenylpyrrole class of fungicides are upon the most successful to combat these pathogens, precisely because of their specificity and outstanding resistance management. The mode of action (MoA) takes place in a multistep phosphorelay system (MSP) thereby hyperactivating the high osmolarity glycerol (HOG) signaling pathway, but has not yet been clarified in detail on molecular level. Using all-atom molecular dynamics (MD) simulations, we investigate the structural and functional mechanisms of the cytosolic osmosensor MoHik1, its phosphotransfer signaling cascade, and nuclear import of downstream effectors. With this, we aim to design a multidimensional model of signal encryption and fungicide action in fungal MSP systems which will provide both, fundamental insights into fungal signal transduction and the chance to shed light on MSP systems as target for antifungal strategies.

BP 14.75 Tue 18:00 P2

Cryogenic Structural Stability of Human Serum Albumin in Aqueous Solution Studied by SAXS/WAXS — •Lukas Tepper, Michael Paulus, Jaqueline Savelkouls, and Metin Tolan — TU Dortmund, Maria-Goeppert-Mayer-Straße 2, 44227 Dortmund

The behavior of proteins during extreme temperature changes plays a crucial role in the development of stable biopharmaceutical formulations. Freezing and thawing processes are widely used in the production, processing, and long-term storage of protein-based drugs, but they can cause denaturation, aggregation, or loss of biological activity.

Cryoprotectants such as glycerol or other polyols are commonly used to mitigate these effects. They can stabilize proteins and prevent aggregation, among other things by changing the water structure and the hydration shell.

For structural characterization of these processes, Small- and Wide-Angle X-ray Scattering offer direct access to protein conformation, intermolecular distances, and mesoscale ordering phenomena, enabling analysis of proteins in solution without crystallization.

In this work, we use SAXS/WAXS at beamlines BL2 and BL9 at DELTA to study human serum albumin in aqueous and cryoprotective environments during cooling down to −100 °C and subsequent thawing. This allows us to analyze structural changes, stability, and possible reorganization processes across the entire cryogenic temperature range.

BP 14.76 Tue 18:00 P2

Coarse grained simulations for the peptide lge1 1-80 — Agaya Johnson[1], Anton Polyansky[2], Terpsichori Alexiou[1], Bojan Zagrovic[2], and •Sofia Kantorovich[1] — [1]Computational and Soft Matter Physics, University of Vienna, Kollingasse 14-16, 1090 Vienna — [2]Department of Structural and Computational Biology, Campus-Vienna-Bio Centre 5, 1030, Vienna

Due to the structural heterogeneity and fast dynamics of the bimolecular condensates, capturing their organization requires a coarse-grained modeling approach that bridges atomistic details with mesoscale properties. In this work, we develop a coarse-grained model based on atomistic potentials to study the formation of condensates of Lge1, a protein of interest in biomolecular phase separation. We implemented non-bonded interactions for these peptides derived from iterative Boltzmann inversion, with Martini force field parameters and votca tool kit into the espresso simulation package. We employ cluster analysis as a criterion to ensure that all these CG models retain key features of the self-assembly and phase separation comparatively, as it is observed in atomistic simulations. By leveraging CG modeling, we extend simulations to longer timescales and larger system sizes, enabling us to explore whether biomolecular condensates form through phase separation, self-assembly, or aggregation. Our approach provides insights into the structural transitions of Lge1 within condensates and the fundamental mechanisms governing these transitions. This work contributes to the development of predictive models for biomolecular organization in crowded cellular environments.

BP 14.77 Tue 18:00 P2

Investigating the binding of clients to small heat shock protein 16.5 using electrospray ion bean deposition and cryogenic electron microscopy — •Manami Imada, Noor Naseeb, and Stephan Rauschenbach — University of Oxford, Oxford, UK

Small heat shock proteins (sHSP) act as the first line of defence, preventing protein aggregation. sHSP do this by binding to the protein under stress to form a stable complex. We explore how these sHSPs bind to clients such as lysozymes using cryogenic electron microscopy (cryo-EM). However, sHSP are hard to image due to their dynamic nature and potential to form different oligomers.

Electrospray ion bean deposition (ES-IBD) is used to deposit the sample onto the cryo-EM grids. ES-IBD utilises native mass spectrometry (nMS), which transfers the complexes into the gas phase intactly and allows for mass filtration of the ion beam by a quadrupole. This allows specific complexes and binding stoichiometries to be deposited selectively onto the cryo-EM grids to be imaged.

BP 14.78 Tue 18:00 P2

Sparse sampling in single molecule spectroscopy — •Sebastian Stadler and Markus Lippitz — Universitätsstraße 30, 95447 Bayreuth

Single-molecule spectroscopy (SMS) is fundamentally limited by photobleaching, leaving only a short time window to record spectra from individual emitters. These constraints motivate measurement strategies that extract maximal information from minimal data. Sparse sampling provides a compelling alternative to traditional Fourier spectroscopy, which requires dense, uniformly spaced measurements to satisfy the Nyquist condition. In contrast to traditional Fourier spectroscopy, sparse or sub-Nyquist sampling enables accurate spectral reconstruction from substantially reduced datasets.

In this theoretical study, we explore optimized sparse sampling strategies using simulated single-molecule spectra. By systematically varying sampling patterns, we identify regimes and procedures in which sparse acquisition offers significant gains in efficiency without compromising spectral fidelity. As a conceptual example of such optimized strategies, we discuss the pathway toward sampling optimization based on ensemble spectra and adaptive sampling approaches that iteratively adjust measurement points based on previously obtained information.

Our results outline design principles for efficient measurement protocols and highlight the potential of sparse acquisition to push SMS beyond traditional limits imposed by photobleaching and limited interrogation time.

BP 14.79 Tue 18:00 P2

Single-molecule PIE-FRET and nsFCS Studies of Metal Ion-dependent Folding of an rRNA Tertiary Contact — •Mara Henschel[1], Vanessa Schumann[1], Andreas Hartmann[2], Michael Schlierf[2], and Richard Börner[1] — [1]Laserinstitut Hochschule Mittweida, Mittweida, Germany — [2]Technische Universität Dresden, Dresden, Germany

Tertiary interactions in ribosomal RNA are crucial for shaping the folding landscape. However, the dynamics of these interactions across different timescales are not well understood. We investigate the tertiary contact of a double fluorescent-labelled ribosomal RNA from Saccharomyces cerevisiae at the single-molecule level in vitro. We quantify metal-ion-dependent folding and dy-

namics during K(I) and Mg(II) titrations using single-molecule PIE-FRET as a nanometre-distance readout combined with nanosecond fluorescence correlation spectroscopy (nsFCS). FRET-histograms reveals ion-dependent broadening beyond shot noise, indicating structural dynamics on the microsecond to millisecond timescale. Furthermore, nsFCS measurements show fast domain motions ranging from nanoseconds to microseconds. By employing two complementary labeling schemes, we distinguish local folding of the kissing loop from formation of the long-range tertiary contact, resolving distinct folding trajectories within the same RNA construct. Our results provide a dynamic insight of rRNA tertiary-contact formation and lay the foundation for a quantitative, mechanistic model of metal-ion-regulated folding of ribosomal RNA.

Multiplexed magnetic tweezers for high-throughput measurements — •Leonhard Schatt, Stefanie D. Pritzl, Alptuğ Ulugöl, and Jan Lipfert — University of Augsburg, Augsburg, Germany

Single-molecule techniques, such as magnetic tweezers, are powerful tools for studying forces and torques on the nanoscale. However, throughput in single-molecule measurements can still be limiting. To solve this problem, we present a multiplexed magnetic tweezer setup that can perform real-time high-throughput force and torque measurements. In addition, our setup enables controlled excitation in the UV and visible range, to study the response to photo-triggers and photo-excitation.

BP 14.81 Tue 18:00 P2

Pulling Geometry as a Design Parameter for Coiled Coil-Based Molecular Force Sensors — •Laura M. Wolfthaler[1], Zeynep Atris[2], Angelo Valleriani[2], Russell J. Wilson[1,2], and Kerstin G. Blank[1,2] — [1]Johannes Kepler Universität, Linz, Austria — [2]Max Planck Institute of Colloids and Interfaces, Potsdam, Germany

Molecular force sensors (MFSs) measure piconewton-scale forces central to cell adhesion, migration and differentiation. While DNA-based MFSs are well established, their functionalization requires multistep chemistry. We introduce a protein-based MFS building block derived from heterodimeric coiled coils (CCs). Building on our prior work showing how CC length, helix stability and core packing shape mechanics, we now identify pulling geometry as a powerful and versatile parameter for tuning CC mechanical stability without altering thermodynamic or kinetic properties. Using atomic force microscope-based single-molecule force spectroscopy, we applied force parallel and perpendicular to the CC superhelix and observed strongly geometry-dependent rupture forces, including distinct responses for the two shear modes of a 4-heptad heterodimer. These results highlight how local helix stability and structural anisotropy determine CC mechanical behavior. This work establishes a foundation for using MFSs across a wide range of cell culture applications. Their ability to report forces at molecular scales could transform how mechanical signaling is studied at cell-material interfaces.

BP 14.82 Tue 18:00 P2

Thermal noise particle tracking and interaction measurements at interfaces under minimal external force — •Nils le Coutre and Alexander Rohrbach — Bio- and Nano-Photonics, IMTEK, University of Freiburg, Germany

Forces play a vital role in experimental biophysics. From receptor-binding studies to flow-drag analysis, understanding the magnitude, direction, and origin of these forces is essential for uncovering underlying mechanisms. Optical tweezers are widely used in this context because they not only enable the measurement of biophysical interactions, but also deliberately manipulate a biological system to trigger and observe otherwise highly unlikely yet relevant interactions between the system's individuals.

To leverage this advantage for studying specific interaction processes, a robust understanding of the probe position distributions, defined by both the trapping and the surface potential and the interferometric tracking response is required, especially near interfaces and surfaces such as cell membranes. We discuss the question how far an optical trap has to approach an interface such that a natural interaction process between two binding partners is enabled (e.g. receptor on surface and ligand in optical trap).

In this presentation, I expound experiments by exploring the underlying theory and by conducting benchmark measurements in electrolyte-controlled systems, characterizing the behavior of trapped probes as their microscopic environment is altered.

BP 14.83 Tue 18:00 P2

Plasma elastic properties in cross microchannels — •Michelle Kron, Joséphine Van Hulle, and Christian Wagner — Experimental Physics Saarland University

Cross-slot microfluidic geometries produce planar extensional flows and are used to investigate flow instabilities in Newtonian and complex fluids. In Newtonian liquids, an inertial instability produces a steady vortex beyond a critical Reynolds number. In viscoelastic polymer solutions, elastic stresses near the stagnation point lower this threshold. Here we investigate human plasma, which is weakly elastic under extensional flow. Using cross-slot experiments, we quantify how plasma elasticity shifts the Reynolds number threshold for vortex onset and compare the impact of common anticoagulants on this response. We show that plasma reduces the Reynolds-number threshold for vortex onset, underscoring the importance of considering its weak elasticity for physiological studies.

BP 14.84 Tue 18:00 P2

Effective binary models of multicomponent phase separation — •Henri Schmidt and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

Biological cells rely on biomolecular condensates for spatiotemporal organization. Condensates consist of many differently interacting biomolecules, which leads to a rich and complex configuration space.

Yet, only a few types of molecules can be measured in experiments, and the resulting phase behavior is typically explained using low-dimensional models. To understand the conditions under which such dimensionality reduction is feasible, we numerically explore multicomponent phase separation and ask when the behavior of a particular component can be explained by simple binary phase separation. This is surprisingly often the case, even when the unobserved components undergo phase separation on their own. However, the predicted interaction parameters and molecular volumes typically deviate from their true values, indicating that the reduction introduced systematic measurement errors.

Understanding the details of the dimensionality reduction will allow us to better probe multicomponent phase separation by observing a few components in the future.

BP 14.85 Tue 18:00 P2

Dynamics of tissue sampling of resident tissue macrophages — •Miriam Schnitzerlein[1,2], Eric Greto[3,4], Stefan Uderhardt[3,4], and Vasily Zaburdaev[1,2] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen — [3]FAU und Universitätsklinikum Erlangen — [4]Optical Imaging Competence Center Erlangen, FAU

Resident tissue macrophages (RTMs) are a type of immune cell present in essentially every tissue in the human body. One of their main functions is to keep the tissue in homeostasis by resolving lesions or removing dead cells, thereby preventing unnecessary inflammation and avoiding collateral damage to the tissue. To find such incidents, RTMs show continuous sampling behaviour by extending and retracting cell protrusions. This sampling behaviour needs to be tightly regulated - due to finite amounts of available cell cytoplasm and membrane - while still guarding the entirety of the tissue.

In this project, we have employed a high-resolution, intravital imaging protocol to generate dynamic data of murine RTMs in vivo in the peritoneum. Next we have built a custom image processing pipeline to segment RTM protrusions and their dynamic behaviour. We could then analyse the sampling range of protrusions and found correlations between outgrowth and shrinking of protrusions. Furthermore, the data hints at a division of labour approach protrusions employ when scanning the tissue.

BP 14.86 Tue 18:00 P2

Bottom-up emergence of a primitive replicator — •Magdalena Häupl, Ivar Haugerud, and Christoph Weber — Faculty of Mathematics, Natural Sciences, and Materials Engineering: Institute of Physics, University of Augsburg, Universitätsstraße 1, 86159 Augsburg, Germany

Non-equilibrium selection pressures were proposed as a mechanism of forming oligonucleotides whose sequences encode rich functionalities, including catalysis. Since phase separation was shown to direct various chemical processes, we ask whether condensed phases can provide mechanisms for sequence selection.

To answer this question, we develop a non-equilibrium thermodynamic theory to describe oligomerization, templated ligation, and sequence fragmentation away from equilibrium and under non-dilute conditions prone to phase separation.

We show the emergence of a strong selection mechanism. Most strikingly, a primitive replicator arises that is solely based on the inter-sequence interactions that drive sequence condensation. These results highlight that out-of-equilibrium condensed phases may provide versatile hubs for Darwinian-like evolution toward functional sequences, both relevant for the molecular origin of life and de novo life.

BP 14.87 Tue 18:00 P2

Wetting of Chemically Active Condensates on Membranes — •Mengmeng Wu and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany

Droplets undergo partial spreading, division, merging, engulfment, and exocytosis in cellular environments. When these droplets are chemically active, as is common for many condensates in cells, the resulting long-range fluxes further enrich and modify these behaviors. To analyze the interplay between chemically active droplets and membranes, we develop a coarse-grained molecular dynamics model together with a continuum theory based on Cahn-Hilliard

reaction-diffusion dynamics coupled to membrane curvature elasticity. Our approach demonstrates how chemical reactions and the resulting fluxes control both droplet morphology and membrane deformation, providing physical insight for cellular condensates as well as for the design of synthetic responsive membrane-droplet systems.

BP 14.88 Tue 18:00 P2

staged self-organized attack mechanisms of camponotus japonicus against intruders — •YIFAN ZHANG and ZHANGANG HAN — School of Systems Science, Beijing Normal University, Beijing, China

Social insect colonies display complex collective behaviors that emerge from local interactions, enabling decentralized strategies to counter external threats. Although ant collective activities such as foraging and nest construction are well studied, the self-organized attack mechanisms ants employ against specific intruders remain poorly understood. Using the camponotus japonicus and earwigs as research subjects, we show that ants exhibit a staged escalation pattern when confronting an invader: from individual probing, to small-group containment, and ultimately large-scale coordinated assaults. Building on a master-equation framework, we establish continuous-space dynamical equations and propose an ant attack behavior model to characterize these processes. Notably, the collective attack displays strong nonlinear synergy*six ants generate an attack intensity far exceeding a simple tripling of that from two ants. These findings highlight the adaptive advantages of coordinated aggression, demonstrating how cooperative interactions among individuals greatly amplify group-level defensive efficiency. Our study offers new insights into how decentralized biological systems achieve swarm intelligence and produce emergent combat behavior, and clarifies the role of self-organization in shaping effective group decision-making.

BP 14.89 Tue 18:00 P2

Protein self-assembly, infinitely complex yet simple? — •LUKAS KALVODA[1] and MARTIN LENZ[1,2] — [1]LPTMS, CNRS, Université Paris-Saclay — [2]PMMH, CNRS, ESPCI Paris, PSL University

Cells rely on protein self-assembly to form functional complexes, but a lack of regulation gives rise to pathological fibers in diseases like Alzheimer's and sickle cell anemia. Why proteins robustly form these well-defined morphologies is largely unknown.

Beyond the molecular details, the complexity of proteins in shape and interactions suggests that their self-assembly may be governed by the laws of statistical physics. We introduce an analytical lattice model of anisotropic self-assembling particles to study what we term the "infinite complexity limit". Therein the number of distinct interactions grows to infinity. Strikingly, in this limit, the "molecular" details of the interactions do not matter anymore. Instead their distribution and extreme value statistics determine the self-assembly outcome.

BP 14.90 Tue 18:00 P2

From Individuals to Waves: Mechanisms Shaping Collective Responses in Sulphur Mollies — •BIANCA PACINI[1], YUNUS SEVINCHAN[1,3], DAVID BIERBACH[2,3], KORBINIAN PACHER[2,3], JENS KRAUSE[2,3], and PAWEL ROMANCZUK[1,3] — [1]Institute for Theoretical Biology, HU Berlin, Berlin, Germany — [2]Leibniz-Institute of Freshwater Ecology and Inland Fisheries, Berlin, Germany — [3]Science of Intelligence, TU Berlin, Berlin, Germany

Collective biological systems, from neuronal networks to animal groups, exhibit the remarkable ability to rapidly modify their collective behaviour in response to changing environmental cues. By integrating local interactions with external information, they achieve flexible and coordinated group-level responses.

We investigated large fish shoals of sulphur mollies (*Poecilia sulphuraria*) in Southern Mexico, which perform collective diving cascades as a response to predation, producing wave-like patterns on the water surface. Interestingly, as a form of collective perception, we found that the group responds as a unified entity, showing a gradual stimulus-response pattern in their initial reaction.

Informed by empirical patterns extracted from a large video dataset of surface waves triggered by synthetic stimuli or bird attacks, we developed an agent-based model which captures the system's essential features. Systematic exploration of the model identifies the key individual-level mechanisms driving collective dynamics and shows how changes in local behaviour can drive collective adaptations across ecological contexts.

BP 14.91 Tue 18:00 P2

Confirmation of Jarzynski's equality based on single molecular and macroscopic interaction force measurements — •IAGO PETERS, LAURA MEARS, STEFAN SZOKOLL, and MARKUS VALTINER — TU Wien, Wien, Austria

Knowledge about the free energy landscape of biomolecular reactions is necessary to understand how life works on the smallest scale. Unfortunately, obtaining experimental values of the free energy difference between two states like an unbound and a bound state of two molecules is rather difficult. Jarzynski proposed an equality that connects the free energy difference between two states with the irreversible work that leads from one state to the other. Precisely, an average of all possible realizations of a process that moves the system from an equilibrium state to another state in equilibrium. Here, we test this hypothesis with experimental values. Using a simple model system, the different nucleobase-pair interactions are measured using three different techniques that are able to measure the interaction forces between two single molecules and up to several million interactions in a single experiment run. Using the Atomic Force Microscope (AFM), Optical Tweezers and the Surface Force Apparatus allows us to additionally investigate the scaling of biological single molecule interactions. Together with molecular dynamics simulations a strong foundation is laid to confirm Jarzynskis equality and investigate the scaling of single-molecule interactions.

Phase separation in chemically reacting systems controls cross-phase pH difference — •LINGE LI, OMAR ADAME-ARANA, and FRANK JÜLICHER — Max Planck Institute for the Physics of Com- plex Systems, Nöthnitzer Str. 38, 01187, Dresden

Biomolecular condensates are increasingly recognized as dynamic chemical environments whose properties are strongly modulated by their pH environment. Recent experiments have focused on the pH differences between the coexisting liquid phases, but a minimal theoretical framework that can account for these observations and elucidating their physical principles is still lacking. Here, we develop a minimal thermodynamic model that integrates charge-regulated macromolecules and their counterions. By identifying the conjugate thermodynamic variables constrained by chemical equilibrium and charge neutrality, we construct the thermodynamics at equilibrium and uncover a variety of phase behaviors. We show that asymmetric partitioning of ions in phase separated compartments naturally generates electric potential and pH differences, with the dense-phase pH consistently buffered toward the macromolecular isoelectric point. We further demonstrate that these pH differences are governed by macromolecular interactions and molecular properties. Together, our results suggest that phase separation provides a robust mechanism for buffering dilute-phase pH variations and enabling controlled modulation of pH in the presence of condensates. The framework uncovers general physical principles of how pH regulation can be achieved phase-separated environments.

BP 14.93 Tue 18:00 P2

Phase separation in chemically reacting systems controls cross-phase pH difference — LINGE LI, •OMAR ADAME-ARANA, and FRANK JÜLICHER — Max Planck Institute for the Physics of Com- plex Systems, Nöthnitzer Str. 38, 01187, Dresden

Biomolecular condensates are increasingly recognized as dynamic chemical environments whose properties are strongly modulated by their pH environment. Recent experiments have focused on the pH differences between the coexisting liquid phases, but a minimal theoretical framework that can account for these observations and elucidating their physical principles is still lacking. Here, we develop a minimal thermodynamic model that integrates charge-regulated macromolecules and their counterions. By identifying the conjugate thermodynamic variables constrained by chemical equilibrium and charge neutrality, we construct the thermodynamics at equilibrium and uncover a variety of phase behaviors. Statistical mechanics of disordered buckling instabilities — •TANGDI LUAN[1,2,3] and PIERRE A. HAAS[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems — [2]Max Planck Institute of Molecular Cell Biology and Genetics — [3]Center for Systems Biology Dresden

Buckling instabilities drive the emergence of biological shape during morphogenesis, but the effect of the large variability of these systems at the microscopic cell scale on these instabilities at the macroscopic scale of tissues is largely unknown. The buckling of a rod with disordered growth [1] is perhaps the simplest setup of this problem. Numerical simulations [1] reveal that even in this minimal setup, the distribution of growth disorder has complex effects on the buckling threshold.

Here, we provide the theoretical underpinnings for these observations: we develop the statistical theory that explains how the spatial distributions of disorder of growth and material properties conspire to determine the threshold for the instability. Our results thus indicate how correlations and hence feedbacks between stress and growth can control mechanical instabilities and, by extension, the emergence of biological shape in development.

Exchange controls coarsening of surface condensates — •Riccardo Rossetto[1,2], Marcel Ernst[1,2], Gerrit Wellecke[1,2], and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany — [2]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Biological membranes often exhibit heterogeneous protein patterns, which cells control. Strong patterns, like the polarity spot in budding yeast, can be described as surface condensates formed by physical interactions between constituents. However, it is unclear how these interactions affect the material exchange with the bulk. To study this, we analyze a thermodynamically consistent model which reveals that passive exchange leads to new equilibrium phenomena, such as reentrant phase transitions, and generally accelerates the coarsening of surface condensates. Active exchange can further accelerate coarsening, although it can also fully arrest it and induce complex patterns involving various length scales. We reveal how these behaviors are related to non-local transport via diffusion through the bulk, rationalizing the various scaling laws we observe and allowing us to interpret biologically relevant scenarios.

BP 14.96 Tue 18:00 P2

Noisy mixtures at the mesoscale: Vacuoles dancing in chemically active droplets — •Estéban Araspin, Leonardo Silva Dias, and Christoph A. Weber — Faculty of Mathematics, Natural Sciences, and Materials Engineering: Institute of Physics, University of Augsburg, Universitätsstrasse 1, 86159 Augsburg, Germany.

Understanding biological mixtures at the mesoscale calls for models that connect microscopic reactions with emergent continuum behavior in a thermodynamically consistent way. At such coarse-grained scales, noise, generally of multiplicative nature, is essential to capture phenomena like nucleation or stochastic switching between non-equilibrium steady states.

We developed a theoretical framework based on effective mesoscopic reaction-diffusion master equations that is applicable to both passive systems and non-equilibrium scenarios in which chemostatted fluxes make the mixture active. The framework connects to the macroscopic limit, recovering reactive Cahn-Hilliard-Cook dynamics.

As an application, we explore chemically active droplets in which a chemostatted ATP concentration leads to striking morphological dynamics. We find dilute-phase vacuoles that form and dissolve, reminiscent of bubbly phase separation in Model B+. We observe growth of small vacuoles at the expense of larger ones, dynamics that can be considered an inverse-ripening process.

Our results highlight the value of mesoscopic stochastic frameworks for understanding active phase separation and other soft-matter systems maintained away from equilibrium.

Local chain stiffening regulates non-equilibrium maturation and clustering in biomolecular condensates — •Subhadip Biswas[1] and Davit A Potoyan[2] — [1]Iowa State University, Ames, Iowa, USA — [2]Iowa State University, Ames, Iowa, USA

Biomolecular condensates formed through liquid-liquid phase separation display complex structural and dynamical features that are essential for cellular organization, signaling, and aging. Using coarse-grained molecular dynamics simulations based on a polymer model with tunable local semiflexibility and sticker stickiness, we systematically examine how angular rigidity modulates aging and clustering within condensates. We investigate four regimes involving coupled variations of sticker/spacer stiffness and interaction strength. By quantifying structural heterogeneity, orientational ordering, and rheological responses, including oscillatory shear, Green-Kubo viscosity, and uniaxial deformation, we uncover distinct non-equilibrium behaviors and maturation pathways that emerge from local chain stiffening. These results highlight angular rigidity as a key regulator of condensate stability and internal organization, with implications for understanding condensate aging in cells and for designing programmable biomaterials.

BP 15.2 Wed 9:45 BAR/SCHÖ

Uncovering the thermodynamic principles of enzymatic regulation in biomolecular condensates with reactive simulations — •Enrico Lavagna[1], Francesco Delfino[1], Georgii Koniukov[1], Matteo Paloni[1,2], Luca Ciandrini[1,3], and Alessandro Barducci[1] — [1]Centre de Biologie Structurale (CBS), Montpellier, France — [2]Department of Chemical Engineering, Thomas Young Centre, University College London, London WC1E 7JE, United Kingdom — [3]Institut Universitaire de France (IUF)

Biomolecular condensates are dynamic cellular assemblies often regulated by energy-consuming processes such as post-translational modifications (PTMs). Nevertheless, the coupling between reaction dynamics and cellular spatial organization remains poorly understood at the molecular scale. Using a minimal, particle-based model, we investigate how phosphorylation controls condensate steady-state behavior. We find that condensate formation is regulated by the steady-state fraction of phosphorylated scaffold proteins, which increases with enzyme activity. This chemical regulation exhibits a non-linear, non-trivial dependence on the phosphorylation strength. Furthermore, reaction fluxes are spatially heterogeneous, with phosphorylation activity sharply peaking at the condensate interface. Our findings highlight novel, general features of chemically active biomolecular condensates. Moreover, we observe that incorporating local detailed balance is essential for understanding how energy-consuming reactions shape the steady-state properties of phase-separated systems.

Multiscale Simulation of Phosphofructokinase-1 Assemblies: From Transient Interactions to Large-Scale Assembly Formation — Mehrnoosh Khodam Hazrati, Tom Miclot, and •Stepan Timr — J. Heyrovsky Institute of Physical Chemistry, Czech Academy of Sciences, Prague, Czech Republic

Human phosphofructokinase-1 (PFK1)—a key glycolytic enzyme—forms filaments and localizes into large-scale assemblies that are thought to play a major role in the regulation of glycolysis. However, the molecular interactions driving this assembly and the precise mechanisms by which it regulates the pathway remain poorly understood. In this work, we combine three levels of description—atomistic, residue-level coarse-grained, and highly coarse-grained—to characterize interactions between PFK1 tetramers and to elucidate factors governing PFK1 assembly formation. Atomistic molecular dynamics simulations of PFK1 filament interfaces reveal specific side-chain interactions that are critical for filament stability. These insights enable us to improve the description of filament formation in residue-level coarse-grained models. Using the Martini 3 and OPEPv7 coarse-grained models, we further identify key regions mediating transient PFK1–PFK1 interactions and show that these include filament-forming interfaces. Finally, we construct a highly coarse-grained model that integrates information from the more detailed simulations. Using this model, we investigate the role of membranes in PFK1 filament formation and describe how filaments may affect the recruitment of other constituents into large-scale glycolytic assemblies.

BP 15.4 Wed 10:15 BAR/SCHÖ

Multiscale Approaches to Phase Behaviour and Mechanical Properties of Synthetic DNA Networks — •Aaron Gadzekpo[1], Xenia Schneider[1], and Lennart Hilbert[1,2] — [1]Karlsruhe Institute of Technology, Institute of Biological and Chemical Systems — [2]Karlsruhe Institute of Technology, Zoological Institute

DNA can be used as a programmable material whose sequence-level design governs emergent properties. However, approaches that link sequences to the macroscopic behaviours needed in biotechnology remain limited. Here, we integrate coarse-grained simulations, Bayesian optimisation, and graph-based rheology to connect sequence-encoded, molecular-scale parameters to network-level properties. We apply our methods to DNA nanomotifs, which are nanometre-sized, multi-armed molecules assembled from single strands. Network formation among nanomotifs via sticky-end overhangs enables phase separation into liquid-like condensates or the assembly of viscoelastic hydrogels. Our multiscale approaches reveal how nanomotif flexibility, affinity, and concentration govern network formation, phase behaviour, and viscoelasticity. By combining our approaches, we propose inverse design strategies to select sequences that yield targeted emergent properties.

BP 15.5 Wed 10:30 BAR/SCHÖ

Self-Assembly of KAHRP Spirals in Malaria-Infected Red Blood Cells — Devika Magan[1], Michael Lanzer[2], and •Ulrich S. Schwarz[1] — [1]Institute for Theoretical Physics, Heidelberg University — [2]Center for Infectious Diseases, University Hospital Heidelberg

Malaria infections alter the mechanical and adhesive properties of red blood cells (RBCs). To avoid clearance by the spleen, infected RBCs develop thousands of nanoscale protrusions called knobs, which stiffen the RBC and mediate cytoadhesion to the endothelium. A central player in this process is the exported para-

site protein KAHRP. The parasite sends KAHRP to the RBC membrane skeleton, where it interacts with spectrin and actin to reorganize the local architecture. Strikingly, KAHRP also forms prominently sized spirals underneath the knobs, yet the physical principles governing their formation and how such structures might influence membrane mechanics are still not understood. In this talk, I present a coarse-grained, patchy-particle framework designed to explore how simple interaction rules can give rise to spiral formation. By tuning local binding geometry and torsional preferences, the model produces a rich variety of self-organized states, ranging from compact rings to extended curved chains. These simulations provide a starting point for connecting protein-level organization to cell-level mechanics. I will outline how this approach can be extended toward membrane-associated scenarios to investigate whether KAHRP assemblies can generate spontaneous curvature or store elastic energy - providing a path toward understanding their potential function during parasite cytoadhesion and egress.

BP 15.6 Wed 11:15 BAR/SCHÖ

From Data to Discovery: Machine Learning Force Fields for Fast and Accurate Ligand-Protein Screening — •Sergio Suárez-Dou[1], Miguel Gallegos[1], Hamza Ibrahim[2], Joshua T. Berryman[1], Andrea Volkamer[2], and Alexandre Tkatchenko[1] — [1]Department of Physics and Materials Science, University of Luxembourg, Luxembourg — [2]Data Driven Drug Design, Center for Bioinformatics, Saarland University, Germany

Pretrained Machine Learning Force Fields (MLFF) are transforming computational chemistry by combining speed and accuracy. In drug discovery, predicting binding energies and affinities is key to identifying viable candidates. Among MLFFs, SO3LR excels in both performance and efficiency, enabling accurate ligand and binding predictions at low computational cost, surpassing semiempirical methods.

However, data coverage remains a challenge. While datasets like OMol25 and QCell offer broad molecular diversity, drug-like chemical space requires more targeted representation. To address this, we are developing a dataset optimised for docking evaluations, covering key regions of drug-like space. Our goal is a pretrained model capable of predicting drug-ligand affinities with PBE0+MBD DFT-level accuracy, bridging quantum precision with high-throughput screening and accelerating drug discovery.

BP 15.7 Wed 11:30 BAR/SCHÖ

Modelling Protein Dynamics with Machine Learned Coarse-Grained Models — •Klara Bonneau — Freie Universität Berlin, Germany

The most popular and universally predictive protein simulation models employ all-atom molecular dynamics (MD). However, understanding dynamical processes like protein folding, interactions, and aggregation requires accessing timescales beyond conventional MD capabilities. Coarse-graining (CG) accelerates simulations by focusing on essential degrees of freedom, but a universally predictive CG model for proteins remains elusive. Our work introduces the first thermodynamically consistent CG model that extrapolates to unseen protein sequences. By leveraging state-of-the-art machine learning techniques, we simulate the folding of unknown proteins, protein-protein interactions, intrinsically disordered proteins, and mutation effects. Current extensions include larger proteins and protein-ion/small molecule interactions, surpassing conventional MD timescale limitations. Additionally, explainable AI techniques enable us to interpret results and demonstrate that deep learning models capture physically consistent interactions.

BP 15.8 Wed 11:45 BAR/SCHÖ

Gradient-Estimating Gillespie Simulators for Parameter Inference in Stochastic Models — •Ludwig Burger[1], Annalena Kofler[2], Lukas Heinrich[3], and Ulrich Gerland[1] — [1]Physics of Complex Biosystems, School of Natural Sciences, Technical University Munich — [2]Max Planck Institute for Intelligent Systems, Tübingen — [3]Data Science in Physics, School of Natural Sciences, Technical University Munich

Stochastic models are ubiquitous in (biological) physics, yet fitting such parameterized models to experimental data remains challenging. While gradients in deterministic systems can be obtained efficiently through numerical or automatic differentiation, these tools cannot be directly applied to stochastic simulation algorithms such as the Gillespie algorithm, where sampling from a discrete set of reactions introduces non-differentiable operations. In this work, we adapt three gradient estimators from machine learning for use in Gillespie simulations: the Gumbel-Softmax Straight-Through estimator, the Score Function estimator, and the Alternative Path estimator. We extend all three estimators to address the specific requirements of gradient estimation in Gillespie simulations. We analyze the statistical properties of the estimators and highlight practical advantages and limitations in two representative systems: a minimal bimolecular association-dissociation model and the repressilator. Our results demonstrate that gradient estimators can be effectively integrated into the Gillespie algorithm, providing a systematic approach for gradient-based parameter inference in stochastic models.

Deep-Pose-Tracker: a unified model for behavioural analysis of *Caenorhabditis elegans* — •Debasish Saha[1], Shivam Chaudhary[1], Dhyey Vyas[2], Anindya Ghosh Roy[2], and Rati Sharma[1] — [1]Indian Institute of Science Education and Research Bhopal, Bhopal, India — [2]BRIC-National Brain Research Centre, Gurugram, India

The ability to respond to environmental stimuli by living organisms is essential for survival and adaptation. Locomotion and posture-based analyses of animals are commonly performed; however, manually performing these tasks is effort-intensive, time-consuming, and error-prone. Automation of this process is therefore crucial for accurate and fast detection. To this end, in this work, we report the development of Deep Pose Tracker (DPT), an end-to-end deep learning model to automate the study of posture dynamics and locomotion behaviour of *C. elegans*, a model organism useful to study neuroscience, genetics, drug design, *etc*. The DPT model enables automatic detection and tracking of these animals while measuring essential behavioural features like locomotion speed, orientation, forward or reverse locomotion, complex body bends as omega turns, and eigenworms (representing the overall posture dynamics in a low-dimensional space). Our DPT model can generate highly accurate data, with very high inference speed, while being user-friendly and robust to experimental variabilities. DPT, therefore, can be a valuable toolkit for researchers studying behaviour under different environmental stimuli.

BP 15.10 Wed 12:15 BAR/SCHÖ

Adaptive Determination of Cluster Number in Single-Cell RNA-seq — •Cornelius Miller, Felix Wehrenberg, Dominik Egger, and Sophia Rudorf — Institute of Cell Biology and Biophysics, Leibniz University Hannover, Hannover, Germany

Single-cell RNA sequencing (scRNA-seq) has transformed transcriptomic research by enabling gene expression profiling at the resolution of individual cells. The complexity and high dimensionality of scRNA-seq data pose substantial challenges for effective data interpretation. Current analysis pipelines often struggle with computational scalability and the subjective nature of parameter selection. Here, we introduce a comprehensive Python-based framework that automates key analytical stages while maintaining user flexibility. A critical innovation of this framework is the implementation of an adaptive clustering algorithm designed to estimate cluster count without prior knowledge. This method was specifically developed to define the number of distinct subpopulations in Mesenchymal Stem Cell (MSC) datasets, where cellular heterogeneity is often ambiguous. Furthermore, by leveraging parallelization, the proposed architecture handles high-dimensional datasets with improved latency compared to sequential execution. This approach resolves common ambiguities in defining cell types, offering a robust tool for unbiased exploratory data analysis.

BP 15.11 Wed 12:30 BAR/SCHÖ

AI-Guided Transition Path Sampling of Lipid Flip-Flop and Membrane Nanoporation — •Matthias Post and Gerhard Hummer — Max Planck Institute of Biophysics, Frankfurt, Germany

We studied lipid translocation (or *"flip-flop"*) between leaflets of a bio-membrane and the possible involvement of water nanopores via molecular dynamics simulation.[1] We used transition path sampling[2] within the AIMMD[3] framework to efficiently sample unbiased lipid flip-flops and pore formation. A neuronal network model was trained to predict the *"committor"*, that is the probability of a successful transition from a given microscopic conformational state. While coarse-grained DMPC lipids flip via tunneling through the intact membrane, atomistic (CHARMM36) simulations reveal that flip-flop requires the formation of metastable water pores. DSPC bilayers and plasma membrane mimetics[4] facilitate flip-flop via transient water threads or nanodroplets to cross a locally thinned membrane. Deep neural networks map the transition mechanism from a high-dimensional (660d) feature space to a nearly linear committor model, consistent with Cover's theorem[5] and the concept of dominant reaction tubes.[6]

Invited Talk BP 16.1 Wed 9:30 BAR/0205

Illuminating mitochondrial permeabilisation in apoptosis — •Ana J. Garcia Saez — Max Planck Institute of Biophysics, Frankfurt am Main, Germany

Mitochondrial permeabilization is a key step in the signaling pathway of apoptosis and in the cell*s commitment to death. It affects the outer and subsequently the inner mitochondrial membranes through the opening of membrane pores via mechanisms that are not fully clear. This releases cytochrome c and SMAC into the cytosol, leading to the activation of caspases, a set of proteases that accelerate cell death and that block inflammation by inactivating intracellular innate immunity effectors. Mitochondrial inner membrane permeabilization additionally releases mtDNA into the cytosol, which in turn activates intracellular innate immunity pathways unless counterbalanced by caspases. Here, I will discuss our work using advanced microscopy methods to advance our understanding of the molecular mechanisms of mitochondrial pores in apoptosis and how they function in the regulation of cell death and of inflammatory signaling outcomes.

BP 16.2 Wed 10:00 BAR/0205

Phase separation driven by membrane binding of receptor proteins of different size — •Samuel S. Gomez[1], Lennart Kleinschmidt[2], Daxiao Sun[2], Alf Honigmann[2], and Christoph Weber[1] — [1]Faculty of Mathematics, Natural Sciences, and Materials Engineering, Institute of Physics, University of Augsburg, Augsburg, Germany — [2]Technische Universität Dresden, Biotechnologisches Zentrum, Center for Molecular and Cellular Bioengineering (CMCB), Dresden, Germany

We aim to understand the physical mechanisms governing the spatial organisation and assembly of adherens junctions (AJs). A key open question is how size differences in the extracellular domains of AJ receptor proteins contribute to their segregation during junction formation. To address this, we develop a theoretical model of receptor-mediated adhesion between a GUV and a SLB, using both simulations and an experimental in-vitro setup to test and refine our model. Our model suggests that differences in receptor length are sufficient to drive spatial segregation, even in the absence of cis-interactions with similar adhesion affinities. We extend our model to understand the link between spatial organisation at the mesoscopic level of receptor segregation at membrane adhesion contact sites to the macroscopic heterogenous organisation of receptor proteins on the GUV. Our model aims to provide new insights into the physical principles underlying AJ assembly, in particular spatial organisation of receptor proteins on the mesoscopic and macroscopic level of the membrane within the AJ complex.

BP 16.3 Wed 10:15 BAR/0205

Selective information processing by particle distributions at living interfaces — •Jenna Elliott[1,2] and Anna Erzberger[1,2] — [1]European Molecular Biology Laboratory (EMBL), Heidelberg, Germany — [2]University of Heidelberg, Heidelberg, Germany

Living cells are capable of responding to environmental cues under noisy conditions, even in the absence of a centralised control unit or brain. Such systems therefore provide an ideal platform for uncovering the physical principles behind robust, decentralised information processing in soft materials. Motivated by the role interfaces play in relaying signals across cell boundaries, we investigate how spatially-varying particle distributions on interfaces facilitate information transmission in living cells. Starting from a statistical description of particle dynamics, we show that these distributions act as signal filters that non-linearly amplify heterogeneities in their environment. This mechanism permits a form of pattern recognition, with inter-particle interactions tuning the response function of the filter. We explicitly identify both thresholding and edge-detecting regimes and, accounting for thermal noise in the filters, quantify the flow of information across the interface. We find that, when suitably tuned, the noisy filters selectively compress input signals, resulting in the efficient encoding of information relevant to downstream tasks. Overall, our results indicate that the noisy patterning of membranes may be used to selectively sense environmental cues in biologically inspired systems, suggesting exciting implications for how physical interactions may encode computational logic in soft materials.

BP 16.4 Wed 10:30 BAR/0205

Synthetic cell-based artificial tissues to study T cell activation — Anna Burgstaller[1] and •Oskar Staufer[1,2,3] — [1]INM - Leibniz Institute for New Materials, Saarbrücken, Germany — [2]Campus D2 2 — [3]Max Planck Bristol Center for Minimal Biology, Bristol, United Kingdom

T cells integrate biochemical and biophysical cues within lymph nodes, collectively determining activation of adaptive immunity. Quantitatively understanding how mechanical and biochemical signals converge at the single-cell and tissue level requires new model systems. To address this, we developed millimeter-sized artificial lymph nodes assembled from synthetic cells. The mechanical properties of the synthetic cells, specifically their Young*s modulus, can be precisely tuned, while their surfaces can be functionalized with biochemical stimuli. This allows to independently tune their biomechanics and biochemistry. The resulting tissue architecture, including its anisotropy and stiffness, can be engineered to probe emergent, tissue-scale phenomena. Performing live cell microscopy of migrating T-cells within synthetic lymph nodes, we validate that they reproduce in vivo T-cell motility. Statistical modeling of migration trajectories reveals that tissues must support search strategies for effective signal integration and that confinement degree promotes regulatory phenotypes of the T cells. Our synthetic cell-based tissues recapitulate architectural features of lymphatic organs, providing a platform to dissect how mechano-signaling interacts with biochemical cues to shape T-cell immunity

BP 16.5 Wed 10:45 BAR/0205

Excitable lipid nanotubes as a model system of neuron signaling and for neuromorphic systems — •Jan Steinkühler — CAU Kiel University, Germany

Voltage-sensitive ion channels stand at the centre in the study of cellular excitability in neuronal networks. However, the spatial propagation of electrical waves along nerve fibres is not a property inherent to an individual ion channel but rather emerges from the arrangement of ion channels along a tubular lipid membrane. While the *in vitro* study of functional ion channels in model membranes is well established, the propagation of an action potential along a lipid-bilayer nanotube has not yet been investigated. Here we present our experimental work examining these phenomena with electro-optical measurements on force-induced lipid nanotubes and demonstrate the cable-like properties of such nanotubes. Furthermore, we study memory effects arising from the interplay between electrical-field-induced lipid migration and ionic nanofluidic conductance. Finally, we show our lab's efforts toward automated cell-free expression of ion channels and data-driven modeling of membrane excitability. More broadly, our results help establish the interplay between membrane phase, shape, and electrical properties in a controlled experimental setup.

BP 16.6 Wed 11:15 BAR/0205

Membrane reshaping across the tree of life — •Felix Frey — Institute of Science and Technology Austria, Klosterneuburg, Austria — Eindhoven University of Technology, Eindhoven, The Netherlands

Across the tree of life, different designs of cellular membranes have evolved that are both stable and flexible. In bacteria and eukaryotes single-headed lipids self-assemble into flexible bilayer membranes. By contrast, archaea have distinct membranes that typically contain mixtures of single-headed bilayer lipids and double-headed bolalipids. While this composition is believed to enable extremophile archaea to survive harsh environments, the physical mechanisms underlying the reshaping of archaeal membranes are often unknown. Here, through the development of coarse-grained molecular dynamics simulations, we systematically compare the different membrane designs [1]. We explore the physical properties of archaeal membranes and explain how their stability and response to reshaping depends on the flexibility of single bolalipids and the amount of bilayer lipids they contain.

Fluctuating triply periodic membranes: a phase-field study of diffusion in dynamic, confining environments — •Jakob Mihatsch and Andreas M. Menzel — Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Universitätsplatz 2, 39106 Magdeburg, Germany

Understanding how individual entities move through interconnected structures is crucial for applications in biology and technology. A key example is the diffusive motion of molecules in porous networks. This porous environment is usually not static, but subject to thermal fluctuations and interactions with the object that is transported through it. Focusing on the situation of a spherical diffusive particle confined by fluctuating triply periodic membrane structures, we investigate numerically the effect of such a dynamic environment on the motion of a confined object [1]. We employ a phase-field approach to model the membrane surface, which allows us to apply dynamic perturbations to the shape of the membrane, without having to track its location explicitly. Triply periodic membranes can form channels with narrow pores, which lead to transient trapping. We find that thermal fluctuations can widen these pores, which speeds up diffusive transport and allows larger particles to pass through the pores than one would expect for an unperturbed membrane. Our work also shows that deformation of the membrane induced by the particle plays an important role in enhancing diffusion. Our results should be directly observable, for example, during protein diffusion through biological environments.

BP 16.8 Wed 11:45 BAR/0205

Optimizing Dynamin for Membrane Fission — •Russell Spencer and Marcus Muller — Georg-August University Göttingen, Göttingen, Germany

Membrane tube fission is a fundamental cellular process, facilitated by the dynamin protein family. The primary energetic barrier to fission arises from the (constriction-catalyzed) collapse of the tube into a hemifused intermediate. We previously developed a self-consistent field theory (SCFT) framework to systematically study this process, and validated it against experiments. The precise mechanisms by which dynamin promotes this transition, however, remain unclear. We now model membrane tubes in the presence of dynamin-like proteins, incorporating both steric constriction and surface interactions. We explore the effect of different protein-membrane coupling mechanisms on the fission barrier, including excluded volume, head-group adhesion, and leaflet splay. While membrane attraction is necessary for protein assembly and induces curvature, it also opposes local constriction, inhibiting tube collapse. In contrast, insertion of the PH domain into the head groups leads to their splaying and produces a localized chevron-shaped membrane deformation. This facilitates tube collapse without opposing local constriction, thus promoting fission.

BP 16.9 Wed 12:00 BAR/0205

Interferometric and Fluorescence Nanoparticle Tracking for Analysis of Extracellular Vesicles — •Shuhan Jiang[1,2], Anna Kashkanova[4], Morgan Miller[1,2], Hannarae Lee[1,2,3], Hamed Qazvini[1,2], and Vahid Sandoghdar[1,2,3] — [1]Max Planck Institute for the Science of Light, Erlangen, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — [3]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [4]AE Eindhoven, Groene Loper 19, Flux, Netherlands

Extracellular vesicles (EVs) are considered to be important disease markers. However, their inherent heterogeneity poses a major challenge for the characterization of their physical properties and biochemical content. We combine interferometric nanoparticle tracking analysis (iNTA) with fluorescence detection to measure particle size, refractive index, and fluorescence intensity with single-molecule sensitivity. We verify that the fluorescence signal increases with particle size for dye-labeled liposomes, and that count rates shift as one changes the labeling density. In an exemplary case study applied to HEK293-derived EVs, we show that the method resolves CD9/CD81-positive subpopulations, while marker-negative particles appear more heterogeneous, suggesting contaminants or altered composition. We discuss the potential of this multimodal approach for precise differentiation of heterogeneous nanoparticles and quantitative biomarker analysis.

BP 16.10 Wed 12:15 BAR/0205

Active and Brownian Colloids interacting with Lipid Vesicles — •Antonio Stocco, Clément Marque, and Florent Fessler — Institut Charles Sadron, CNRS, Strasbourg, France

Motion of active and passive Brownian particles is strongly affected by confinement effects, which impact the persistence of the ballistic dynamics and can guide transitions and instabilities when dealing with deformable interfaces. Here, I will present some experimental results describing the dynamics of active and passive colloids interacting with soft fluctuating membranes. Our experimental systems are composed of Giant unilamellar vesicles (GUVs) with tunable membrane tension and bare or Janus self-propelled colloids showing different hydrodynamic and particle-membrane interactions. We were able to observe emerging dynamics such as autonomous particle engulfment by the vesicle membrane, hysteresis of the particle wrapping dynamics and membrane tension dependent particle drag [1,2,3]. References: [1] F Fessler, M Wittmann, J Simmchen, A Stocco. Dynamics of Active Colloid Engulfment by Giant Lipid Vesicles, Soft Matter 2024, 20, 5904. BP 16.11 Wed 12:30 BAR/0205

pH Dependence of the Structure of Drug-Free Lipid Nanoparticle Dispersions — •Marta Gallo[1], Klaus Götz[1], Bishoy Hakim[1], Carola Vogel[1], Christian Bär[1], Lionel Porcar[2], and Tobias Unruh[1] — [1]Institute for Crystallography and Structural Physics, Friedrich Alexander University Erlangen Nürnberg — [2]Institut Laue-Langevin, 71 Avenue des Martyrs, Grenoble 38042, France

Lipid nanoparticle (LNP) dispersions are promising drug-delivery systems due to their ability to encapsulate diverse therapeutics and release them in controlled ways. A key advantage of many LNPs is their sensitivity to environmental pH, enabling drug release in acidic endosomal conditions through lipid conformational changes that destabilize the particles. To clarify these mechanisms, we synthesized drug-free LNPs mimicking the Comirnaty formulation and examined how pH affects their structure. Using simultaneous small angle X-ray and neutron scattering (SAXS/SANS) at the ILL D22 instrument, we monitored particle swelling and ordered-structure formation across different pH levels. Dialysis experiments, transitioning samples between pH 3.3 and 7, demonstrated fully reversible structural changes, as confirmed by cryo-TEM. Coupling SAXS/SANS with photon correlation spectroscopy (PCS) revealed a complex particle size distribution and deeper insight into LNP dynamics under different contrasts and pH conditions. The results clarify how pH-triggered structural transitions govern LNP behavior, supporting the design of next-generation delivery systems with enhanced release control and targeting.

BP 17: Statistical Physics of Biological Systems I (joint session DY/BP)

Time: Wednesday 9:30–12:45 Location: ZEU/0114

See DY 33 for details of this session.

BP 18: Focus session: Integrative Structural Modeling

Modern biological questions - and the growing recognition that biomolecular dynamics are central to molecular function - demand increasingly integrated technological strategies to probe the structure and behavior of biomolecules. Yet bringing insights from diverse experimental techniques together in a rigorous, quantitative way remains a formidable challenge, requiring deep expertise across methods as well as sophisticated modeling approaches. This focus session aims to ignite collaboration at this interface. By gathering experimentalists with complementary skill sets and researchers specializing in computational and theoretical modeling, we will create a space for vibrant exchange, cross-disciplinary learning, to lead to the development of well-informed, predictive models of complex biological systems.

Organized by Richard Börner (HS Mittweida) and Sigrid Milles (FMP Berlin)

Time: Wednesday 10:30–12:45 Location: BAR/0106

Protein complex structure prediction, state-of-the-art and challenges — •Ezgi Karaca — Izmir Biomedicine and Genome Center — Dokuz Eylul University, Izmir, TR

The advent of artificial intelligence has reshaped structural biology, enabling unprecedented accuracy in protein modeling. As the assessor for CASP14 and CASP15, I witnessed remarkable progress facilitated by AlphaFold. While CASP14 participants struggled with intersubunit contacts, CASP15 saw prediction success rates rise from 31-percent to 90-percent by incorporating AlphaFold2 (AF2) into customized pipelines. This improvement was driven by curated multiple sequence alignments (MSAs), though complexes with shallow MSAs remained challenging. Addressing this, we developed MinnieFold, an efficient protocol achieving a 50-fold reduction in GPU usage while maintaining accuracy in antibody-antigen complexes. Further investigating AF's performance,

we analyzed 276 human-parasite interactions across 15 species. Comparing AF2 and AlphaFold3 (AF3), we observed striking differences in predicted structures. This presentation highlights these advances, challenges, and our contributions to AI-driven structural biology.

BP 18.2 Wed 11:00 BAR/0106

Extending the Fluorophore Dye Library for FRET-guided Modeling — •Isolde Kirk[1], Felix Erichson[1], Josephine Meitzner[1], Patrick K. Quoika[2], and Richard Börner[1] — [1]Laserinstitut Hochschule Mittweida, Mittweida, Germany — [2]Technische Universität München, Munich, Germany

Integrative structural modeling combines experimental observables with computational methods to obtain realistic descriptions of biomolecular structures and their dynamics. One such approach integrates Förster Resonance Energy Transfer (FRET) and dynamic fluorescence anisotropy with molecular dynamics (MD) simulations. Ensuring comparability between experiment and simulation requires realistic modeling of fluorescent dyes in silico. In practice, existing dye libraries do not cover the full range of available fluorophores, including phosphate-backbone-linked carbocyanine (Cy) dyes. We therefore modeled and parametrized a FRET dye pair of Cy3 and 5 with a backbone-linked Cy3 fragment for MD simulations. We used Gaussian to assign partial charges with the restrained electrostatic potential method, as implemented in Antechamber, yielding several parametrization variants. The dye fragments were then incorporated into a DNA hairpin model and characterized using MD simulations with GROMACS. Depending on the parametrization, the DNA hairpin showed different structural responses, ranging from stable dye intercalation to partial helix destabilization. One parametrization showed agreement with the experimental data and therefore provides a validated extension for future FRET-guided modeling.

BP 18.3 Wed 11:15 BAR/0106

Structural dynamics and long-range interactions controlling timing of the Neurospora circadian clock — •Muriel Hartsch[1], Ida Marie Vedel[1], Kathrin Motzny[1], Michael Brunner[2], and Sigrid Milles[1] — [1]Leibniz-FMP Berlin, Robert-Roessle-Str. 10, 13125 Berlin — [2]Heidelberg University, Biochemistry Center (BZH), Im Neuenheimer Feld 328, 69120 Heidelberg

The function and maintenance of the circadian clock in Neurospora crassa are governed by a feedback loop involving both negative and positive regulatory elements, which together drive the oscillating circadian rhythm with a period of approximately 24 hours. The dimeric, intrinsically disordered protein FREQUENCY (FRQ) is a key component of the negative feedback complex and subject to post-transcriptional hyperphosphorylation by casein kinase 1a (CK1a). Phosphorylation of clock proteins is highly conserved across species, from fungi to mammals, with the human PERIOD (PER) protein being a notable example. However, the precise functions associated with hyperphosphorylation remain poorly understood. We hypothesize that time-dependent hyperphosphorylation of FRQ at multiple sites facilitates a transition from closed to open conformation, regulating interactions with its partners. Using nuclear magnetic resonance (NMR) and single-molecule fluorescence resonance energy transfer (smFRET), we investigate the conformational dynamics going along with FRQ phosphorylation by recombinant CK1a. This will allow, combined with structural modeling of the intrinsically disordered protein, to understand how phosphorylation alters the conformation and triggers a switch in FRQ.

Invited Talk BP 18.4 Wed 11:45 BAR/0106

From Sparse Restraints to All-Atom Models: Integrative Reconstruction of Hidden GPCR Conformations — •Matthias Elgeti — Institute for Drug Discovery, Leipzig University Medical School, Leipzig, Germany

Transmembrane proteins such as G protein coupled receptors (GPCRs) play central roles in cellular signal transduction and constitute major targets for therapeutic intervention. Their intrinsic conformational flexibility, however, leads to the coexistence of multiple interconverting states, which complicates structural characterization by high-resolution methods. Site-directed spin labeling (SDSL) EPR spectroscopy is uniquely suited to probe such flexible systems independent of molecular size, but it provides only sparse structural restraints. To bridge this gap, we integrate SDSL-EPR distance data with deep-learning-based structure prediction and molecular dynamics simulations. Using the angiotensin receptor (AT1R), a key regulator of cardiovascular function, we demonstrate how this integrative approach reveals a ligand-stabilized conformational state with distinct functional properties. We further present a computational pipeline that reconstructs corresponding all-atom models from sparse spectroscopic restraints and enables systematic exploration of hidden conformational states, providing a general framework for structure-guided analysis of signaling mechanisms and future drug discovery.

BP 18.5 Wed 12:15 BAR/0106

RNA 3D Folding Using Diffusion Models and Agentic Tree Search — •Arunodhayan Sampathkumar and Danny Kowerko — Professorship of Media Informatics, Technische Universität Chemnitz

Accurate prediction of RNA three-dimensional structure is essential for understanding RNA function and guiding RNA-based therapeutics. However, RNA folding remains challenging due to complex tertiary interactions, context-dependent base pairing and limited structural data, especially for short sequences with fewer than 80 nucleotides. To address this, we introduce a multi-model RNA structure prediction framework that combines an RNA-adapted Protenix model, a Boltz diffusion sampler and a template-based modeling (TBM) baseline together with GAN-augmented training for underrepresented short RNAs. Protenix offers accurate local geometry, Boltz supplies diverse global conformations and TBM contributes strong constraints when templates exist. All models are evaluated on the Kaggle RNA 3D public and private test sets. Protenix reaches TM-scores of 0.48/0.46, Boltz 0.41/0.40 and TBM 0.61/0.57. We further introduce an agentic tree-search ensemble that selects and refines conformations using consensus scoring and RMSD-based diversity. This ensemble significantly improves performance, achieving TM-scores of 0.68 (public) and 0.63 (private). Our results demonstrate that integrating generative models, template signals and agentic search yields more accurate RNA structures and improves robustness for novel RNA families.

BP 18.6 Wed 12:30 BAR/0106

RNA adsorption in confinement, from electrostatic properties to spatial organization — •Horacio V. Guzman, Willy Menacho, and Ian Addison-Smith — Biophysics & Intelligent Matter Lab, Material Science Institute of Barcelona, CSIC, 08193 Barcelona, Spain

Electrostatic interactions are the main driving force of the RNA-protein association during viral assembly and disassembly processes. However, the properties of confined single stranded ss-RNA inside diverse proteinaceous viral geometries remain largely unexplored due to challenges associated with their high-resolution characterization. Electrostatics and mechanical properties at the RNA-proteins interface are also the origin of ss-RNA stability in confinement. Combining archetypical RNA fragments and diverse confined symmetries, we present multiple-solvent molecular models to explore the most favorable initial spatial organization as a function of the type of confinement. Our method shows that electrostatic interactions drive the 3D RNA structure path towards possible initial conformations. In particular for small RNAs, which are frequently interacting with the proteinaceous subunits during the virus assembly process, also known as packaging signals. We compared our results to X-ray structures of small plant viruses validating the most favorable initial conformations with our method and the virus folding symmetry. Our findings start a quantitative route to elucidate the electrostatic character of RNA-protein interfaces, and a complementary understanding to RNA packaging, assembly and disassembly processes.

BP 19: Round Table Discussion: The Future of Neutrons in France and Germany (joint session CPP/BP)

Organized by Benoit Coasne and Christine M. Papadakis.

Enhanced Conformational Dynamics of Biomolecules with Quantum-Accurate Machine Learning Force Fields — •Naziha Tarannam — University of Luxembourg, Luxembourg

Machine Learning Force Fields (MLFFs) address a long-standing challenge in computational biophysics: lifting quantum accuracy in the treatment of biomolecules to the large scales, above nanometres and nanoseconds, normally available only to classical-like molecular mechanics force fields (MMFFs). Our recently developed SO3LR model was trained on a diverse set of over four million configurations and achieves ab initio-level accuracy while remaining computationally efficient for large systems in explicit solvent. We explore the dynamics of several globular proteins in aqueous systems comprising up to 35,000 atoms using SO3LR, and compare its performance against a set of widely used MMFFs. While SO3LR faithfully reproduces the static structural properties of proteins, it exhibits enhanced exploration of conformational space during molecular dynamics simulations compared to MMFFs, showing qualitatively different properties of sampling and convergence. This stems from its relatively accurate treatment of quantum many-body forces. Notably, SO3LR enables proteins to explore a broader spectrum of dihedral angles (ψ/ϕ distributions) that are inaccessible to conventional force fields, leading to higher configurational entropy over comparable simulation timescales. These results imply that classical treatments of biomolecules, even if they reach an adequate thermodynamic accuracy, may often do so for the wrong reasons.

BP 20.2 Wed 15:15 BAR/0106

Molecular dynamics simulations of native state collagen fibrils — Konstantinos Steiakakis[1], Alan Pichard[2], and •Maxime Vassaux[2] — [1]Processing and Performance of Materials, Department of Mechanical Engineering, Eindhoven University of Technology, Eindhoven, 5600 MB, The Netherlands — [2]Univ. Rennes, CNRS, IPR - UMR 6251, Rennes, 35000, France

Collagen fibrils are the building block of many biological tissues, which viability depend on the fibrils properties. Altered properties of collagen fibrils are central to the appearance of many diseases, and physiological or native properties must be reproduced for tissue engineering. Yet, the self-assembly, the structure, and therefore the properties of collagen fibrils remain elusive. One main reason is the extreme sensitivity of the fibrils to their environmental conditions, and in particular hydration which is only loosely bound by experimental measurements. Furthermore, mechanics are an integral part of the self-assembly process and may result in internal stresses in collagen fibrils in native conditions. Here, we investigate hydradtion, structure and internal stresses in collagen fibrils by means of molecular dynamics simulations of the collagen microfibril model. Overall, our findings provide insights into the native properties of collagen fibrils such as longitudinal pre-strain and water content. More than ever, collagen fibrils appear to be assembled via an out-of-equilibrium process key for the synthesis of viable tissues.

BP 20.3 Wed 15:30 BAR/0106

Atomic-Level Insights into Amyloid Resistance Gained from Molecular Dynamics Simulations — •Adrian Felix Schnell[1], Tim Moderer[2], Marcus Fändrich[2], and Nadine Schwierz[1] — [1]Institute of Physics, Computational Biology, University of Augsburg, Universitätsstraße 1b, 86159 Augsburg, Germany — [2]Institute of Protein Biochemistry, Ulm University, 89081 Ulm, Germany

Systemic AA amyloidosis arises from the misfolding and aggregation of normally soluble serum amyloid A1 (SAA1) protein into pathogenic fibrils. Despite extensive experimental efforts, the molecular driving forces that govern fibril formation and resistance remain only partly understood.

Using atomistic molecular dynamics (MD) simulations of experimentally resolved structures in both the fibrillar and native states, we investigated sequence-specific features that modulate amyloid stability and resistance. Simulations of wild-type SAA1 and two naturally occurring variants known to display amyloid resistance reveal how single-point mutations can markedly influence fibril stability and impede fibril growth. Specifically, the atomistic MD trajectories show that the resistant variants fail to stably adopt the pathogenic fibril conformation, pointing to distinct structural and dynamical mechanisms underlying their protective effect.

Invited Talk BP 20.4 Wed 15:45 BAR/0106

Solution scattering and MD simulation as quantitative probes of protein-specific and temperature-dependent hydration — •Jochen S Hub — Saarland University, Saarbrücken, Germany

The hydration shell is an integral part of proteins since it plays key roles for confor- mational transitions, molecular recognition, and enzymatic activity. While the dynam- ics of the hydration shell have been described in detail by spectroscopic techniques, the structure of the hydration shell remain less understood due to the lack of hydration shell-sensitive structural probes with high spatial resolution. Whether MD simulations correctly reproduce the hydration shell structure is not known. Small-angle scattering (SAS) with X-rays or neutrons (SAXS/SANS) is sensitive to the hydration shell; however, the hydration shell effects on SAS data has traditionally been considered as a problem, which had to be absorbed into free fitting parameters, rather than a chance to learn the hydration shell structure. We combine SAS data with MD simulations and explicit-solvent SAS predictions to reveal how factors such as surface properties, temperature, and force fields influence protein hydration. We find that (i) MD simulations with certain (but not all) force fields yield excellent agreement with the SAS data; (ii) chemical characteristics of surface-exposed moieties strongly modulate the hydration shell contrast and structure; (iii) temprature-ramp SAXS and MD show consistently that the protein hydration shell is remarkably temperature-sensitive. Our studies demonstrate the combination of SAS and explicit-solvent MD simulations as quantitative structural probes of protein hydation.

Microscopic Insights into the Solvation of Stapled Peptides A Case Study of p53-MDM2 — Vikram Gaikwad, •Asha Rani Choudhury, and Rajarshi Chakrabarti — Indian Institute of Technology Bombay, Mumbai, India

Water often termed the universal solvent, plays a vital role in numerous biomolecular processes, including protein-protein interactions. One such critical complex is p53-MDM2, which is central to cellular regulation. Inhibiting the p53-MDM2 interaction remains a therapeutic challenge, and stapled peptides have emerged as promising candidates in this context.The stapled peptides are peptidomimetics in which the side chains of two suitably positioned amino acids are covalently linked using an appropriate chemical moiety. In this study, we investigate the role of water in the binding of stapled p53 peptides to MDM2 using molecular dynamics simulations. Our aim is to understand how variations in the chemical nature and stapling position of the hydrocarbon cross-linker influence the behavior of water molecules surrounding the p53 peptide. Using rigorous entropy calculations, we rationalize the enhanced binding affinity of stapled p53 peptides compared to that of their unstapled counterparts from a solvent-centric perspective. Specifically, the entropy gain of water molecules around the stapled peptides, combined with the conformational entropy loss of the peptide, contributes favorably to binding. These findings offer valuable insights into the rational design of stapled peptides and support the development of improved therapeutic inhibitors targeting the p53-MDM2 interaction.

BP 20.6 Wed 16:45 BAR/0106

What is the structure of biomolecular condensates? — •Charlotta Lorenz[1,2], Nathaniel Hess[3], Sully Bailey-Darland[1], Teagan Bate[1], Takumi Matsuzawa[1], Tong Wang[1], Kaarthik Varma[1], Dana Matthias[1], Harsha Koganti[1], Lois Pollack[1], Benjamin Schuler[2], Jerelle Joseph[3], and Eric Dufresne[1] — [1]Cornell University, Ithaca, NY, USA — [2]University of Zurich, Zurich, Switzerland — [3]Princeton University, Princeton, NJ, USA

Biomolecular condensates are important for a variety of cellular functions, such as biochemical regulation, structural organization, and RNA metabolism. While the properties and physiology of these condensates depend on their structure, this important aspect has received little experimental consideration. We expect a structure-function relationship determined by protein-protein interactions. Recent simulations of disordered proteins with interactions based on the sticker-and-spacer suggest fascinating structures in the bulk and surface of condensates. We reveal the structure of biomolecular condensates using small-angle X-ray scattering. We show that condensates made from a simple model system of bovine serum albumin (BSA) and polyethylene glycol (PEG) behave like a classical liquid. We extend our approach to the structure of condensates made of disordered proteins such as fused in sarcoma (FUS) and we find that FUS inside condensates structurally behaves like a gas. Our approach is applicable to a variety of different condensates and shows that diverse condensates have diverse structures.

Dynamics and (self-)interactions of the endocytic protein Eps15 — •Andromachi Papagiannoula, Ida M Vedel, Arbesa Saiti, Kathrin Motzny, and Sigrid Milles — Leibniz-Forschungsinstitut für Molekulare Pharmakologie im Forschungsverbund, Berlin

Eps15 is one of the earliest initiators of clathrin-mediated endocytosis (CME). The dimeric protein carries three EH domains per monomer, which are known to recognize Asn-Pro-Phe (NPF) motifs in intrinsically disordered regions (IDRs). Using nuclear magnetic resonance (NMR) spectroscopy, we examined interactions between EH domains and the IDR of the endocytic partner Dab2. In ad-

dition to canonical NPF recognition, we detect a high level of binding promiscuity leading to interaction with other phenylalanine-rich regions. This behavior enables EH domains to also engage with Eps15's own IDR, creating partial competition with Dab2. Nevertheless, Dab2 and the Eps15 IDR can bind EH domains simultaneously, leading to recruitment of Dab2 into Eps15 condensates. When EH domains are expressed in row, as they naturally occur in the wild type full length protein, EH2 and EH3 tumble together as one entity, while EH1 moves independently. Using single molecule Forster resonance energy transfer (smFRET), we assess the three dimensional organization of the three EH domains with respect to each other and assess binding with both Dab2 and Eps15 IDRs.

ASAXS Based Absolute Intra-Molecular Distance Measurements for Proteins — •Samuel Stubhan[1], Anna Baptist[1], Caroline Körösy[1], Alessandra Narducci[2], Gustavo Gabriel Moya Munoz[2], Nicolas Wendler[2], Aidin Lak[1], Michael Sztucki[3], Thorben Cordes[2], and Jan Lipfert[1] — [1]Department of Physics and Center for NanoScience, LMU Munich, Amalienstr. 54, 80799 Munich, Germany — [2]Physical and Synthetic Biology, Faculty of Biology, LMU Munich, Großhadernerstr. 2-4, 82152 Planegg-Martinsried, Germany — [3]ESRF, 71 Avenue des Martyrs, 38043 Grenoble, France

Intramolecular distance measurements are key to understanding macromolecular structure and dynamics. Anomalous Small-Angle X-ray Scattering (ASAXS) interferometry enables such measurements by attaching small (~1 nm) gold nanoparticles to target molecules and using X-ray scattering to extract distance distributions. ASAXS provides absolute distances over >10 nm, full ensemble distributions, and minimal sensitivity to label orientation, offering advantages over FRET and NMR.

We demonstrate ASAXS on proteins for the first time using two cysteine variants of maltose binding protein in apo and holo states, directly revealing ligand-induced conformational changes. The resulting distance distributions agree with single-molecule FRET measurements. Requiring only a double-labeled sample and accommodating diverse solution conditions, ASAXS offers a robust, broadly applicable tool for probing protein conformational ensembles.

BP 20.9 Wed 17:30 BAR/0106

Probing membrane protein dynamics on lipid-functionalized graphene transistors through low-frequency noise — •Florian Steinbach[1], Mykola Fomin[1], Eduard Haar[2], Svetlana Vitusevich[3], Mykhaylo Petrychuk[3], Christian Ungermann[2], and Carola Meyer[1] — [1]Institute of Physics, University of Osnabrück — [2]Department of Biology/Chemistry and Center for Cellular Nanoanalytics, University of Osnabrück — [3]Institute of Biological Information Processing (IBI-3), Forschungszentrum Jülich

Graphene field-effect transistors (GFETs) functionalized with lipid monolayers provide a controlled and label-free platform for studying membrane-associated proteins [1]. Here, we present electronic transport experiments where the Rab7-like GTPase Ypt7 is immobilized within a lipid monolayer. While there is not electrostatic gating effect observed, the addition of the protein causes a pronounced increase in low-frequency 1/f noise. This noise signal is diminished upon binding of the membrane tethering HOPS complex [2]. The persistence of distinct noise signatures despite strong screening indicates a transduction mechanism that may circumvent the screening within the Debye length.

BP 21: Focus Session: Sequence Spaces, Populations and Evolution

Evolutionary processes are central in the living world: they leave patterns in sequence databases and underlie phenomena such as cancer progression and antibiotic resistance. Achieving a quantitative understanding of evolution relies on two key components: variation and selection. The first component - variation - arises from random mutations in genotypic sequences that lead to selectable changes in phenotype and fitness. Thus, variation depends on how phenotype and fitness are distributed in biological sequence spaces. The second component - selection * shapes the composition of future generations and thus acts at the population level. Since these components jointly shape evolutionary processes, this focus session will encompass both: variation in sequence spaces and selection on the population level.

Organized by Nora Martin (Centre for Genomic Regulation, Barcelona) and Paula Garcia Galindo (University of Cambridge)

Time: Wednesday 15:00–17:30 Location: HÜL/S386

Invited Talk BP 21.1 Wed 15:00 HÜL/S386

Microbial Behavior in Context — •Fernanda Pinheiro — Human Technopole, Milan, Italy

Predicting microbial responses to antibiotics, nutrient shifts, or invading species requires models linked to metabolic pathways and cellular functions. In this talk, I present quantitative approaches for characterizing microbial behavior, from growth kinetics to coarse-grained models of cell metabolism and empirical growth laws. I will connect growth parameters to resource allocation and physiological constraints, and I will show how growth perturbations reveal layers of organization, from cellular physiology to ecological interactions and evolutionary change. In a broader context, I will discuss how metabolic models linking systems biology, ecology, and evolution can become tools for prediction.

BP 21.2 Wed 15:30 HÜL/S386

Insertions and Deletions make important contributions to the arrival of phenotypic variation — •Manuela Giraud[1,2] and Nora Martin[1] — [1]CRG (Barcelona Collaboratorium for Modelling and Predictive Biology), Dr. Aiguader 88, Barcelona 08003, Spain — [2]Universitat Pompeu Fabra (UPF), Barcelona, Spain.

In evolution, phenotypic variation is a prerequisite for selection and arises from random genotypic mutations. An extensive mapping of genotypes to their corresponding phenotype (GP map) provides us with a quantitative model for variation, thus informing evolutionary predictions. The features of GP maps and their relevance for evolutionary processes have been analyzed for different model systems, but these analyses have largely been limited to short substitutions. Insertions and deletions (InDels) of different lengths have been neglected despite their presence in natural sequence families. In this study, we analyze InDels in computational GP maps modelling RNA secondary structure, enzyme functionality, and a toy-model for protein quaternary structure self-assembly. We find that InDels are more likely to preserve the phenotype than expected from null models. These phenotype-conserving indels imply large sequence changes, affecting the effect of subsequent mutations: after a phenotype-conserving InDel, the distribution of accessible phenotypes shifts increasingly with the mutation size. Evolutionary simulations indicate that such phenotype-conserving indels can fix and strongly affect the number of encountered phenotypes. These results imply that InDels, even if rare, can make an important contribution to the arrival of phenotypic variation.

BP 21.3 Wed 15:45 HÜL/S386

Bias toward simplicity and symmetry in protein self-assembly — •Prarthana Agrawal — University of Oxford

Symmetry is ubiquitous in protein complexes and other biological assemblies and is often attributed to natural selection. Algorithmic information theory offers an alternative explanation: when structures are generated by simple local rules, outcomes that require less information to specify are intrinsically more likely [1]. Because symmetry enables reuse of the same assembly instructions, symmetric structures typically have low algorithmic (Kolmogorov) complexity and are therefore strongly favored.

We test this idea using a three-dimensional polycube self-assembly model as an abstract representation of protein quaternary structure. By sampling interaction rule spaces, we find a strong bias toward low-complexity assemblies, with symmetric structures occurring far more frequently than asymmetric ones. We further show that not all symmetries are equally accessible: some symmetry operations reduce assembly complexity more effectively than others and are therefore disproportionately likely.

These results indicate that biases toward simple and symmetric structures in self-assembly arise from intrinsic generative constraints rather than natural selection alone, suggesting that evolutionary outcomes are shaped not only by selection but also by how phenotypic variation is generated.

The navigability of fitness landscapes shaped by global and universal epistasis — •Joachim Krug — Institute for Biological Physics, University of Cologne, Germany

Epistasis is the dependence of the effect of a mutation on the genetic context in which it occurs. Epistatic interactions shape the topography of the fitness landscape, the mapping from genotype to reproductive success. Global epistasis refers to interactions that arise when a nonlinear phenotype-fitness map acts on a lower-dimensional set of non-epistatic phenotypes, and has been argued to be a common occurrence at different scales of biological organization. It is therefore of interest to ask what features characterize fitness landscapes when epistasis is purely global. Here I show that, under certain conditions, global epistasis implies universal negative epistasis [1], an order relation on sequence space that is closely related to submodularity of set functions [2]. Universal epistasis makes fitness landscapes easily navigable, because any fitness peak is accessible through combinatorially many fitness-increasing mutational paths. I will discuss the theoretical results within the context of recent studies of large-scale empirical fitness landscapes that have found that rugged landscapes may also be highly navigable.

Adaptive Response of Quantitative Traits to a Moving Fitness Landscape — •Sakshi Pahujani, Yuna Zhang, Markus G. Stetter, and Joachim Krug — University of Cologne, Cologne, Germany

Phenotypic adaptation to long term persistent changes in the environment is typically studied using moving optimum models which consider a fitness landscape traversing the phenotypic space over time. Invoking the strong-selection-weak-mutation regime, we study adaptation as a walk towards the moving fitness optimum described by a continuous-state-discrete-time stochastic process. In this framework, at a critical speed of the optimum, we elucidate a transition, from a regime where the phenotypic gap of the adapting population from the optimum attains a stationary mean value to one where it increases indefinitely. Through a special case of the problem, we provide an alternative description of this transition in terms of a force that drives the adaptive process and a corresponding potential that switches from being confining to non-confining at the critical speed. Further analysis of this case suggests that adaptation is rather successfully carried out, until the population becomes limited by the maximum rate at which it can adapt. Remarkably, despite the simplicity of this special case, its predictions align well with observations from the original, more complex model [1].

A simplified Rough Mount Fuji model clarifies how local adaptive walks can reach the highest peaks in rugged fitness landscapes — •Kye E Hunter[1,2] and Nora Martin[1] — [1]CRG (Barcelona Collaboratorium for Modelling and Predictive Biology) — [2]Facultat de Física, Universitat de Barcelona (UB)

Adaptive evolution selects random genotypic mutations according to their fitness. This can be modeled using a fitness landscape, a network of possible genotypes with a fitness value associated to each sequence. In the simplest models of adaptive evolution, populations move through this network in fitness-increasing steps until reaching a genotype whose fitness exceeds that of all its neighbors—a fitness peak. In evolutionary simulations on their empirical folA landscape, Papkou et al. (Science 2023) found that such fitness-increasing walks are likely to reach the globally-highest-ranked peaks among a large number of peaks, despite only being based on local rules. Similar results were found in a mathematical model of fitness landscapes, the Rough Mount Fuji model (Li & Zhang MBE 2025).

We use a simplified Rough Mount Fuji model to find simple analytical explanations for how a landscape can have both a large number of peaks and populations that reach the highest-ranked peaks. Our explanation proceeds by dividing the landscape into different regions, and considering the number of peaks relative to the total number of genotypes in each region. We then identify the degree to which those same arguments apply in the empirical folA landscape.

BP 21.7 Wed 17:15 HÜL/S386

Mean adaptive basin size for fitness peaks in the House of Cards landscape — •Daniel Oros and Joachim Krug — Institute for Biological Physics - University of Cologne

Fitness landscapes have been studied extensively in evolutionary theory. In a simple form, the fitness landscape maps the genotype of an organism to its reproductive success, denoted by fitness. While being a drastic simplification of biology, the concept is useful for understanding how evolution navigates such a landscape. When the time between mutations is much larger than the fixation time, one can think of a genetically homogeneous population moving one mutation at a time. The fitness value increases at each step and the population eventually reaches a fitness peak, a genotype having larger fitness than all its single mutant neighbors. The adaptive basin of a peak is composed of all genotypes which have a monotonically increasing fitness path to it.

Large scale fitness landscape measurements show that the basins of high fitness peaks contain a large fraction of all genotypes, a finding that has been argued to be inconsistent with existing fitness landscape models [1]. In House of Cards (HoC) landscapes fitness values are assigned independently at random, resulting in a maximally rugged landscape. Building on previous work on accessibility percolation [2] we show that typical peak adaptive basins in the HoC landscape contain a positive fraction of all genotypes, and derive an explicit expression for the mean basin size.

Characterization and Application of Honey-PVA Electrospun Scaffolds in Tissue Engineering — •Catalina Navarrete-Vera[1], Karen Yáñez[2], Cristian Acevedo[2], and Tomas Corrales[1,2] — [1]Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile — [2]Centro de Biotecnología Daniel Alkalay Lowitt, Universidad Técnica Federico Santa María, Chile

Tissue engineering seeks to develop functional biomaterials that integrate seamlessly with biological systems. Electrospinning with static collectors enables the production of nanostructured scaffolds suitable for cell regeneration (10.1021/acsomega.3c06436). Incorporating natural components, such as honey, valued for its regenerative, anti-inflammatory, and antimicrobial properties, offers a route to bioactive wound-dressing alternatives (10.1016/j.carbpol.2019.05.004).

In this study, Manuka and Ulmo honeys were each combined with PVA to generate nanofibers and scaffolds via electrospinning. AFM force spectroscopy was used to assess individual fiber mechanics, and SEM and cell-culture assays were employed to evaluate morphology and biocompatibility. Both formulations produced fibers of similar diameter (100-300 nm) and nanomechanical stiffness (~200 MPa), while honey-containing scaffolds improved cell growth over controls. These results indicate that Ulmo honey is a promising alternative to Manuka honey for tissue-engineering applications.

BP 26.2 Thu 9:45 BAR/SCHÖ

Additive Manufacturing in Wound Care Innovation from Sugarcane Bagasse — •Ahmed El-Hussein Elnewishy[1], Muhammad Mounir[1], Mona Tarek[1], and Ita Junkar[2] — [1]Biotechnology Program, Faculty of Science, Galala University — [2]Department of Surface Engineering, Jožef Stephan Institute, Ljubljana, Slovenia

Three-dimensional (3D) printing technology is capable of creating highly complex, customizable objects, offering unique advantages for various biomedical applications through methods such as inkjet-based, extrusion-based, and light-assisted techniques. This study focuses on using direct ink writing for additive manufacturing to print antibacterial wound dressings, addressing a critical gap in the current wound care market. The management of chronic and acute wounds presents significant challenges facing human health and overall wellness. Current wound dressing fails to meet patients needs in terms of high adhesion, poor gas exchange, low moisture retention, and the use of systemic and synthetic antibiotics. Additionally, the presence of unused agricultural waste and weak waste management increase greenhouse gas emissions, thus contributing to global warming. To address these issues, we utilized agricultural waste, specifically sugarcane bagasse, to create biopolymer 3D printing ink for wound dressings. We extracted cellulose from sugarcane bagasse and antibacterial bioactive compounds from plant extracts. The synthesized ink was then printed and post treated to enhance mechanical properties. We evaluated the cytotoxicity, antibacterial activity, and morphological structure of the patches using scanning electron microscopy.

FCS-Based RNA Payload Quantification and FLIM Analysis of pH-Dependent Lipid Phase Transitions in Lipid Nanoparticless — •Bernhard Kirchmair[1], Judith Müller[1], Thomas Kellerer[2], Ekaterina Kostyurina[1], and Joachim Rädler[1] — [1]Ludwig-Maximilians-Universität München, Germany — [2]Max Planck-Institut für Biochemie, Martinsried, Germany

Lipid nanoparticles (LNPs) emerged as one of the most promising delivery systems for transfecting mammalian cells with synthetic messenger RNA (mRNA). However, LNPs show a substantial heterogeneity both in shape and cargo and the precise mRNA payload and stoichiometric ratios in multi-component nucleic acid delivery remain poorly quantified. In this project we investigate how mRNA payload depends on LNP size and surface composition using fluorescence correlation spectroscopy (FCS) supported by dynamic light scattering, enabling estimation of particle concentration and RNA copies per LNP. Fluorescence cross-correlation spectroscopy further allows measurement of siRNA/mRNA ratios in mixed cargos. To link payload properties to endosomal escape rates and hence delivery efficiency, we probed pH-dependent lipid phase transitions using fluorescence lifetime imaging (FLIM) and fluorescence anisotropy, capturing changes both in bulk lipid phases and in intact LNPs. These measurements build a framework to monitor structural changes relevant to endosomal escape and can be applied to other LNP formulations and cargo types. Quantitative knowledge about content and ratios will ultimately support the delivery of genetic programs for regulated gene expression.

BP 26.4 Thu 10:15 BAR/SCHÖ

pH-dependent phase transitions in ionizable lipid mesophases — •Ekaterina Kostyurina[1], Susanne Liese[2], Akhil Sudarsan[2], Julian Philipp[1], and Joachim Rädler[1] — [1]Faculty of Physics, Ludwig-Maximilians University, 80539 Munich, Germany — [2]Faculty of Mathematics, Natural Science, and Materials Engineering, Institute of Physics, University of Augsburg, 86159 Augsburg, Germany

Lipid Nanoparticles (LNPs) have proven valuable in modern medicine as a medium for RNA delivery. Nanoparticles containing cationic ionizable lipid (CIL), cholesterol and structural lipids complex with nucleic acids into size-controlled particles that transport nucleic acid molecules across cell membranes via the endocytic uptake pathway. The delivery efficiency of a drug or vaccine is directly related to the efficiency of the endosomal release. Here, we study pH-dependent structural transitions of the CIL core phase which are believed to play an essential role in this process. We use bulk phases of ionizable lipid/cholesterol as a model system of the LNP core which allows us to study the structure of the lipid phases with high precision using X-ray diffraction. We show that the commonly used ionizable lipids overcome the inverted micellar-inverted hexagonal phase transition within the pH range typical for endosomal life cycle, and connect structural properties of the phases with LNP efficacy. Furthermore, we are aiming to understand the thermodynamics of these phase transitions by combining experimental measurements with theoretical modeling. This will help to better understand the structure-activity relation of LNPs and to increase the delivery efficiency in clinically relevant LNP delivery systems.

BP 26.5 Thu 10:30 BAR/SCHÖ

To gel or not to gel? Assembly phase changes of engineered spidroin proteins induced by temperature and time — •Isabell Tunn[1,2,3], Dmitry Tolmachev[2,4], Adam L. Harmat[2,4], Nea B. Möttönen[1,2], Alberto Scacchi[2,4,5], Maria Sammalkorpi[2,4], and Markus B. Linder[1,4] — [1]Department of Bioproducts and Biosystems, Aalto University, Finland — [2]Academy of Finland Center of Excellence in Life-Inspired Hybrid Materials (LIBER), Aalto University, Finland — [3]Fraunhofer Institute for Applied Polymer Research (IAP), Germany — [4]Department of Chemistry and Materials Science, Aalto University, Finland — [5]Department of Mechanical and Materials Engineering, University of Turku, Finland

Bioinspired silk-like proteins offer exciting possibilities for developing the next generation of advanced materials - from medicine to food packaging. Here, we investigate the temperature- and time-dependent assembly behaviour of engineered silk-like proteins into hydrogels conducting experiments and molecular dynamics simulations.* Phase transitions are controlled by entropic changes in flexible glycine-rich regions and hydrophobic interactions of alanine-rich α-helical regions. High-temperature gelation proceeds through interactions between alanine-rich domains, leading to β-sheet formation while time-induced gelation occurs via protein percolation mainly driven by dimerization of terminal domains. These findings provide guidelines for engineering protein-based materials with tailored assembly properties and gel characteristics, advancing the rational design of biomimetic soft materials. *https://doi.org/10.1016/j.ijbiomac.2025.147712

BP 26.6 Thu 10:45 BAR/SCHÖ

Power-Law Analysis of Force Relaxation and Creep Compliance in Nanoindentation of Glassy Gelatin in Humid Air — Paul Zech, Martin Dehnert, Mario Zerson, and •Robert Magerle — Fakultät für Naturwissenschaften, TU Chemnitz

Gelatin-based materials are widely used in food technology, drug delivery systems, and tissue engineering. Water acts as a plasticizer, softening gelatin and reducing its glass transition temperature. Using AFM-based nanoindentation experiments, we examined the mechanical response of a gelatin film to nanoindentations under constant strain (force relaxation) or constant stress (creep compliance) at a wide range of tip approach velocities and relative humidity levels. Scaling analysis using a fractional rheology model reveals that force relaxation and creep compliance exhibit universal power-law behavior. Temporal evolution depends only on the tip indentation time, which defines the externally imposed timescale of the process, and the power-law exponent α, which characterizes the degree of viscoelasticity. At relative humidity > 85%, the α values differ between the force relaxation and creep compliance data. This indicates differences in the underlying molecular processes.

Directed evolution of material-producing bacteria — •André Studart — Complex Materials, Department of Materials, ETH Zürich

Engineers often use high temperatures, pressures and polluting chemicals to make synthetic materials. By contrast, biology produces remarkable materials like wood and bone using widely available chemicals in water and at ambient temperature. The ability of organisms to create materials under mild conditions relies on the intricate biological machinery of living cells. Notably, natural selection processes have evolved such machinery for hundreds of millions of years to fulfill the demands of biological environments. Can we harness the machinery and evolutionary processes of biology to create materials more sustainably while still meeting engineering needs ? To explore this question, we utilized a microfluidic platform to evolve material-forming microorganisms towards cell mutants that meet the high productivity needed in industrial processes. Using cellulose-producing bacteria as an example, we show that this directed evolution approach enabled the isolation of a bacterial mutant that produces up to 70% more cellulose than its native counterpart. The overproducing bacterial strain offers an attractive alternative to wood to meet the growing demand for cellulose in the textile, medical and packaging industries. Beyond cellulose, the proposed technology offers a compelling approach to isolate bacteria for the biofabrication of other sustainable materials, such as silk, polyesters and clay-based bricks.

BP 26.8 Thu 11:45 BAR/SCHÖ

Controlling Axonal Outgrowth of Organoids by 3D Nanoprinted Scaffolds — •Tobias Müller[1], Malte Siegmund[1], Emma Wollesen[1], Kim Krieg[2], Ole Pless[2], Jan Hahn[3], Robert Zierold[1], and Robert Blick[1] — [1]Center for Hybrid Nanostructures, University of Hamburg, 22761 Germany — [2]Fraunhofer ITMP, Discovery Research Screening Port, 22525 Germany — [3]Section Facility Mass Spectrometry and Proteomics, University Medical Center Hamburg-Eppendorf, 20246 Germany

Cortical organoids are promising models for neurodegenerative disease research, yet their integration into defined neural networks remains challenging. We use two-photon polymerization (2PP) to fabricate three-dimensional scaffolds that direct axonal outgrowth and support organoid integration into engineered circuits.

Scaling structures from single neurons to millimeter-scale organoids introduces adhesion and imaging challenges. We address this by combining tailored scaffold geometries with a polydimethylsiloxane (PDMS)-based anchoring strategy, critical-point drying and quantitative analysis of electron microscopy images. Walls, stairs and microwires enhance organoid-scaffold interactions, promoting axonal outgrowth along intended paths and reducing extension into non-target regions.

These results demonstrate that 2PP-fabricated microarchitectures can guide axon growth and stabilize organoid-substrate contact, enabling more controlled organoid-based neuronal networks and advancing brain-on-a-chip approaches.

BP 26.9 Thu 12:00 BAR/SCHÖ

Stimulus-induced biomechanical perturbations via smart hydrogel microstructures — •Katja Zieske — Max Planck Institute for the Science of Light, Erlangen, Germany

Cells reside within complex three-dimensional extracellular matrices, where mechanical interactions play essential roles in tissue development, and disease progression. To mimic these interactions, we developed a lab-on-a-chip platform that applies spatially and temporally controlled mechanical perturbations using intelligent hydrogel microstructures.

First, we optimized material composition and photopolymerization parameters and demonstrated reliable, stimulus-dependent expansion and contraction of the hydrogel microstructures within microfluidic chambers. Using these microstructures, we then applied compressive forces to Matrigel and collagen networks. Finally, we applied mechanical perturbations to cellular systems.

By mimicking cellular pushing forces with hydrogel microstructures, this lab-on-a-chip system provides a versatile tool for studying mechanical remodeling of biopolymers and cellular systems.

BP 26.10 Thu 12:15 BAR/SCHÖ

Functionally Connecting High- and Low-Density Neuronal Networks Using 3D-Nanoprinted Structures — •Emma Wollesen, Malte Siegmund, Tobias Müller, Josephine Hoppe, Robert Zierold, and Robert Blick — Center for Hybrid Nanostructures, University of Hamburg, 22761 Hamburg, Germany

Tracing the propagation of interneural communication from high- to low-density networks is essential for exploiting information processing at the single-cell level. Given the multitude of synaptic connections, high-density networks of hiPSC-derived neurons may generate bursts of action potentials, a key communication mode that can be analyzed at the single-cell level in receiving low-density networks. Here, we move toward such a cultivation platform by evaluating 3D nanoprinted (3DN) structures fabricated by two-photon polymerization for their efficiency in facilitating connected high- and low-density networks. We demonstrate the prerequisite formation of hiPSC-derived low-density neuronal networks in tower-shaped 3DN structures. For augmentation with high-density networks, a stomach-shaped structure and connecting elements were fabricated. A minimum structure height of 30 micrometers proved critical for clear network demarcation. For future region-specific chemical stimulation, millimeter-scale structures for media reservoir separation were conceptualized, and fabrication feasibility was confirmed, requiring a 10 micrometer overlap and a suitable shear angle at structure interfaces. These results extend established 3DN platforms for low-density networks and support the integration of neural networks into Brain-on-a-Chip applications.

BP 26.11 Thu 12:30 BAR/SCHÖ

Multiplex sensing of respiratory viruses using surface plasmon resonance spectroscopy — •Ghazaleh Eshaghi[1], David Kaiser[1], Hamid Reza Rasouli[1], Dominik Gary[2], Tobias Fischer[2], Katrin Frankenfeld[2], Abhishek Sharma[3], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, 07743 Jena — [2]Forschungszentrum für Medizintechnik und Biotechnologie (fzmb) GmbH, 99947 Bad Langensalza, Germany — [3]BioNavis Ltd., Hermiankatu 6-8H, 33720 Tampere, Finland

We present label-free and real-time biosensing of three major respiratory viruses using the Multi-Parametric Surface Plasmon Resonance (MP-SPR) technique. In this approach, MP-SPR SPR Au sensors are functionalized with ultrathin (~1 nm) azide-terminated carbon nanomembranes (N3-CNMs), enabling covalent attachment of virus-specific antibodies and thereby providing selective immobilization of target antigens on the sensor surface. We demonstrate specific detection of SARS-CoV-2, Influenza A, and Respiratory Syncytial Virus (RSV) antigens with negligible cross-reactivity and high reproducibility in both PBS-P buffer (physiological pH) and clinically relevant nasopharyngeal swab matrices. For SARS-CoV-2, Influenza A, and RSV antigens, we determine dissociation constants (KD) of 7.0 * 0.5 nM, 86 * 4 pM, and 3.0 * 0.2 pM, respectively, with corresponding limits of detection (LOD) of ~65 pM, ~80 pM, and ~2 pM.

Tissue interplay and the coordination of morphogenesis — •Elias Barriga — Physics of Life (PoL), Dresden, Germany

How tissues achieve robust morphogenesis in development and regeneration is the driving question in our research. In my talk I will share our results arising from a combination of mechanical and electrical measurements and perturbations in living tissues; and will discuss how our work support the exciting idea that biophysical properties emerging from tissue interplay coordinate morphogenesis in time and space.

BP 27.2 Thu 10:00 BAR/0205

Mechanical polarity in cell migration — •Steffen Grosser[1], Leone Rossetti[2], Isabela Corina Fortunato[3], Ricard Alert[4,5], and Xavier Trepat[1,5,6,7] — [1]Institute for Bioengineering of Catalonia (IBEC), Barcelona — [2]Faculty of Dentistry, Oral & Craniofacial Sciences, King's College, London — [3]Institut d'Investigació Sanitària Illes Balears (IdISBa), Palma — [4]MPI für Physik komplexer Systeme (MPI-PKS), Dresden — [5]University of Barcelona, Barcelona — [6]ICREA, Barcelona — [7]CIBER-BBN, Barcelona

Cells migrate on substrates in the absence of any net force, which poses a fundamental challenge in cell dynamics. All forces transmitted from the cells to the substrate cancel out. Neither force magnitude nor force dipole are related to neither cell speed nor direction.

We have recently found, however, that a higher moment of the cell traction distribution, the quadrupole, is in fact closely related to cell velocity - to both speed and direction. The quadrupole characterizes the asymmetry of the traction distribution, even when the total net force cancels out. It can be thought of as a mechanical cell polarity readout. Experimentally, the relation between force asymmetry and velocity holds for single cells and for short multicellular trains, and even for cells moving along gradients of adhesion.

To interpret this traction asymmetry, we propose to decompose the force into an active, unbalanced part that drives cell motion, and a frictional component. This leads to a novel, actual force-velocity relation for cell dynamics.

BP 27.3 Thu 10:15 BAR/0205

Mechanics of "apical bulkheads" in the bile canaliculi of the liver — •Matthew J. Bovyn[1,2,3], Maarten P. Bebelman[2], Yannis Kalaidzidis[2], Marino Zerial[2,4], and Pierre A. Haas[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden — [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden — [3]Center for Systems Biology Dresden — [4]Human Technopole, Milan

In the liver, bile is transported through the network of bile canaliculi. They are bicellular tubes ("lumina"), in which the apical cortices of apposed cells bear bile pressure. When bile canaliculi must hold high pressures, either in development or disease, they generate folds protruding into the tubes, termed "apical bulkheads". These structures are under tension and contribute significantly to the ability of the bile canaliculus as a whole to bear pressure [1]. Here, we use lightsheet microscopy to discover that bulkheads are also dynamic, forming and retracting on a timescale of 20 min. We investigate the mechanical origins of this process by constructing a mechanical model balancing pressure and anisotropic surface tensions and spontaneous curvature of the apical cortices. We discuss the cell biological origins of these mechanical ingredients, the experimental evidence for them, and their role in bulkhead formation.

[1] Bebelman, M. P., Bovyn, M. J., *et al.* Hepatocyte apical bulkheads provide a mechanical means to oppose bile pressure. J. Cell Biol. **222**, e202208002 (2023).

BP 27.4 Thu 10:30 BAR/0205

Blebbing under confinement functions as a pressure-relief mechanism following cortical contraction — •Fatemeh Abbasi[1,2], Timo Betz[2], and Eva Kiermaier[1,3,4] — [1]Life and Medical Sciences (LIMES) Institute, Immune and Tumor Biology, University of Bonn, Bonn, Germany. — [2]Third Institute of Physics-Biophysics, Georg August University Göttingen, Göttingen, Germany. — [3]Department of Medicine, Friedrich-Alexander University Erlangen-Nürnberg (FAU), Erlangen, Germany. — [4]Deutsches Zentrum Immuntherapie (DZI), Universitätsklinikum Erlangen, Erlangen, Germany.

Cells migrating through tissues experience mechanical confinement that reshapes their morphology and internal stress. Using Confinement Force Microscopy (CFM), we dynamically controlled vertical confinement during live imaging and quantified 3D stress responses. A single confinement step triggered a biphasic response: an immediate passive stress spike from nuclear compression followed by a slower, actomyosin-driven buildup linked to bleb formation. Both blebbistatin and Y-27632 reduced traction stresses; notably, Y-27632 fully blocked blebbing, while blebbistatin allowed it only under strong compression, indicating partial decoupling between contractility and morphology. Blebbistatin also lowered cellular stiffness and viscosity, promoting rapid stress relaxation. These results suggest that blebbing functions as a pressure-relief mechanism allowing cells to maintain mechanical balance under confinement.

BP 27.5 Thu 10:45 BAR/0205

Moving without motors: Amoeboid cell migration and shape dynamics driven by actin polymerization — •Winfried Schmidt, Alexander Farutin, and Chaouqi Misbah — Univ. Grenoble Alpes, CNRS, LIPhy, F-38000 Grenoble, France

Mammalian cell migration is essential for many physiological and pathological processes, such as embryonic development, wound healing, and cancer metastasis. Cells have developed the amoeboid migration mode, which is characterized by large, dynamic shape deformations. This strategy allows cells to move rapidly and in the absence of strong adhesion across a variety of different environments, including two-dimensional confinement, three-dimensional matrix, and bulk fluids. Molecular motors, such as myosin, are traditionally considered essential for cell polarization or motility. Here, a model of an amoeboid cell is analyzed both analytically and numerically. It is shown that actin polymerization alone is sufficient to trigger both cell polarity and motility, in line with recent experiments on T-lymphocytes showing that inhibition of molecular motors does not significantly affect motility. Depending on parameter values, the cells exhibit straight, circular, or even chaotic trajectories. A similar variety of motion is observed in experiments across multiple motile cells. These findings open up a new perspective on amoeboid motility, providing a scenario for the onset of polarity, migration, and dynamical cell shape changes without contractile activity.

Living Cells Respond to the Surface Tension of Soft Solids — •Johannes Rheinlaender, Leah Gumbsch, Hendrik von Eysmondt, and Tilman E. Schäffer — Institute of Applied Physics, University Tübingen, Germany

It is widely known that living cells respond to the stiffness of their environment in terms of spreading area as well as other properties such as the cytoskeletal structure, migration, or gene expression. These effects are usually investigated by seeding cells on elastic substrates with varying bulk stiffness, either hydrogels or soft elastomers. However, cellular behavior differs on hydrogels and elastomers, which has been attributed to various material properties like surface roughness or porosity. Using scanning ion conductance microscopy (SICM), we show that elastomers routinely used in mechanobiology studies exhibit a significant surface tension on the order of several tens of mN/m, independent of their bulk stiffness. We thereby demonstrate that living cells mostly respond to the surface tension rather than the bulk stiffness of the substrate on soft elastomers with Young's moduli below approximately 10 kPa and introduce possible solutions to address this problem. To conclude, the influence of surface tension is an important yet underestimated aspect in cellular mechanobiology.

BP 27.7 Thu 11:30 BAR/0205

Complex Rheology in Single Cells: Compression Stiffening but Shear Softening — •James P. Conboy[1], Luis Alonso[2], Haiqian Yang[2], Nicole van Vliet[1], Pouyan E. Boukany[1], Fred C. MacKintosh[3], and Gijsje H. Koenderink[1] — [1]TU Delft, NL — [2]MIT, USA — [3]Rice University, USA

In multicellular organisms, cells are constantly subjected to physical forces. Cells in the heart, lungs and skin experience primarily compression and stretching, whereas shear forces are dominant in the brain and in blood vessels. The mechanical resilience to compression and shear forces is essential for preventing cell damage or even rupture. Our aim is to understand the response of cells to external mechanical cues. For this purpose, we have developed a novel single cell rheology setup that allows us for the first time to make direct comparisons between a living mammalian cell's response to compression and shear strain. In this work, we have identified the relative contribution of actin and vimentin intermediate filaments in uniaxial compression experiments on single fibroblasts. Our findings reveal that individual fibroblasts undergo stiffening under physiologically relevant compressive strains, but the removal of vimentin reduces this stiffening effect. Furthermore, we present, to our knowledge, the pioneering example of single-cell shear rheology experiments, where we discovered that cells soften when sheared, in stark contrast to their stiffening behaviour under compression. Finally, we propose a minimal model to elucidate these phenomena and compare our results to semiflexible polymer models used to explain the mechanics of reconstituted cytoskeletal systems.

Intracellular ROS generation under ultra-high dose rate electron irradiation at FLASHlab@PITZ — •Y. Komar[1,2,3], E. Fujan[2], C Richard[1], X. Li[1], N. Aftab[1], A. Aksoy[1], Z. Amirkhanyan[1], A. Chiravuri[1,2], J. Good[1], M. Gross[1], F. Hausmann[3], S. Khammee[1], M. Krasilnikov[1], B. Li[1], Z. Lotfi[1], G. Montoya-Soto[1], F. Müller[1], A. Oppelt[1], F. Riemer[1], K. Suzart[1], E. Tarakci[1,2,3], I. Tinhofer[3], D. Villani[1], S. Worm[1], D. Xu[1], S. Zeeshan[1], M. Frohme[2], F. Stephan[1], S. Aminzadeh[1,2], and A. Grebinyk[1,2] — [1]Deutsches Elektronen-Synchrotron, Zeuthen, Germany — [2]Technical University of Applied Sciences Wildau, Wildau, Germany — [3]Charité University Medicine Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany

The new FLASHlab@PITZ beamline commissioning started in August 2025 for radiobiological studies at the Photo-Injector Test Facility at DESY in Zeuthen (PITZ). It enables irradiation with dose rates ranging from conventional (CDR, 0.05Gy/s) up to ultra-high (UHDR, 10^14Gy/s). The in vitro effects of UHDR versus CDR irradiation were examined using human lung cancer A549 and healthy HEL299 cells exposed to CDR (0.05Gy/s) and UHDR (7.8*10^5Gy/s). Reactive oxygen species production assessment showed 84% decrease in HEL299 cells and no difference in A549 at ~7.5Gy under UHDR compared with CDR. That indicates UHDR irradiation having a milder impact on healthy than on cancer cells, highlighting the potential of FLASHlab@PITZ for future in vivo studies.

BP 27.9 Thu 12:00 BAR/0205

Probing the influence of mechano-chemical cues on the size of nuclei — •Pooja Yadav, Florian Rehfeldt, and Matthias Weiss — University of Bayreuth, Experimental Physics I,95447,Bayreuth

The size of nuclei in eukaryotes is frequently observed to scale with the size of the cell that harbours them. Yet, our understanding of how cells can measure and regulate nuclear size is still fragmentary. A recently developed model suggests nuclear size to be determined by a dynamically maintained but limited amount of membrane material that needs to be distributed between organelles and the plasma membrane. Given that membrane homeostasis and cell morphology can be altered biochemically and mechanically, we have used drug treatments and polyacrylamide (PA) hydrogels of varying stiffness as a substrate for cells. As a result, we have found that softening the substrate alters the shape and size of cells and nuclei, but maintains the ratio of their projected areas. Similarly, affecting the actomyosin cortex had little effect on this ratio. However, when enforcing changes in membrane homeostasis by pharmaceuticals, the ratio of cellular and nuclear cross-sectional areas was markedly altered. Altogether, our data suggest that dynamically maintaining and limiting membrane material is a core mechanism of how cells determine the size of their nuclei.

BP 27.10 Thu 12:15 BAR/0205

Nuclear downsizing: Dynamic volume and cell-cycle control in emerging tumour spheroids — •Vaibhav Mahajan[1], Keshav Gajendra Babu[1], Markus Mukenhirn[1], Antje Garside[1], Timon Beck[1,2], Byung Ho Lee[3], Kyoohyun Kim[2], Carsten Werner[4], Alf Honigmann[1], Sebastian Aland[5], Raimund Schlüssler[1], and Anna Taubenberger[1,4] — [1]Dresden University of Technology, Dresden, Germany — [2]Max Planck Institute for the Science of Light, Erlangen — [3]MPI-CBG, Dresden — [4]Leibniz Institute of Polymer Research Dresden — [5]Hochschule für Technik und Wirtschaft Dresden

Tumour development involves biophysical changes across scales, yet how cancer cells regulate properties such as volume and mechanics within dense multicellular environments remains unclear. Using tuneable biohybrid hydrogels, we quantified cell and nuclear volumes as single cancer cells formed multicellular tumour spheroids. We found that transition to multicellularity led to strong reductions in cellular and nuclear volumes, delayed cell-cycle progression, and altered mechanics, with these changes tightly coupled. Nuclear volume dropped by up to 60%, not primarily due to confinement but due to cell-cycle adaptations, namely accumulation of smaller-sized G1 cells-an effect reversed by CDK1 inhibition. Additional nuclear volume decreases within clusters were associated with increased mass density and cell stiffness, both reversible upon cell release. Conversely, cells invading out of spheroids increased nuclear volumes and softened. These findings reveal how cancer cells dynamically adjust volume, cell-cycle state, and mechanics in the multicellular context.

BP 27.11 Thu 12:30 BAR/0205

A protein-DNA surface hydrogel mechanically reinforces the cell nucleus — •Yahor Savich[1,2,3], Ramesh Adakkattil[1], Pranay Mandal[1,2,3], Valentin Ruffine[4], Mareike Jordan[1], Henrik Dahl Pinholt[5], Elisabeth Fischer Friedrich[4], Frank Jülicher[2,3,4], Stephan Grill[1,3,4], and Alexander von Appen[1,4] — [1]MPI-CBG, Dresden — [2]MPI-PKS, Dresden — [3]Center for Systems Biology Dresden — [4]TUD, Dresden — [5]MIT, Cambridge

Cells safeguard their genome while nuclei are deformed. The nuclear envelope is known to protect DNA from such mechanical stress, but how forces are buffered across the scales from individual DNA strands to the nucleus remains unknown. We show that the nuclear envelope protein LEM2 and the DNA-binding protein BAF, together with DNA, form an unconventional stiffening system. When DNA is held at a given force in optical tweezers, the addition of these proteins causes a force increase proportional to the initial force. This behaviour can be captured by an effective spring model that emerges from multivalent protein-protein and protein-DNA interactions. At the nuclear surface, the same components form an elastic surface hydrogel in which the multivalent interactions contract the surface hydrogel relative to its relaxed state, introducing a pre-stress. Using parameters obtained at the molecular scale, a continuum model of this surface hydrogel yields free-energy-minimizing nuclear shapes and an area stiffness that are in agreement with measurements in control and LEM2 knockdown cells. These results identify a load-bearing, mesoscale protein-DNA surface hydrogel that mechanically reinforces the nucleus.

BP 28: Active Matter V (joint session DY/BP)

BP 29: Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates I (joint session CPP/BP)

Biomolecular condensates play a central role in many cellular processes and provide a fascinating example of self-organized, highly dynamic systems. Physical methods, particularly from statistical physics and soft matter, have emerged as valuable tools for understanding and predicting their fundamental properties. Conversely, the complexity and diversity of biological systems open new perspectives and challenges for physical modeling. This focus session will highlight current research at the interface of physics and biology, with an emphasis on theoretical modeling and simulation of the physics of biomolecular condensates.

Topical Talk BP 29.1 Thu 9:30 ZEU/0260

Wetting transitions in biomolecular coacervates — •Susanne Liese[1], Tiemei Lu[2], Evan Spruijt[3], and Christoph Weber[1] — [1]University of Augsburg — [2]University of Oxford — [3]Radboud University

Biomolecular coacervates are liquid-like droplets that can interact with membranes and self-organize into complex structures. Understanding the principles governing their shapes and higher-order assemblies is crucial for controlling compartmentalization in biological and synthetic systems.

We present a theoretical framework describing the shape and organization of biomolecular coacervates interacting with membranes and each other. Large coacervate droplets adopt morphologies determined by the balance of surface tensions, from partial adhesion to full engulfment. Scaled membrane tension and droplet-membrane interactions predict transitions between spherical, lens-shaped, partially wrapped, and endocytosed droplets, with composition-dependent contact angles linking molecular properties to macroscopic shapes.

For multiphase coacervates, we model the impact of interfacial species on droplet organization. Enrichment of an interfacial component at phase boundaries drives partial wetting between droplets, promoting the formation of dimers and extended chains. Numerical simulations show that surface tension minimizes the contact area, straightening droplet arrangements and generating polymer-like behavior with bending stiffness and segment-length constraints.

BP 29.2 Thu 10:00 ZEU/0260

Elastic regulation of biomolecular condensates — •Oliver Paulin and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany

In recent years, biomolecular condensates have emerged as a vital component of sub-cellular organisation. Here, we discuss the role that elastic interactions can play in regulating condensate size, count, and mechanical properties. First, we focus on the impact of 'external' elasticity that arises from a confining mesh such as the cytoskeleton. We find that the additional energetic cost of network deformations induced by condensate growth limits condensate size, and can even suppress condensate formation entirely. Additionally, when condensate size is comparable to characteristic heterogeneities of the network, non-local interactions may arrest thermodynamic coarsening and drive the formation of stable patterned states with an energetically selected length scale. Second, we study how 'internal' elasticity, resulting from the intrinsic viscoelasticity of condensate material, can inhibit condensate growth, but also impart condensates with mechanical strength. For the case in which condensate growth is driven by active incorporation of new material, we demonstrate how a delicate balance of material properties provides condensates with solid-like mechanical strength, without compromising their liquid-like ability to form and grow rapidly. For both examples, we construct dynamic continuum models that couple phase separation with elastic deformation, analysing the key parameters that control condensate form, and identifying how cells can use elasticity to fine-tune condensate behaviour to fulfil a specific function.

BP 29.3 Thu 10:15 ZEU/0260

Phase Separation of a Nucleator in a Self Straining Active Filament Network — •Jakob Schindelwig[1], Quentin Bodini-Lefranc[1,2], and Sebastian Fürthauer[1] — [1]Institute of Applied Physics, TU Wien, Lehargasse 6, 1060 Vienna, Austria — [2]Ecole polytechnique, Institut Polytechnique de Paris, Route de Saclay, 91120 Palaiseau, France

Many membraneless compartments of cells, such as stress-granules, form via liquid-liquid phase separation. In cells many compartments of the same type and similar sizes can coexist. Since this is inconsistent with equilibrium phase separation physics, we ask if active mechanics could explain this observation. We develop a model coupling dynamics of the droplet material to an active self-straining filament network. This model shows (i) arrested coarsening , (ii) oscillations, (iii) scale selection. We establish that our model is physiologically plausible by comparing to recent work on a phase separating nucleator of actin.

BP 29.4 Thu 10:30 ZEU/0260

Active Transport as a Mechanism of Microphase Selection in Biomolecular Condensates — •Le Qiao, Peter Gispert, and Friederike Schmid — Institut für Physik, Johannes Gutenberg-Universität Mainz, D55099 Mainz, Germany

Cells control the size and organization of biomolecular condensates formed by liquid-liquid phase separation (LLPS), yet the underlying physical principles remain incompletely understood. We propose a transport-driven mechanism in which undirected motor-mediated motion along cytoskeletal filaments redistributes phase-separating components, generating an effective non-equilibrium long-range repulsion that arrests coarsening. This is explored using a minimal reaction-diffusion-transport model that captures the interplay between binding-release kinetics, diffusion, and active transport. A linear stability analysis and three-dimensional simulations reveal a transition from macroscopic to microphase separation at remarkably low binding/release fractions, corresponding to minute fractions of motor-bound proteins. Tuning motor binding rates b or transport velocities enables sublinear control of condensate dimensions ($L \sim b^{1/4}$) from nanometers to micrometers. This mechanism provides a simple physical route for spatially programmable condensate organization in living cells and active materials.

BP 29.5 Thu 10:45 ZEU/0260

Positive feedback in chemically active droplets — •Xi Chen[1], Jens-Uwe Sommer[1,2], and Tyler Harmon[1] — [1]Leibniz Institute of Polymer Research, Dresden, Germany — [2]Dresden University of Technology

Biomolecular condensates are dynamic compartments that can be maintained far from equilibrium by active chemical reactions. Active condensates can be driven by phase-dependent reaction fluxes, for example via localized enzymatic activity, and thereby exhibit emergent behaviors that cannot be realized in equilibrium condensates. We analyzed condensates with positive feedback between phase separation and reactions: droplets enhance reactions, and the resulting products stabilize the droplets. We show that this feedback produces pronounced hysteresis, making droplets resilient to cellular fluctuations. We show the hysteresis persists across a broad range of reaction schemes and parameter choices, indicating that it is a robust feature of droplets with positive feedback. Condensates that form to satisfy transient cellular needs may benefit from such hysteresis, because it ensures that they persist long enough to carry out their functions despite fluctuating conditions.

BP 29.6 Thu 11:00 ZEU/0260

Chemically driven simulations of enzymatic phosphorylation in protein condensates — •Emanuele Zippo[1], Dorothee Dormann[1,2], Thomas Speck[3], and Lukas Stelzl[1,2] — [1]Johannes Gutenberg University Mainz, Mainz, Germany — [2]Institute of Molecular Biology (IMB), Mainz, Germany — [3]University of Stuttgart, Stuttgart, Germany

The condensation and aggregation of intrinsically disordered proteins (IDPs) in cells are governed by enzyme-driven, non-equilibrium processes. Kinases such as Casein kinase 1 delta (CK1d) phosphorylate proteins using ATP as chemical fuel, tuning intermolecular interactions and modulating condensate assembly. The neurodegeneration-linked protein TDP-43 undergoes CK1d-mediated hyperphosphorylation, proposed as a cytoprotective mechanism through condensate dissolution, yet the mechanisms underlying kinase-condensate interactions remain unclear. Using coarse-grained molecular dynamics simulations, we investigate how CK1d phosphorylates TDP-43 and how this reaction drives the structural reorganization and dissolution of its condensates. To ensure thermodynamic consistency in such fuel-driven simulations, we employ an automatic, generally applicable Markov state modeling framework. Post-translational modifications (PTMs), such as phosphorylation, can actively regulate condensate stability and suppress Ostwald ripening, offering a mechanism to control mesoscale structure in soft materials. Understanding such reaction-structure coupling in non-equilibrium environments is key to explaining cellular self-organization and designing biomimetic systems.

BP 30: Focus Session: Controlling Microparticles and Biological Cells by Ultrasound (joint session BP/CPP/DY)

Recently ultrasound has emerged as a very promising physical modality to control the behavior of microparticles and even of biological cells, which can be moved and stimulated by sound waves. For biological cells, one can further control the effect of sound through gene expression (sonogenetics), similar to the control by light (optogenetics). However, because the wavelength of sound is much larger than the one of light, one of the challenges is to localize the effect of sound waves, e.g. by using gas bubbles. Here, we bring together experimental and theoretical researchers who currently explore the potential of ultrasound to control active and passive microsystems and to develop new applications ranging from biomedicine to soft robotics.

Organized by Peer Fischer and Ulrich S. Schwarz (Heidelberg)

Time: Thursday 10:15–12:45 Location: BAR/0106

Invited Talk BP 30.1 Thu 10:15 BAR/0106

Mechanogenetics for Cell ImmunoTherapy — •Yingxiao Wang — 1002 childs way, Los Angeles, CA 90089

Cell-based cancer immunotherapy is a promising therapeutic intervention for cancer treatment. However, non-specific toxicity against healthy tissues (e.g. off-tumor toxicity) is a major hurdle for solid tumor treatment. We have developed controllable on-switch gene cassettes in which a specific antigen production on the target cancer cell can be remotely and mechanically induced by an external focused ultrasound (FUS). FUS was applied to stimulate the production of the synthetic and clinically validated antigen on tumor cell surface orthogonal to the endogenous proteins. SynNotch was further engineered into primary human T cells (SynNotch-CAR T) to recognize the synthetic antigen expressed on the ultrasound-induced tumor cells and activate the production of CAR, which can lead to the recognition of a native tumor specific antigen (TSA) universally expressed on the whole population of tumor cells for immunotherapy. We applied this system to treat prostate cancer cells whose locally metastasized tumors are confined in space but intermingled with vessels and nerves. Our results showed that FUS can mechanically induce the synthetic antigen production in prostate cancer cells, which results in the engagement and activation of SynNotch CAR T cells for the tumor eradication. This local activation of engineered tumor cells by FUS should allow a high precision and safety in eradicating tumors. Hence, this approach for immunotherapy should open new opportunities to integrate engineering mechanics with genetic medicine for successful translation.

BP 30.2 Thu 10:45 BAR/0106

Shaping sound to tickle cells — •Dimitris Missirlis[1,2], Athanasios Athanassiadis[1,2], Rom Lerner[1,2], and Peer Fischer[1,2] — [1]Institute for Molecular Systems Engineering and Advanced Materials, Im Neuenheimer Feld 225, 69120 Heidelberg, Germany — [2]Max Planck Institute for Medical Research, Jahnstr. 29, 69120, Heidelberg, Germany

The ability to shape ultrasonic waves precisely is finding growing relevance in biomedical applications, where ultrasound is increasingly used to noninvasively stimulate biological tissues for therapeutic purposes. However, it remains an unsolved question how high-frequency ultrasound can interact with cells to excite biological responses. Our recent work on shaping and controlling ultrasound waves has provided us with a new tool to address the fundamental question how ultrasound interacts with and influences cells. To this end we have developed adaptable setups where we can control relevant ultrasound parameters in vitro as well as in vivo. By systematically examining the critical parameters, we discuss the role of different ultrasonic effects, including thermal effects, radiation forces, and sound-induced shear flows. Further, we discuss both physical and sonogenetic methods that can be used to enhance the coupling of ultrasound to cells.

BP 30.3 Thu 11:00 BAR/0106

A Theoretical Model for Ultrasound-Induced Intracellular Streaming — •Niels Gieseler[1,2,3], Falko Ziebert[1,2], and Ulrich S. Schwarz[1,2] — [1]Institute for Theoretical Physics, Heidelberg University, Philosophenweg 19, Heidelberg 69120 Germany — [2]BioQuant, Heidelberg University, im Neuenheimer Feld 267, Heidelberg 69120 Germany — [3]Max Planck Institute for Medical Research, Jahnstrasse 29, Heidelberg 69120, Germany

Ultrasound is not only the basis of an essential imaging method for biomedicine, recently it has also become a promising avenue to control biological systems, for

example, in sonogenetics or ultrasound neuromodulation. However, the underlying physical effects are not well understood, and a complete theoretical description is missing. In fact, many different physical effects compete, including radiation forces, streaming, cavitation, and local heating. Here, we focus on intracellular streaming, which might induce organelle movement or alter gene expression, as the steady second-order rotational flow generated by an acoustic source. As a model for the viscoelastic nature of cells and their surroundings, we use Oldroyd-B fluids. Building on existing work, we calculate the streaming flows inside and outside of a sphere sonicated with a plane wave. The streaming is treated as a second-order perturbation expansion of the Navier-Stokes equations, which is solved separately for both media and combined using suitable boundary conditions. Our work shows under which conditions intracellular streaming can be induced in biological cells.

BP 30.5 Thu 12:00 BAR/0106

Rarefaction wave amplification from non-resonant deforming bubbles — Yuzhe Fan, Saber Izak Ghasemian, and •Claus-Dieter Ohl — Otto-von-Guericke University, Magdeburg, Germany

Gas bubbles in liquids or soft matter exposed to acoustic waves behave as oscillators, with maximum response at their resonance frequency. When driven below resonance at sufficient pressure amplitudes, bubbles can collapse with strong energy focusing and even emit light; when driven near resonance, surface instabilities and fast jet flow develop during oscillation. Like other oscillators, bubbles cease to respond when driven far above resonance. Although their oscillations are minimal, bubbles in this regime act as pressure-release interfaces, can reflect high peak pressure shock into rarefaction wave, and may therefore seed cavitation when interacting with high-power therapeutic ultrasound. Yet, here we show that even diagnostic ultrasound with peak positive pressures as low as ~10 MPa can nucleate cavitation in microseconds. This is caused through the non-resonant deformation of the bubble into a concave shape that refocuses scattered waves, amplifying the tension leading to microcavitation. Our findings reveal that cavitation can be triggered by high-frequency positive pressure over a much wider amplitude range than previously recognized, offering a new perspective for current safety guidelines for ultrasound bioeffects and applications in medical ultrasound.

BP 30.6 Thu 12:15 BAR/0106

Optimizing acoustically propelled microrobots using genetic algorithms — •Lennart Gevers[1,2,3] and Raphael Wittkowski[1,2,3] — [1]Department of Physics, RWTH Aachen University, Aachen, Germany — [2]DWI – Leibniz Institute for Interactive Materials, Aachen, Germany — [3]Institute of Theoretical Physics, Center for Soft Nanoscience, University of Münster, Münster, Germany

The promising potential applications of acoustically propelled microparticles demand methods to create particle designs that allow for targeted autonomous motion. Current methods remain largely based on experiments due to the intricate nature of the underlying dynamics. Large-scale computational studies, specifically when combined with optimization algorithms, are impeded by the cost of traditional acoustofluidic simulations.

In this talk, we present the implementation of an analytical framework describing non-Brownian motion of colloidal molecules driven by acoustic streaming. The analytical framework is combined with vectorized, GPU-accelerated, and distributed computation. This enables fast, large-scale simulations, where 10^5 trajectories over 10 s real time can be simulated on a normal personal computer within one minute. Coupling this approach with genetic algorithms reveals particle geometries, control parameters, and underlying principles for acoustically propelled particles that exhibit controllable and stable behavior over long times.

Funded by the Deutsche Forschungsgemeinschaft (DFG) – 535275785.

BP 30.7 Thu 12:30 BAR/0106

Equations of motion for arbitrarily shaped acoustically propelled rigid microparticles — •Justus Schnermann[1,2,3] and Raphael Wittkowski[1,2,3] — [1]Department of Physics, RWTH Aachen University, Aachen, Germany — [2]DWI – Leibniz Institute for Interactive Materials, Aachen, Germany — [3]Institute of Theoretical Physics, Center for Soft Nanoscience, University of Münster, Münster, Germany

Much experimental research concerns the acoustic propulsion of microparticles, but theoretically, only axisymmetric particles with a stable orientation have been studied thus far. In this talk, we present an analytical derivation of the ordinary differential equation of motion for an arbitrarily shaped acoustically propelled rigid microparticle. This equation governs the time evolution of the orientation and position of the particle. Its parameters depend only on the particle's leading-order oscillation velocity field. Based on this equation, we classify qualitatively the possible long-term trajectories of arbitrary particles in unidirectional ultrasound.

BP 31.1 Thu 11:30 ZEU/0260

Exponential Size Control in Biomolecular Condensates via Universal Scaling of Power-Law Distributions — •Yifan Huang[1], Chuan Tang[1], Haoyu Song[2], Bing Miao[3], and Qiyun Tang[1,4] — [1]Key Laboratory of Quantum Materials and Devices of Ministry of Education, School of Physics, Southeast University, Nanjng 211189, China — [2]School of Physics, Zhejiang University, Hangzhou 310058, China — [3]Center of Materials Science and Optoelectronics Engineering, College of Materials Science and Opto-Electronic Technology, University of Chinese Academy of Sciences, Beijing 100049, China — [4]Jiangsu Physical Science Research Center, Nanjing 210093, China

Power-law distributions are ubiquitous phenomena in diverse systems, whereas concomitant scale invariance hinders the exploration of precise size control for biocondensates in recent experiments. Using massive computer simulations and the kinetic theory of coalescence, we demonstrate that the cutoff volume can collapse all power-law distributions of biocondensates in different parameters onto one master curve. Remarkably, the cutoff size can increase exponentially by increasing monomer concentrations $R \sim e^{\phi}$, of which nanometer condensates in simulations can be extrapolated to micrometer droplets in experiments. The findings provide a new mechanism to rapidly tailor the biocondensates to appropriate sizes through power-law distributions, which can stimulate explorations in biological and other nonequilibrium systems

BP 31.2 Thu 11:45 ZEU/0260

Droplet-assisted folding of long regulatory RNAs — Simon Doll[1], Lukas Pekarek[1], Fathima Ferosh[1], Jovana Vasiljević[1], Marcus Jahnel[1], and •Tyler Harmon[2] — [1]BIOTEC, Dresden, Germany — [2]IPF, Dresden Germany

Long regulatory RNA regions orchestrate complex cellular processes, including gene expression and epigenetic modifications. How these RNAs dynamically fold and refold in response to cellular signals remains poorly understood. Given that RNAs interact with ubiquitous RNA-binding proteins (RBPs) prone to form biomolecular condensates, we explore how protein droplets interacting along an RNA impact its folding process. Attached droplets prevent premature folding by competing with RNA:RNA interactions. When droplets dissolve due to cellular signals, capillary effects cause the RNA to collapse while refolding. We test this process of condensate-guided RNA folding by adapting established RNA secondary structure predictors to mimic various folding pathways and supplement this with coarse-grained simulations. We find that interactions with transient droplets robustly leads to the formation of long-range RNA contacts, which are otherwise hard to achieve. Our results compare favorably with available experimental data. We propose that this strategy, which we call droplet-assisted RNA folding, represents a previously unexplored mechanism for shaping RNA structures. Given the widespread propensity of RBPs to form condensates, this process could play a fundamental role in the structural organization, conditional reshaping, and functional regulation of long regulatory RNAs.

BP 31.3 Thu 12:00 ZEU/0260

Simulation Insights into the Assembly of Polyplexes for RNA Delivery — •Jonas Hans Lehnen[1], Jorge Moreno Herrero[3], Heinrich Haas[3], Friederike Schmid[1], and Giovanni Settanni[1,2] — [1]Department of Physics, Johannes-Gutenberg University Mainz — [2]Faculty of Physics and Astronomy, Ruhr University Bochum — [3]BioNTech SE, Mainz

RNA-based pharmaceuticals proved successful with the COVID-19 vaccines and are now undergoing clinical trials for a broad range of therapeutic indications. Lipid-based nanoparticles (LNPs) have been used so far as delivery systems, although alternatives are still needed to meet efficacy and safety requirements across a broader range of applications. Polyplexes, formed by the self-assembly of cationic polymers with the anionic nucleic acids, constitute a valuable substitute, especially if precise control of the number and shape of the encapsulated RNA chains is possible. Here[1], we use molecular dynamics simulations of a coarse-grained polyplex model to show that the most important factors controlling it are the charge ratio between polyelectrolytes and RNA and their concentration during assembly. Close to the isoelectric point, the polyplexes are large, whereas in large excess of cationic polymer, their size decreases, allowing one RNA copy per nanoparticle. Our results are consistent with recent experimental work on polyethylenimine polyplexes.

[1] Simulation Insights into the Assembly of Polyplexes for RNA Delivery, Lehnen et al., Biomacromolecules (2025), DOI: 10.1021/acs.biomac.5c01219

BP 31.4 Thu 12:15 ZEU/0260

Polymer-assisted condensation as key to chromatin localization — •Arghya Majee[1] and Jens-Uwe Sommer[1,2,3] — [1]Leibniz Institute of Polymer Research Dresden, Germany — [2]Institute for Theoretical Physics, TU Dresden, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, Germany

We put forward a novel mechanism [1] to account for the experimentally observed [2] positional shifts of chromosomes within the cell nucleus, which appear to be driven by compositional alterations in the nuclear lamina. By considering chromatin as a biomolecular condensate we demonstrate that the adsorption of the chromatin-binding proteins at the lamina leads to a wetting of the condensate while spreading of the chromatin on the lamina is avoided. This leads to the non-monotonous density profile of the polymer with respect to the surface which can be explained by the competition between the tendency of the protein component to wet the surface and the conformational restrictions of the polymer near the impenetrable surface. A change in the composition of the the lamina can lead to repositioning of chromatin towards the center of the nucleus. Our theory not only offers an explanation for specific chromatin conformation experiments, but also contributes to the broader understanding of wetting onto responsive surfaces in multi-component systems.

BP 31.5 Thu 12:30 ZEU/0260

Bridging Scales to Understand the Role of Ubiquitylation and Sumoylation in Protein Phase Separation — •Supriyo Naskar, Kurt Kremer, and Oleksandra Kukharenko — Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany

The post-translational modifiers, such as mono- and poly-ubiquitins and SUMOs, are known for their ability to modulate protein-protein interactions by becoming covalently attached to other target proteins. Despite the high similarity in the tertiary structure and sequence, they differentially influence the target protein properties. In this work, we employed a multiscale simulation approach that encompasses atomistic to different levels of coarse-grained modeling techniques, combined with data-driven methods, to explore the structural differences and multidimensional energy landscapes of ubiquitin, SUMO, and their conjugates. We finally investigate the influence of distinct features of the targets and modifiers on protein phase separation and aggregation, providing molecular-level insight into the corresponding in vitro measurements and informing further experiments through the adjustment of relevant parameters.

BP 32: Statistical Physics of Biological Systems III (joint session BP/DY)

Time: Thursday 15:00–18:15 Location: BAR/SCHÖ

BP 32.1 Thu 15:00 BAR/SCHÖ

Efficiency of Droplet Formation and Dissolution by Chemical Reactions — •Gerrit Wellecke[1,2], Riccardo Rossetto[1,2], Jan Kirschbaum[1], and David Zwicker[1] — [1]Theory of Biological Fluids, Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany — [2]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Droplets formed by phase separation are vital for intracellular organization, and cells often control the formation and dissolution of these droplets through chemical reactions. To understand how cells can influence droplets in space and time, we consider a ternary system that exhibits a bistability between homogeneous and phase-separated states. We use a thermodynamically consistent approach to describe the diffusive and reactive dynamics, which allows us to quantify the energy dissipation and entropy production during transitions between these states. We find that reaction-controlled droplet formation and dissolution in the bistable regime are fundamentally different processes. While droplet formation is generally aided by relaxation to equilibrium, we find that a droplet's size determines whether it is best dissolved internally or externally. Further, our model identifies plausible mechanisms by which cells may regulate their intracellular droplets, providing insights that could guide the development of synthetic soft matter systems with tunable droplet behaviour.

BP 32.2 Thu 15:15 BAR/SCHÖ

Size control and fluctuations of chemically active droplets — •Guido Kusters and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

Biological cells use liquid-liquid phase separation to dynamically compartmentalize their environment for various applications, many of which require size control. This process is challenging because (i) large droplets tend to grow at the expense of smaller ones, and (ii) thermal fluctuations can disturb droplets since cells are typically small and soft. Chemical reactions can, in principle, control droplet sizes, but there are no clear guidelines on how to robustly achieve size control. To provide guidelines, we consider a binary fluid model driven out of equilibrium by chemical reactions. We reveal two different classes of size-controlled droplets, depending on the ratio of droplet radius to the reaction-diffusion length. Moreover, we determine parameter regimes in which droplets become small. To study fluctuations in this case, we use fluctuation-dissipation arguments to predict the size fluctuations of size-controlled droplets, consistent with our numerical simulations. Taken together, our theory allows us to predict the chemical reactions necessary for maintaining small droplets, e.g., in biological cells or synthetic applications.

BP 32.3 Thu 15:30 BAR/SCHÖ

Anomalous diffusion and directed coalescence of condensates out of equilibrium — •Andriy Goychuk — Helmholtz Centre for Infection Research, Braunschweig, Germany — Lower Saxony Center for Artificial Intelligence and Causal Methods in Medicine, Hannover, Germany

Phase separation is ubiquitous in engineered and in biological systems. For example, biomolecular condensates contribute to the organization of the cytoplasm and nucleoplasm in cells. Here, I will first extend our understanding of textbook phase separation models by showing how condensates consisting of nonpolar molecules can effectively polarize and undergo coarsening by directed coalescence when subjected to a global drift, for example due to electrostatic potential gradients, chemical concentration gradients, or gravitation. Next, to better model the intracellular solution, I will incorporate viscoelastic stress propagation and nonequilibrium fluctuations. In this context, the Brownian motion of condensates has been barely explored despite being a cornerstone of statistical and colloidal Physics. If the active stresses, for example generated by molecular motors, have a different correlation time than the viscoelastic relaxation time of the solution, then the fluctuation-dissipation theorem is broken and the mixture is driven out of equilibrium. In this case, the size-dependence of the center-of-mass diffusion coefficient of the condensates can be either suppressed or enhanced, and the droplet can show superdiffusive motion. Together, these findings improve our understanding of the dynamics of domains in viscoelastic media and conserved order parameters in general.

BP 32.4 Thu 15:45 BAR/SCHÖ

A Minimal Theoretical Framework Linking Translation Activity to Stress-Induced Condensates — •Pascal S. Rogalla[1], Alessandro Barducci[1], and Luca Ciandrini[1,2] — [1]Centre de Biologie Structurale, Université de Montpellier, CNRS, INSERM, Montpellier, France. — [2]Institut Universitaire de France

The formation of intracellular membraneless organelles, such as stress-granule-like condensates formed via liquid-liquid phase separation (LLPS), is a common response to cellular stress. RNA, including mRNA, promotes the assembly of many of these condensates, while the resulting aggregation of mRNAs reduces their availability for translation and thereby modulates ribosome loading. This establishes a feedback loop between condensate formation and translational activity. Here we develop a minimal physical model that makes this coupling explicit by combining Flory-Huggins theory for LLPS with the Totally Asymmetric Simple Exclusion Process (TASEP) for ribosomal traffic on mRNAs. This hybrid framework provides a proof-of-principle description of how LLPS and translation dynamically influence one another. Our analysis reveals that the phase behaviour of both subsystems becomes mutually dependent: a

low-occupancy ribosomal phase promotes mRNA aggregation, whereas a high-occupancy phase suppresses condensate formation. These results suggest that cells may regulate condensate formation through translation modulation and, conversely, that LLPS can reshape the translatome. This provides a first proof-of-principle framework for quantifying stress-induced reorganisation of the translational landscape.

BP 32.5 Thu 16:00 BAR/SCHÖ

Optimal sensing through phase separation — •Henry Alston[1], Mason Rouches[2], Arvind Murugan[2], Aleksandra Walczak[1], and Thierry Mora[1] — [1]Laboratoire de Physique, Ecole Normale Superieure — [2]The James Franck Institute & Department of Physics, The University of Chicago

Cells are constantly tasked with making accurate measurements of their surroundings. A paradigmatic example is the sensing of signalling molecule concentrations: the work of Berg and Purcell derived limits for the precision and speed of this sensing through ligand-receptor binding. However, recent experimental work has identified the formation of condensates (liquid droplets coexisting with the cell cytoplasm through phase separation) as a potential mechanism for selectively initiating downstream processes by effectively amplifying small concentration differences between competing signalling molecules. Using a minimal model for droplet nucleation and growth in a fluid mixture, we observe that phase separation can distinguish concentration differences of 1% in minutes, a significant improvement upon well-established pathways for precise concentration sensing.

BP 32.6 Thu 16:15 BAR/SCHÖ

Thermodynamics of DNA sequence recognition by a transcription factor — •Jonas Neipel[1,2,3], Anne Schwager[1], Yahor Savich[1,2,3], Douglas Diehl[1], Anthony A. Hyman[1], Frank Jülicher[2,3], and Stephan W. Grill[1,3] — [1]Max Planck Institute for Molecular Cell Biology and Genetics, Dresden Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden Germany — [3]Center for Systems Biology Dresden, Dresden, Germany

Transcription factors (TFs) are proteins that regulate the transcription of genes by binding to specific genomic positions defined by the DNA sequence. The sequence of preference of a TF is typically characterized by a single sequence motif that maximizes binding affinity. However, eukaryotic TFs bind to a spectrum of low affinity binding sites that vastly outnumber canonical motif sequences in the genome. Here, we develop an Ising model of DNA sequence recognition that yields quantitative prediction of TF binding energies across sequence space for the human TF KLF-4. The model is parametrized by in vitro experiments, where we quantify relative binding energies for various sequences in a competitive assay using fluorescence anisotropy. Strikingly, we find that the thus fully parametrized thermodynamic model quantitatively predicts KLF-4 occupancy across the human genome. Finally, we discuss how this genomic energy landscape guides the formation of TF condensates.

BP 32.7 Thu 16:45 BAR/SCHÖ

Kinetic inference of entropy production — •Ivan Di Trelizzi — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Nonequilibrium steady states, from planetary dynamics to biological processes, constantly dissipate energy to their environment, producing entropy at a constant rate. Quantifying this dissipation is key to understanding how far systems operate from equilibrium but remains experimentally challenging. I will present a new approach to infer entropy production directly from trajectory data, using measurable kinetic quantities known as traffic and inflow rate, without requiring knowledge of microscopic forces or fluxes. The method remains effective even under partial observation, providing a practical framework to quantify nonequilibrium behaviour in complex physical and biological systems.

BP 32.8 Thu 17:00 BAR/SCHÖ

Frequency-space trajectory Fisher Information to quantify sensitivity in complex living systems — •Zhiheng Wu[1] and Isabella Graf[1,2] — [1]European Molecular Biology Laboratory, Heidelberg, Germany — [2]Department of Physics and Astronomy, Heidelberg University, Heidelberg, Germany

Living systems sense their environment by stochastically mapping external signals onto internal states. For example, several animals including fruit flies and pit vipers encode small changes in the ambient temperature in terms of changes in the interspike time of neurons. The sensitivity of these measurements can be evaluated by the so-called Fisher information (rate). While living systems constantly adapt to changing environments, calculations of Fisher information have so far mostly focused on static signals and internal states. To evaluate measurement sensitivity in the non-static case, we evaluate the trajectory Fisher information and show that, under common assumptions, it can be expressed as an integral over frequency space involving the power spectral density. This expression provides a tractable way to quantify information in adaptive and complex biological systems and we discuss some interesting applications.

BP 32.9 Thu 17:15 BAR/SCHÖ

Ergodicity shapes inference in biological reactions driven by a latent trajectory — •Ricardo Martinez-Garcia[1], Benjamin Garcia de Figueiredo[2], Justin Calabrese[1], and William Fagan[3] — [1]CASUS-HZDR, Görlitz, Germany. — [2]Princeton University, Princeton NJ, USA. — [3]University of Maryland, College Park MD, USA.

Many natural phenomena, from intracellular reactions to predator-prey encounters, can be described as counts of events triggered at random intervals when an underlying dynamical system enters reactive regions of its phase space. These reactions control biological functions across scales, from cellular processes to ecosystem services and stability. We compute the exact distribution of inter-count times under the only assumption that the latent dynamical system is Markovian and ergodic, recovering widely used Poisson statistics as a limiting case. These results limit what information about the latent process can be inferred from a local detector, which we explore in two biophysical scenarios. First, in estimating an animal's activity from detector crossings, we show that mean counts may fail to capture movement parameters, encoded in higher-order moments. Second, we show that the variance of inter-reaction times imposes a fundamental limit on how precisely detector measurements can infer the size of an ensemble of trajectories, generalizing the Berg-Purcell limit for chemosensation. Overall, we develop a flexible framework for quantifying inter-event time distributions in reaction-diffusion systems that shows which properties of latent processes are inferable from observed reactions.

BP 32.10 Thu 17:30 BAR/SCHÖ

Information Bottleneck in Gene Regulation — •Marianne Bauer — TU Delft

Biological systems need to process information in order to perform specific functions. In the context of gene regulation, regulatory regions process transcription factor signals in order for cells to differentiate towards correct fates. Previously, we have shown that the information bottleneck (IB) framework provides a useful framework for understanding regulatory binding site regions. Here, I will discuss two recent collaborative advances to provide an improved biological understanding from IB based predictions. First, using two complementary models for clustering transcription factors at binding site sensors, we can study information transfer during early fly embryo development with local transcription factor clustering. We find that weak cooperativity or clustering can allow for maximal information transfer, especially about the relevant variable, and that weak clustering also allows the binding site sensors to achieve optimality consistent with the IB bound. Second, we investigate how optimal activation changes when multiple binding site elements can process information, and find that activation profiles consistent with IB optimality resemble gene expression profiles in the early fly embryo.

BP 32.11 Thu 17:45 BAR/SCHÖ

Binary karyotypes are universally selected for across cancers — •Lucija Tomašić[1], Shane A. Fiorenza[1], Hajime Okada[2], Thomas W. van Ravesteyn[3], Uri Ben-David[2], Geert J.P.L. Kops[3], and Nenad Pavin[1] — [1]Univ. of Zagreb, Zagreb, Croatia — [2]Tel Aviv University, Tel Aviv, Israel — [3]Hubrecht Institute, Utrecht, the Netherlands

Aneuploidy, an abnormal chromosome number, is a defining feature of most cancers, yet its vast diversity has made it difficult to identify universal evolutionary rules. By analyzing over 90,000 patient-derived cancer karyotypes using a new visualization approach and mathematical modeling, we uncover a simple organizing principle. Across cancer types, and even in yeast, aneuploid genomes overwhelmingly assemble into "binary karyotypes" composed of only two chromosome copy numbers. Despite the enormous space of theoretically possible chromosome configurations, these states dominate patient data, comprising more than three-quarters of observed karyotypes. Our model shows that this pattern arises from a modest but consistent fitness advantage of binary karyotypes over more complex configurations. This principle also provides insight into how aneuploid cells withstand stress responses, as binary karyotypes exhibit lower rates of tumor suppressor gene inactivation. Together, our results identify binary karyotypes as a conserved evolutionary class of aneuploidy, governed by global organizational rules that may reveal shared vulnerabilities across cancers.

BP 32.12 Thu 18:00 BAR/SCHÖ

Inertial instability of blood in cross microchannels — •Joséphine Van Hulle and Christian Wagner — Experimental Physics, Saarland University, Germany

A localized reduction of vessel diameter (stenosis) increases the local blood flow speed and can trigger downstream recirculation which promotes conditions for the vessel blockage (thrombosis). The role of fluid elasticity in these flows remains underexplored. We isolate the extensional effects using cross-slot microfluidics, which creates an elongation plane with a well-defined inertial instability. By varying the hematocrit and plasma composition, we show that red blood cell deformability and plasma viscoelasticity lower the critical Reynolds number for the onset of vortex formation. These results highlight that even weak elastic stresses of blood can favor recirculation, a characteristic rarely modeled but necessary for physiologically realistic arterial simulations.

Expanding the Bag of Optical Tricks for (Neuro)Biology — •Fabian F. Voigt — Department for Molecular and Cellular Biology, Harvard University, Cambridge, USA — Max Planck Institute for the Science of Light, Erlangen, Germany — Max Planck Center for Physics and Medicine, Erlangen, Germany

Seeing is believing and thus, optical imaging techniques are extremely useful to study brain structure and function. I will present several projects aimed at providing the neuroscience community with bet- ter instrumentation: These range from open-source light-sheet micro- scopes for imaging cleared tissue (https://mesospim.org/) to novel multi-immersion microscope objectives that take inspiration from scallops and astronomical telescopes as well as utilizing metasurfaces for improving light collection efficiency in light-sheet microscopy.

BP 33.2 Thu 15:30 BAR/0205

Using Rotating Coherent Scattering (ROCS) Microscopy for Binding and Uptake Analysis of Virus-Mimicking Particles — •Dominik Huber and Alexander Rohrbach — Lab for Bio- and Nano-Photonics, University of Freiburg, Germany

The investigation of viruses with their host cell is an important topic in medical research, yet direct observation of these nanoscale dynamics remains challenging, since conventional fluorescence microscopy is limited by photobleaching and labelling constraints. To address these limitations, we employ label-free Rotating Coherent Scattering (ROCS) microscopy, an imaging approach that enables high-speed, high-resolution visualization of virus-mimicking particle behaviour at the cell.

ROCS microscopy uses backscattering of oblique illumination of a rotating laser beam to achieve around 160 nm spatial resolution at imaging rates up to around 200 Hz. By combining several illumination wavelengths and illumination angles, ROCS microscopy can be used in brightfield and darkfield as well as in total internal reflection mode. Leveraging this flexibility in imaging, allows us to capture the binding dynamics of particles to cells and to investigate them from their first attachment up to the investigation of single particle uptake events.

The analysis of particle fluctuation widths and mean square displacements enabled us to detect differences in binding characteristics of two different types of virus-mimicking particles, thus demonstrating that ROCS microscopy provides a powerful tool for investigation of particle-cell interactions at the single-particle level.

BP 33.3 Thu 15:45 BAR/0205

Pharmacological modulation of intrinsic tissue transparency for enhanced microscopy — •Adrián Puerta, Susan Wagner, and Moritz Kreysing — Institute of Biological and Chemical Systems, Karlsruhe Institute of Technology, 76344 Eggenstein Leopoldshafen, Germany

Light microscopy remains as one of the primary methods for data acquisition in biological research, yet its performance is frequently limited by the strong scattering properties of experimental tissues. Hence, the use of clearing agents that are incompatible with living samples is often required (1). To overcome these limitations, we aim to modulate the intrinsic transparency of biological samples, enabling more effective live-cell imaging.

Conventional clearing strategies rely on chemicals that modify the refractive index of aqueous or lipid-rich tissue components (2). In contrast, our approach involves screening small molecules with pharmacological properties that may enhance transparency in mammalian cells. To investigate this, we have developed a high-throughput screening system based on flow cytometry that will allow us to identify potential changes at a single-cell scale.

Imaging viral infection in live cells with confocal interferometric scattering microscopy (iSCAT) — •Anirudh Khemani[1], David Albrecht[1], Jan Renger[1], Marco Heisig[1], Kiarash Kasaian[1], and Vahid Sandoghdar[1,2] — [1]Max Planck Institute for the Science of Light, 91058 Erlangen, Germany — [2]Max-Planck-Zentrum für Physik und Medizin, 91054 Erlangen, Germany.

Fluorescence-based microscopy can suffer from observational bias, functional perturbation, phototoxicity, or insufficient signal. Confocal interferometric scattering microscopy [1] provides quantitative, label-free imaging of nanoscale dynamics in live-cell processes. iSCAT is a shot-noise-limited homodyne interferometric technique. By rejecting out-of-focus light, confocal iSCAT yields high structural contrast of nano-bioparticles, like vesicles and viruses, and we validate structural assignments with fluorescence. We apply this platform to study rare, dynamic events in the vaccinia virus life cycle. To improve experimental control and statistics, we developed a microfluidic system to deliver individual virions with defined timing and position. Furthermore, we combine confocal SCAT with concomitant wide-field iSCAT [2] to span a large range of spatial and temporal resolutions. We report on complex processes such as virus-induced nucleation of actin tails and high-speed tracking of single virions at cell-cell junctions and on membranes.

Image segmentation of treated and untreated tumor spheroids by fully convolutional networks — Matthias Streller[1], Soňa Michlíková[2], Katharina Lönnecke[1], Leoni A. Kunz-Schughart[2], Anja Voss-Böhme[1], and •Steffen Lange[1,2] — [1]HTW Dresden — [2]OncoRay, TU Dresden, HZDR, Germany

Multicellular 3D tumor spheroids (MCTS) are advanced preclinical cell culture systems for assessing the impact of combinatorial radio(chemo)therapy as they exhibit therapeutically relevant in vivo-like characteristics. State-of-the-art assays quantify long-term curative endpoints based on collected brightfield image time series from large treated spheroid populations, which requires laborious spheroid segmentation of up to 100,000 images per treatment arm. While several image analysis algorithms are available for spheroid segmentation, they all focus on compact MCTS with a clearly distinguishable outer rim throughout growth and often fail for the common case of treated MCTS, which may partly be detached and destroyed and are usually obscured by dead cell debris. To address these issues, we successfully train 2 fully convolutional networks, UNet and HRNet, and optimize their hyperparameters to develop an automatic segmentation for both untreated and treated MCTS[1]. We extensively test the automatic segmentation on larger, independent datasets and observe high accuracy for most images with Jaccard indices around 90%, with deviations consistent to inter-observer variability. We also successfully test against previously published datasets and spheroid segmentations.

BP 33.6 Thu 16:30 BAR/0205

Predicting treatment response of tumor spheroids from radiomics analysis of post-treatment dynamics — Pejman Shojaee[1,2], Tom Bischopink[1], Daria Bolotova[1], Sona Michlikova[2], Leoni A. Kunz-Schughart[2], Steffen Lange[1,2], and •Anja Voss-Böhme[1] — [1]DataMedAssist Group, Faculty of Informatics/Mathematics, HTW Dresden — [2]OncoRay - National Center for Radiation Research in Oncology Dresden

Radiomics has significantly advanced radiation oncology by providing quantitative, objective metrics to predict therapeutic efficacy. However, these methods have not been applied to three-dimensional, multicellular tumor spheroids yet, which are the preferred in vitro model for pre-animal, pre-clinical selection of novel, future-oriented treatment modalities. We present an AI-driven predictive modeling workflow to predict long-term tumor spheroid relapse using radiomics data from early post-treatment imaging of spheroids of two human cancer cell lines subjected to radiation therapy and hyperthermia. Our approach integrates multiple feature selection methods and machine learning algorithms for optimal classification performance. A detailed evaluation of the model performance reveals a time gain by early prediction of 2-14 days, while cases of late relapse remain challenging. The presented radiomics-based approach reduces the resource-intensive demands associated with prolonged experimental monitoring and allows accurate prediction for up to three days beyond the observation horizon.

Photothermal chemical imaging of nano-structured cells and cell organelles with less than 5 nm resolution — Maryam Ali[1,2], Christin David[1,3], and •Daniela Täuber[1,2] — [1]Friedrich Schiller University Jena — [2]Leibniz Institute of Photonic Technology, Jena — [3]University of Applied Sciences Landshut, Germany

Mid-infrared photoinduced force microscopy (PiF-IR) is a new imaging technique that enables the chemical characterization of surfaces with an unprecedented spatial and high spectral resolution. PiF-IR bridges the gap between high-resolution structure elucidation using electron microscopy, fluorescence microscopy and conventional infrared spectroscopy. It is complementary to tip-enhanced Raman spectroscopy (TERS). PiF-IR was successfully applied to map the local chemistry and structure of the antibiotic interaction on the surface of individual bacterial cells with a resolution of a few nanometers using the model system Bacillus subtilis and vancomycin [Ali et al., Anal. Chem., 2025, 97, 23914] and to map the surface of retina pigment organelles. Frequently observed anisotropic signal distributions on soft nanostructures in tip-enhanced

photothermal imaging methods could be attributed to hybrid field coupling in a study combining modeling and experiment [Anindo et al., J. Phys. Chem. C, 2025, 129, 4517].

BP 33.8 Thu 17:15 BAR/0205

Phase Analysis of Photothermal Signal Enables Sub-Cellular Chemical Mapping of Complex Biological Systems — •Felix Hermann Patzschke and Frank Cichos — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, Leipzig University, Linnéstraße 5, 04103 Leipzig

Optically probed Photothermal Infrared (O-PTIR) microscopy is a powerful technique for label-free chemical imaging at sub-micron resolution, promising for cell and tissue analysis. However, the mechanism of signal generation is complex, suffering from the dynamic crosstalk between background and target heating. This lack of a rigorous, quantitative understanding of these dynamics currently forces users to sacrifice either chemical specificity or spatial resolution.

We conducted systematic experiments on defined nanoscale structures to motivate and validate a quantitative theoretical model based on the transient heat equation. This model reveals that the phase of the photothermal signal, a dynamic quantity often neglected, contains essential, localized information.

This phase directly encodes the time delay associated with thermal wave propagation, allowing for precise quantification of sub-cellular structural detail through effective thermal distance, even when the amplitude signal is insufficient to resolve closely-spaced features. By leveraging the full phase and amplitude response, we overcome existing spatial resolution limits, achieving enhanced, label-free chemical mapping for next-generation bioimaging, using existing hardware.

BP 33.9 Thu 17:30 BAR/0205

Effects of Optical Stimulation on the Adhesion of Human Osteoblasts — •Franziska Dorn[1], Wiebke Wollenberg[2], Meike Bielfeldt[3], Regina Lange[1], Susanne Stählke[3], Ingo Barke[1], Henrike Rebl[3], Berit Zeller-Pulmhoff[2], and Sylvia Speller[1] — [1]Physics of Surfaces and Interfaces, University Rostock — [2]Data-Driven Analysis and Design of Materials, University of Rostock — [3]Institute of Cell Biology, University Medical Center Rostock

Accelerated growth of autologous bone tissue is a promising strategy in regenerative medicine. In this study, we investigated how optical stimulation influences cell adhesion. We cultured the osteoblast-like (MG-63) cells in fetal bovine serum-free physiologic medium. As substrates, we used plain glass and glass surfaces with structured gold nanotriangular islands fabricated by nanosphere lithography. After cell seeding, the samples were illuminated with green light, inducing a spatially varying light intensity due to reflection and plasmons. Afterwards, we examined the cells using scanning electron microscopy and applied machine-learning-based/random-forest-based segmentation to extract morphological features. We found that opto-stimulated cells form more concave borders than unstimulated controls, suggesting that the cytoskeleton and the focal adhesions develop at non-uniform speed. Additionally, the adhesion area of illuminated cells is substantially larger than that of control cells on glass surfaces. However, when cells are seeded on surfaces with gold nanotriangular islands, this effect is absent. In a next step the peripheral region of the cells, in terms of lamellipodia and filopodia is addressed. (SFB 1270-299150580)

BP 33.10 Thu 17:45 BAR/0205

Imaging biomolecules for improving single-molecule diffraction — •Stefanie Lenzen[1,2], Lukas V. Haas[1,2], Kevin Janson[1], Amit K. Samanta[1,2], and Jochen Küpper[1,2] — [1]Center for Free-Electron Laser Science (CFEL), Deutsches Elektronen-Synchrotron DESY, Hamburg — [2]Department of Physics & Department of Chemistry & Center for Ultrafast Imaging, Universität Hamburg

Determining the structure and dynamics of single native biomolecules is still a challenge. In protein-crystallography and cryo-EM the molecule needs to be fixed, which might lead to structural disentegration, and the temporal resolution of these methods are limited. X-ray free-electron lasers (XFELs) provide ultrashort pulses, enabling diffraction before destruction, and a large number of photons, promising the observation of diffraction patterns *off* single nanoparticles [1]. Aerodynamic-lens stacks were used to deliver focused dense particle beams for such experiments on large nanoparticles [2]. Localization microscopy (LM), based on Mie-scattering is used to study and optimize these beams, an important step in improving single particle imaging. Due to the limitation in particle size [3], small biomolecules do not provide sufficient intensity for being detected with LM. We optimized the optical and analysis system and developed a promising method for the detection of smaller biomolecules, based on fluorescence.

Optically addressable spins in proteins — •Dominik Bucher — Technical University of Munich, TUM School of Natural Sciences, Chemistry Department

Optically addressable spins have attracted significant interest for their potential in quantum sensing technologies. The current workhorses rely on spin defects in solids (such as the nitrogen-vacancy center in diamond), which lack the possibility for precise synthetic control over their properties. In my talk I will highlight our latest research on optically addressable spins in proteins, specifically flavin-based proteins. Upon excitation, these proteins generate radical pairs that can be detected optically via their flourescence and manipulated through radio wave-controlled spin chemistry. We further show that this optical spin interface is tunable by the protein structure. I will explain how these systems differ from the well-established NV center and discuss their potential as genetically encoded quantum sensors for future applications.

BP 33.12 Thu 18:15 BAR/0205

Beyond Molecular Sensitizers: Illuminating the Role of Nanomaterials in Singlet Oxygen Photochemistry — •Zahid Ullah Khan[1], Latif Ullah Khan[2], Hermi Felinto Brito[1], and Paolo Mascio[1] — [1]Institute of Chemistry, University of São Paulo (USP), 05508-000, São Paulo-SP, Brazil — [2]Synchrotron-light for Experimental Science and Applications in the Middle East (SESAME) P.O. Box 7, Allan 19252, Jordan

Singlet molecular oxygen (1O2) plays a crucial role in various fields, including optoelectronics, photooxygenation reactions, and biomedical therapies, particularly as a major contributor to the success of photodynamic therapy (PDT). Since direct excitation of oxygen from the triplet ground state (3O2) to the singlet-excited state is spin-forbidden, thus, making the design of heterogeneous sensitizers crucial for efficient 1O2 production. For this purpose, nanomaterials, such as quantum dots (QDs) and rare earth fluoride nanoparticles (NPs), have emerged as versatile sensitizers for 1O2 generation, either individually or in combination with other inorganic or organic materials. Hence, conjoining the photophysical properties of QDs and rare earth NPs with other materials, e.g., coupling/combining with other inorganic materials, doping with the transition metal ions or lanthanide ions, and conjugation with a molecular sensitizer provide the opportunity to achieve high-efficiency quantum yields of 1O2 which is not possible with either component separately. Hence, the current work focuses the development of semiconductor QDs and rare earth-based nanosensitizer for efficient production of 1O2.

BP 34: Focus Session: Emergent Transport in Active Systems (joint session DY/BP)

Collective motion and directed transport are hallmark phenomena of active matter, arising from the interplay of self-propulsion, interactions, and nonequilibrium fluctuations. Even in the absence of global biases, assemblies of active particles can exhibit spontaneous currents, self-organized chemotaxis, and rectified transport due to broken symmetries or nonlinear feedbacks. Directed transport often emerges in inhomogeneous environments, where variations in particle activity or interaction strength can bias motion and organization. Activity gradients represent a particularly relevant example, providing a tunable mechanism to steer collective motion and pattern formation. These processes link microscopic activity to macroscopic material behavior and transport. This focus session aims to bring together theorists and experimentalists working on the fundamental mechanisms and control of emergent transport in active systems.

Organized by Abhinav Sharma (Augsburg) and Jens-Uwe Sommer (Dresden)

Time: Thursday 15:00–18:00 Location: ZEU/0160

See DY 55 for details of this session.

BP 35: Focus Session: 75 Years Division Polymer Physics: From Curiosity to Smart Materials (joint session CPP/BP)

Polymer materials are ubiquitous in modern society. In recent years, the focus has been on the development of functional, tunable or responsive materials, oftentimes inspired by biological materials. At this, a number of fundamental problems arise, e.g. regarding the interaction of polymers with water, biomolecules or inorganic nanoparticles and the resulting self-assembled morphologies as well as the underlying dynamics and the kinetics of morphological changes upon a stimulus. These problems are nowadays addressed in an interdisciplinary way by experimental methods, computer simulations and theory, often in close collaboration with polymer chemists. In five talks by renowned speakers, the focus session aims at highlighting few of these aspects that are currently under investigation worldwide. The fact that the Polymer Physics Division of the German Physical Society was founded in 1951 and hence, 2026 is the 75th anniversary, seems to be a good occasion to bring modern polymer physics into the focus.

Organized by Christine M. Papadakis, Christian Holm, Tayebeh Ameri and Kristian Franze.

Time: Thursday 15:15–17:45 Location: ZEU/LICH

Topical Talk BP 35.1 Thu 15:15 ZEU/LICH

The Loops of Life — Brian Chan and •Michael Rubinstein — Duke University, Durham, NC, USA

In mammalian cells, the cohesin protein complex is believed to regulate chromatin during interphase through active loop extrusion, in which dynamic loops are formed by cohesin translocating along chromatin. We developed a theoretical model that quantifies how key parameters, including cohesin residence time on chromatin, extrusion velocity, and the number density of chromatin-bound cohesins, regulate genomic contacts. The model describes chromatin contact probabilities and predicts that loop formation probability is a nonmonotonic function of loop length. Our theory demonstrates that active loop extrusion causes the apparent fractal dimension of chromatin to cross over between two and four at contour lengths on the order of 30 kilobase pairs. This work provides a theoretical basis for the compact organization of interphase chromatin, explaining the physical reason for the segregation of topologically associated domains and suppression of chromatin entanglements by up to a factor of 50, which contributes to efficient gene regulation by distal elements such as enhancers or silencers.

Topical Talk BP 35.2 Thu 15:45 ZEU/LICH

Polyelectrolytes and Biological Systems: A Charged Relationship — •Matthias Ballauff — Chemie und Biochemie, Freie Universitaet Berlin

If charges are appended to linear or crosslinked polymers, a polyelectrolyte results. Polyelectrolytes are ubiquitous and play a major role in biophysics. Important natural polyelectrolytes as e.g. DNA or Heparin are central in biology, and a thorough understanding of these systems and of charge-charge interaction is one of the main tasks of biophysics. In my lecture, I will discuss our recent research done on -Interaction of linear polyelectrolytes with proteins. This problem is also relevant for the formation of biocondensates by the interaction of cationic and anionic proteins; -Charged polymer networks and their interaction with proteins; -Role of polyelectrolytes in virus infections. In all cases, a quantitative understanding of the systems in terms of analytical models can be achieved, which may pave the way for future pharmaceutical applications.

Topical Talk BP 35.3 Thu 16:15 ZEU/LICH

From block copolymer morphologies to functional polymer membranes — •Volker Abetz — Helmholtz-Zentrum Hereon, Institute of Membrane Research, Max-Planck-Str. 1, 21502 Geesthacht, Germany — University of Hamburg, Institute of Physical Chemistry, Martin-Luther-King-Platz 6, 20146 Hamburg, Germany

Depending on solvent selectivity and the time of evaporation different structures can be obtained in cast block copolymers, showing that there is an interplay between kinetics and thermodynamic driving forces during the self-assembly before the sample is dry. When preparing membranes from block copolymer solutions, besides molecular weight, composition of the block copolymer and its concentration, also the choice of solvent, and the casting conditions play an important influence on the obtained morphology of the finally obtained membrane. This is especially important when membranes are prepared via the so-called non-solvent induced phase separation process after initial self-assembly by partial evaporation of solvent. The obtained membranes, when prepared successfully, display a rather isoporous top layer and can be subsequently post functionalized, in order to tune pore size and pore surface property. Different examples of the separation properties will be shown and also the potential use as a membrane reactor will be discussed.

Topical Talk BP 35.4 Thu 16:45 ZEU/LICH

Molecular electronic materials and devices for solar energy conversion — •Jenny Nelson — Imperial College London

To maximize the potential of solar power, new materials will be needed to harvest and convert solar energy alongside existing photovoltaic technologies. Molecular electronic materials, such as conjugated polymers and molecules, can achieve photovoltaic conversion through a process of photon absorption, charge separation at a heterojunction, and charge collection. Through a remarkable series of advances in materials design, the efficiency of photovoltaic energy conversion in molecular materials has risen from 1% to over 20% within two decades. We will discuss the factors that control the function of molecular solar cells including the nature of the charge separating heterojunction, and the impact of chemical and physical structure on phase behaviour, energy and charge transport, light harvesting, and loss pathways, comparing experimental measurements with a computational model of the generation and evolution of excited states and charges in such systems. We identify key molecular parameters that are likely to assist charge generation and consider the extent to which these parameters are optimised in the best performing materials. Finally, we will address the limits to conversion efficiency in such systems.

Topical Talk BP 35.5 Thu 17:15 ZEU/LICH

Control of cell and tissue stiffness by biopolymer networks and particle inclusions — •Paul Janmey — University of Pennsylvania, Philadelphia, PA, USA

Filamentous networks of semiflexible polymers are ubiquitous in biology. Collagen fibers form much of the extracellular matrix, the cytoskeleton controls cell mechanics, and chromatin fibers span the volume of the nucleus. The mechanical properties of the biopolymer fibers, the way in which the fibers link into networks, and the types of cells within the network all affect the way in which tissues respond to mechanical stress.

BP 36: Statistical Physics of Biological Systems IV (joint session BP/DY)

Time: Friday 9:30–12:45 Location: BAR/SCHÖ

Invited Talk BP 36.1 Fri 9:30 BAR/SCHÖ

Swimming in complex environments — •Christina Kurzthaler — Max Planck Institute for the Physics of Complex Systems

Microorganisms are omnipresent in the ocean, the human body, and our soils and therefore play an important role for various geological, biological, and medical processes. To optimize their survival and perform biological functions many microorganisms convert chemical energy into directed motion. In this talk, I will illustrate the underlying physical concepts and show concrete examples of our research, focusing on the interactions of microorganisms with their complex habitats. I will first discuss the motion of sperm in complex fluids and address their emergent dynamics in the presence of a hyperactivation agonist, modifying the sperm beating pattern. Second, I will focus on the first-passage-time statistics of active agents moving towards a target boundary. Our results highlight how swim gait impacts spreading and search efficiency in active systems with potential consequences for sperm motion in the reproductive tract and the accumulation of microbial communities.

BP 36.2 Fri 10:00 BAR/SCHÖ

Motor shot noise explains active fluctuations in a single cilium — •Maximilian Kotz[1], Veikko F. Geyer[2], and Benjamin M. Friedrich[1] — [1]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany — [2]B CUBE, TU Dresden, Dresden, Germany

Molecular motors drive seemingly regular motion, making living matter move - yet also cause non-equilibrium fluctuations that can serve as a probe of internal motor dynamics. Here, we use motile cilia as a model system to investigate how small-number fluctuations shape collective dynamics. Motile cilia exhibit regular bending waves; this motion is driven by the self-coordinated activity of thousands of molecular motors inside the cilia's cytoskeletal core. By developing, to the best of our knowledge, the first stochastic model of cilia beating, we show that the finite number of motors leads to active fluctuations on the mesoscale, sufficient to explain frequency jitter in beating cilia observed in experimental data. We rigorously compare observables of this model, including the quality factor of the oscillation, to experimental data in which motors have been partially extracted from cilia. This is a strong test of this stochastic model. The model also reproduces other phenomena of experimental data, like correlation lengths of intra-cilium synchronization and noise-induced phase slips. We propose that active fluctuations are important new observables, which can guide theoretical models of motor dynamics in beating cilia and other motor systems.

BP 36.3 Fri 10:15 BAR/SCHÖ

Theory of Forces Between Crosslinked Filaments — •Cedrik Barutel and Sebastian Fürthauer — Institute of Applied Physics TU Wien Austria

The cytoskeleton drives essential cellular processes like cell division and chromosome segregation. It consists of filaments that are crosslinked by proteins, many of which are molecular scale motors that consume ATP to do work. The forces that crosslinking proteins generate between cytoskeletal filaments are the key drivers of active cellular mechanics. We derive a generic theory to describe such crosslinking forces.

We construct a theory to describe and predict the forces generated collectively by crosslinking proteins between biofilaments using symmetries, conservation laws, and out-of equilibrium thermodynamic principles. Our approach identifies the full set of phenomenological coefficients governing entropic, active, and frictional crosslinking forces, which allows a quantitative comparison between the effects of different crosslinker mixtures between two filaments. We demonstrate the power and validity of this framework by quantitatively explaining a set of different experimental setups, which combine the effects of passive and active crosslinks

BP 36.4 Fri 10:30 BAR/SCHÖ

Modeling Cooperative Remodeling and Energy Landscapes in the Bacterial Flagellar Motor — •Nils-Ole Walliser — Laboratoire Charles Coulomb, University of Montpellier, Montpellier, France

Bacteria use the flagellar motor to adapt their motility to changing mechanical conditions. This rotary motor tunes its torque by recruiting and releasing torque-generating stator units. I will present statistical-physics-based models that use single-motor measurements to infer interaction potentials and energy landscapes in the bacterial flagellar motor. First, using single-motor bead assays that resolve stepwise changes in rotation speed and thus stator occupancy, we model stator recruitment as a finite-size lattice gas and infer stator-stator cooperativity from occupancy fluctuations. This reveals moderate attractive interactions and shows that the motor operates in a regime that balances responsiveness to load changes with noise in stator number. Second, I will discuss experiments where the motor load is actively perturbed, uncovering a strong asymmetry in the relaxation to the steady state when starting from higher versus lower stator occupancy. A two-state catch-bond model quantitatively explains this stoichiometry-dependent asymmetry and captures the mechanosensitive nature of stator anchoring to the cell wall. Finally, I will show how high-temporal-resolution rotation traces can be used to reconstruct, in a model-independent way, the tilted periodic energy landscape of the rotor/LP ring within a Smoluchowski framework, yielding barrier heights, torque and internal friction.

BP 36.5 Fri 10:45 BAR/SCHÖ

Anisotropic (sub)diffusion of organelles in living cells — •Aranyak Sarkar, Pooja Yadav, and Matthias Weiss — Experimental Physics I, University of Bayreuth, Universitätsstraße 30, 95447 Bayreuth

Eukaryotic cells are neatly organized into distinct, membrane-enclosed compartments ('organelles') with specific duties. A prominent example are peroxisomes, which feature vesicle-like shapes with radii 0.1 – 1 μm that are dispersed across the cytoplasm. Using time-lapse fluorescence microscopy, we have tracked the motion of individual peroxisomes over extended periods. Analysis of the experimental data revealed two distinct modes of motion: a prevailing (sub)diffusive motion and a quite rare super-diffusive characteristics that is associated with motor-driven transport along microtubules. Focussing on the seemingly unremarkable subset of (sub)diffusive trajectories, we have found a significant anisotropy in the motion that persisted even when microtubules were disrupted. In particular, diffusive steps along the cells' long axis were seen to be favored over steps in the perpendicular direction, indicating an anisotropic materials characteristic of the cytoplasm. Using a simple model, we were able to capture and explain the observed features of the anisotropic diffusion of organelles.

BP 36.6 Fri 11:15 BAR/SCHÖ

Understanding Influenza A Virus particles detaching from reconstructed cell surfaces — •Thomas Kolbe[1,2], Pierre Gaspard[1], and Bortolo Matteo Mognetti[1,2] — [1]CENOLI, Université Libre de Bruxelles (ULB) — [2]IB2 - Interuniversity Institute of Bioinformatics in Brussels

Influenza infection is a multistage process that involves the trafficking of viral particles across the cell membrane. Before endocytosis, virions target the membrane by binding hemagglutinin ligands to sialic acid residues on cell receptors. After budding, neuraminidase cleaves these residues, enabling virions to detach from the infected cell surface.

We examine detachment dynamics through simulations and theoretical analysis. We explain experimental findings showing that the time required for virions to detach can decrease as the single-trajectory average number of bonds increases - a counterintuitive result specific to neuraminidase activity. Furthermore, we demonstrate that the detachment time is not governed by a Poisson distribution but depends on multiple factors, including ligand-receptor reaction rates, virion size, and receptor diffusion constant. These results clarify how biochemical parameters regulate the residence time of virions at the cell surface.

BP 36.7 Fri 11:30 BAR/SCHÖ

Band pattern formation of erythrocytes in density gradients is due to competing aggregation and net buoyancy — •Felix Maurer[1], Camila Romero[1], Nikolas Lerch[1], Thomas John[1], Lars Kaestner[1,2], Christian Wagner[1,3], and Alexis Darras[1,4] — [1]Experimental Physics, Saarland University, Saarbruecken, Germany — [2]Department of Theoretical Medicine and Biosciences, Saarland University, Homburg, Germany — [3]Physics and Materials Science Research Unit, University of Luxembourg, Luxembourg — [4]School of Physics, University of Bristol, Bristol, United Kingdom

Centrifugation of biological matter in density gradient solutions is a standard method for separating cell types or components. It is also used to separate RBCs by age, as they lose water and become denser over their lifespan. When the density gradient is prepared with Percoll, discrete bands of RBCs are systematically observed, despite the continuous density distribution of RBCs. We developed a continuity equation incorporating cell aggregation to describe the macroscopic evolution of RBC volume fraction in a density gradient, considering a continuous RBC density distribution. Numerical solutions demonstrate that the competition between net buoyancy and aggregation is sufficient to create band patterns. Our model reproduces the temporal evolution observed in experiments, but also predicts several types of bifurcation-like behaviors for the steady-state patterns in constant gradients, depending on RBC volume fraction and aggregation energy.

BP 36.8 Fri 11:45 BAR/SCHÖ

Adaptive self-organization in excitable biological collectives — •Bianca Ariani[1,3], Yunus Sevinchan[2,3], and Pawel Romanczuk[2,3] — [1]Bernstein Center for Computational Neuroscience, Berlin — [2]Science of Intelligence, TU Berlin — [3]Institute for Theoretical Biology, HU Berlin

Biological collectives often display complex, context-dependent behavior, such as coordinated responses to predators, despite individuals following simple local rules. This class of phenomena is broadly understood as self-organization.

We examine a system showing rich spatio-temporal dynamics: Sulphur Mollies, Mexican freshwater fish whose group behavior resembles a stochastic excitable medium. To probe the mechanisms behind their collective activity, we study a bio-inspired agent-based model in which individuals estimate the shoal's mesoscale activity from the cues they perceive as they move. Each agent adjusts its sensitivity to cues through a simple homeostatic plasticity rule, allowing the group to regulate its collective state. This formulation links individual adaptation to population-level patterns.

Our results show that local adaptive regulation reproduces key qualitative features of the biological system. More generally, they illustrate how distributed plasticity mechanisms can support robust self-organization in complex biological collectives.

BP 36.9 Fri 12:00 BAR/SCHÖ

Visual-based Collective Shepherding in Swarm Robotic System — •Yating Zheng[1,2] and Pawel Romanczuk[1,2] — [1]Department of Biology, Humboldt Universität zu Berlin, Berlin, Germany — [2]Research Cluster of Excellence 'Science of Intelligence', Berlin, Germany

Collective shepherding presents a rich example of two interacting multi-agent systems coupled through non-reciprocal interactions. While most existing models assume that shepherd agents have global knowledge of the flock-an unrealistic premise for physical or biological systems-we introduce a vision-based, locally interacting model that captures the essential physics of shepherd-flock coordi-

nation. The model produces robust, self-organized behavior among shepherds without explicit communication, and we analyze how key control parameters, such as flock size and the number of shepherds, shape the resulting dynamics.

The framework also performs effectively in more challenging regimes, including the manipulation of non-cohesive agents and passive (non-self-propelled) agents, demonstrating its broad dynamical applicability. We further validate the model on a mixed-reality swarm-robotic platform, where physical robots successfully shepherd a virtual flock.

Overall, these results provide a minimal yet powerful physics-based description of multi-agent herding using only local visual information, offering insight into non-reciprocal collective behavior and enabling scalable real-world implementations in swarm robotics.

BP 36.10 Fri 12:15 BAR/SCHÖ

Polymer theory shows DNA motors extrude loops in the monomeric mode — Kirill Polovnikov[1,2] and •Dmitry Starkov[2] — [1]Institute for Physics and Astronomy, University of Potsdam, Potsdam-Golm, Germany — [2]Moscow, Russia

Cohesin-dependent loop extrusion is a key active mechanism of DNA organization, yet it remains unclear whether chromatin loops in living cells are generated primarily by individual cohesin motors or by higher-order structures. To fill this major gap, we build an analytical polymer-physics model that extracts a missing parameter - *the linear density of loops* - directly from Hi-C data. We focus on short genomic distances, where contact statistics simplify, resulting in a perturbative expression for the contact probability of a looped chain under a finite contact-detection radius. Our theory recapitulates a characteristic dip in the *logarithmic derivative* of the contact-probability that is *broadly observed in experiments*. By fitting this minimal model to a diverse range of mammalian Hi-C datasets, we infer approximately six loops per megabase. Independent imaging and mass spectrometry measurements of cohesin density are consistent with our inferred loop density, supporting the monomeric mode of DNA motors extrusion.

BP 36.11 Fri 12:30 BAR/SCHÖ

Universal loop statistics from active extrusion — •Anastasia Chervinskaya[1] and Kirill Polovnikov[1,2] — [1]Moscow, Russia — [2]Institute for Physics and Astronomy, University of Potsdam, Potsdam-Golm, Germany

Cohesin-dependent loop extrusion is a key active mechanism of genome organization, yet quantitative links between extrusion kinetics and measurable loop statistics remain incomplete. We develop an analytical model that predicts the mean loop scale, full loop-length distributions, state composition, and arm-arm correlations for one-sided versus two-sided extrusion. The theory maps the master equations onto diffusion on a state graph yielding state-resolved loop-length PDFs.

We show that one-sided extrusion yields a universal exponential loop-length distribution, whereas two-sided extrusion generates a sum of exponentials that approaches a gamma-like form at high barrier density. The model also predicts a strictly positive lower bound of 1/4 on arm-arm correlations.

Parameterized with independent measurements for HeLa G1 (cohesin residence and spacing; barrier densities and lifetimes), our model quantitatively accounts for the observed loop size. Also, it reproduces the experimentally measured distribution of CTCF-CTCF loop lengths under the assumption of two-sided extrusion, providing additional evidence that cohesin extrusion in living cells is predominantly bidirectional. Our results provide a compact route to infer biophysical parameters of active extrusion from experimental data.

BP 37: Tissue Mechanics II

Time: Friday 9:30–12:45 Location: BAR/0106

BP 37.1 Fri 9:30 BAR/0106

Active rheology and feedback-controlled stress in a multi-purpose platform for tissue mechanics — •Anna Mukhina[1,2], Till Muenker[1], Mattias Luber[1], Polina Malova[1,2], and Timo Betz[1,2] — [1]Third Institute of Physics - Biophysics, University of Goettingen — [2]Max Planck School Matter to Life

3D tissue engineering offers unique opportunities to study simplified, but accurate models of complex biological systems, where especially force generation, mechanical properties, and active regulation can be addressed. However, most current methods to raise engineered tissues do not allow quantitative characterization of their mechanics without a strong perturbation of these delicate systems.

Here, we present a novel experimental platform to apply well-defined strain to tissues and measure the resulting forces with an optical readout. Tissues are grown between flexible posts, where one post can be actuated by a piezo bending element, and direct optical detection of both posts movement allows for precise force and strain measurement. With this setup, we avoid complex microscopy measurements, can position the system in an incubator, and the rapid readout enables a large variety of experimental protocols. The system can conduct oscillatory rheology, simulate isometric/eccentric contractions, reproduce changes in environmental stiffness during physiological and pathological processes, and adapt stress or strain to mechanical changes of the system. We demonstrate the potential of the developed setup by carrying out oscillatory rheology of engineered skeletal muscles over the course of their maturation, covering three orders of frequency magnitude.

BP 37.2 Fri 9:45 BAR/0106

demonstrating normal tissue sparing with pitz PITZ electron beams in zebrafish embryos — •E Tarakci[1,2,3], C Schulze[2], C Richard[1], M Gross[1], N Aftab[1], A Aksoy[1], Z Amirkhanyan[1], A Chiravuri[1,2], J Good[1], F Hausmann[3], S Khammee[1], Y Komar[1,2,3], M Krasilnikov[1], B Li[1], X Li[1], Z Lotfi[1], G Montoya-Soto[1], F Mueller[1], A Oppelt[1], F Riemer[1], K Suzart[1], I Tinhofer[3], D Villani[1], S Worm[1], D Xu[1], S Zeeshan[1], M Frohme[2], F Stephan[1], S Aminzadeh Gohari[1], and A Grebinyk[1] — [1]Deutsches Elektronen-Synchrotron, DESY, Zeuthen — [2]Technische Hochschule Wildau,Wildau — [3]Charité Universitätsmedizin Berlin, Berlin

Zebrafish (Danio rerio) embryos provide a sensitive model for studying normal tissue responses. This study was conducted within FLASHlab@PITZ, where PITZ delivers electron beams from conventional to ultra-high dose rates up to 10^15 Gy/s. Wild-type AB embryos at 24 hours post fertilization (hpf) received 10 Gy via conventional X-rays (0.04 Gy/s), low dose rate electrons (LDR, 0.05 Gy/s), or ultra-high dose rate electrons (UHDR, 10^5 Gy/s). At 119 hpf, toxicity was assessed through spinal curvature, pericardial edema, eye diameter, and body length. X-rays and LDR increased toxicity (X-rays: 50% medium, 50% none*mild; LDR: 33% severe, 17% mild, 50% normal). UHDR greatly reduced effects, with no medium or severe toxicity and 42% none and 58% mild changes. These results demonstrate a marked tissue-sparing trend under UHDR conditions and provide early evidence for a FLASH-mediated normal tissue sparing effect.

BP 37.3 Fri 10:00 BAR/0106

Holographic vibration spectroscopy - extracting mechanical properties of adherent cells from their vibrational response — •Eric Schneider[1], Bob Fregin[1], Dominic Mokbel[2], Sebastian Aland[2], and Oliver Otto[1] — [1]Institute of Physics, University of Greifswald, Greifswald, Germany — [2]Institute of Numerical Mathematics and Optimization, TU Bergakademie Freiberg, Freiberg, Germany

The mechanical properties of biological cells are closely linked to their pathophysiological state, and high-throughput quantification is essential for using them as biomarkers in basic and translational research. While microfluidic technologies can characterize suspended cells at rates above 1,000 cells per second, no comparable method exists for adherent cells or tissues. Here, based on preliminary experiments with holographic vibration spectroscopy (HVS), developed in our group, we present a theoretical framework to address this gap. In HVS, adherent cells are harmonically oscillated at defined frequencies and amplitudes, and their deformation and phase shift encode their mechanical properties. To validate this concept, we developed a finite-element simulation framework using the open-source library AMDIS, capable of modeling cellular vibration across a broad parameter space. From these simulations, we derive a protocol to solve the inverse problem and show that viscoelastic properties can be uniquely determined using only the amplitude response at two vibration frequencies. Combined with HVS, this framework will next be used to rapidly and non-invasively quantify the viscoelastic properties of adherent cells and tissues.

BP 37.4 Fri 10:15 BAR/0106

Investigating the dynamics of cellular rearrangements in minimal four-cell clusters — •Agathe Jouneau, Tianyi Cao, and Joachim Rädler — Faculty of Physics and Center for NanoScience, Ludwig-Maximilians-Universität, Munich, Germany

Animal cells assemble into tissues that exhibit diverse mechanical responses, from solid-like to liquid-like states. In solid-like states, tissues can withstand mechanical stress, whereas in liquid-like states, they release stress through cellular rearrangements. Recent evidence suggests that the transition between solid and liquid-like states is central to biological processes such as embryogenesis, wound healing and cancer metastasis. However, the way in which local interactions between the constituent cells control the tissue fluidity remains unclear. The process by which cells exchange neighbors is known as a cell intercalation, or a T1 transition in foam physics terminology. Theoretical models have shown that the height of the energy barrier associated with T1 transitions determines tissue fluidity. In our work, we study the dynamics of T1 transitions in a minimal

system of four epithelial cells. We confine the cells onto adhesive micropatterns or in hydrogel microcavities, and use time-lapse microscopy to record the evolution of cell-cell junctions over time. We aim to use this platform to study how perturbations of cell-cell adhesion proteins impact cell rearrangement, as well as to experimentally test existing models for cellular dynamics.

BP 37.5 Fri 10:30 BAR/0106

Collective actuation in solid tissues: Dynamics and mechanics of an oscillating tissue shell during morphogenesis — •Zoë Lange[1], Henrik Jaeschke[1], Lea Möller[1], Mariia Golden[2], Artemiy Golden[2], Marc Pereyra[1], Frederic Strobl[2], Ernst H.K. Stelzer[2], and Franziska Matthäus[1] — [1]Frankfurt Institute for Advanced Studies — [2]Buchmann Institute for Molecular Life Sciences

Morphogenesis relies on coordinated mechanical deformations of embryonic tissues, yet the dynamic material properties that enable these shape changes remain incompletely understood. In the *Tribolium castaneum* embryo, the extraembryonic serosa tissue forms a closed and oscillating epithelial shell, providing a powerful model to study active mechanical processes in vivo. Here, we combine quantitative live imaging with particle image velocimetry, cell-boundary segmentation, cell-boundary tracking, and stress inference methods to characterize the spatiotemporal mechanics of the oscillatory contractions in the tissue shell. We show that the extraembryonic epithelium behaves as an active elastic solid whose global oscillation emerges from synchronizing cellular contraction. By integrating measured deformation with inferred force maps, we identify a cellular program of mechanosensitive remodeling. Our results provide a mechanistic link between active force production at the cellular scale and emergent morphogenetic dynamics at the tissue scale, establishing the *Tribolium* tissue shell as a model system for collective actuation in active elastic materials *in vivo*.

BP 37.6 Fri 10:45 BAR/0106

Plant movement systems enabled by plant hinges: diversity, evolution, form-structure-function relationships and their biomimetic potential — Arooj Sajjad and •Simon Poppinga — Technische Universität Darmstadt, Botanischer Garten, Schnittspahnstraße 2, 64287 Darmstadt, Germany.

Plants are often described as comparatively static systems, yet many species exhibit diverse and mechanically sophisticated forms of movement. In recent decades, such plant movement systems have gained increasing attention due to their remarkable flexibility, versatility, and structural robustness. Plants move in a variety of ways, e.g. to align themselves with sunlight or the earth's gravitational field, to catch prey, to interact with pollinators, and to adhere to nearby structures in the environment. Plant movements are often enabled by joint-like structures, commonly referred to as plant hinges in the literature. Unlike technical hinges, which allow for rigid body movements and are maintenance-intensive and prone to failure, compliant mechanisms as found in plant movement systems fulfil roles analogous to technical joints, albeit fundamentally differing in form, kinematics, and structure. Interestingly, the hinges in most motile plant structures (e.g. motile sepals in orchids or lever mechanisms in sages) have not been investigated regarding their form-structure-function relationships. In this broad research study, we approach these compliant mechanisms in plants from an engineering perspective on kinematic pairs. Our research also aims to understand convergent mechanisms in plants. One aim is to develop future biomimetic actuator design.

15 min. break

BP 37.7 Fri 11:15 BAR/0106

Understanding tissue mechanics through tumour organoids — •Mathilde G. Lettinga[1], Vaibhav Mahajan[1], Raimund Schlüssler[1], Stefanie Hübner[2,3], Valeria Lozovanu[2,3], Franziska Baenke[2,3,4], Daniel E. Stange[2,3,4], and Anna V. Taubenberger[1] — [1]BIOTEC, CMCB, TU Dresden — [2]VTG, University Hospital Carl Gustav Carus, TU Dresden — [3]DKTK, Heidelberg — [4]NCT/UCC, Dresden

Tumours exhibit altered physical properties that manifest across spatial scales. Compared to healthy tissue, solid tumours are typically stiffer, which can partly be attributed to the extracellular matrix. However, the contributions of the epithelial cancer cells to the emergent tissue properties remain unclear.

Aiming to elucidate the role of cells in tissue mechanics, we investigated the mechanical and morphological properties of patient-derived colorectal liver metastasis organoids. Organoids from different patients varied in morphology, displaying either a large central lumen or a multitude of small lumina. We performed bulk compression with AFM and found that single-luminal organoids are stiffer and more elastic than multi-luminal organoids. Concurrently, Brillouin microscopy in situ showed a higher Brillouin frequency shift for single-luminal organoids, indicating lower compressibility. 3D segmentation revealed more elongated, ordered, homogeneous and smaller nuclei in the single-luminal organoids compared to their multi-luminal counterparts. Thus, our data suggest that the mechanical properties of organoids are coupled to the physical properties of their constituent cells.

BP 37.8 Fri 11:30 BAR/0106

A morphoelastic phase field model predicts buckling instability in tumor growth — Luise Zieger[1], Min Wu[3], John Lowengrub[4], and •Sebastian Aland[1,2] — [1]TU Freiberg — [2]HTW Dresden — [3]Worcester Polytechnic Institute, USA — [4]UC Irvine, USA

It is well known that growing tumors generate and respond to stress in their local environment. On the one hand, local cell proliferation and apoptosis lead to complex strain patterns in the tissue. On the other hand, tissue re-arrangements can relax the resulting mechanical shear stresses and make the tissue more fluid-like. To predict the outcomes of these nonlinear visco-elastic interactions, we introduce the framework of morphoelasticity to phase field modeling of a growing tumor embedded in a surrounding host tissue. Coupling this continuum system to diffusible growth-promoting nutrient, our simulations identify a symmetry-breaking instability in 2D and 3D driven by two primary mechanisms: (i) elastic buckling instability generated by tangential stresses along the tumor-host interface and (ii) instabilities generated by local imbalances between cell divisions and cell death. Further, tissue fluidity and compressibility can lead to changes in tumor topologies. Our modeling framework provides a robust methodology for investigating how tissue mechanics and growth factor signaling influence the progression and invasive potential of solid tumors.

BP 37.9 Fri 11:45 BAR/0106

Orientational lineage memory and mechanical ordering during diffusion-limited growth — •Ilias-Marios Sarris[1], Ramin Golestanian[1,2], and Philip Bittihn[1] — [1]MPI for Dynamics and Self-Organization, Göttingen, Germany — [2]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, United Kingdom

Growth and shape formation in crowded multicellular assemblies arise from the interplay of chemical gradients, single-cell expansion, and mechanical interactions. Using a particle-based model that resolves nutrient fields and cellular orientations with tunable lineage memory, we study how orientational order emerges in expanding fronts whose morphology is set by nutrient limitation. We find a transition in nematic order controlled by front morphology: under strong orientation inheritance, both thin active layers (fingering fronts) and thick active layers (flat fronts) produce strong alignment, while intermediate cases are less ordered. Velocity, reorientation, and stress statistics reveal a crossover from inheritance-dominated to mechanically driven alignment that progressively overrides lineage memory. As a result, orientational memory yields a fitness advantage only in the diffusion-limited, memory-dominated regime, elucidating how nutrient supply and mechanics jointly shape self-organization during growth.

BP 37.10 Fri 12:00 BAR/0106

Feedback-controlled epithelial mechanics: emergent soft elasticity and active yielding — •Fridtjof Brauns[1,2], Pengyu Yu[3,4], and M. Cristina Marchetti[3] — [1]MPI-PKS, Dresden, Germany — [2]KITP, Santa Barbara, USA — [3]University of California, Santa Barbara, USA — [4]Tsinghua University, Beijing, China

Biological tissues exhibit distinct mechanical and rheological behaviors during morphogenesis. While much is known about tissue phase transitions controlled by structural order and cell mechanics, key questions regarding how tissue-scale nematic order emerges from cell-scale processes and influences tissue rheology remain unclear. Here, we develop a minimal vertex model that incorporates a coupling between active forces generated by cytoskeletal fibers and their alignment with local elastic stress in solid epithelial tissues. We show that this feedback loop induces an isotropic–nematic transition, leading to an ordered solid state that exhibits soft elasticity. Further increasing activity drives collective self-yielding, leading to tissue flows that are correlated across the entire system. This remarkable state, that we dub plastic nematic solid, is uniquely suited to facilitate active tissue remodeling during morphogenesis. It fundamentally differs from the well-studied fluid regime where macroscopic elastic stresses vanish and the velocity correlation length remains finite, controlled by activity. Altogether, our results reveal a rich spectrum of tissue states jointly governed by activity and passive cell deformability, with important implications for understanding tissue mechanics and morphogenesis.

BP 37.11 Fri 12:15 BAR/0106

Neuromechanics of peristalsis — •Sifan Yin[1], Suraj Shankar[2], and Lakshminarayanan Mahadevan[3] — [1]MPI-PKS, Dresden, Germany — [2]University of Michigan, Ann Arbor, MI, US — [3]Harvard University, Cambridge, MA, US

The peristalsis of cylindrical-shaped organisms or organs is driven by the propagation of rhythmic waves of contraction and relaxation along the tube wall. These waves are generated by coupled interactions of neural control, mechanotransduction, and active muscular contraction. Here, we propose a minimal neuromechanical model for spontaneously coordinated peristaltic waves by locally coupling the neuro-muscular dynamics to the mechanics of an active elastic tube, such as the Nematostella body, the gastro-intestinal tract, and the ureters. We analyze our model using a combination of analytical and numerical methods to investigate the nucleation, propagation and extinction of pulse, and the transi-

tions between disordered twitching and coordinated traveling waves. Our theory naturally elucidates how the interactions among mechanics and neural activities can give rise to coordinated peristaltic motion without any center pattern generator (CPG). This work can supplement ways to robustly design robotics with neural feedback and help to understand early peristaltic wave generation before CPG formation, especially in early embryonic development.

BP 37.12 Fri 12:30 BAR/0106

Muscle growth by sarcomere divisions — Clement Rodier[1], Ian D. Estabrook[2,3], Frank Schnorrer[1], and •Benjamin M. Friedrich[2] — [1]IBDM, Marseilles, France — [2]EXC Physics of Life, TU Dresden, Germany — [3]EMBL, Heidelberg, Germany

The sarcomere is the elementary contractile unit of muscles. Sarcomeres are organized into highly regular periodic chains termed myofibrils, which span the millimeter-length of muscle cells. During development, new sarcomeres are added to mechanically tensed myofibrils as muscle cells increase in length. Yet, how muscles add new sarcomeres to facilitate muscle growth remained elusive. Using live imaging and high-throughput image analysis of the Drosophila flight muscle, we identified a new mechanism of tension-driven sarcomere addition where individual sarcomeres divide along the myofibril tension axis into daughter sarcomeres. Thereby, new sarcomeres can be inserted into contractile myofibrils without compromising their mechanical integrity. A similar mechanism may apply in vertebrate muscle development and regeneration.

See DY 62 for details of this session.

BP 39: Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates III (joint session CPP/BP)

Time: Friday 9:30–11:15 Location: ZEU/0260

Topical Talk BP 39.1 Fri 9:30 ZEU/0260

Data-driven modelling of phase-separating intrinsically disordered regions — •Giulio Tesei[1,2], Fatima Kamal Zaidi[3], Shanlong Li[4], Julian O. Streit[1], Jianhan Chen[4], Tanja Mittag[3], and Kresten Lindorff-Larsen[1] — [1]Department of Biology, University of Copenhagen, Copenhagen, Denmark — [2]Department of Biomedical Science, Malmö University, Malmö, Sweden — [3]Department of Structural Biology, St. Jude Children's Research Hospital, Memphis, U.S.A. — [4]Department of Chemistry, University of Massachusetts, Amherst, U.S.A.

Intrinsically disordered regions (IDRs) constitute about one third of the human proteome and play important roles in biological processes. While lacking well-defined 3D structures, IDRs adopt heterogeneous ensembles influenced by multivalent interactions; these same interactions can promote phase separation and contribute to the formation of biomolecular condensates. I will first present CALVADOS, an efficient one-bead-per-residue model optimized on experimental data reporting on IDR conformational properties and extensively validated on both single-chain and phase behavior across diverse sequences. I will then describe how we used large sets of CALVADOS simulations to train machine-learning models that accurately predict single-chain compaction and homotypic phase-separation propensity directly from sequence. Finally, I will introduce a hybrid-resolution model with an atomistic backbone representation that matches the accuracy of CALVADOS for global dimensions and phase separation while also capturing local structure and backbone hydrogen bonding.

BP 39.2 Fri 10:00 ZEU/0260

Born to Condense: Polysomes Drive Co-Translational Condensation of Biomolecular Condensate Proteins — •Zhouyi He, Jens-Uwe Sommer, and Tyler Harmon — Leibniz Institute of Polymer Research, 01069, Dresden, Germany

Biomolecular condensates formed by protein LLPS are ubiquitous and crucial in cells. While the physics and functions of LLPS are well studied, its interplay with protein synthesis, translation, remains largely unexplored. Here we propose Co-Translational Condensation (CTC), a mechanism in which nascent protein chains of polysomes, multiple ribosomes on one mRNA, interact with condensates, localizing translation to condensate surfaces. Using coarse-grained simulations, we show that protein domain architecture dictates the extend of CTC, consistent with a Langmuir adsorption model. Bioinformatic analysis reveals that most condensate-associated proteins have architectures favoring CTC, with strong interaction regions of nascent chains exposed on polysomes. Dynamically, simulation and reaction-diffusion modeling reveal that CTC is kinetically feasible within typical polysome lifetimes, either through large polysomes nucleating new condensates or via diffusion to pre-existing condensates. As a case study, we demonstrate that CTC enhances post-translational modifications by minimizing unmodified intermediates. More broadly, we anticipate CTC may also influence protein folding, misfolding, and signal-integration latency. Together, our results establish CTC as a general mechanism coupling translation with phase separation, with broad implications for protein evolution, cellular organization, and synthetic biology.

BP 39.3 Fri 10:15 ZEU/0260

Local RNA/protein stoichiometry tunes the electrostatic microenvironment inside reconstituted multicomponent condensates — •Patrick M. McCall — Leibniz Institute for Polymer Research Dresden, Dresden, DE

Biomolecular condensates are demixed phases of biopolymers and, in living cells, commonly form through the associative phase separation of strongly-charged nucleic acids together with protein polyampholytes carrying a weak net charge. While condensates are proposed to offer distinct aqueous environments for the organization of cellular biochemistry, it remains unclear which physical aspects of the microenvironment are relevant and how widely they can vary between condensates. Motivated by the large asymmetry in structural charge between typical condensate components such as RNAs and RNA-binding proteins, we explore here the implications of electroneutrality on the electrostatic environment within model multicomponent condensates. Combining classical Donnan theory with recent measurements of the macromolecular composition of condensates reconstituted from full-length FUS protein and a homopolymeric RNA [McCall et al Nat Chem 2025], we compute the partitioning of salt ions as well as the Donnan potential across the phase boundary. We find that RNA/FUS stoichiometry tunes both co-ion exclusions over a wide range and is coupled to a pH jump across droplet interface. We also find that co-ion exclusion is suppressed by counter-ion condensation and enhanced by non-ideality of un-bound ions. These results provide insight into the range of ionic conditions accessible to a prominent class of biomolecular condensate.

BP 39.4 Fri 10:30 ZEU/0260

Coarse-grained model to study the effects of electric fields on protein interactions — •Agaya Johnson[1], Debes Ray[2,4], Mahnoush Madani[3], Jan Dhont[2,3], Florian Platten[2,3], Kyongok Kang[2], and Sofia Kantorovich[1] — [1]University of Vienna, Kolingasse 14-16, 1090, Vienna, Austria. — [2]nstitute of Biological Information Processing IBI-4, Forschungszentrum Jülich, 52428 Jülich, Germany. — [3]Faculty of Mathematics and Natural Sciences, Heinrich Heine University Düsseldorf, 40225 Düsseldorf, Germany. — [4]Solid State Physics Division, Bhabha Atomic Research Centre, Trombay, Mumbai 400085, India.

Proteins can undergo transition between a wide range of organisational states, from soluble monomers to disordered phases and ordered structures. Experiments have shown that lysozyme in sodium thiocyanate solution can form homogeneous, crystalline, or liquid phases depending on the salt and protein concentrations, and that these phase boundaries can be shifted by applying an electric field. We present a coarse-grained model of lysozyme in sodium thiocyanate solution, representing the protein as an ellipsoid decorated with charged and adhesive surface patches. Counterions and monovalent salt are treated explicitly via excluded-volume repulsion and Coulombic interactions. We investigate (i) how patch size and salt*patch interactions influence ion distributions around a single protein, with and without an external electric field, and (ii) the resulting effective interactions between two proteins as functions of patch properties, salt concentration, and applied electric field.

BP 39.5 Fri 10:45 ZEU/0260

Entropic Clustering of Stickers Induces Aging in Biocondensates — •Hugo Le Roy[1] and Paolo De Los Rios[2] — [1]Department of Civil, Chemical and Environmental Engineering, University of Genoa, Genoa, Italy — [2]Institute of Physics, Ecole Polytechnique Fédérale de Lausanne

Neurodegenerative conditions, such as Parkinson's disease, results from the aggregation of synaptic proteins such as alpha-synuclein. In a healthy presynaptic neuron, effective neurotransmission relies on the spatial organization of synaptic vesicles within phase-separated droplets. These vesicles release neurotransmitters into the synaptic cleft to activate ion-gated channels on the postsynaptic neuron.

In this work, we investigate how this transmission process is impaired during neurodegeneration. Specifically, we focus on the solidification of these phase-separated droplets, a phenomenon described as aging, leading to protein aggregation and associated with the emergence of pathology. We explore the connection between the mechanical properties of the condensates and their microscopic structure using a minimal physical model that treats complex molecules as stickers and spacers. We show that entropy maximization of spacers leads to an effective attractive force between stickers. As a result, our system displays a surprisingly slow relaxation toward equilibrium, reminiscent of glassy systems and consistent with the liquid-to-solid transition observed in aging droplets. By analyzing the clustering dynamics of stickers, we successfully explain the microscopic origin of this glassy relaxation.

BP 39.6 Fri 11:00 ZEU/0260

Biomolecular condensates with a Twist: From Assembly to Arrest — •Mahesh Yadav[1,2] and Lukas Stelzl[2] — [1]Institute of Physics, Johannes Gutenberg University, Mainz — [2]Institute of Molecular Physiology, Johannes Gutenberg University, Mainz

In this work, we investigate the phase behavior of RNA-binding protein Fused in Sarcoma (FUS), whose multivalent and intrinsically disordered regions drive the formation of biomolecular condensates through liquid-liquid phase separation. FUS is a multi-domain protein with arginine-glycine-rich segments (RG-rich domains) that participate in essential cellular proceses. We examine how characteristic sequence motifs such as RGG.. mediate homotypic and nucleic acid binding, and how targeted point mutations (e.g., RtoK, RtoA) disrupt these motifs and impair condensate formation. Using the thermodynamics phase diagram as a benchmark we highlighted the shift in phase separation propensity of the FUS and its variants. Furthermore, we identify the role of key interactions such as electrostatics, π-π and cation-π in nucleic acid binding at atomistic scale. We further characterized the emergent viscoelastic behavior of FUS condensates at multiple scales. We observe that upon mutations the overall dynamics slows down which reflects the gel-like state. Within the condensate interior, protein chains exhibit sub-diffusive dynamics arising from intermittent binding and viscoelastic resistance, mobility at the interface is further suppressed due to anisotropic interactions and interfacial confinement. To quantify these behaviors across relevant scales, we employ multi-resolution simulation models.

BP 40: Cell Mechanics II / Cytoskeleton II

Time: Friday 10:00–11:15 Location: BAR/0205

BP 40.1 Fri 10:00 BAR/0205

The keratin network adapts the nucleus to cellular strain — •Ruben Haag[1], Ruth Meyer[1], Sascha Lambert[2], Hajaani Manoharan[3], Ulrike Rölleke[1], Jens Konrad[3], Bernd Hoffman[3], Rudolf Merkel[3], Stefan Klumpp[2], and Sarah Köster[1] — [1]Institute for X-Ray Physics, University of Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany — [3]Institute of Biological Information Processing, Forschungszentrum Jülich, Germany

Intermediate filaments (IFs) comprise one of the cytoskeletal network types and are cell-type specific. In epithelial cells, the keratin IF network connects the desmosomes in the cell membrane with the perinuclear keratin cage, thus forming a mechanical link from the nucleus to the cell membrane. We now ask whether this link transmits mechanical signals from outside the cell to the nucleus. To answer this question, we stretch both epithelial wild type and keratin knockout cells uniaxially and equibiaxially. During stretching, we image cell nuclei and measure their individual deformation to study the influence of the keratin IF network on them. To understand how the keratin network transmits force to the nucleus, we image the keratin network during cell stretching and create a minimal model to mimic how the keratin network deforms the nucleus. Our results suggest that stretching the keratin network is a two-step process: individual keratin bundles are initially pulled straight and are then stretched. Possibly, by this two-step process, the keratin network adapts the nucleus to cellular strain.

BP 40.2 Fri 10:15 BAR/0205

Improving T cell migration and invasion with the Microtubule destabilizing agent Pretubulysin. — •Lukas Schuster[1], Galia Montalvo[1], Reza Shaebani[1], Anna Burgstaller[2], Shweta Nandakumar[1], Rhoda Hawkins[3], Laura Schaedel[1], Bin Qu[4], and Franziska Lautenschläger[1] — [1]Saarland University, Saarbrücken, Germany — [2]Leibniz Institute for New Materials, Saarbrücken, Germany — [3]School of Mathematical and Physical Sciences, University of Sheffield, Sheffield, United Kingdom — [4]Center for Integrative Physiology and Molecular Medicine (CIPMM), Saarland University, Homburg, Germany & Department of Biomedical Sciences, Osnabrück University, Osnabrück, Germany

The immune response depends on the ability of cytotoxic T lymphocytes (CTLs) to migrate and invade into dense 3D environments, such as tumors, and to kill cancer cells. Thus, optimizing the migratory behavior of CTLs is crucial to boost immune response in the treatment against cancer. Here, we focused on the role of destabilized microtubules (MTs) in cell migration. We showed that the disruption of MTs in CTLs with the compound Pretubulysin enhances the infiltration of 3D collagen gels and the killing of target cells. In addition, we confirmed the motile phenotype in 2D and 1D migration assays. We further studied the mechanism of how MT disruption induces cell motility in a theoretical active droplet model. We found enriched actomyosin in the back of CTLs to be linked to a fast and persistent migrating cell.

BP 40.3 Fri 10:30 BAR/0205

Role of mechanics in early immune recognition — •Kheya Sengupta — CINaM, CNRS, Luminy, France.

Our immune system depends on cell scale forces, which are implicated in various phenomena ranging from migration to recognition of pathology or for potentiating diseased cells for killing. Here the focus will be on the first steps of immune recognition which hinges on formation of bonds between specialised receptors and their specific ligands called antigens, where mechanics and forces are thought to be essential to discriminate our own antigens from those indicative of pathology. Intriguingly, unlike for tissue forming cells, the response of T cells is biphasic with the stiffness of their environment when the interaction is mediated through the T-cell receptors (TCRs). However, when the adhesive ligands of integrins are additionally involved, the cellular response becomes monotonic. Based on a mesoscale model, this ligand-specific response can be attributed to molecular properties of a putative link between the ligand/receptor pair and the cytoskeleton. While the molecules linking integrins and actin are known, the equivalent molecules for TCR are yet to be identified. Our model predicts kinetic and mechanical parameters for this putative link, whose existence we prove by mechanical extraction of membrane tubes. We also measure cell scale forces and show that their spatio-temporal patterns depend on chemistry, mechanics and T cell sub-type. Overall, our findings reinforce the proposition that force application provides a general mechanism for immune cells to discriminate mechanosensitive bonds.

BP 40.4 Fri 10:45 BAR/0205

Investigating the interaction between cardiac fibroblasts using ROCS and fluorescence microscopy — •Arash Felekary and Alexander Rohrbach — IMTEK, University of Freiburg, Germany

Cell-cell interaction is essential for cardiac function. Tunneling nanotubes (TNTs), thin actin-based membrane protrusions, mediate long-range interactions by transporting organelles and signaling molecules. To study their role in cardiac fibroblast (FB) interaction, we combined Rotating Coherent Scattering (ROCS) microscopy with fluorescence imaging. ROCS provides label-free, high-contrast recordings at up to 100 Hz and resolves TNTs and lamellipodia across several micrometers above the substrate. Using this approach, we observed a linear correlation between TNT density and lamellipodia motion velocity. Collagen labeling revealed that TNTs frequently align with collagen fibers, suggesting a structural coupling between ECM-linked TNTs and actin-driven protrusions. These observations motivated a spatially resolved simulation of actin filament polymerization and branching, incorporating integrin*collagen interactions and Arp2/3 activation. The model reproduces the experimentally observed increase in lamellipodial velocity with TNT density and supports a mechanism in which TNTs locally amplify integrin-mediated actin remodeling. In this presentation, we discuss how TNTs, lamellipodia, and ECM components cooperatively guide FB interaction, offering new insight into the structural and mechanical coordination underlying cardiac tissue remodeling.

BP 40.5 Fri 11:00 BAR/0205

How to determine cell property distributions from high-throughput experiments via computer simulations — •Stephan Gekle — Biofluid Simulation and Modeling, Theoretische Physik VI, Universität Bayreuth

A central challenge in computer simulations of living cells is the accurate determination of model parameters based on experimental data. This challenge arises since cell properties such as membrane or cytoplasm viscosities are often difficult or impossible to directly measure in an experiment. The current paradigm in the field is to try to find a single "optimal" value for each such property. This approach completely disregards biological heterogeneity and cell-to-cell variability.

Here, we will present a novel inference method which starts from the assumption that *the* optimal value of a cellular property does not exist and that biological reality must rather be reflected by a *distribution* of values for each cell property. We will show how to obtain such property distributions for a realistic and technologically relevant scenario of disease detection via red blood cell membrane alterations.

For this, we will present boundary-integral simulations of red blood cells passing through a microchannel setup corresponding to real-time deformability cytometry (RT-DC) experiments. We will show how the resulting large amounts of scattered experimental data can be combined with our efficient simulations to infer distributions of cytosol and membrane viscosities in a heterogeneous cell population taking full account of cell-to-cell variability.

BP 41: Franco-German Session: Bacterial Biophysics II

Time: Friday 11:30–12:45 Location: BAR/0205

Invited Talk BP 41.1 Fri 11:30 BAR/0205

Probing spatiotemportal electrochemical dynamics on single bacterial cells — Anaïs Biquet-Bisquert[1], Baptiste Carrio[1], Nathan Meyer[1], Thales Fernandes[1], Manouk Abkarian[1], Farida Seduk[2], Axel Magalon[2], •Ashley Nord[1], and Francesco Pedaci[1] — [1]Centre de Biologie Structurale, Université de Montpellier, CNRS, INSERM. Montpellier, France. — [2]Aix Marseille Université, CNRS, Laboratoire de Chimie Bactérienne (UMR7283), IMM, IM2B, 13402 Marseille, France.

Electrochemical gradients across biological membranes are fundamental to cellular bioenergetics. In bacteria, the proton motive force (PMF) drives critical functions such as ATP synthesis and motility. Although historically regarded as temporally and spatially stable, recent studies have revealed dynamic PMF behaviors at single-cell and community levels, which are implicated in processes like intracellular communication and coordination. The bacterial flagellar motor, a rotary nanomachine directly powered by the PMF, provides a unique and sensitive tool for probing these dynamics. By employing light-activated proton pumps and monitoring changes in flagellar motor activity, we perturb and investigate the PMF at the single-cell level. This approach reveals millisecond-scale temporal fluctuations and rapid lateral homogenization of the PMF, reminiscent of the electrotonic potential spread observed in passive neurons.

BP 41.2 Fri 12:00 BAR/0205

Cable Bacteria as Conductive Interfaces: Towards Scalable, Bacteria-derived Electronics — •Hannah Ferenz[1,2], Rakesh Nair[2], and Hans Kleemann[2] — [1]Sächsisches Landesgymnasium Sankt Afra zu Meißen, 01662 Meißen, Germany — [2]Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden, 01187 Dresden, Germany.

Cable bacteria (Electrothecera and Electronema spp.) are multicellular filamentous bacteria that perform centimeter-scale electron transport via parallel conductive fibers embedded in their cell envelope, achieving conductivities up to 30 S cm^-1, rivaling synthetic conjugated polymers. We present a robust bioprocess using controlled oxygen-sulfide gradients in natural sediments to produce mechanically coherent, dense biofilms (>10^5 filaments cm^-2). These living conductive networks self-assemble, remain stable for months in-culture, and self-repair via continued growth after damage.

We demonstrate how these bacterial cultures can be used for the development of bio-derived electrodes based on their inherent nickel-sulfur complexes. These results establish cable bacteria as the first genetically tractable, self-growing biological conductor suitable for integration into transient and sustainable electronics, offering a path toward low-cost, environmentally benign bioelectronic interfaces for sensing, energy harvesting, and wearable devices.

BP 41.3 Fri 12:15 BAR/0205

Biophysics of bacterial survival during starvation — •Severin Schink — LMU München, Fakultät für Biologie

Most bacteria live in nutrient-limited states, yet the physical principles that set their lifespan and govern loss of viability during starvation remain poorly understood. I present a framework that links death dynamics, proteome adaptation and competition under starvation in E. coli.

Using time-lapse microscopy, we show that starving cells maintain a plasmolysed state and typically die via a rapid collapse of ion homeostasis. A coarse-grained model of ion transport maps death to a Kramers-like escape process set by nutrient recycling. The model predicts how death rates scale with permeability, ionic strength and cell geometry, and how modified media extend lifespan by lowering maintenance costs.

Proteome-wide analysis reveals that envelope proteins are key for survival: reallocating proteome into the envelope lowers ion permeability and death rate but constrains growth, generating a trade-off between proliferation and starvation survival. Co-cultures of physiologically distinct populations reveal cross-feed feedback: nutrients released by dying cells are recaptured by survivors, amplifying small differences in maintenance and uptake into large fitness advantages. Together, these results identify a minimal set of physical parameters ion gradients, permeability, recycling yield and uptake capacity that control lifespan and selection under starvation.

BP 41.4 Fri 12:30 BAR/0205

Selective inhibition of microbial methanogenesis - a shortcut toward climate change mitigation — •Benedikt Sabass — TU Dortmund — LMU München

In a world that is increasingly affected by climate change, new solutions are urgently needed to reduce greenhouse gas emissions. One of the most effective measures to limit global warming is to reduce methane emissions, a significant proportion of which is produced in the rumen of cattle. Rumen methanogenesis is a complex process that involves various biochemical pathways and cooperation among species from all three domains of life.

A reduction of methane emissions through feed additives has been shown to be feasible in principle, but effective and economical solutions are not yet available. Here, I present an overview of our research on compounds that selectively inhibit methanogenesis. I summarize existing strategies, describe our in-vitro screening assay, and present results from animal tests. Finally, I outline basic open questions regarding the molecular mechanisms of methanogenesis from a biological physics perspective.

BP 42: Closing Talk (joint session CPP/BP/DY)

Time: Friday 13:15–14:00 Location: HSZ/0002

Invited Talk BP 42.1 Fri 13:15 HSZ/0002

Biomolecular Condensates: Challenges for Polymer Physics — •Jens-Uwe Sommer — Leibniz-Insitut für Polymerforschung Dresden, Bereich Theorie der Polymere,Hohe Straße 6, 01069 Dresden, Germany — TU Dresden, Insitut für Theoretische Physik, Zellescher Weg 17, D-01069 Dresden, Germany

Biomolecular condensates (BMCs) constitute an emerging paradigm in the understanding of biological functions. They shift the focus from individual biochemical processes toward the collective behavior of biopolymers, in which phase-separation mechanisms and intrinsically disordered proteins lacking canonical enzymatic roles play central and often decisive functions. Consequently, universal principles of complex (bio)polymer solutions gain relevance, and several classical questions in the physics of living matter can now be revisited from this polymer-physics perspective. In this talk, I will discuss theoretical approaches and concepts that are based on universal principles, with a particular emphasis on current challenges in the field.

Chemical and Polymer Physics Division
Fachverband Chemische Physik und Polymerphysik (CPP)

Christine M. Papadakis
Technical University of Munich
James-Franck-Str. 1
85748 Garching
papadakis@tum.de

The 2026 Meeting of the CPP Division is marked by the 75th anniversary of the Polymer Physics Division, which is celebrated in the Focus Session "75 Years Division Polymer Physics: From Curiosity to Smart Materials". Two Focus Sessions address the topics "Theoretical Modeling and Simulation of Biomolecular Condensates" and "Water: From Atmosphere to Space". To honor the guest country France, we have organized the following French-German sessions: "Membranes and Porous Materials", "Nanomaterials, Composites and Hybrids", "Simulation Methods and Modeling of Soft Matter", "2D Materials, Thin Films and Interfaces" as well as a Round Table Discussion "The Future of Neutrons in France and Germany". Plenary speakers include Peter Müller-Buschbaum, Hugues Chaté, Antony Hyman, and Annabella Selloni. The former chairman of the CPP Division, Kurt Kremer, is this year's awardee of the Max Planck Medal. The CPP Division supports the Symposia "The Sustainability Challenge: A Decade of Transformation" and "Fluids with Broken Time-Reversal Symmetry: Odd/Hall Viscosity between Active Matter and Electron Flows" as well as the French-German Symposium "Soft, Active and Alive: Emergent Properties in Living Matter". The Meeting concludes with a Highlighted Invited Talk given by Jens-Uwe Sommer.

Overview of Invited Talks and Sessions

CPP 12.6	Mon	16:30–17:00	ZEU/0255	**Thin-film and interface properties in energy conversion devices unveiled by X-rays** — •Marcus Bär
CPP 13.1	Mon	15:00–15:30	ZEU/0260	**Modelling and simulation of pH-sensitive polyelectrolyte microgels** — •Stefanie Schneider
CPP 16.1	Mon	17:15–17:45	ZEU/0260	**Understanding the Passivation Properties of Solid Electrolyte Interphases (SEIs) in Batteries: Generator-Collector Experiments combined with a Transport and Reaction Model** — •Bernhard Roling, Falk Krauss, Annalena Duncker, Isabel Pantenburg
CPP 21.1	Tue	9:30–10:00	ZEU/0255	**Molecular modelling of gas solubility and free volume trends in Si-functionalized ionic liquids** — •Kateryna Goloviznina, Eduards Bakis, Inês C. M. Vaz, Agilio Padua, Margarida Costa Gomes
CPP 22.1	Tue	9:30–10:00	ZEU/0260	**From Solution to Thin Films: Structure Formation Pathways in Organic Photovoltaic Films** — •Eva M. Herzig
CPP 26.1	Tue	14:00–14:30	HÜL/S386	**Investigating lignin graphitisation depending on botanical source and extraction method** — Lucie Dieval, Phuthiphong Ouitrakoon, Robert Hunter, Sébastien Schaefer, Louis Hennet, Erik Elkaim, Julie Ruellou, Milo S. P. Shaffer, Agnieszka Brandt-Talbot, •Pascale Launois

CPP 30.1	Tue	14:00–14:30	ZEU/0260	**Solvent effects on amphiphile self-assembly in Deep Eutectic Solvents** — •Karen Edler
CPP 31.1	Wed	9:30–10:00	ZEU/0255	**Hydrogels with a Pinch of Embodied Intelligence** — •Andreas Walther
CPP 33.1	Wed	10:00–10:30	ZEU/LICH	**Shape-induced superstructure formation in concentrated ferrofluids** — •Sabrina Disch
CPP 37.1	Wed	15:00–15:30	ZEU/LICH	**Predicting molecular ordering in deposited molecular films** — •Denis Adrienko
CPP 38.1	Wed	15:00–15:30	ZEU/0255	**Engineering, processing and application of recombinant spider silk proteins** — •Thomas Scheibel
CPP 39.1	Wed	15:00–15:30	ZEU/0260	**A polarizable model for atomistic simulations of metals and graphitic material/liquid interfaces** — Krishan Kanhaiya, Hendrik Heinz, •Marialore Sulpizi
CPP 42.1	Wed	17:00–17:30	ZEU/0260	**Mesopores filled with (poly)ionic liquids: phase transitions under confinement, and structure seen by SAXS and SANS** — •Julian Oberdisse, Anne-Caroline Genix
CPP 44.1	Thu	9:30–10:00	ZEU/LICH	**Shedding light on wide bandgap perovskites** — •Michael Saliba
CPP 53.1	Fri	9:30–10:00	ZEU/LICH	**Limits and Prospects of Organic Solar Cells** — •Dieter Neher
CPP 54.1	Fri	9:30–10:00	ZEU/0255	**NMR-based molecular rheology and structural characterization of model gels** — •Kay Saalwächter, Bidit Lamsal
CPP 56.1	Fri	10:45–11:15	HÜL/S386	**Liquid Dynamics at Interfaces** — •Michael Vogel
CPP 61.1	Fri	13:15–14:00	HSZ/0002	**Biomolecular Condensates: Challenges for Polymer Physics** — •Jens-Uwe Sommer

Topical Talks

CPP 19.1	Tue	9:30–10:00	ZEU/LICH	**Surface adsorption and protonation equilibrium of atmospheric organics at the aqueous surface** — •Nønne Prisle
CPP 27.1	Tue	14:00–14:30	ZEU/LICH	**Why water in plants survives negative pressure** — Marin Šako, Emanuel Schneck, Roland Netz, •Matej Kanduč
CPP 32.1	Wed	9:30–10:00	ZEU/0260	**Synchrotron X-Ray Studies on Structural Transitions in Water and Alcohol containing Ice Analogues** — •Christina M. Tonauer
CPP 45.1	Thu	9:30–10:00	ZEU/0260	**Wetting transitions in biomolecular coacervates** — •Susanne Liese, Tiemei Lu, Evan Spruijt, Christoph Weber
CPP 51.1	Thu	15:15–15:45	ZEU/LICH	**The Loops of Life** — Brian Chan, •Michael Rubinstein
CPP 51.2	Thu	15:45–16:15	ZEU/LICH	**Polyelectrolytes and Biological Systems: A Charged Relationship** — •Matthias Ballauff
CPP 51.3	Thu	16:15–16:45	ZEU/LICH	**From block copolymer morphologies to functional polymer membranes** — •Volker Abetz
CPP 51.4	Thu	16:45–17:15	ZEU/LICH	**Molecular electronic materials and devices for solar energy conversion** — •Jenny Nelson
CPP 51.5	Thu	17:15–17:45	ZEU/LICH	**Control of cell and tissue stiffness by biopolymer networks and particle inclusions** — •Paul Janmey
CPP 55.1	Fri	9:30–10:00	ZEU/0260	**Data-driven modelling of phase-separating intrinsically disordered regions** — •Giulio Tesei, Fatima Kamal Zaidi, Shanlong Li, Julian O. Streit, Jianhan Chen, Tanja Mittag, Kresten Lindorff-Larsen

Discussion on Sustainability on Monday during Lunch Break

PSV I	Mon	13:00–13:45	HSZ/AUDI	**Sustainability! And now? – Opportunities for young researchers** — •Roxana Scharpegge, Hiroki Sayama, Thomas Schubatzky, Birte Höcker, Uwe Riedel, John Plane, Pauleo Nimtz, Stefanie Falk

Invited Talks of the joint Symposium SKM Dissertation Prize 2026 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	HSZ/0002	**Stochastic-Calculus Approach to Non-equilibrium Statistical Physics** — •Cai Dieball
SYSD 1.2	Mon	10:00–10:30	HSZ/0002	**Nonuniform magnetic spin textures for sensing, storage and computing applications** — •Sabri Koraltan
SYSD 1.3	Mon	10:30–11:00	HSZ/0002	**Anomalous Quantum Oscillations beyond Onsager's Fermi Surface Paradigm** — •Valentin Leeb

SYSD 1.4	Mon	11:00–11:30	HSZ/0002	**Coherent Control Schemes for Semiconductor Quantum Systems** — •Eva Schöll
SYSD 1.5	Mon	11:30–12:00	HSZ/0002	**On stochastic thermodynamics under incomplete information: Thermodynamic inference from Markovian events** — •Jann van der Meer

Invited Talks of the joint Symposium The Sustainability Challenge: A Decade of Transformation (SYSC)

See SYSC for the full program of the symposium.

SYSC 1.1	Mon	15:00–15:30	HSZ/AUDI	**Open-Endedness and Community-Based Approaches to Sustainability Challenges** — •Hiroki Sayama
SYSC 1.2	Mon	15:30–16:00	HSZ/AUDI	**Education as a Social Tipping Element: Evidence from Climate and Physics Education Research** — •Thomas Schubatzky
SYSC 1.3	Mon	16:00–16:30	HSZ/AUDI	**Mechanistic and Material Perspectives on Enzymatic Hydrolysis of Semicrystalline Polyesters** — •Birte Höcker
SYSC 1.4	Mon	16:45–17:15	HSZ/AUDI	**Decarbonization Options for Industry** — •Uwe Riedel
SYSC 1.5	Mon	17:15–17:45	HSZ/AUDI	**Impacts of Cosmic Dust and Space Debris in the Terrestrial Atmosphere** — •John Plane

Invited Talks of the joint Symposium Fluids with Broken Time-Reversal Symmetry: Odd/Hall Viscosity between Active Matter and Electron Flows (SYBS)

See SYBS for the full program of the symposium.

SYBS 1.1	Tue	9:30–10:00	HSZ/AUDI	**Odd viscosity in three-dimensional fluids: flows, wakes, and eddies** — •Tali Khain
SYBS 1.2	Tue	10:00–10:30	HSZ/AUDI	**Odd viscosity in two-dimensional hydrodynamic electron transport** — •Igor Gornyi, Dmitry Polyakov
SYBS 1.3	Tue	10:30–11:00	HSZ/AUDI	**Odd slip on chiral active surfaces** — •Andrej Vilfan, Yuto Hosaka
SYBS 1.4	Tue	11:15–11:30	HSZ/AUDI	**Parity-odd transport in electron fluids** — •Johanna Erdmenger
SYBS 1.5	Tue	11:30–11:45	HSZ/AUDI	**Curved Odd Elasticity** — Lazaros Tsaloukidis, Yuan Zhou, Jack Binysh, Nikta Fakhri, Corentin Coulais, •Piotr Surówka

Invited Talks of the joint Symposium France: Soft, Active and Alive: Emergent Properties in Living Matter (SYGF)

See SYGF for the full program of the symposium.

SYGF 1.1	Wed	15:00–15:30	HSZ/AUDI	**Liquid crystal geometries in type I collagen-based tissues** — •Nadine Nassif
SYGF 1.2	Wed	15:30–16:00	HSZ/AUDI	**Self-organization of the cytoplasm by physical instabilities** — •Jan Brugues
SYGF 1.3	Wed	16:00–16:30	HSZ/AUDI	**From morphogenesis to space partitioning by microtubules and molecular motors.** — •Manuel Thery
SYGF 1.4	Wed	16:45–17:15	HSZ/AUDI	**More than the sum: how composite interfaces govern function** — •Alba Diz-Muñoz
SYGF 1.5	Wed	17:15–17:45	HSZ/AUDI	**Swimming and Swarming of Intelligent Active Particles** — Segun Goh, Priyanka Iyer, Rajendra Singh Negi, •Gerhard Gompper
SYGF 1.6	Wed	17:45–18:15	HSZ/AUDI	**Perturbing the collective motion of fish with challenging environments** — •Aurélie Dupont

Sessions

CPP 1.1–1.11	Mon	9:30–12:45	BAR/SCHÖ	**Active Matter I (joint session BP/CPP/DY)**
CPP 2.1–2.4	Mon	9:30–10:30	MER/0002	**Sustainability: Challenges and Solutions (joint session UP/CPP/SOE)**
CPP 3.1–3.5	Mon	9:30–11:00	ZEU/LICH	**French-German Session: Membranes and Porous Materials I**
CPP 4.1–4.6	Mon	9:30–11:15	ZEU/0255	**Energy Storage Materials and Devices I**
CPP 5.1–5.5	Mon	9:30–11:00	ZEU/0260	**Wetting, Fluidics and Liquids at Interfaces and Surfaces I (joint session CPP/DY)**
CPP 6.1–6.5	Mon	11:15–12:45	ZEU/LICH	**French-German Session: Membranes and Porous Materials II**
CPP 7.1–7.5	Mon	11:30–12:45	ZEU/0255	**Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods I**

CPP 8.1–8.5	Mon	11:30–12:45	ZEU/0260	**Wetting, Fluidics and Liquids at Interfaces and Surfaces II (joint session CPP/DY)**
CPP 9.1–9.7	Mon	15:00–17:00	ZEU/LICH	**French-German Session: Simulation Methods and Modeling of Soft Matter I**
CPP 10.1–10.13	Mon	15:00–18:30	ZEU/0118	**Droplets, Wetting, and Microfluidics (joint session DY/CPP)**
CPP 11.1–11.12	Mon	15:00–18:30	ZEU/0160	**Active Matter II (joint session DY/BP/CPP)**
CPP 12.1–12.6	Mon	15:00–17:00	ZEU/0255	**French-German Session: 2D Materials, Thin Films and Interfaces I**
CPP 13.1–13.7	Mon	15:00–17:00	ZEU/0260	**Charged Soft Matter, Polyelectrolytes and Ionic Liquids**
CPP 14.1–14.7	Mon	17:15–19:00	ZEU/LICH	**French-German Session: Simulation Methods and Modeling of Soft Matter II**
CPP 15.1–15.7	Mon	17:15–19:00	ZEU/0255	**Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods II**
CPP 16.1–16.6	Mon	17:15–19:00	ZEU/0260	**Energy Storage Materials and Devices II**
CPP 17.1–17.51	Mon	19:00–21:00	P5	**Poster I**
CPP 18.1–18.12	Tue	9:30–12:45	BAR/SCHÖ	**Active Matter III (joint session BP/CPP/DY)**
CPP 19.1–19.5	Tue	9:30–11:00	ZEU/LICH	**Focus Session: Water – from Atmosphere to Space I (joint session CPP/DY)**
CPP 20.1–20.12	Tue	9:30–12:45	ZEU/0160	**Complex Fluids and Soft Matter (joint session DY/CPP)**
CPP 21.1–21.6	Tue	9:30–11:15	ZEU/0255	**French-German Session: Simulation Methods and Modeling of Soft Matter III**
CPP 22.1–22.6	Tue	9:30–11:15	ZEU/0260	**Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics I**
CPP 23.1–23.6	Tue	11:15–12:45	ZEU/LICH	**Focus Session: Water – from Atmosphere to Space II (joint session CPP/DY)**
CPP 24.1–24.5	Tue	11:30–12:45	ZEU/0255	**French-German Session: Simulation Methods and Modeling of Soft Matter IV**
CPP 25.1–25.5	Tue	11:30–12:45	ZEU/0260	**Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics II**
CPP 26.1–26.5	Tue	14:00–15:30	HÜL/S386	**French-German Session: 2D Materials, Thin Films and Interfaces II**

CPP 56.1–56.4	Fri	10:45–12:00	HÜL/S386	**Molecular and Polymer Dynamics, Friction and Rheology I**
CPP 57.1–57.6	Fri	11:30–13:00	ZEU/LICH	**Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics VIII**
CPP 58.1–58.6	Fri	11:30–13:00	ZEU/0255	**Gels, Polymer Networks and Elastomers III**
CPP 59.1–59.6	Fri	11:30–13:00	ZEU/0260	**Crystallization**
CPP 60.1–60.3	Fri	12:15–13:00	HÜL/S386	**Molecular and Polymer Dynamics, Friction and Rheology II**
CPP 61.1–61.1	Fri	13:15–14:00	HSZ/0002	**Closing Talk (joint session CPP/BP/DY)**

Members' Assembly of the Chemical and Polymer Physics Division

Thursday 18:00–19:00 Raum ZEU/LICH

- Report of the current speakers
- Election of the second deputy speaker
- Award of the poster prize of the CPP Division
- Miscellaneous

Sessions

– Invited, Topical, Contributed Talks, Discussions, and Posters –

CPP 1: Active Matter I (joint session BP/CPP/DY)

Time: Monday 9:30–12:45 Location: BAR/SCHÖ

CPP 1.1 Mon 9:30 BAR/SCHÖ

Bayesian inference of magnetosensing in a magnetotactic bacterium — •Sascha Lambert[1], Emilie Gachon[2], Damien Faivre[2], and Stefan Klumpp[1] — [1]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany. — [2]Aix Marseille Université, CEA, CNRS, BIAM, 13115 Saint-Paul-Lez-Durance, France.

Magnetotactic bacteria are often assumed to align only passively with external magnetic fields, yet recent observations of the magnetotactic bacterium SS-5 reveal a pronounced increase in swimming speed under geomagnetic conditions. Because flagellated microorganisms typically follow helical paths, magnetic torques could, in principle, straighten their trajectories and create an apparent increase in speed, offering a purely mechanical explanation. We test this hypothesis using a physical swimming model based on Active Brownian Particles that incorporates magnetic torques, rotational propulsion, and helical motion, and we explore the relevant parameter space using Bayesian inference constrained by three-dimensional trajectory data. Posterior predictive simulations demonstrate that the mechanically induced increase in apparent speed is far too small to account for the experimental observations, even under extreme parameter choices. The results quantitatively rule out swaying as a sufficient explanation for the behaviour of SS-5 and instead support the presence of an active magnetic sensing mechanism.

CPP 1.2 Mon 9:45 BAR/SCHÖ

Vorticity-induced surfing and trapping in porous media — •Pallabi Das[1], Mirko Residori[1], Axel Voigt[2,3,4], Suvendu Mandal[5], and Christina Kurzthaler[1,3,4] — [1]Max Planck Institute for the Physics of Complex Systems, Germany — [2]Institute of Scientific Computing, TU Dresden, Germany — [3]Center for Systems Biology Dresden, Germany — [4]Cluster of Excellence, Physics of Life, TU Dresden, Germany — [5]TU Darmstadt, Germany

Microorganisms often encounter strong confinement and complex hydrodynamic flows while navigating their habitats. Combining finite-element methods and stochastic simulations, we study the interplay of active transport and heterogeneous flows in dense porous channels. We find that swimming always slows down the traversal of agents across the channel, giving rise to robust power-law tails of their exit-time distributions. These exit-time distributions collapse onto a universal master curve with a scaling exponent of $\approx 3/2$ across a wide range of packing fractions and motility parameters, which can be rationalized by a scaling relation. We further identify a new motility pattern where agents alternate between *trapping* along fast streams and extended *surfing* phases, the latter determining the power-law exponent. Unexpectedly, trapping occurs in the flow backbone itself – not only at obstacle boundaries – due to vorticity-induced reorientation in the highly-heterogeneous flow environment. These findings provide a fundamentally new active transport mechanism with direct implications for biofilm clogging and the design of novel microrobots capable of operating in heterogeneous media.

CPP 1.3 Mon 10:00 BAR/SCHÖ

Adhesion Patterns in Gliding Filamentous Cyanobacteria — •Elias Fischer[1], Paul Nieschwitz[2], Stefan Karpitschka[2], and Holger Stark[1] — [1]Institute of Physics and Astronomy, TU Berlin, Germany — [2]Department of Physics, Universität Konstanz, Germany

Filamentous cyanobacteria play an important role in many ecosystems and the carbon cycle of our planet. They exhibit gliding motility when in contact with solid surfaces or each other. Despite their ecological relevance and increased use in biotech applications, the exact nature of the force-generating process remains not fully understood.

Our recent measurements of filamentous cyanobacteria gliding across flat surfaces and visualized in kymographs show spatio-temporal adhesion regions along the filament, indicating an intrinsic helical shape. Based on our a novel approach for modeling the mechanical aspects of individual cyanobacteria filaments, we are able to interpret the complex kymograph patterns. Each filament is modeled as a helical chain of thin cylindrical segments in 3D with bending and twisting elasticity. The filaments interact with nearby surfaces and filaments via a hard-core repulsion and an exponentially decaying adhesion force. Importantly, the propulsion forces that push the filament forward are only applied locally at surface-contacting segments.

Our simulated kymographs reveal how both the helical shape and the adhesion strength strongly influence the filament's gliding speed and the dynamics of the surface-attachment regions. Thereby, we crucially contribute to the understanding of how real filamentous cyanobacteria generate their propulsion forces.

CPP 1.4 Mon 10:15 BAR/SCHÖ

The 3D chirality of malaria parasites determines their motion patterns in 2D and originates at the apical pole — •Leon Lettermann[1], Mirko Singer[2], Smilla Steinbrück[2,3], Falko Ziebert[1], Sachie Kanatani[3], Photini Sinnis[3], Friedrich Frischknecht[2], and Ulrich Schwarz[1] — [1]Institute for Theoretical Physics & BioQuant, Heidelberg University — [2]Parasitology, Center for Infectious Diseases, Heidelberg University — [3]School of Public Health and Malaria Research Institute, Johns Hopkins University

Plasmodium sporozoites, the slender forms of the malaria parasite injected by mosquitoes into the skins of their vertebrate hosts, provide a medically highly relevant model system for active chiral particles. Using 3D tracking in synthetic hydrogels, we show that sporozoites consistently move on right-handed helical trajectories. When they encounter a two-dimensional substrate, they switch to clockwise circular motion, whereas circling on glass in medium occurs with the opposite sense of rotation, suggesting on glass they try to invade the medium above. Using a sandwich assay, we demonstrate that chirality also determines the reverse transition from two-dimensional to three-dimensional motion. Combining these measurements with a theory for gliding motility allows us to identify the likely origin of chirality, namely an asymmetric distribution of adhesins. After confirming this via two-sided traction force microscopy, we finally use STED super-resolution microscopy to reveal a corresponding tilt in the apical ring complex. In summary, our analysis thus uncovers both the biological relevance and the molecular basis of chirality in the movement of malaria parasites.

CPP 1.5 Mon 10:30 BAR/SCHÖ

Squirmer dynamics in porous environments — •Mirko Residori[1], Christina Kurzthaler[1], and Sebastian Aland[2] — [1]Max Planck Institute for the Physics of Complex Systems — [2]TU Freiberg

We introduce a computational framework for simulating the dynamics of microswimmers in complex porous environments. Specifically, we adopt a diffusive domain approach to represent the surface of a micro-swimmer, modeled as a squirmer. This method ensures accurate and stable finite-element simulations, even in highly confined geometries. Validation against analytical and numerical benchmarks confirms the model*s accuracy and robustness. We then apply it to explore squirmer motion in heterogeneous porous media, revealing how hydrodynamic interactions lead to behaviors such as dynamic trapping due to hydro-dynamically induced re-orientations. Moreover, we demonstrate that the squirmer parameter and the repulsive potential critically influence a squirmer's ability to navigate and escape confinement. The proposed framework offers a versatile and efficient tool for studying active motion in complex fluids and provides new insights into micro-swimmer transport and control in natural and engineered systems.

CPP 1.6 Mon 10:45 BAR/SCHÖ

Dynamics of passive tracers in active dumbbell suspension — •Chandranshu Tiwari and Sunil P. Singh — Department of Physics, Indian Institute of Science Education and Research, Bhopal 462066, India.

The transport of passive tracers in active fluids exhibits rich dynamics arising from persistent interactions between active agents and the tracer. In our work, we employ Brownian dynamics simulations to investigate the dynamical behaviour of both isotropic(circular) and anisotropic(elliptical) tracers in active dumbbell suspension, considering only steric interactions. For circular tracers, we find that the speed shows a crossover from monotonically decreasing to increasing with tracer size as the dumbbells' speed is increased. The tracer's effective diffusion also displays a non-monotonic dependence on area fraction: the diffusivity first increases and then decreases at higher area fractions.

For anisotropic tracers, the characteristic non-monotonic trend persists. Moreover, their motion along the major and minor axes differs significantly. Anisotropic accumulation of active particles around the tracer generates direction-dependent forces and fluctuations, favouring motion along the major axis. Consequently, both the speed and diffusivity along the major axis exceed those along the minor axis.

15 min. break

Invited Talk CPP 1.7 Mon 11:15 BAR/SCHÖ

Modeling and inference of magnetotactic motility in complex environments — •Stefan Klumpp — Institute for the Dynamics of Complex Systems, University of Göttingen, Göttingen, Germany

Magnetotactic bacteria orient themselves and swim along field lines of the geomagnetic field. Their magnetically directed self-propelled motion makes them an instance of dipolar active matter. Here we focus on the interaction of these bacteria with walls or obstacles. Experiments in microfluidic systems show that interactions with walls result in (possibly transient) alignment parallel to the wall, which may compete with the alignment with the magnetic field. The dynamic behavior arising from the competition of the two alignments includes U-turn trajectories in circular chambers and trapping and escape dynamics in channels with overlapping cylindrical obstacles. In a phenomenological picture, the resulting motion can be described in an Active Brownian Particle model by introducing a wall torque that competes with the magnetic torque, which results in good agreement with experimental observations. Systematic Bayesian inference of the wall torque from observations shows that only a part of the torque function (dependence on incident angle) can be learned reliably from the data.

CPP 1.8 Mon 11:45 BAR/SCHÖ

Quantifying aggregation behaviour of filamentous cyanobacteria — •Elias Illing and Stefan Karpitschka — Fachbereich Physik, Universität Konstanz

Cyanobacteria are ubiquitous in nature, frequently causing ecological and economic harm by explosive growth, so called blooms.

We investigate the collective dynamics of entangled filamentous cyanobacteria in open liquid media, reminiscent of their aggregates found during later stages of blooms. We investigate the impact of illumination on the clustering and spreading of the bacteria and quantify the morphology of the bacterial aggregates by image analysis. We determine the critical density necessary for initial clustering and track the evolution of the subsequent stages, ranging from stable clusters to spreading mats. These states can be modulated by light intensity variations, potentially allowing for control of the morphological evolution of cyanobacterial aggregates.

CPP 1.9 Mon 12:00 BAR/SCHÖ

Dynamically Induced Spatial Segregation in Multi-Species Bacterial Bioconvection — •Mingqi Yan[1,2], Chenxi Wang[3], Oscar Gallardo-Navarro[4], Rinat Arbel-Goren[4], Joel Stavans[4], and Erwin Frey[1,2] — [1]Department of Physics, Ludwig-Maximilians-Universität München, Theresienstraße 37, 80333 München, Germany — [2]Max Planck School Matter to Life, Hofgartenstraße 8, 80539, München, Germany — [3]School of Science, Harbin Institute of Technology, 518055, Shenzhen, China — [4]Department of Physics of Complex Systems, Weizmann Institute of Science, 7610001, Rehovot, Israel

Bacterial bioconvection is a classic example of collective behavior in active matter, where upward-swimming bacteria create density instabilities leading to large-scale fluid flows. While this phenomenon is well-studied in single-species suspensions, natural environments are typically inhabited by diverse microbial communities. Here, we investigate the collective dynamics of multi-species bacterial suspensions. Combining experiments with a continum model, we show that different bacterial species can spontaneously segregate into stable, spatially interlocked domains. Our theoretical analysis reveals that this segregation is not driven by biochemical antagonism but rather by the interplay between species-specific motility characteristics and the self-generated hydrodynamic flows. This work provides new insights into how physical interactions alone can drive the spatial organization of complex microbial communities.

CPP 1.10 Mon 12:15 BAR/SCHÖ

Light-switchable microbial rafts at air-liquid interfaces — •Gustav F. Nolte, Alexandros A. Fragkopoulos, Timo Völkl, Mechthild Rappold, and Oliver Bäumchen — University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany

In biological active matter, clustering occurs across a wide range of time and length scales, from molecular assemblies such as actomyosin networks to macroscopic systems like fire ant rafts. Here, we report on a fast, light-switchable, and fully reversible clustering phenotype on the microscale, observed at air-liquid interfaces: the raft formation of the biciliated microalga *Chlamydomonas noctigama*.

C. noctigama is a relative of the model organism *Chlamydomonas reinhardtii*, which exhibits light-switchable adhesion and subsequent clustering at solid-liquid interfaces [1,2]. We show how the cluster morphology depends on cell density and discuss potential growth mechanisms by analyzing dynamics of individual clusters. Furthermore, we characterize the dependence of raft formation on the light spectrum and interfacial free energy. Using micropipette force spectroscopy [3], we show that single cells exploit capillary forces for light-switchable ciliary adhesion to the air-liquid interface, enabling raft formation. In their natural habitats, reversible clustering may provide an advantage by allowing cells to accumulate in locations optimal for photosynthesis while increasing resilience to environmental stress.

CPP 1.11 Mon 12:30 BAR/SCHÖ

Circadian gravitaxis: Photosynthetic microswimmers remodel local pH to actively tune vertical migration — Arkajyoti Ghoshal[1], Soumitree Mishra[1], Jayabrata Dhar[2], Hans-Peter Grossart[3,4], and •Anupam Sengupta[1,5] — [1]Physics of Living Matter, Department of Physics and Materials Science, University of Luxembourg, Luxembourg — [2]Department of Mechanical Engineering, National Institute of Technology Durgapur, India — [3]Department of Plankton and Microbial Ecology, Leibniz Institute of Freshwater Ecology and Inland Fisheries, Stechlin, Germany — [4]Institute of Biochemistry and Biology, Potsdam University, Germany — [5]Institute for Advanced Studies, University of Luxembourg, Luxembourg

Motile phytoplankton shuttle between bright surface waters and deeper nutrient rich layers, usually controlled by internal circadian clocks. Yet many species show irregular movements, defying the expected circadian rhythm. Studying a bloom forming photosynthetic species, we found that cells adjust their vertical migration by altering local pH, mediated by a shift in their gravitactic behavior. This self-modulation of pH generates sub-populations which are physiologically similar but swim differently, remaining vertically separated even under uniform conditions. Supported by a cell-level analysis and mathematical model, we confirm that the pH-mediated circadian shift is underpinned by morphological adjustments. Our results support a circadian gravitactic model in which diurnal pH control drives diversified migration, enhancing fitness particularly in acidifying oceans.

Making a university climate neutral: First experiences from implementing a Climate Protection Strategy at the University of Greifswald — •Christoph G. Hoffmann, Tiemo Timmermann, and Christian von Savigny — University of Greifswald, Greifswald, Germany

With a resolution of its Academic Senate, the University of Greifswald has in 2021 set the goal to achieve climate neutrality by the end of the decade.

While the aim of achieving climate neutrality within a few years is expectedly ambitious, a university as a bigger research institution has also a unique combination of knowledge to achieve it. This has already led to synergies from which particularly the teaching in the environmental subjects can benefit due to "home-made" practical experiences. This makes the whole University a living lab, in which the opportunities but also challenges of necessary transformations can be explored in an assessable setting.

Therefore, also the environmental physics group aims at contributing to and benefiting from this process. While our group is originally focused on basic atmospheric research, we cover a broader range of environmental physics topics in teaching, which overlap with the needs of the transformation process.

In this talk, we will give a short overview of the Climate Protection strategy of the University of Greifswald before we show some examples from our own work regarding the energy consumption of buildings.

CPP 2.2 Mon 9:45 MER/0002

Life Cycle Assessment practices for PV technologies: systematic literature review — •Zeena Patel — Technische Universität Ilmenau

In response to the growing importance of sustainability in solar energy development, this study addresses critical gaps in the application of Life Cycle Assessment (LCA) to photovoltaic (PV) technologies. A systematic review of 48 recent LCA studies across first-, second-, and third-generation PV systems was conducted to evaluate current practices, identify methodological inconsistencies, and highlight emerging trends. Despite increasing research interest and technological diversification, substantial variability exists in the definition of functional units, system boundaries, and impact categories, which hinders comparability and reproducibility. The widespread reliance on secondary databases and the limited use of primary, site-specific data further constrains the accuracy of environmental impact assessments. Additionally, the underutilization of Life Cycle Costing (LCC) and inconsistent application of sensitivity analyses reveal significant gaps in comprehensive sustainability evaluation. To advance the

field, this study proposes standardization of LCA methodologies, improved data transparency, and expansion of impact categories beyond global warming potential to include toxicity and resource depletion. These measures are essential for enhancing the robustness, reliability, and policy relevance of PV LCA studies, thereby supporting sustainable innovation and deployment in the solar energy sector.

CPP 2.3 Mon 10:00 MER/0002

Electrochemical Modeling of SOFCs with Emphasis on Microkinetic and Anode Overpotential — •Iram Gul[1], Gabriela Soffiati[2], and Thiago Lopes[3] — [1]Research Center for Greenhouse Gas Innovation, University of São Paulo (USP), 05508-030, São Paulo * SP, Brazil — [2]Institute of Physics (IFUSP), University of São Paulo, Universidade, R. do Matão, 1371 - Butantã, São Paulo - SP, 05508-090 — [3]Research Center for Greenhouse Gas Innovation, University of São Paulo (USP), 05508-030, São Paulo * SP, Brazil

This study investigates Solid Oxide Fuel Cells (SOFCs) using a CO/H fuel mixture, focusing on thermodynamics, mass transport, and electrochemical kinetics. Thermodynamic properties such as heat capacity, enthalpy, entropy, and Gibbs free energy were analyzed across 600-800°C using MATLAB simulations. The Dusty Gas Model (DGM) revealed key mass transport behaviors in the anode, while Density Functional Theory (DFT) using VASP provided insights into surface reaction mechanisms. A microkinetic model examined the impact of anode overpotential on reaction kinetics and cell performance. Results show that higher temperatures improve mass transport and reduce Ohmic losses but slightly decrease the thermodynamic driving force. This multi-scale model enhances our understanding of SOFC behavior and offers a basis for improving fuel cell efficiency and material performance.

CPP 2.4 Mon 10:15 MER/0002

Thermal stability of ceria-zirconia oxides(CeZrO4) nanoparticles using combustion synthesis for the CO oxidation and NOx reduction — •Hamza Mohamed — IMMM, UMRS 6283 CNRS, Le Mans Université, Bd O. Messiaen, 72085 Le Mans Cedex 09, France

The study presents a green synthesis approach for fabricating ceria-zirconia oxide nanoparticles (CeZrO4 NPs) using the solution combustion synthesis method. The synthesized CeZrO4 nanoparticles were characterized using various sophisticated instruments and methods to determine their detailed properties. The UV-Vis spectra showed a characteristic absorbance peak at 242 nm and a band gap (Eg) of 3.05 eV. Simultaneously, Fourier transform infrared spectra of CeZrO4 NPs displayed bands at 418 cm-1, 991 cm-1, 1382 cm-1, 1658 cm-1, 2306 cm-1, 3288 cm-1, and 3643 cm-1, which indicates the presence of phytochemicals that facilitate the reduction and stabilization of CeZrO4 NPs. The major peaks for cubic CeZrO4 NPs were obtained with a crystalline size of 9.6 nm by X-ray diffraction. The microscopic analyses revealed irregular, ovoid, and aggregated morphologies with sizes ranging from 3 to 10 nm. The XPS analysis revealed the existence of Ce3d, Zr3d, C1s, and O1s states with their corresponding atomic percentages. Therefore, this investigation focuses on synthesizing catalysts that demonstrate both thermal stability and high catalytic activity for the oxidation of CO and the reduction of NOx.

CPP 3: French-German Session: Membranes and Porous Materials I

Invited Talk CPP 3.1 Mon 9:30 ZEU/LICH

Theory and Modeling of Fluid Adsorption and Transport in Nanoporous Materials — •Benoit Coasne — CNRS/University Grenoble Alpes, Grenoble, France — Institut Laue-Langevin, Grenoble, France

Nanoporous materials are at the heart of numerous important applications: adsorption (gas sensing, chromatography), energy (hydrogen storage, fuel cells and batteries), environment (phase separation, water treatment, nuclear waste storage), etc. Among these materials, nanoporous solids which have pores of the order of nm (e.g. active carbons, zeolites), are particularly interesting as ultra-confinement in their porosity leads to novel adsorption and transport phenomena. In this talk, we will present how molecular simulation and statistical physics allows developing models for adsorption and transport in these extremely confining materials. We will see how simple thermodynamic modeling allows rationalizing adsorption by considering reminiscent capillarity at vanishing length-scales. Then, we will show how transport in nanoporous media can be described without having to rely on macroscopic concepts such as hydrodynamics. In particular, using parameters and coefficients available to experiments, we will see how transport coefficients can be rigorously upscaled using simple models such as intermittent brownian motion and free volume theory.

CPP 3.2 Mon 10:00 ZEU/LICH

Optimizing the Fabrication of Isoporous Block Copolymer Membranes by Concurrent Multi-fidelity Simulations — •Gregor Häfner and Marcus Müller — Institute for Theoretical Physics, University of Göttingen, Germany

Integral-asymmetric copolymer membranes promising promising class of functional macromolecular systems with diverse potential applications, including water purification and protein separation. Their fabrication is a two-step process: solvent evaporation and subsequent nonsolvent-solvent exchange to create an isoporous top-layer, and a spongelike substructure. We model the process using two complementary schemes – a highly coarse-grained, particle-based model that treats the polymer chains directly, and a continuum model, describing the system only by its concentration fields. To exploit the accuracy of the former while retaining the efficiency of the latter, we couple these for a concurrent multi-fidelity simulation. The continuum simulation treats the whole system, spawning a particle-based simulation in the region of its lowest accuracy. For this, a neural network is employed to estimate the future error and guide the decision of the subdomain position. We achieve a tenfold increase in computational efficiency compared to pure particle-based simulations, enabling us to investigate large film depths. Our simulations delineate a process window for successful membrane fabrication, which fully match the experimentally accessible parameters, showing an isoporous top layer, a porous substructure and finger-like macrovoids, allowing us to guide experimental membrane optimization.

CPP 3.3 Mon 10:15 ZEU/LICH

In situ monitoring of relaxation dynamics in polyethylenimine during CO2 absorption and desorption — •Martin Tress — Peter Debye Institute for Soft Matter, Leipzig University

Chemical reactions between carbon dioxide (CO2) and amine have been extensively characterized, however, their influence on the dynamics of polyamines remains largely unexplored. In this work, we compare the dynamics of polyethylenimine (PEI) before and after CO2 absorption through broadband dielectric spectroscopy (BDS) [1]. Upon CO2 absorption, thin film PEI shows a slower dynamics, which is consistent with an elevated glass transition temperature revealed in complementary differential scanning calorimetry measurements. In-situ kinetics measurements in thin film samples as well as PEI-infused porous silica demonstrate complex changes in the overall permittivity as well as relaxation times and relaxation amplitudes of some processes during CO2 sorption or desorption. This suggest an intriguing interplay between physical and chemical CO2-sorption, diffusion and the dynamics of PEI. Finally, a tentative model will be presented to describe the observed curves qualitatively. These results demonstrate that BDS is a powerful in-situ-platform to resolve the temporal dynamical changes of polyamines and their impact on sorption kinetics, and may inform specific system adjustments to improve CO2 capture performance.

CPP 3.4 Mon 10:30 ZEU/LICH

Scalable and Tunable Carbon Nanomembranes for Selective Molecular Transport — •Zhen Yao[1], Jan Biedinger[1], Martin Wortmann[1], Nikolaus Meyerbröker[2], Yang Yang[1], Andreas Hütten[1], Günter Reiss[1], and Armin Gölzhäuser[1] — [1]Bielefeld University, Bielefeld, Germany — [2]bCNM Technologies GmbH, Bielefeld, Germany

Carbon nanomembranes (CNMs), molecularly thin two-dimensional materials with intrinsic sub-nanometer pores, provide a versatile platform for nanofluidics. Their ultrathin structure enables fast molecular flux, while surface chemistry and pore architecture can be tailored for selective transport. We present a scalable synthesis route based on electron-induced crosslinking of spin-coated poly(4-vinylbiphenyl) films, combined with atomic layer deposition (ALD) for pore and surface functionalization. This strategy enables precise tuning of pore dimensions and hydrophilicity, yielding CNMs with water vapor permeance as high as 1.9×10^{-5} mol s^{-1} m^{-2} Pa^{-1} and H_2O/N_2 selectivity above 10000, outperforming state-of-the-art polymer and graphene oxide membranes. These results establish CNMs as promising candidates for energy-efficient dehumidification and gas separation. Together, these studies demonstrate how scalable fabrication and nanoscale interface engineering translate into tunable nanofluidic transport, highlighting CNMs as a versatile materials platform for separations, sensing, and controlled molecular flow.

CPP 3.5 Mon 10:45 ZEU/LICH

Is it possible to use nano-confined water for cloaking or magnifying of static electric fields? — •Kira Fischer[1], Julia Brandt[1], Philipp Stärk[2], Alexander Petrov[1], and Alexander Schlaich[1] — [1]Hamburg University of Technology — [2]University of Stuttgart

Assuming radial anisotropy in the dielectric response of water in cylindrical or spherical confinement, Kettunen et al., have shown that for certain ratios of per-

mittivity contrast it is possible to cloak the interior sample, or to magnify the response of an inner cylinder. Indeed, water at interfaces and in confinement shows a strongly anisotropic dielectric response, with high dielectric permittivity in parallel and low permittivity perpendicular to the interface, as observed experimentally by Fumagalli et al.

Here, we probe the radial and azimuthal dielectric response of water in cylindrical confinement. We do so by calculating the dielectric permittivity profile from molecular dynamics simulations, both using a Green-Kubo relation as well as applied fields. Near the interface, we observe a high dielectric permittivity in the azimuthal direction and a low dielectric permittivity in the radial direction of the cylinder, supporting the concept of radial anisotropy.

Applying a static, homogenous external field we then analyse the resulting water polarization. The observed effective response of water inside a cylinder is almost bulk like, and no significant cloaking effect is observed. We use effective medium theory to rationalize this behavior and discuss possible applications of cloaking in model fluids.

CPP 4: Energy Storage Materials and Devices I

Invited Talk CPP 4.1 Mon 9:30 ZEU/0255

Exploration of Cathode Materials for Li-S Batteries — •Yan Lu — Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany

Recently, a lot of efforts have been devoted into lithium-sulfur (Li-S) battery system due to its high theoretical capacity (1675 mAh g-1) and low cost, which could be a competitive candidate for the next-generation batteries in the future. However, it suffers from a poor cycling stability during charging-discharging, which is blamed to the "shuttle effects" of lithium polysulfides. Fundamental understanding of the formation and dissolution processes of both solid phases, S8 and Li2S, is necessary for the development of advanced cathode materials (both organosulfur and metal compound-based sulfur host) with improved electrochemical performance. Synchrotron-based operando high-resolution X-ray imaging has been successfully used for the detailed morphology study of sulfur particles during cycling of the battery cells. Using colloidal route, complex hybrid carbon nanostructures have been synthesized using colloidal polymeric particle as soft template, which have been applied as cathode materials for Li-S batteries.

CPP 4.2 Mon 10:00 ZEU/0255

Temperature-dependent Crystal Structure of Dimethyl Carbonate — •Lea Westphal[1,2], Peter Müller-Buschbaum[1], and Anatoliy Senyshyn[2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]MLZ, TUM, Garching, Germany

The performance and safety/stability of Li-ion batteries (LIBs) can be enhanced by optimizing the charge-storing electrode materials and/or the charge-mediating liquid electrolytes. In LIB research, the major focus has been on the electrode subsystem, while liquid electrolytes are studied much less. Upon cooling of LIBs to investigate their performance at low temperatures, a series of Bragg reflections has been observed, which was assigned to the freezing of liquid electrolyte. Further measurements reveal the development of long-range order in the model electrolyte mixture LP30. To better understand this emerging order, it is essential to investigate the system's individual components, especially under conditions near room temperature relevant to in situ sub-ambient LIB studies.

This contribution outlines our efforts to crystallize Dimethyl Carbonate with minimized preferred orientation, in order to study the unit cell across the entire solid temperature range using neutron- and synchrotron-based powder diffraction. The datasets are complemented by synchrotron single-crystal diffraction experiments. Additionally, the liquid state is investigated by Total Scattering and Pair Distribution Function analysis.

CPP 4.3 Mon 10:15 ZEU/0255

Electron Energy Loss Spectroscopy for oxidation state analysis on ammonia synthesis catalysts — •Daniela Ramermann, Michael Poschmann, Elisabeth H. Wolf, Holger Ruland, and Walid Hetaba — Max-Planck-Institut für Chemische Energiekonversion, Mülheim (Ruhr)

Electron energy loss spectroscopy (EELS) is a powerful technique, not only for the determination of elemental compositions, but also for the investigation of chemical bonding and oxidation states. For the analysis of EELS data, the use of cross-section models is quite common, but the use of reference spectra improves the quantification results. In addition, it allows for the fitting of the edge shapes to investigate oxidation states with the spatial resolution of the electron microscope.

Because the available databases for EELS references [1] are not exhaustive, reference materials are obtained from acquired commercial materials of well-known and defined properties. It is crucial to thoroughly characterize these materials before measuring the reference spectra, as the materials may have local impurities or differ from the desired oxidation state. For the Fe-based catalyst system some reference materials are of mixed oxidation state, presenting an additional challenge.

We show the process of acquiring suitable EELS references for materials used in catalysis and the application of mapping the oxidation state and phase composition on a Fe based ammonia synthesis catalyst.

[1] https://eelsdb.eu, https://eels.info/atlas

CPP 4.4 Mon 10:30 ZEU/0255

Investigating the Conversion Reaction of the Cathode Active Material FeS_2 in Solid-State Batteries via Transmission Electron Microscopy — •Franziska Hüppe[1], Matilde Pavan[2], Shamail Ahmed[1], Jürgen Belz[1], Jürgen Janek[2], and Kerstin Volz[1] — [1]Philipps-Universität Marburg, Department of Physics and mar.quest, Hans-Meerwein-Straße, 35043, Marburg, Germany — [2]Justus-Liebig-Universität Gießen, Institute of Physical Chemistry and Center for Materials Research, Heinrich-Buff-Ring, 35392, Gießen, Germany

Solid-state batteries are particularly promising for high-energy storage, as they potentially allow for the use of electrode materials with higher specific capacities. In the case of FeS_2 as cathode active material, also the cost effectiveness and the environmental impact would be drastically enhanced. However, FeS_2 is a conversion-type material that undergoes continuous compositional and structural changes during cycling that is not yet fully understood at the micro- and nanoscale.

Scanning transmission electron microscopy (STEM) offers structural insights at high resolution and is combinable with deepening investigation methods like energy dispersive X-ray spectroscopy (EDX) and electron energy loss spectroscopy (EELS) to identify the different compounds forming during different depth of discharge (lithiation).

The pristine, uncycled cathode sheet contains FeS_2 particles with cubic structure. With increasing depth of discharge, the particles react from the outside in, forming core-shell structures. The multimodal STEM analysis will be discussed in detail during the presentation.

CPP 4.5 Mon 10:45 ZEU/0255

Dual-cation pre-intercalated hydrated vanadium oxide for ultralong cycling stability in aqueous zinc-ion batteries — •Yan Ran, Huaping Zhao, and Yong Lei — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

In this work, hydrated vanadium oxide with pre-intercalated K and Mn ions (K0.07Mn0.13V2O5*1.47H2O) was synthesized via a one-step hydrothermal method, demonstrating an excellent specific capacity of 524.7 mA h g-1 at 0.1 A g-1, and outstanding stability with 82.47% capacity retention after 20,000 cycles at 5 A g-1. The co-intercalation of dual cations increases the interlayer spacing while stabilizing the material structure, expanding the ion transport channels, and improving both the specific capacity and long-cycle stability. Moreover, the Zn2+/H+ co-intercalation mechanism was confirmed by ex-situ characterization. This work will provide insights for the development of competitive cathodes in high-performance aqueous batteries.

CPP 4.6 Mon 11:00 ZEU/0255

Unveiling the Interfacial Behavior of Lithium Batteries by Operando X-ray Scattering — •Yuxin Liang[1], Fabian Apfelbeck[1], Kun Sun[1], Yingying Yan[1], Lyuyang Cheng[1], Guangjiu Pan[1], Tianle Zheng[1], Yajun Cheng[2], Anton Davydok[3], Christina Krywka[3], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]College of Renewable Energy, Hohai University, Changzhou, China — [3]Helmholtz-Zentrum Hereon, Geesthacht, Germany

Poly(ethylene oxide) based solid composite electrolytes suffer from poor conductivity and lithium dendrite growth, especially toward the metallic lithium metal anode. In our recent work, we focus on the fabrication and comprehensive characterization of performance-enhanced PEO-based composite electrolytes for lithium batteries. Advanced nano-focus X-ray scattering techniques were used to investigate the interfacial behavior within the lithium metal battery, as well as its failure mechanisms. With the modification of plasticizer, the electrolyte exhibit good electrochemical performance and interfacial compatibility. However, the reference electrolyte exhibit early dendrite formation from the lithium surface into the electrolyte, leading to persistent structures that degrade performance. The results highlight the potential of these fabrication and analysis methods, demonstrating their application in advancing lithium battery technologies and contributing to the development of cutting-edge characterization techniques.

CPP 5: Wetting, Fluidics and Liquids at Interfaces and Surfaces I (joint session CPP/DY)

Time: Monday 9:30–11:00 Location: ZEU/0260

Invited Talk CPP 5.1 Mon 9:30 ZEU/0260

Cleaning of dusty surfaces — •Doris Vollmer[1], Franziska Sabath[1], Abhinav Naga[2], Stefanie Kirschner[1], Tarik Karakaya[1], Rüdiger Berger[1], Hans-Jürgen Butt[1], and Halim Kusumaatmaja[2] — [1]Max Planck Institute for Polymer Research, 55128 Mainz, Germany — [2]Ackermannweg 10

The accumulation of dust, sand or other contaminants on solar modules leads to significant efficiency losses. Billions of litres of water are used annually to clean solar modules, and other natural or man-made surfaces. However, the complex interplay between capillary and frictional forces, which determines successful removal or unwanted redeposition, is still poorly understood. By combining confocal microscopy and Boltzmann lattice simulations, we observe and quantify the removal of particles from smooth and rough surfaces by a water droplet, varying the hydrophobicity of the surface and the particles. Hydrophilic particles aquaplane, resulting in negligible friction and easy particle removal. For hydrophobic particles, the tangential component of the capillary force promotes or counteracts particle removal. Undesirable redeposition depends on the number and wettability of the particles. On superhydrophobic surfaces, the small contact area facilitates easy removal. For individual particles, we propose a phase diagram for particle removal.

CPP 5.2 Mon 10:00 ZEU/0260

Marangoni contracted droplets on Textured Surfaces: Insights from Lubrication Theory — •Raphael Saiseau, Ze Xu, and Stefan Karpitschka — Fachbereich Physik, Universität Konstanz, 78464 Konstanz, Germany

Wetting and evaporation of droplets on micropatterned surfaces are central to both natural processes and technological applications, from anti-icing and spray cooling to inkjet printing and semiconductor processing. Droplet behavior on such surfaces is set by surface chemistry and topography, and most control strategies traditionally rely on specific materials or designs, limiting their versatility.

By depositing droplets on top of a pillars-decorated substrate in a vapor-controlled chamber, we show that the spreading and wicking can be controlled, and even temporarily suppressed, by using the vapor of a second, low-surface tension liquid, generating Marangoni stresses through its condensation near the droplet edge. We present numerical and semi-analytical solutions of the thin film equation coupled to a composition evolution equation, and diffusion-limited evaporation. The wicking effect of the texture is implemented through an effective height-dependent pressure, analogous to classical hemiwicking models. The emerging Marangoni flows oppose the prevailing capillary flows, leading to a quasi-stationary rather than a spreading or wicking drop. We derive a predictive relation between material parameters and drop shape, opening the way for designing controlled coating, cleaning and drying strategies on textured surfaces.

CPP 5.3 Mon 10:15 ZEU/0260

Photoswitchable Arylazopyrazole Monolayers on Aluminum Oxide for Tunable Wettability — •Tim Blinzer, Christian Honnigfort, and Björn Braunschweig — Institute of Physical Chemistry and Center of Soft Nanoscience, University of Münster, Corrensstraße 28-30, Münster 48149, Germany

Smart surfaces that can change their wettability on demand are interesting for applications such as self-cleaning or microreactors. To tune the surface wettability, we functionalized aluminum oxide surfaces with arylazopyrazole (AAP) phosphonic acids using a Langmuir-Blodgett transfer. AAP molecules in the deposited monolayers undergo reversible E/Z photoisomerization driving changes in surface wettability. This was investigated as a function of surface coverage, where the responsiveness—i.e. the changes in molecular structure and in the apparent contact angle—was studied in detail. Here time-dependent sum-frequency generation (SFG) was used to obtain in situ information on the dynamic changes in monolayer upon E/Z switching with 520 nm green and 365 nm UV light. Furthermore, we show that increasing surface roughness by depositing nanoaggregates of the AAP phosphonic acid leads to a drastic increase in the change of the contact angle when switching from the E to the Z isomer. Indeed, the change in contact angle increased from only 7° for homogeneous monolayers to about 20° for nanostructured surfaces using AAP aggregates.

CPP 5.4 Mon 10:30 ZEU/0260

Motion and interaction of Marangoni contracted droplets on micropatterned surfaces — •Ze Xu, Raphael Saiseau, and Stefan Karpitschka — Fachbereich Physik, Universität Konstanz, Konstanz, Germany

Wetting of micropatterned surfaces is ubiquitous in nature and key to many technological applications like inkjet printing and semiconductor processing. Overcoming the intrinsic, chemistry- and topography-governed wetting behaviors often requires specific materials, leading to contradicting requirements between the processing strategy and the final product. Here, we demonstrate that droplet spreading and wicking on hydrophilic patterns can be controlled by the vapor of a lower-surface-tension liquid. Condensation of the vapor induces Marangoni forces that delay capillary wicking and contract liquid into a droplet on top of the imbibed film. Consequently, a Marangoni-contracted droplet coexists with a finite imbibition film for prolonged times. We demonstrate how these droplets interact with each other, both by their vapor cloud, and by the imbibed liquid film that surrounds them. Modulating the ambient vapor, also these interactions can be modulated, devising new strategies for coating, cleaning, and drying functional surfaces.

CPP 5.5 Mon 10:45 ZEU/0260

Wetting of Swelling Polyelectrolyte Surfaces on a Macroscopic and Nanoscopic Scale — •Mona Meltschoch and Regine von Klitzing — Soft Matter at Interfaces, Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 8, D-64289 Darmstadt, Germany

Wetting on adaptive polymer interfaces plays an important role in soft matter physics, particularly when spreading is affected by substrate hydration. Polyelectrolyte multilayers (PEMs) are suitable model systems because they absorb water and evolve across multiple time scales, creating a link between nanoscale polymer mobility and macroscopic contact line motion. PEM films were prepared by the layer-by-layer method, and their wetting behaviour was examined at different scales. Nanoscale morphology and hydration were characterised by atomic force microscopy (AFM), while macroscopic wetting was followed via optical contact angle (CA) measurements. Previous studies report a decrease in water CA on PSS-terminated PEMs under humid atmosphere. To assess how film architecture affects wetting, PEMs with varying bilayer numbers and terminal charge (PSS vs. PAH) were fabricated, showing smooth surfaces and a linear thickness increase. Current work explores AFM beyond static surface imaging by applying it directly to droplets on PEM films. This approach aims to track local swelling, interface deformation and contact line behaviour under liquid exposure. Measurements with different droplet liquids are being established, with the long-term goal to link nanoscale hydration dynamics to macroscopic changes in contact angle and wetting evolution.

Hierarchical Porosity Meets Nanoconfined Water: Toward Water-Driven Functional Materials — •Patrick Huber — Hamburg University of Technology — Deutsches Elektronen-Synchrotron DESY

Natural materials achieve remarkable functionality using only simple chemical building blocks, relying on architectures that span multiple length scales. A key feature of many biological systems is their hierarchical porosity, which guides fluid transport from large channels down to nanopores where water acts as a nanoscale working fluid. In such confined spaces, water displays distinct structural dynamics and interfacial behaviour that strongly influence mechanical, transport, and optical responses. This contribution introduces a new class of sustainable water-driven materials whose active behaviour originates from the interplay between hierarchically porous solid networks and interfacial or nanoconfined water. These Blue Materials exploit water-mediated processes such as humidity-responsive actuation, capillary-driven transport, and pore-structure controlled optical effects. Their functionality is rooted in the precise design of their pore architecture, especially at the nanoscale where confined water governs dynamic material behaviour. Beyond emulating natural processes, these principles open pathways for harvesting electrical energy from environmental wetting-drying cycles, offering a sustainable approach to energy generation in porous materials.

CPP 6.2 Mon 11:45 ZEU/LICH

Accessing topological properties of mesoporous materials via SDGW model — •Georgiy Baroncha[1], Rustem Valiullin[1], and Eustathios Kikkinides[2] — [1]Felix Bloch Insitute for Solid State Physics, Leipzig University, Leipzig, Germany — [2]Department of Chemical Engineering, Aristotle University of Thessaloniki, Thessaloniki, Greece

Gas sorption is commonly used to characterize mesoporous materials, but its ability to reveal how pores are interconnected remains limited due to an incom-

plete understanding of network effects on phase behavior. In this work, we represent mesoporous structures using statistically disordered Bethe, and apply a statistical-thermodynamic approach to interpret adsorption/desorption or melting/freezing phase transitions. We demonstrate that gas sorption analysis can be used not only to determine pore size distributions, but also to quantitatively infer the average interpore connectivity and correlations between pore diameters in the material. At the same time, we find that sorption isotherms are largely unaffected by other aspects of pore network topology. These results identify the key structural factors shaping sorption behavior and broaden the capabilities of gas sorption for simultaneous assessment of pore size distribution and mean connectivity in mesoporous materials.

CPP 6.3 Mon 12:00 ZEU/LICH

2D Water in Clay Nanoconfinement: Tiny Space for Large Implications — •Vasily Artemov — Hamburg University of Technology

This talk presents recent advances in understanding the behavior of two-dimensional water in clay nanoconfinement, with a focus on its dielectric properties. Although clays are abundant, their crystal particles typically lack directional alignment. I will discuss an approach for self-assembling clay particles into large, scalable membranes in which the flakes are oriented parallel to each other, enabling a controlled and reproducible platform for studies of confined water at the nanoscale. Using this self-assembled nanofluidic platform, I will present experimental evidence of confinement-induced charge-separation effects that support electricity storage in water channels of 1 nm wide [1]. By combining insights from nanoscale physics, electrochemistry, and materials science, I will highlight how confinement within clay interlayers can influence ion transport, energy-storage phenomena, and our broader understanding of water at the interfaces.

CPP 6.4 Mon 12:15 ZEU/LICH

Two coexisting populations of sorbed DMSO drive distinct structural changes in a swelling porous material — Raimund Teubler[1,3], Alexandra Serebrennikova[1,2,3], Maximilian Fuchs[1,3], Eduardo Machado Charry[1], Robert Saf[1], Erich Leitner[1,3], and •Karin Zojer[1,3] — [1]Graz University of Technology, Graz, Austria — [2]Wood Kplus Competence Center, Linz, Austria — [3]CDL for mass transport through paper, Graz, Austria

Understanding the swelling of cellulose-lignin-based fibers is essential for describing the mechanisms governing water and volatile uptake in porous materials such as paper. We reveal the dynamics of dimethyl sulfoxide (DMSO) uptake and quantify the resulting changes in fiber and sheet structure by combining three recently developed techniques based on concentration determination in coupled uptake/release experiments, microcomputed tomography (μ-CT), and optical microscopy. DMSO interacts with the fibers in a manner similar to water. We show that DMSO is incorporated into the paper sheet in two distinct populations, each contributing differently to the structural evolution of the material. The first population consists of DMSO molecules incorporated into the fibers, leading to fiber swelling. The second population accumulates at the fiber surfaces; although these molecules bind to and are released from the surface rapidly, they gradually modify the fiber surface [1]. As a consequence, built-in stresses within the fiber network are released, causing structural changes that persist long after fiber swelling has ceased.

CPP 6.5 Mon 12:30 ZEU/LICH

Electrochemical control of photoluminescence emission by a porous silicon membrane — •Manuel Brinker[1] and Patrick Huber[1,2] — [1]Institute for Materials and X-ray Physics, Hamburg University of Technology, Denickestr. 15, Hamburg 21073, Germany — [2]Centre for X-ray and Nano Science CXNS, Deutsches Elektronen-Synchrotron DESY, Notkestr. 85, Hamburg 22607, Germany

Porous silicon is a highly versatile porous material with a broad range of exceptional properties. Due to the geometrical confinement of the pore walls, the band structure is strongly altered and the pore walls effectively act as quantum wires. Thus, photons are emitted in the visible range when the membrane is excited by a UV source. This optical effect has been widely researched and is the foundation for porous silicon to be applied, e.g., as a sensor material in the life sciences. Here, we study the influence of electrochemo-mechanical coupling on the photoluminescence performance. Thereby, charge carriers are accumulated in the electric double layer of a porous silicon electrode by charging it in an electrolyte solution. A change in surface stress at the interface with the porous material is induced and results in an overall mechanical reaction of the porous material. The strain acting on the pore walls consecutively influences the emission characteristics of the photoluminescence emission. An extensive in-situ study ascertains a highly linear dependence of the emission peak's wavelength on the charging state of the electrode. This research establishes the groundwork for porous silicon electrodes to be utilized as mechano-optical sensors.

CPP 7: Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods I

Time: Monday 11:30–12:45 Location: ZEU/0255

Exploration of quantum-mechanical space towards olfactorial receptor and body odor volatilomes interaction — •Li Chen[1], Leonardo Medrano Sandonas[1], Shirong Huang[1], and Gianaurelio Cuniberti[1,2] — [1]Institute for Materials Science and Max Bergmann Center for Biomaterials, TUD Dresden University of Technology, 01062 Dresden, Germany — [2]Dresden Center for Computational Materials Science (DCMS), TUD Dresden University of Technology, 010628 Dresden, Germany

We present the MORE-QX dataset generated from quantum-mechanical (QM) simulations of atomistic systems spanning diverse design stages for gas sensing. The dataset contains 23,838 and 10,441 BOV*receptor dimer systems in the gas phase and on graphene surfaces, respectively, to obtain sensing-related binding features. By analyzing the property space spanned by MORE-QX, we observe substantial flexibility in identifying interaction configurations with desired electronic binding characteristics, owing to the weak correlations among the properties. To gain insights into the complex interplay between these sensing properties, we construct tree-based machine-learning models for fast evaluation of binding features using only QM molecular properties, and combine them with an explainability framework to identify the key design factors of BOV*receptor systems that govern sensing performance. Our work provides valuable insights into the sensing mechanism and design principles of olfactorial receptors for BOV sensing.

CPP 7.2 Mon 11:45 ZEU/0255

Non-local diffusion model as a description for non-Gaussian diffusion in scattering experiments — •Harish Srinivasan[1,2], Veerendra Kumar Sharma[2], and Subhankur Mitra[2] — [1]Institute of Applied Physics, University of Tübingen, Tübingen, Germany — [2]Solid State Physics Division, Bhabha Atomic Research Centre, Mumbai, India

We introduce a non-local diffusion (NLD) model that provides a unified theoretical framework for describing non-Gaussian diffusive dynamics in fluids. The NLD formulation generalizes conventional diffusion by incorporating a jump kernel, enabling analytical characterization of van-Hove self-correlation functions with exponential tails. This framework naturally connects two major classes of anomalous transport observed in scattering experiments: non-Gaussian fractional Brownian motion (nGfBm) in sub-diffusive glass-formers, and Fickian yet non-Gaussian diffusion (FnGD) in cage-jump dominated liquids. In the nGfBm regime, the NLD description captures the crossover from non-Gaussian to Gaussian sub-diffusion seen in molecular and polymeric glass-formers [1]. In the FnGD regime, the NLD model predicts the exponentially fast approach to Fickianity and the much slower algebraic restoration of Gaussianity [2]. Comparison with incoherent quasielastic neutron scattering data across multiple systems demonstrates the universal applicability of the NLD model and establishes non-local diffusion as the common physical origin of non-Gaussian signatures in molecular fluids. [1] H. Srinivasan et. al., Phys. Rev. Lett. 132, 058202 (2024) [2] H. Srinivasan et. al., arXiv:2504.15020 (2025)

CPP 7.3 Mon 12:00 ZEU/0255

Optimizing EquiDTB potentials for large-scale molecular simulations — •Zekiye Erarslan, Gianaurelio Cuniberti, and Leonardo Medrano Sandonas — Chair of Materials Science and Nanotechnology, TUD Dresden University of Technology, 01062 Dresden, Germany

Density Functional Tight-Binding (DFTB) is a semi-empirical method that enables efficient large-scale simulations at moderate computational cost compared to first-principles quantum-mechanical methods. However, its generalizability is limited by the use of parameterized pairwise repulsive potentials. The recently developed EquiDTB framework [chemRxiv, 10.26434/chemrxiv-2025-z3mhh] has shown that replacing this repulsive term with a many-body ΔTB potential—trained using equivariant neural networks—significantly improves both the accuracy and transferability of the DFTB method. As a result, EquiDTB achieves hybrid DFT-PBE0 level accuracy across diverse electronic, structural, and vibrational properties of large molecules and molecular dimers containing C, N, O, and H atoms. In this work, we extend the EquiDTB framework by training a more general ΔTB potential on the chemical space covered by the newly gen-

erated QCML dataset. This expansion broadens EquiDTB beyond its original four-element scope and enables accurate simulations of neutral molecular systems containing C, N, O, H, P, S, Na, and Cl. We validate the performance of the optimized EquiDTB model through extensive calculations on large molecular dimers, RNA systems, and organic periodic materials.

CPP 7.4 Mon 12:15 ZEU/0255

MolecuTas: an ML platform for refining quantum properties and bioactivity of complex molecules — •Álvaro Vallejo Bay[1], Jannis Krüger[2], Thomas Hellweg[2], Gerardo Prieto[1], and Vicente Domínguez Arca[2,3] — [1]Applied Physics, University of Santiago de Compostela, Spain — [2]Physical and Biophysical Chemistry, Bielefeld University, Germany — [3]Biosystems and Bioprocesses Engineering, IIM-CSIC, Spain

This work introduces MolecuTas, a neural architecture designed for the ultra-fast prediction of atomistic and molecular properties with accuracy approaching density functional theory, yet at negligible computational cost. The project tackles core challenges in computational chemistry, particularly the size dependence of predictive models and the loss of structural detail in conventional representations. To overcome these limitations, we develop a custom data extraction and molecular fragmentation pipeline based on large quantum datasets, ensuring the preservation of essential information such as connectivity, symmetries, chemical environments, and electronic features.

Building on this foundation, we propose a family of advanced Graph Neural Networks that explicitly integrate physicochemical principles and disentangle local from global information, enabling robust generalization across diverse molecular systems. Ultimately, MolecuTas aims to provide a reliable tool for molecular dynamics, enabling precise and fast prediction of partial charges and other key descriptors required for accurate simulations and next-generation chemical design.

CPP 7.5 Mon 12:30 ZEU/0255

Property-guided diffusion modeling for efficient exploration of chemical spaces — •Leonardo Medrano Sandonas[1], Michael Hanna[1], Julian Cremer[2], and Gianaurelio Cuniberti[1] — [1]TUD Dresden University of Technology, Germany. — [2]Pfizer Worldwide R&D, Germany.

The rational in silico design of chemical compounds requires a deep understanding of both structure-property and property-property relationships across chemical compound space, as well as efficient methodologies for defining inverse property-to-structure mappings. In this presentation, I will discuss our recent efforts to leverage the "freedom of design" concept [Chem. Sci. 14, 10702 (2023)] in the chemical space of drug-like molecules to develop an efficient generative AI framework capable of designing molecular compounds with targeted quantum-mechanical (QM) properties. To this end, we have implemented a property-guided active learning approach that optimizes the performance of equivariant diffusion models within each property space. Generated molecules and their associated QM properties are validated through exhaustive DFT calculations at the PBE0+MBD level using the FHI-aims code. Our findings reveal a consistent improvement in property accuracy when guiding the diffusion model to explore less populated regions of the target property space. This performance is further enhanced by incorporating molecular building blocks into the initial training set. We expect our work to advance the development of sustainable generative AI frameworks for identifying molecules tailored to specific chemical processes.

CPP 8: Wetting, Fluidics and Liquids at Interfaces and Surfaces II (joint session CPP/DY)

Time: Monday 11:30–12:45 Location: ZEU/0260

CPP 8.1 Mon 11:30 ZEU/0260

Do the particle number and wettability affect their removability by a single water drop? — •Franziska Sabath[1], Abhinav Naga[2], Halim Kusumaatmaja[2], and Doris Vollmer[1] — [1]Max Planck Institute for Polymer Research, 55128 Mainz, Germany — [2]Institute for Multiscale Thermofluids, School of Engineering, University of Edinburgh, United Kingdom

The accumulation of dust on surfaces, *e.g.* windows and solar panels, is a well-known phenomenon in everyday life. The ratio of the capillary force between particles and drop and the resistive forces between particles and surface, *i.e.* friction and adhesion, determine whether the particles can be removed by a water drop. The likeliness of particle removal depends on both particle and surface wettability. It is still questionable how the particle arrangement, the total resistive force acting and the unwanted redeposition of particles depend on the number and wettability of the particles. Here, we investigate the removal of hydrophobic and hydrophilic spherical particles from a flat surface. As the number of hydrophobic particles increases, the total resistive force increases, but not linearly, and overcomes the capillary force, causing particle redeposition. In contrast, the hydrophilic particles slide on a thin water film, reducing the particle-surface friction and no resistive force is measured within our experimental resolution.

CPP 8.2 Mon 11:45 ZEU/0260

Modelling and simulation of capillary adhesion between rough surfaces — •Yizhen Wang, Martin Ladecký, and Lars Pastewka — University of Freiburg, Freiburg, Germany

At a small enough length scale, surfaces are always rough, regardless whether they are generated by nature or via artificial process. When two such surfaces are placed close enough, the water molecules in the humid air are adsorbed and hence form capillary bridges. Theories for adhesive interactions typically use simple cohesive laws, which are good models for Van-der-Waals interactions but may not be appropriate for capillary adhesion. We here construct a phase-field model that explicitly represents water present between two contacting rough interfaces. We show results obtained with this model on synthetic, computer-generated, self-affine rough interfaces. In quasi-static simulation, we observe the merging and splitting of droplets under the normal and shear movement of the interfaces. The overall force is dominated by the perimeter of the droplet, indicating the importance of a detailed understanding of droplet morphology.

CPP 8.3 Mon 12:00 ZEU/0260

Impact of surface wettability on the removal of montmorillonite aggregates by water drops How natural dirt is removed from various surfaces — •Stefanie Kirschner, Franziska. Sabath, Azadeh Sharifi-Aghili, Tarik Karakaya, and Doris Vollmer — Max Planck Institute for Polymer Research, 55128 Mainz, Germany

Natural dust on photovoltaic modules or windows, is a critical factor that reduces their performance. Previous experiments focused on the removal on single or many spherical particles. The removal of aggregates of natural particles, is not yet understood. Here, we focus on minerals, commonly present in desert dust. Using confocal laser scanning microscopy the detachment behavior upon contact with a water drop is measured on surfaces with different wettability. In addition, the force required to remove the aggregate by a sliding water drop was investigated. During drying on a hydrophilic surface, the dispersed particles cover a larger area. This increases the total contact area, resulting in higher adhesion and reduced detachment. In contrast, hydrophobic surfaces promoted more compact aggregates with improved removability. Finally, I will compare the detachment forces and the removal behavior of different natural aggregates, e.g. soot, salt and humic acid.

CPP 8.4 Mon 12:15 ZEU/0260

Equilibrium droplets on deformable substrates exhibit cloaking and demixing at the three-phase contact line — •Khalil Remini[1], Ralf Seemann[1], Dirk Peschka[2], and Barbara Wagner[2] — [1]Universität des Saarlandes — [2]Weierstrass Institute for Applied Analysis and Stochastics

This work examines the equilibrium shape of liquid droplets on viscoelastic PDMS substrates with varying elasticities. By combining atomic force microscopy (AFM) with an initial lift-off step, we reveal not only the top contour of the droplets but also the buried droplet*substrate interface. A second lift-off step provides additional structural details near the three-phase contact line (TPCL), where the interfacial tensions adopt a Neumann balance. Quantitative analysis of the reconstructed 3D droplet shapes shows that non-crosslinked, liquid PDMS molecules are extracted from the elastic network under stress and accumulate as a liquid rim around the droplet base, thereby altering both the droplet shape and the substrate profile close to the TPCL. These liquid molecules also cloak the droplets with a thin film, modifying the effective surface tensions. Furthermore, dewetting experiments demonstrate that this demixed liquid already appears at an early stage of dewetting and remains at an approximately constant amount throughout the process.

CPP 8.5 Mon 12:30 ZEU/0260

Tuning Sliding Drop Shape — •Fiona Berner, Chaurasia Rishi, Sajjad Shumaly, Chirag Hinduja, Hans-Jürgen Butt, and Rüdiger Berger — Max-Planck-Institut für Polymerforschung

The understanding of wetting phenomena plays a crucial role in many daily processes. For example, dirt repelling glasses can be achieved by a hydrophobic coating. Recently, Hinduja et al, reported on a scanning drop friction force instrument (sDoFFI) to analyse friction forces of drops on surfaces. A drop is fixated to an elastic force sensor with spring constant κ. The sample underneath the drop is moved with a constant speed u leading to sliding of the drop at a defined trajectory along surfaces. The deflection of the capillary,d, provides information

about the friction force between the drop and the surface, $F_{meas} = \kappa \cdot d$ Forces arising from CAH are given by the Furmidge equation, where the drop*s sliding force F_{CAH} corresponds to

$$F_{CAH} = k \cdot \gamma \cdot w \cdot \Big(cos(\theta_{rec}) - cos(\theta_{adv}) \Big) \quad (1)$$

where k is a geometrical factor, γ is the liquid surface tension, w the width of the drop and θ_{rec} and θ_{adv} are the receding and advancing contact angles, respectively. For small u we assume $F_{meas} = F_{CAH}$. The parameters γ, w, θ_{rec} and θ_{adv} are known or can be measured optically. Thus, the geometrical factor k can be calculated. We realize different geometries of the drop by glueing metal rings to the elastic glass capillary. Shaping the metal rings forces the drop to shape. We discuss experiments where we shape the drop into different width and length and discuss dependence of the geometrical factor k.

Why Polymers Swell or Collapse: Molecular Insights into Cosolute Effects — •Nico van der Vegt — Department of Chemistry, Technical University of Darmstadt

Water-soluble amphiphilic polymers are widely used as stimuli-responsive materials. Their performance is governed by the coil-globule transition, characterised by the theta temperature, which can be tuned by adding small organic molecules (cosolutes). Although related phenomena - such as cononsolvency and salting-out - are well understood at a phenomenological level, their underlying molecular mechanisms remain unclear. This talk explores the solvation physics that determine how different classes of cosolutes influence the coil-globule transition of both generic hydrophobic polymers and realistic systems such as poly(N-isopropylacrylamide), using computer simulations. We identify two distinct molecular driving forces that regulate cosolute-induced hydrophobic interactions, leading to either polymer swelling or collapse. These driving forces depend sensitively on the relevant length scales and expose the interplay between microscopic and macroscopic solvation physics, underscoring the key role of solvent entropy in determining the properties of responsive soft-matter systems. [1] Comm. Chem. 3, 165 (2020), [2] PCCP 24, 2080-2085 (2022), [3] J. Chem. Phys. 160, 164902 (2024)

CPP 9.2 Mon 15:30 ZEU/LICH

THz Pump Pulse Drives Nonlinear H-bond Dynamics in Liquid Water — •Philipp Schienbein — Lehrstuhl für Theoretische Chemie II, Ruhr-Universität Bochum, 44780 Bochum, Germany — Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, 44780 Bochum, Germany

Light-matter interactions are central to processes in nature, chemical engineering, and fundamental research. Of particular interest is the frequency-dependent excitation of molecular systems by incident light. Here, we present machine-learning-accelerated molecular dynamics simulations of water subjected to an intense, monochromatic THz pump pulse, generating a total of 32 ns of trajectory data. The light pulse is explicitly modeled via a time-dependent external electric field, extending our previous framework for field-driven machine learning MD simulations, allowing us to observe the excitation in realtime. Our simulations reproduce key experimental observables, including transient dichroism and birefringence, and reveal that the pulse transiently modulates hydrogen-bond dynamics: H-bonds become markedly shorter-lived compared to unperturbed bulk water. This response is nonlinear, ruling out pure heating and resolving the experimental controversy. These results demonstrate that our machinery to incorporate electric fields in machine learning MD simulations can directly connect microscopic dynamics with measurable observables, further paving the way to controlling water dynamics - and potentially chemical reactivity - through tailored light pulses, a long-standing goal in chemistry.

CPP 9.3 Mon 15:45 ZEU/LICH

Fluctuating Solvent Fields and Vibrational Shifts Revealed by Machine Learned Force Fields — •Florian Brünig and Alexandre Tkatchenko — Department of Physics and Materials Science, University of Luxembourg, Luxembourg

Fluctuating solvent fields is one of the driving mechanism behind vibrational shifts observed in solvatochromic experiments [1]. Previously, experimental infrared spectra have been correlated with mean electric fields obtained from empirical force field molecular dynamics simulations [2]. However, vibrational dynamics of these force fields are insufficient to reproduce the experimental line shape properties.

Here, machine learned force fields (MLFFs) offer multiple opportunities: they are highly accurate, efficient, and can be interpretable if based on physical models. We explore the capabilities of modeling solvatochromism of vibrational probes in solvent and protein environments employing the SO3LR [3] MLFF. SO3LR combines the SO3krates architecture with pairwise analytical electrostatic and dispersion potentials in the long range, and was pretrained on a diverse data set of molecular complexes. We show how fluctuating solvent electrostatic and dispersion fields can be related to vibrational bands in a self consistent manner due to the versatility of MLFFs.

CPP 9.4 Mon 16:00 ZEU/LICH

Machine learning potentials for redox chemistry in solution — •Redouan El Haouari[1,2], Emir Kocer[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

Most Machine-Learning Potentials (MLPs) currently in use are local, which prevents the construction of accurate potentials for systems in which long-range charge transfer is important. One example is the distinction of different oxidation states of transition metal ions such as ferrous (Fe^{2+}) and ferric (Fe^{3+}) ions in aqueous solution. In this case the near-sightedness of local MLPs cannot account for distant counter ions or non-local charge transfer. We show that 4th-Generation High-Dimensional Neural Network Potentials (4G-HDNNPs), which employ atomic charges obtained from charge equilibration as globally-determined descriptors, do not suffer from this short-coming. For aqueous ferric and ferrous chloride, the model predicts iron oxidation states correctly matching the total number of chloride ions in the system demonstrating that physical knowledge about the system of interest remains essential to construct reliable MLPs.

CPP 9.5 Mon 16:15 ZEU/LICH

Bridging Accuracy and Sampling: Insights into dAMP Solvation from ML-potentials — •Laurie Stevens[1,2], Riccardo Martina[2], Alberta Ferrarini[2], and Marialore Sulpizi[1] — [1]Chair of Theoretical Physics of Electrified Liquid-Solid Interfaces, Faculty of Physics and Astronomy, Ruhr-Universität Bochum, Germany — [2]Department of Chemical Sciences, Università degli Studi di Padova, Italy

Although nucleotides are essential biomolecular building blocks, key aspects of their structure and interactions, in particular the steps enabling their assembly and polymerization, remain unclear. Here, we investigate the conformational behavior of deoxyadenosine monophosphate (dAMP) in solution using a combined computational-experimental approach. We developed a highly accurate machine-learning potential via active learning that thoroughly samples the free-energy landscape, capturing critical conformational degrees of freedom with near-chemical accuracy. This potential enables nanosecond-scale simulations of water and nucleotides at a level previously inaccessible with hybrid DFT methods. We find that, in solution, dAMP accesses both anti and syn glycosidic conformations. We identify the anti and high anti conformers as the most stable ones, we show that they underlie the intensity variations observed in mid-IR experimental spectra.

Fine-Tuning Unifies Foundational Machine-learned Interatomic Potential Architectures at ab intio Accuracy — •Christian Dressler, Jonas Hänseroth, Nawaz Qaisrani, and Aaron Flötotto — TU Ilmenau, Institute of Physics, Germany

Machine-learned force fields (MLFFs) have enabled ab initio quality molecular dynamics at speedups of several orders of magnitude. Foundation-model MLFFs, trained on extremely large and diverse datasets, aim to provide broadly transferable force predictions, yet their accuracy remains system-dependent. We investigate five state-of-the-art foundation models (MACE, GRACE, ORB, MATTERSIM, SEVENNET) and fine-tune them for seven chemically diverse systems.[1] Our results show that foundation models provide a useful baseline but still deviate significantly from AIMD. Fine-tuning consistently improves accuracy across all frameworks and yields predictions that closely match AIMD reference data, while also reducing performance differences between models. The final accuracy is largely independent of the underlying architecture. These findings suggest that, after fine-tuning, model choice is no longer the main bottleneck. Prioritizing inference speed and computational efficiency may therefore offer the greatest benefit for accelerating the practical use of ML-based interatomic potentials in materials modeling.

NMR crystallography at finite temperatures — •Matthias Kellner and Michele Ceriotti — Laboratory of Computational Science and Modeling, Institut des Matériaux, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

In this talk I will present our latest developments in machine-learning models for predicting NMR chemical shieldings in organic molecular solids. NMR shielding-driven structure determination protocols rely on comparing experimental solid-state NMR shifts with simulations whose accuracy is often limited by computational cost. We address these limitations by combining ensembles of transformer-based shielding predictors with molecular dynamics simulations using a novel, broadly applicable machine-learning interatomic potential. This framework systematically improves agreement with experiment across many benchmark systems, removes the need for empirical corrections and makes it applicable also to disordered and amorphous materials. I will conclude by showing applications of this framework to the structure determination of amorphous active pharmaceutical ingredients.

CPP 10.1 Mon 15:00 ZEU/0118

Rayleigh instability in the presence of elastocapillarity — •Niphredil Klint and Andreas Isacsson — Chalmers University of Technology, Gothenburg, Sweden

A liquid jet, such as a stream of water, will disintegrate and form droplets if the length-to-radius ratio exceeds a critical value. This occurs due to propagating surface instabilities, a phenomenon known classically as the Rayleigh instability. At the nanoscale, thermal fluctuations affect the breakup dynamics, which may enter a stochastic regime [1]. Placing an elongated nanoscale liquid drop with a high aspect ratio on top of a highly compliant surface, the breakup process is affected by additional noise from thermally excited flexural phonons [2] as well as effects whereby the wetting causes the underlying surface to deform. We use large scale molecular dynamics (MD) simulations to examine the dynamics of the Rayleigh instability in the presence of elastocapillary effects at ambient temperatures. Specifically, we study the interactions between water and suspended graphene, where wetting induced deformations may occur for nanoscale droplets [3]. We focus on characterising the breakup and instability wavelength and isolate the effects of introducing graphene through a comparison of these results to simulations of only water. We also identify the correlation between out-of-plane fluctuations of the graphene and the concentration of water.

CPP 10.2 Mon 15:15 ZEU/0118

Air layers and wetting under drops impacting on pre-wetted surfaces — •Kirsten Harth and Shiva Moradimehr — Fachbereich Technik, Technische Hochschule Brandenburg, Germany

Drop impact at low Weber numbers causes the formation of a (temporary) air cushion between the drop liquid and the substrate. On hard, dry substrates, its qualitative thickness profile and the location of the thinnest point are strongly governed by the Weber number. For impact on bulk, soft surfaces, like PDMS gels, it was found that impacts on softer substrates entrap more air [1]. Are there similar effects of thin liquid films?

We address the air layer shapes, entrapped air volume and wetting underneath droplets impacting on a hard substrate pre-wetted by microscopic oil layers. We control the Weber number, the oil layer thickness (in the range of micrometers), the oil viscosity, and in that way the *softness* of the substrate. Despite the thinness of the film, we observe clear effects of the oil layer on the volume and drainage of the air entrapment, its profile shapes, and the wetting behavior.

CPP 10.3 Mon 15:30 ZEU/0118

Memory Effects in Contact Line Friction — •Niklas Wolf and Nico van der Vegt — TU Darmstadt, Darmstadt, Germany

When a drop of liquid comes into contact with a solid surface, it relaxes towards an equilibrium configuration, either wetting the surface or remaining in a droplet-like shape with a finite contact angle. The speed of this relaxation strongly depends on a friction force opposing the movement of the three-phase contact line. In analogy to the treatment of hydrodynamic friction we present an exact method, based on the Mori-Zwanzig formalism, to extract this friction from equilibrium data. Within the linear response regime, we obtain the frequency-dependent dissipative and elastic response of the contact line to an external perturbation, including a frequency-dependent friction coefficient. We find that the contact line exhibits long-lasting memory with a power-law decay due to coupling to the systems hydrodynamic modes. As a result the microscopic contact line dynamics are neither Markovian nor determined by the movement of a few molecules in the vicinity of the contact line.

CPP 10.4 Mon 15:45 ZEU/0118

Reaction-Mediated Arrest and Gradient-Driven Droplet Transport — •Stefan Köstler[1,2], Yicheng Qiang[1], Malcolm Steen[1,2], Guido Kusters[1], and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany — [2]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Controlling droplet size and position is central to many biological and engineering processes. Chemical reactions can arrest coarsening and sustain spatial concentration gradients, while hydrodynamic flows generally accelerate coarsening and drive droplets along chemical gradients. Using continuum theory, we show that the competition between reactions, diffusion, and hydrodynamic advection yields rich behavior even in binary systems: Advection dominates the coalescence of small droplets, diffusion leads to Ostwald ripening for intermediate sizes, and reactions finally suppress coarsening. Interestingly, a range of droplet sizes is stable, depending on initial conditions and the strength of advection. Crucially, chemical gradients can actively steer droplets and couple to size-control. Our results demonstrate practical routes to control both the size distribution and spatial organization of droplets by tuning chemical activity and gradient-driven flows.

CPP 10.5 Mon 16:00 ZEU/0118

From bipedal to chaotic motion of chemically fueled partially wetting liquid drops — •Florian Voss[1] and Uwe Thiele[1,2] — [1]Institute of Theoretical Physics, University of Münster — [2]Center for Data Science and Complexity (CDSC), University of Münster

Chemomechanical coupling is essential to various phenomena in soft matter systems that are kept permanently out of thermodynamic equilibrium, e.g., in reactive complex liquids. Based on a thermodynamically consistent continuum model, we demonstrate that partially wetting liquid drops covered by chemically reacting surfactants display a variety of biomimetic motility modes like shuttling, bipedal, rotational and quasi-random motion when supplied with chemical fuel from an ambient bath. The dynamics originates from chemomechanical feedback between the reaction network on the drop and the Marangoni effect [1] and becomes increasingly complex as a result of competing length scales. Due to the generic underlying thermodynamic structure, we expect that our results are also relevant for other chemically active mixtures and soft matter systems.

CPP 10.6 Mon 16:15 ZEU/0118

Odd Droplets — •Thomas Appleford — University of Amsterdam, Amsterdam, Netherlands

In chiral systems such as active spinning colloidal matter, time-reversal symmetry-breaking interactions often give rise to a macroscopic continuum description in which the stress tensor contains off-diagonal terms. In fluids, these off-diagonal components lead to so-called "odd-viscous" deformations, in which energy is not dissipated. Odd viscous fluids have been shown to exhibit a rich variety of phenomena, including symmetry-broken flow around translating droplets and asymmetric droplet spreading on superhydrophobic surfaces. Our work investigates the behaviour of droplets in suspension. In particular, we present an analytical solution to the droplet-in-shear problem within the framework of two-dimensional odd Stokes flow, followed by the derivation of a formula for the apparent viscosity of a dilute emulsion. We then explore how chirality can be parametrically varied to tune the bulk rheological properties and control the system's overall energy dissipation.

CPP 10.7 Mon 16:30 ZEU/0118

Stretching and Sliding Capillary Bridges — •Lennard Holschuh and Lars Pastewka — University of Freiburg, Department of Microsystems Engineering

Capillary forces play a critical role in the adhesion between two contacting bodies. However, existing theories of macroscopic adhesion on rough surfaces often assume dry conditions, attributing adhesive interactions solely to dispersion forces and overlooking the effects of capillary bridge formation. This study em-

ploys molecular dynamics simulations to directly examine the interactions of nanoscale probes with nominally flat surfaces in the presence of liquid bridges, which form due to condensation in humid environments. The objective is to link the thermodynamic understanding of capillary bridges with molecular simulations and atomic-force microscopy experiments. These calculations focus on investigating energy dissipation during adhesion (normal separation of the probe from the surface) and friction (lateral motion of the probe). By quantifying the interplay between relative humidity, adhesion, and friction, this work aims to improve the understanding of macroscopic adhesion in humid conditions and guide the development of materials with tailored properties for high-precision applications, such as microelectronic manufacturing.

Hyperuniformity in Ternary Fluid Mixtures: The Role of Wetting and Hydrodynamics — •Nadia Bihari Padhan and Axel Voigt — Institute of Scientific Computing, TU Dresden, 01069 Dresden, Germany

Phase separation in multicomponent fluids underlies the organization of complex materials and biological structures, including biomolecular condensates. The Cahn-Hilliard-Navier-Stokes (CHNS) framework provides a natural description of such systems by coupling diffusive and hydrodynamic processes. In this talk, I will present our study of hyperuniformity–suppressed large-scale density fluctuations–in ternary CHNS mixtures. We show that hydrodynamics systematically drives the system toward less hyperuniform states and generates a rich set of morphologies, such as interconnected droplets and double emulsions reminiscent of biological phase separation. In partial-wetting regimes, all three components display comparable hyperuniformity, whereas in complete-wetting regimes the preferred wetting component exhibits a marked loss of hyperuniformity. These results identify wetting asymmetry as a key control parameter for spatial order in multiphase fluids and offer a pathway for tuning large-scale organization in soft-matter and biological systems.

Effect of Flow Coupling on Defect Binding and Unbinding in Nematic Fluids — •Jayeeta Chattopadhyay, Simon Guldager Andersen, Kristian Thijssen, and Amin Doostmohammadi — Niels Bohr Institute, University of Copenhagen, Blegdamsvej 17, Copenhagen, Denmark.

Topological defects play a central role in the ordering and dynamics of nematic fluids. We investigate how coupling to fluid flow modifies defect-mediated phase transitions in two-dimensional nematics using fluctuating nematohydrodynamic simulations. The system is driven by tuning the fluctuation strength, with increasing and decreasing fluctuations defining forward and backward protocols. Without flow coupling, the system undergoes a Berezinskii–Kosterlitz–Thouless (BKT)–like transition via the reversible binding and unbinding of $\pm 1/2$ defect pairs. When hydrodynamics is included, the transition depends on the flow–alignment parameter: non-aligning nematics ($\lambda = 0$) retain BKT-like behavior, whereas strain-rate–aligning nematics ($\lambda \neq 0$) form bend–splay walls, lowering the defect-creation threshold and preventing recombination, leaving defects unbound across all fluctuation strengths. In active nematics, defects remain unbound for all λ, showing that self-generated flows also inhibit bound-pair formation. These results demonstrate that coupling to fluid flow fundamentally alters topological phase behavior, suppressing the equilibrium BKT binding mechanism.

CPP 10.10 Mon 17:30 ZEU/0118

Electrophoresis in charged chiral active fluids with odd viscosity — •Reinier van Buel, Bogdan Cichocki, and Jeffrey Everts — Institute of Theoretical Physics, Faculty of Physics, University of Warsaw, Pasteura 5, 02-093 Warsaw, Poland

Understanding the motion of colloidal particles dissolved in fluids that exhibit odd viscosity – a specific component of the viscous stress tensor found in e.g. chiral active fluids – is of particular interest for realising nontrivial particle transport and characterising out-of-equilibrium thermodynamic properties. Although three-dimensional odd viscosity has not yet been experimentally observed, charge stabilisation is expected to be vital in enabling such measurements. Therefore, we introduce the notion of a charged chiral active fluid and we investigate some of its non-trivial electrokinetic properties. In particular, we focus on electrophoresis of a charged sphere suspended in such an odd viscous fluid. Here, the peculiar nature of odd viscosity breaks the spherical symmetry of the system, and through coupling with the electric double layer and its screening properties, alters the electrophoretic mobility. Using the Lorentz reciprocal theorem, we derive expressions for the electrophoretic mobility of a spherical particle based on the analytical solution for the uncharged flow. Furthermore, we highlight how the Hückel and Smoluchowski limits of the electrophoretic mobility are affected by odd viscosity. Our results demonstrate that odd viscosity leads to directional asymmetries in the electrophoretic mobility tensor, suggesting mechanisms for active control of charged colloidal motion in systems where odd viscosity is prevalent.

CPP 10.11 Mon 17:45 ZEU/0118

Experimentally probing microscale torsional memory in a viscoelastic fluid — •Niloyendu Roy[1], Rupayan Saha[2], Debankur Das[2], Matthias Krüger[2], and Clemens Bechinger[1] — [1]Fachbereich Physik, Universität Konstanz, Konstanz, Germany — [2]Institut für Theoretische Physik, Universität Göttingen, Göttingen, Germany

Motion of a colloid inside viscoelastic fluids follows non-Markovian dynamics, meaning its trajectory is influenced by past motion. Such memory effects are typically attributed to intrinsic material timescales arising from relaxation of the fluid microstructure and are usually probed using translationally driven colloids. Here we show experimentally that rotational driving of a colloid by a controlled torque elicits a far richer form of memory: the relaxation of the resulting torsional stresses spans a broad distribution of timescales, even though the fluid itself possesses a single dominant relaxation time. This behaviour allows time-dependent torsional driving histories to be encoded and subsequently read out through characteristic non-monotonic recoil responses. By mapping the flow field and the spatial distribution of torsional stresses, we demonstrate that the geometry of rotation generates an orthogonality between the propagation of angular momentum and the storage of torsional stresses, producing a spatio-temporal memory field not accessible through translational forcing. These results establish torsional driving as a powerful route to generate, store, and retrieve memory in viscoelastic fluids, opening new possibilities for soft-matter information storage and torque-responsive microdevices.

CPP 10.12 Mon 18:00 ZEU/0118

3D Optofluidic Control Using Reconfigurable Thermal Barriers — •Falko Schmidt[1,2], Carlos David Gonzalez[3], Marc Sulliger[1], Emilio Ruiz-Rena[4], Raul A. Rica[3,5], Jaime Ortega-Arroyo[1], and Romain Quidant[1] — [1]Department of Mechanical and Process Engineering, ETH Zurich, Zurich 8092, Switzerland — [2]Peter Debye Insitute for Soft Matter Physics, Leipzig University, 04103 Leipzig, Germany — [3]Universidad de Granada, Department of Applied Physics, Granada 18071, Spain — [4]Department of Applied Physics II, University of Malaga, Malaga 29071, Spain — [5]Universidad de Granada, Research Unit Modeling Nature (MNAT), Granada 18071, Spain

Optothermal manipulation enables precise control of small particles via optical and thermal forces, leveraging thermo-osmotic and convective flows for short- and long-range motion. We present a reconfigurable optofluidic method enabling diverse manipulations such as guiding, sorting, trapping, and separating particles. Using light absorption on plasmonic surfaces of gold nanorods, localized hot spots are generated, creating temperature-driven flows. A near-infrared laser spatially modulates temperature landscapes, monitored by 3D holographic microscopy and optical diffraction tomography. Single and double heat sources produce three-dimensional flow control. This creates an optofluidic barrier that redirects particles within a microfluidic chamber. This approach offers a versatile foundation for advancing microfluidic technologies, enabling applications in sorting, trapping, and adaptive system design.

CPP 10.13 Mon 18:15 ZEU/0118

Dynamics and Ordering of Microdroplets in Marangoni Flow Field — •Akshay Kallikkunnath and Frank Cichos — Molecular Nanophotonics, Peter Debye Institute for Soft Matter Physics, Faculty of Physics and Earth System Sciences, Leipzig University, Linnéstraße 5, 04103 Leipzig, Germany

Collective organization and internal dynamics are intimately linked and emerge across biological scales, with ordered structures providing a framework within which individual constituents remain dynamically active. Here, we study a system of water-in-oil microdroplets containing heat-releasing particles that organize under thermally induced flows. A sub-kelvin temperature increase from the heated particle at the air-oil interface generates Marangoni circulation that advects the droplets. Interactions through the flow field lead to robust ordering, while internal particle dynamics reflect coupling between local thermal gradients and microscale hydrodynamics. This provides a controllable platform to probe self-organization and emergent order by generating flows driven by weak, localized thermal fields in a fully fluid-in-fluid environment.

CPP 11: Active Matter II (joint session DY/BP/CPP)

Time: Monday 15:00–18:30 Location: ZEU/0160

CPP 11.1 Mon 15:00 ZEU/0160

Field-controlled self-organization in an active spin system — Mintu Karmakar[1,2,3], •Matthieu Mangeat[4], Swarnajit Chatterjee[5,4], Heiko Rieger[4], and Raja Paul[3] — [1]WIUCAS, Beijing, China — [2]Universitat de Barcelona, Barcelona, Spain — [3]IACS, Kolkata, India — [4]Saarland University, Saarbrücken, Germany — [5]CY Cergy Paris Université, Cergy-Pontoise, France

We investigate the collective response of active Potts particles to an external magnetic field and uncover three striking nonequilibrium phenomena. We first examine how the flocking transition is reshaped for a homogeneous and unidirectional field: the coexistence regime between an apolar gas and a polar liquid is replaced by a phase separation between two polar-ordered phases, a low-density, weakly polarized background and a high-density, strongly polarized band, both moving along the field. Second, when the particles self-organize into a high-density longitudinal lane whose long axis is perpendicular to the field, the lane slowly treadmills against the field direction, driven by the weakly polarized background. Finally, we identify a field-induced interface pinning regime that arises when the domain is divided into two regions with opposite field directions, causing particles to accumulate and perform a back-and-forth motion at the interface. This pinning phenomenon also leads to the emergence of a disordered state in the presence of a random field orientation. A coarse-grained hydrodynamic theory supports and confirms the phenomena observed in our microscopic simulations.

CPP 11.2 Mon 15:15 ZEU/0160

Nucleation kinetics in two-dimensional polar active fluids — •Yuta Kuroda and Thomas Speck — Institute for Theoretical Physics IV, University of Stuttgart, Germany

Polar active fluids constitute one of the most important classes of active matter. These systems possess alignment interactions that cause the local polarization to align with that of neighboring particles, leading to a flocking transition in which global polar order emerges. Extensive numerical and analytical studies have established that the flocking transition is discontinuous, and consequently, the phase diagram possesses a coexistence region in which propagating polar bands appear. Despite intensive studies on flocking transitions, the nucleation mechanism responsible for the formation of these bands remains poorly understood. In this work, we numerically investigate the nucleation kinetics of polar bands using a particle model, namely active Brownian particles with a Kuramoto-type alignment interaction, and we report the behavior of the nucleation rate over a wide range of parameters.

CPP 11.3 Mon 15:30 ZEU/0160

Collision dynamics of active Brownian hard disks — •Jonas Buba — Soft Matter Theory Group, Theoretical Physics: Lab for Emergent Phenomena, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Active matter systems, composed of self-driven agents, display emergent behaviors such as collective motion, clustering, and motility-induced phase separation (MIPS). To better understand the microscopic origin of MIPS, we study collisions of active Brownian hard disks within the framework of dynamical density functional theory (DDFT). The particle interactions are modeled using fundamental measure theory (FMT). Each particle is represented by a Gaussian density peak, which allows us to quantify the mean delay from collisions for different configurations. The post-collision density resulting from the simulation can be described by a convolution of the pre-collision density, enabeling the analysis of different contributions to the delay.

CPP 11.4 Mon 15:45 ZEU/0160

Active Ornstein-Uhlenbeck Particles: A Stochastic Path Integral Approach — •Carsten Littek, Mike Brandt, and Falko Ziebert — Institut für Theoretische Physik, Universität Heidelberg, Germany

In a recent publication (arXiv:2509.26296) we have developed a path integral formulation of the stochastic dynamics of a single active Brownian particle (ABP), with or without a constant torque, confined by a harmonic trap. This approach is based on the particle's microscopic degrees of freedom and we have derived exact analytic time-dependent expressions for key observable quantities such as the mean position and mean square displacement without the necessity of solving the Fokker-Planck equation. Here we present the application of this approach to the dynamics of active Ornstein-Uhlenbeck particles (AOUP). In particular, we generalize our formulation to systems of many AOUPs interacting via a suitable two-particle potential and derive the statistical quantities relevant in the context of collective phenomena, such as motility-induced phase separation (MIPS).

CPP 11.5 Mon 16:00 ZEU/0160

Self-alignment and chirality in dense active matter: from flocking to circling crystals — •Marco Musacchio[1], Alexander Antonov[1], Hartmut Löwen[1], and Lorenzo Caprini[2] — [1]Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, Universitätsstraße 1, D-40225 Düsseldorf, Germany — [2]Physics Department, University of Rome La Sapienza, P.le Aldo Moro 5, IT-00185 Rome, Italy

Several experimental systems in active matter are characterized, at the single-particle level, by an effective torque that aligns particle orientation with their instantaneous velocity. This mechanism, known as self-alignment, appears in both biological and granular active systems. In dense active systems, a sufficiently strong self-alignment can suppress mips and drive the system from a clusterized flocking state to an homogeneous one, where all particles move collectively, with aligned velocities. This flocking transition is approached for a broad range of densities, even close to maximal packing, where the system is in a crystalline configuration. Specifically, in the crystal case, the flocking transition can be predicted analytically since the dynamics can be mapped onto a velocity-dependent Landau*Ginzburg free energy, revealing that this disorder*order transition is second order. The onset of chirality drives the system from collective flocking to a circling crystal phase, characterized by coherent circular motion of all the system. Further increasing chirality suppresses the global rotation, leading to a vortex-like structure in the velocity field. These findings are experimentally testable in systems governed by self-alignment and chirality.

CPP 11.6 Mon 16:15 ZEU/0160

Number fluctuations distinguish different self-propelling dynamics — •Tristan Cerdin[1,2], Sophie Marbach[2], and Carine Douarche[1] — [1]Université Paris-Saclay, CNRS, FAST, 91405, Orsay, France — [2]CNRS, Sorbonne Université, Physicochimie des Electrolytes et Nanosystèmes Interfaciaux, F-75005 Paris, France

In nonequilibrium suspensions, static number fluctuations N in virtual observation boxes reveal remarkable structural properties, but the dynamic potential of $N(t)$ signals remains unexplored. Here, we develop a theory to learn the dynamical parameters of self-propelled particle models from $N(t)$ statistics.

Theoretical plots of the mean-squared number difference $\langle \Delta N^2(t) \rangle$ exhibit 3 scaling regimes in time corresponding to the 3 regimes of self-propelled particles: diffusive, advective and effectively diffusive again at long times. By expanding the theory in each of these regimes, we recover limiting laws for the number fluctuations, which can be used in practice to quantify self-propulsion properties.

Additionally, unlike traditional trajectory analysis, $N(t)$ statistics distinguish between models, by sensing subtle differences in reorientation dynamics that govern re-entrance events in boxes. This paves the way for quantifying advanced dynamic features in dense, out-of-equilibrium suspensions.

CPP 11.7 Mon 16:30 ZEU/0160

Flocking transitions in dense mixtures of active self-aligning and passive particles — •Weizhen Tang[1], Amir Shee[2], Zhangang Han[1], Pawel Romanczuk[3,4], Yating Zheng[3,4], and Cristián Huepe[1,5,6] — [1]School of Systems Science, Beijing Normal University, Beijing, China — [2]Department of Physics, University of Vermont, USA — [3]Department of Biology, Humboldt Universität zu Berlin, Unter den Linden 6, Berlin, Germany — [4]Research Cluster of Excellence 'Science of Intelligence', Berlin, Germany — [5]Northwestern Institute on Complex Systems and ESAM, Northwestern University, Evanston, USA — [6]CHuepe Labs, 2713 West Augusta Blvd #1, Chicago, USA

We investigate the passivity-driven flocking transition in a dense mixture of self-aligning active particles and passive particles, using a minimal model of active polar disks. We show that anisotropic damping leads to a discontinuous flocking transition as a function of the fraction of passive components, whereas isotropic damping produces a smooth transition where the final ordered state can display sustained oscillations and remain trapped in a metastable state, depending on the exact spatial arrangement of the passive particles. We also explore in detail the emergence of metastable oscillatory ordered states and their relation to the spatial distribution of passive particles and interstitial voids. Our findings demonstrate that heterogeneous activity and mobility anisotropy can result in a rich variety of self-organized states in various biological systems, synthetic active materials, and robotic swarms.

Invited Talk CPP 11.8 Mon 17:00 ZEU/0160

Topological transition in filamentous cyanobacteria: from motion to structure — •Marco Mazza — Loughborough University, Loughborough, UK

Many active systems are capable of forming intriguing patterns at scales significantly larger than the size of their individual constituents. Cyanobacteria are

one of the most ancient and important phyla of organisms that has allowed the evolution of more complex life forms. Despite its importance, the role of motility on the pattern formation of their colonies is not understood. Here, we investigate the large- scale collective effects and rich dynamics of gliding filamentous cyanobacteria colonies, while still retaining information about the individual constituents' dynamics and their interactions. We investigate both the colony's transient and steady-state dynamics and find good agreement with experiments. We furthermore show that the Péclet number and aligning interaction strength govern the system's topological transition from an isotropic distribution to a state of large-scale reticulate patterns. Although the system is topologically nontrivial, the parallel and perpendicular pair correlation functions provide structural information about the colony, and thus can be used to extract information about the early stages of biofilm formation. Finally, we find that the effects of the filaments' length cannot be reduced to a system of interacting points. Our model proves to reproduce both cyanobacteria colonies and systems of biofilaments where curvature is transported by motility.

CPP 11.9 Mon 17:30 ZEU/0160

Novel Phase Coexistence in a Multi-Species Vicsek Model — •Eloise Lardet[1], Letien Chen[1,2], and Thibault Bertrand[1] — [1]Imperial College London, UK — [2]University of Edinburgh, UK

A hallmark in natural systems, self-organization often stems from very simple interaction rules between individual agents. While single-species self-propelled particle (SPP) systems are well understood, the behavior of mixtures of self-propelled particles with general alignment interactions remains largely unexplored with a few scattered results hinting at the existence of a rich emergent phase behavior. Here, we first present a generalization of the two-species Vicsek model with reciprocal intra- and interspecies (anti-)alignment couplings, uncovering a rich phenomenology of emergent states. Notably, we show that rather than destroying polar order, anti-aligning interactions can promote phase separation and the emergence of global polar order. Secondly, we derive a kinetic theory for the system, finding good agreement between theoretical predictions and particle simulations. This includes a novel mechanism for microphase separation, as predicted by a Turing instability. We finally show that these coexistence patterns can be generalized to multi-species systems with cyclic alignment interactions.

CPP 11.10 Mon 17:45 ZEU/0160

Flocking in weakly nonreciprocal mixtures — •Charlotte Myin — Max Planck Institute for Dynamics and Self-Organization (MPI-DS), 37077 Goettingen, Germany

We show that weakly nonreciprocal alignment leads to large-scale structure formation in flocking mixtures. By combining numerical simulations of a binary Vicsek model and the analysis of coarse-grained continuum equations, we demonstrate that nonreciprocity destabilizes the ordered phase formed by mutually aligning or anti-aligning species in a large part of the phase diagram. For aligning populations, this instability results in one species condensing in a single band that travels within a homogeneous liquid of the other species. When interactions are anti-aligning, both species self-assemble into polar clusters with large-scale chaotic dynamics. In both cases, the emergence of structures is accompanied by the demixing of the two species, despite the absence of repulsive interactions. Our theoretical analysis allows us to elucidate the origin of the instability, and show that it is generic to nonreciprocal flocks.

CPP 11.11 Mon 18:00 ZEU/0160

Collective behavior in nonreciprocal multi-species Vicsek model with permutation symmetry — •Jae Dong Noh[1], Chul-Ung Woo[2], and Heiko Rieger[2] — [1]Department of Physics, University of Seoul, Seoul 02504, Korea — [2]Department of Theoretical Physics and Center for Biophysics, Saarland University, Saarbrücken, Germany

Nonreciprocal systems are typically built upon asymmetric roles among interacting agents, such as a pursuer-evader relationship. We propose a multi-species nonreciprocal active matter model that is invariant under permutations of the particle species. The nonreciprocal, yet symmetric, interactions emerge from a constant phase shift in the velocity alignment interactions, rather from an asymmetric coupling matrix. This system displays rich collective behaviors, including a species-mixed chiral phase with quasi-long-range polar order and a species-separated vortex cell phase. We present numerical evidence for these phases using particle-based Monte Carlo simulations and analytic evidence using continuum Boltzmann and hydrodynamic equations. Our work demonstrates that multi-species chiral fluids can be realized by a nonreciprocal but symmetric alignment interaction, where the rich collective behavior is a consequence of the interplay between nonreciprocity and permutation symmetry.

CPP 11.12 Mon 18:15 ZEU/0160

Flocking with random non-reciprocal interactions — •Jiwon Choi[1], Jae Dong Noh[2], and Heiko Rieger[1] — [1]Department of Physics & Center for Biophysics, Saarland University, Campus E2 6, 66123 Saarbrücken, Germany — [2]Department of Physics, University of Seoul, Seoul, 02504, Korea

Flocking is ubiquitous in nature and emerges from alignment interactions among self-propelled agents. Two species that anti-align or interact non-reciprocally exhibit complex collective phenomena, ranging from parallel and anti-parallel flocking and run-and-chase behavior to chiral phases. Whether such behavior survives in the presence of many species with random non-reciprocal interactions has remained unclear. As a first step, we study a continuous-time Vicsek-like model with fully random non-reciprocal interactions between particles. For infinite-range interactions, flocking emerges once the alignment bias becomes comparable to the non-reciprocal interactions, and deep inside this phase random non-reciprocity can still support slow global chiral and oscillating states. For short-range interactions, even without alignment bias, self-organized cliques form, where medium-sized clusters with predominantly aligning interactions remain stable over long times. We further investigate the robustness of clique formation and the coexistence phase under angular noise using a discrete-time Vicsek model with random non-reciprocal interactions. These results provide a basis for studying multi-species flocking with complex non-reciprocal interactions.

CPP 12: French-German Session: 2D Materials, Thin Films and Interfaces I

Invited Talk CPP 12.1 Mon 15:00 ZEU/0255

Multifunctional films by tailoring chemistry and morphology of polymer brushes at the nanoscale — •Petra Uhlmann and Alexander S. Münch — Leibniz-Institut für Polymerforschung Dresden, Hohe Strasse 6, 01069 Dresden

Functional polymer thin films, like stimuli-responsive polymer brushes or crosslinked polymer networks, are a group of smart surface coatings which are beneficial for the design of intelligent interfaces. One emphasis of our work is the synthesis of polymer brushes as a toolbox for the creation of specific surface functions and stimuli-responsive layers using a bottom-up approach. For many technical applications control and switching of wettability is a key property. In this contribution it will be shown how tailored co-polymers containing zwitterionic phosphorylcholine groups (MPC) and benzophenone (BPO) as anchoring and UV cross-linking units can be used to create multifunctional films with easy-to-clean, anti-fog, anti-fouling and anti-icing properties. For the achievement of the desired surface functions the control of not only the wettability, but also other thin film properties like thickness and degree of swelling, are crucial and require the respective optimization of the chemical polymer composition and the degree of crosslinking. For verification and adjustment of the interfacial and thin film properties atomic force microscopy (AFM), infrared spectroscopy (ATR-FTIR), contact angle measurements, and in-situ spectroscopic ellipsometry were used and correlated with respective coatings performance and sustainability tests.

CPP 12.2 Mon 15:30 ZEU/0255

Increase in elastic modulus of thin elastic films and membranes containing rigid inclusions - revisiting Einstein's relation in two dimensions — •Konstantin Zisiadis and Andreas Menzel — Otto-von-Guericke-Universität Magdeburg

Elastic matrices with well-separated inclusions can be described by effective elastic moduli obtained via homogenization methods. Probably the most basic relation for dilute systems is the Einstein equation $\eta_{\text{eff}} = \eta(1 + 2.5\phi)$. We consider the two-dimensional geometry of an elastic matrix in two dimensions with two-dimensional elastic moduli as counterparts to the three-dimensional case. Both plane-stress and plane-strain geometries are treated. We employ a generalized stresslet formalism. Our derived formulae for the effective moduli of the two-dimensional geometry are expressed using the two-dimensional elastic moduli for an arbitrarily compressible matrix. We find that the plane-stress and plane-strain equations for the effective moduli have the same form, while the associated two-dimensional moduli differ. Our results are consistent with previous research based on different approaches. For an incompressible matrix, we recover the known effective shear modulus $\mu_{\text{eff}} = \mu(1 + 2\phi)$.

We acknowledge support by the German Research Foundation (DFG) through Research Unit FOR 5599 on structured magnetic elastomers.

CPP 12.3 Mon 15:45 ZEU/0255

Structure and optical properties of donor-HATCN blends — •Gianfranco Melis, Dmitry Lapkin, Ainur Abukaev, Alexander Hinderhofer, and Frank Schreiber — Universität Tübingen, Tübingen, Germany

Organic thin films made of molecular semiconductors have the potential to advance the range of functional materials for technological progress. In this regard, electron donor-acceptor complexes (DAC) show unique physical properties at specific ratios due to their non-linear structure-property-composition dependence. A systematic study across the full mixing range is therefore essential to understand how structure and optical response evolve with composition.

Compositional-gradient thin films were prepared in a custom-built organic molecular beam deposition chamber by co-depositing donor materials—diindenoperylene (DIP), pentacene (PEN), coronene (COR), picene (PIC), α-sexithiophene (α-6T), zinc phthalocyanine (ZnPc), and perylenetetracarboxylic acid bis(propylimide) (PTCDI-C_3)—with the prospective non-fullerene acceptor hexaazatriphenylenehexacarbonitrile (HATCN). Grazing-incidence wide-angle X-ray scattering (GIWAXS), atomic force microscope (AFM), and UV-Vis absorption spectroscopy were applied to study and correlate structural and optical properties with the donor-acceptor stoichiometry. New absorption bands appear below the optical bands of pure materials at specific stoichiometric compositions, together with different surface morphologies and the formation of new mixed structural phases.

CPP 12.4 Mon 16:00 ZEU/0255

Optimized Phenyl-Modified g-C3N4/ZnO Hybrid Thin Films: Structural and Optical Insights — •Sahar Aghapour Ghourichay[1,2], Morgan Le Du[2], David P. Kosbahn[2], Guangjiu Pan[2], Hagen Uebele[2], Thomas Baier[2], Jinsheng Zhang[2], Lyuyang Cheng[2], Pier Carlo Ricci[1], and Peter Müller-Buschbaum[2] — [1]Department of Physics, University of Cagliari, Cittadella Universitaria, Monserrato, Italy — [2]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany

Phenyl-modified graphitic carbon nitride (PhCN)/ZnO hybrid thin films were fabricated with different PhCN loadings to investigate the influence of interface engineering on their structural and optical properties. UV-vis reflectance results show that the film containing 1 mL PhCN exhibits the lowest reflectance and the strongest absorption in the visible region. Photoluminescence analysis confirms that this optimized film has significantly reduced emission intensity, indicating more effective charge separation. XRD, AFM, and GIWAXS measurements reveal improved crystallinity and enhanced nanoscale ordering of ZnO in the presence of moderate PhCN content. SEM/EDS mapping verifies uniform hybrid formation, and XPS provides evidence of interfacial chemical interaction. Overall, controlled PhCN incorporation effectively tunes the optical response and nanoscale structure of PhCN/ZnO thin films, offering useful insights for photocatalytic and optoelectronic applications.

CPP 12.5 Mon 16:15 ZEU/0255

Machine Learning for Grazing-Incidence Diffraction (GID): from Raw Data to Crystalline Structure — •Dmitry Lapkin, Ainur Abukaev, Ekaterina Kneschaurek, Mikhail Romodin, Constantin Völter, Vladimir Starostin, Alexander Hinderhofer, and Frank Schreiber — Universität Tübingen

The optimization of novel materials in the form of thin films for specific applications requires the appropriate structural characterization methods. X-ray and neutron scattering techniques, such as grazing incidence small- and wide-angle X-ray/neutron scattering (GISAXS/GIWAXS/GISANS) or grazing-incidence diffraction (GID), offer the ultimate spatial resolution and high surface sensitivity, making them indispensable tools for thin film studies. At the same time, advancements in X-ray and neutron sources, in conjunction with developments in area detector technologies, enable the recording of several terabytes of raw two-dimensional detector data within a single experiment. Conventional methods of analyzing the GID data are severely under-paced compared to the data generation rates, representing a significant bottleneck and leaving much of the measured data unanalyzed. To make the thin film studies more efficient and increase the amount of analysed and published GID data that can be reused, we are developing a comprehensive machine learning based data analysis pipeline that goes from raw detector patterns to the corresponding crystalline structures. This pipeline comprises several stages, including data preprocessing and reduction, Bragg peak identification and refinement, and crystal structure determination.

Invited Talk CPP 12.6 Mon 16:30 ZEU/0255

Thin-film and interface properties in energy conversion devices unveiled by X-rays — •Marcus Bär — Department Interface Design, Helmholtz-Zentrum Berlin für Materialien und Energie GmbH (HZB), Berlin, Germany — Energy Materials In-Situ Laboratory Berlin, HZB, Berlin, Germany — Department of Chemistry and Pharmacy, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — Department of X-ray Spectroscopy at Interfaces of Thin Films, Helmholtz-Institute Erlangen-Nürnberg for Renewable Energy, Berlin, Germany

This invited talk will present recent advances in the characterization of the chemical and electronic structure of interfaces and thin films that are central to modern energy-conversion technologies. A combination of X-ray spectroscopies enables non-destructive, depth-resolved insight into composition, chemical structure as well as bonding and energy-level landscapes across complex and often (deeply) buried interfaces. Interfacial intermixing, interlayer formation, oxidation processes, and energy-level alignment govern charge transport and recombination in energy conversion materials and devices. Illustrative case studies will be used to demonstrate how changes (e.g., in the thin-film deposition process) affect interfacial chemistry and electronic structure, highlighting the importance of the ability to probe interface properties as a prerequisite for deliberate interface design. In addition, the talk will outline recent progress in establishing dedicated sample environments allowing for in-situ and operando studies opening new pathways for understanding dynamic interface phenomena.

CPP 13: Charged Soft Matter, Polyelectrolytes and Ionic Liquids

Invited Talk CPP 13.1 Mon 15:00 ZEU/0260

Modelling and simulation of pH-sensitive polyelectrolyte microgels — •Stefanie Schneider — Institute of Physical Chemistry, RWTH Aachen University, Aachen, Germany

For weak polyelectrolytes (PE) as well as for weak polyampholytes (PA), not only the pH-pKA value but also the local electrostatic environment of the ionisable group determines the degree of ionisation and structural properties of the polymer. The proximity of already ionised groups, which is enforced by the interconnectivity of the polymer chain, influences the probability of additional groups to become ionised. Therefore, the degree of ionisation for polymers with different architectures differs from the ideal value, obtained for monomers at low concentrations.

Polyelectrolyte and polyampholyte microgels of different topologies have been investigated using constant pH-Monte Carlo simulations. Ionisation, swelling as well as the uptake and release of guest molecules were studied. [1-5]

Especially, the interaction with guest molecules is an important aspect for the use of microgels for drug delivery.

Beyond electrostatic screening: Effect of ion pairing on acid-base equilibria in complex electrolyte solutions — •Varun Mandalaparthy[1], Johannes Hunger[2], Mischa Bonn[2], and Nico van der Vegt[1] — [1]Technical University, Darmstadt — [2]Max Planck Institute for Polymer Research, Mainz

The modulation of acid-base equilibria by salts is central to solution chemistry, yet the molecular origins of these effects in multi-component electrolyte mixtures remain incompletely understood. Building on evidence that individual salts induce ion-specific shifts in the pKa values of weak acids, we combine experiments with constant-pH molecular dynamics simulations to examine how ion pairing and specific ion interactions regulate the pKa of acetic acid in single and mixed sodium salt solutions. Across anions of differing charge density (sulfate, chloride, iodide), we show that cation-anion association-rather than electrostatic screening alone-governs the observed pKa changes. In solutions containing mixtures of sodium chloride and sodium sulfate, the impact on acetic acid pKa deviates from simple additivity because of complex ion-ion interactions. We present an ion-pairing-enhanced Debye-Hückel model that quantitatively reproduces these behaviors, offering a predictive framework for pH regulation in multi-salt environments. This work provides a mechanistic foundation for interpreting and forecasting pH-dependent behavior in complex systems relevant to biochemistry and soft matter.

CPP 13.3 Mon 15:45 ZEU/0260

How polymer chain flexibility influences orientation and entanglements in polyelectrolyte solutions — Sascha Bartosch and •Ulrich Scheler — Leibniz-Institut für Polymerforschung Dresden e.V.

Entanglements in long-chain polymers are important for their mechanical properties and strongly impact the processability. In solutions the formation of entanglements depends on chain length, concentration and the chain flexibility. The flexibility of polyelectrolyte chains is influenced by the ionic strength of the solution that may screen the repulsive electrostatic interaction along the chain. That is reflected in the variation of the hydrodynamic radius of the polyelectrolytes measured by diffusion NMR. Upon shear polymers can orient or polymer chains maybe pulled out of entanglements. The NMR transverse relaxation time T2 is a good measure for the slow polymer-chain dynamics affected by polymer entanglements. Aligning polymer chains results in a shortened T2 while the loss of entanglements yielding longer chain segments between entanglements results in a longer T2. Short-chain polyelectrolytes under shear in a Searle cell show chain orientation. Long-chain polyelectrolytes at low ionic strength orient as well, while at higher ionic strength a loss of entanglements is observed. The transition from stiff to flexible entangled polymer is triggered solely by the electrostatic interaction modulated by the ionic strength under experimental control.

CPP 13.4 Mon 16:00 ZEU/0260

Molecular Mechanisms Underlying LCST and UCST Transitions in Thermoresponsive Ionic Liquids — •Hussen Oumer Mohammed[1,2], Abel De Cozar[1,2], and Ronen Zangi[1,2] — [1]Donostia International Physics Center (DIPC), Donostia, Spain — [2]University of the Basque Country UPV/EHU, Donostia, Spain

We investigate liquid-liquid phase separation (LLPS) of ionic liquid (IL)-water mixtures through atomistic MD simulations. Two model systems are studied: [P_{4444}] [TMBS], which exhibits a lower critical solution temperature (LCST) phase separation, and [Hbet][Tf_2N], which displays an upper critical solution temperature (UCST) behavior.

Aiming to elucidate the driving forces governing the two types of phase separation, we performed a detailed analysis of energy decompositions, HB networks, and microstructural organizations. We find that for [P_{4444}][TMBS]/water phase demixing, increasing temperature weakens IL-water HB, augments the enthalpic penalty of hydration, and favors ion pairing and mesoscale segregation. Conversely, for [Hbet][Tf_2N]/water demixing, cooling enhances water self-networking and suppresses ion hydration, promoting like-like association, while heating disrupts the water network and re-establishes miscibility through stronger ion-water HB.

By shedding light on these molecular-level mechanisms underlying those behaviors in distinct ILs, this study offers a predictive simulation-based framework for the rational design of thermoresponsive draw solutes in FO desalination, enabling tunable and energy-efficient regeneration cycles.

CPP 13.5 Mon 16:15 ZEU/0260

Machine-Learning Prediction of Ionic Conductivity from Short-Time Structural Data in Ionic Liquids — •David Bienek — Helmholtz-Institut Münster, Münster, Germany

Molecular dynamics (MD) simulations are a powerful tool for studying electrolyte materials, but the reliable calculation of ionic conductivities and transference numbers requires long trajectories. In this project, we explore whether machine-learning (ML) models can predict dynamic properties of ionic liquids (ILs) from structural information obtained in much shorter simulations. ILs are chosen as model systems because prior work has demonstrated links between structure and hydrodynamic behaviour. Their simple cation-anion composition also allows systematic generation of simulated systems. As structural descriptors, we employ radial distribution functions (RDFs), which are physically interpretable.

We test linear regression, random forests, and neural networks for predicting ionic conductivity. After feature engineering we find substantial improvements in accuracy. A peak-based representation proves particularly helpful for identifying structure-dynamics relations. Feature-importance analyses consistently indicate that the dominant information originates from the first coordination shell. Moreover, simpler models (random forest, linear regression) outperform neural networks, highlighting the necessity to use appropriate model complexity. Overall, our results show that ML can support the identification of structure-dynamics correlations in electrolytes and may help estimate transport properties from short MD trajectories.

CPP 13.6 Mon 16:30 ZEU/0260

Dissociation of weak polyacid systems in solution and brush coatings determined by IR titration — •Martin Müller[1,2], Luise Wirth[1,2], Birgit Urban[1], Leo Dagand[1,2], Alexander Münch[1], and Petra Uhlmann[1] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., Hohe Str. 6, Dresden D-01069, Germany — [2]Technische Universität Dresden, Dresden D-01062, Germany

The dissociation degrees a of poly(acrylic acid) (PAA) and propionic acid (PA) solutions were determined by infrared (IR) titration and potentiometric (POT) titration concept. Stepwise increasing pH value from 2 to 12 by adding NaOH portions, IR spectra of PAA and PA show decrease of n(C=O) band due to carboxyl (COOH) and increase of n(COO-) band due to carboxylate (COO-) groups. From the respective normalized band integrals A, dissociation degree was calculated according to a=A(COO-)/(A(COOH)+A(COO-)). Plotting pH versus a and fitting by modified Henderson-Hasselbalch equation according to pH=pKa+B*log(a/(1-a)) the parameters pKa and B were determined. The slight pKa deviation found for IR and POT titration, the respective deviation between monomeric PA and polymeric PAA and the PAA molecular weight trend (PAA-2K, PAA-50K, PAA-450K) are discussed considering the two-phase model of polyelectrolyte solutions and Gibbs-Donnan theory. Furthermore, a and pKa of thin PAA brush coatings under aqueous ambient and the influence of metal ion type (Na+, Ca++, Ce+++) and concentration were determined by FTIR titration revealing higher pKa values compared to solution state and significant effects of ion valency on a.

CPP 13.7 Mon 16:45 ZEU/0260

Unconventional Layer-by-Layer Assembly of Films with PEDOT: Write, Read, and Delete — •Muhammad Khurram, Martin Hunger, and Christiane A. Helm — muhammad.khurram@uni-greifswald.de

PEDOT:PSS films are widely used because they offer high conductivity & tunable electro-optical properties. We present an unconventional layer-by-layer (U-LbL) method for PEDOT:PSS/PDADMA multilayers. Masking was used to create either homogeneous coatings or narrow conductive strips. Each bilayer is only 7-9 nm thick, indicating that films form by adsorption of PSS-linked PEDOT, with unbound nanoparticles removed during rinsing. Flow-cell produces higher conductive films (260 kS/m) than dip coating. The U-LbL process also provides a natural framework for repeated Write/Read/Delete modulation, including PEDOT addition, partial & controlled PEDOT removal, forming molecular cavities that rebind PEDOT & restore percolative pathways.

Lateral interactions in Bisphenol A adsorption on Carbon Nanotubes — •Oliver Cunningham and David Wilkins — Queen's University Belfast, Belfast, Northern Ireland

Endocrine disrupting chemicals (EDCs) such as Bisphenol A (BPA) are being found in water supplies with increasing frequency and our methods of water treatment need to improve alongside this ever increasing problem to mitigate the risks they pose to human health. Molecular Dynamics paired with enhanced sampling methods such as Metadynamics have proven to be very effective at studying the free energy profiles for processes like adsorption. To this end we present the effects lateral interactions between BPA molecules have on their adsorption onto a single walled carbon nanotube (SW-CNT) and how this depends on the number of BPA. The free energy of adsorption is studied as it gives insight into how well a SW-CNT adsorbs BPA and therefore how effective it is at removing it from water. Studying the free energy of adsorption for systems with varying numbers of BPA, we find that the free energy of adsorption increases with the number of BPA. This shows that lateral interactions between BPA molecules have a noticeable effect on how well they adsorb on the surface. We find two free energy minima corresponding to different conformations of the BPA, and the energy barrier between these minima decreases with the number of BPA. We also show that Parallel Bias Metadynamics provides an efficient way to bias all of the BPA in a system, providing better statistics than individually biased runs, while still achieving free energy's adsorption in agreement with the individual runs.

CPP 14.2 Mon 17:30 ZEU/LICH

Multiscale Modeling of Grain Boundary Effects on Charge Transport in Pentacene — •Sonali Garg, Farhad Ghalami, and Marcus Elstner — Karlsruhe Institute of Technology, Karlsruhe, Germany

Organic semiconductors have emerged as crucial materials in the development of electronic and optoelectronic devices due to their exceptional mechanical flexibility, lightweight nature, and cost-effectiveness. However, the presence of grain

boundaries (GBs) can significantly impede device performance by introducing structural defects that affect charge-carrier movement and reduce mobility. In this study, we developed a model to investigate the influence of GB characteristics, including misorientation angles and GB width, on charge carrier mobility, and compare the results with intrinsic mobility. Non-Adiabatic Molecular Dynamics (NAMD) simulations, employing the Fewest Switches Surface Hopping (FSSH) approach[1,2,3] were used to model charge transport dynamics. The charge transfer Hamiltonian was constructed using a fragment orbital approach, with its elements computed via the Density Functional Tight Binding (DFTB) method[4,5]. These insights provide a deeper understanding of the effects of GBs on charge-carrier mobility in organic semiconductors.

CPP 14.3 Mon 17:45 ZEU/LICH

A classical model to describe the electric potential-dependent water structure at metal interfaces — •Damien Toquer[1], Henrik Stooss[1], Philipp Stärk[1,2,3], and Alexander Schlaich[1] — [1]Institute for Physics of Functional Materials, Hamburg University of Technology, 21073 Hamburg, Germany — [2]Institute for Computational Physics, University of Stuttgart, 70569 Stuttgart, Germany — [3]SC Simtech, University of Stuttgart, 70569 Stuttgart, Germany

Nano- and microfabrication enable the development of functional materials tunable across length scales. While atomistic simulations are a powerful tool for studying and designing such materials bridging atomic-to-macroscopic properties remains challenging. The electrode/water interface exemplifies this challenge, explicit electronic treatment limits simulation scalability. Various schemes have been proposed that aim to incorporate metallic electronic response into classical molecular dynamics. Recently, the constant potential method has shown promise, where charges are attached to the metal atoms to maintain a fixed electrode potential. Our goal is to develop an efficient classical model that reproduces interfacial water structure across various electrode potentials, using gold surfaces as a prototype. Gold charges are adjusted to capture long-range continuum electrostatic interactions, while short-range interactions are tuned to match ab initio energy calculations. We anticipate this model will reliably predict interface-dependent thermodynamic properties both at equilibrium and under applied electrode potential, and plan to use it to study electrowetting in parallel with experimental work.

CPP 14.4 Mon 18:00 ZEU/LICH

Acoustic Effects in Electrolytes with Interfaces: Mechanistic Insights from MD Simulations — •Katharina Kintrup[1], Youssef Mabrouk[1,2], Diddo Diddens[1,3], and Andreas Heuer[1] — [1]Universität Münster, Institut für Physikalische Chemie, Deutschland — [2]Friedrich-Schiller-Universität Jena, Institut für Physikalische Chemie, Deutschland — [3]Helmholtz-Institut Münster, Deutschland

Interfaces such as electrodes strongly affect transport and dynamics in electrolytes. However, Molecular Dynamics (MD) simulations often assume periodic boundary conditions (pbc), thereby neglecting interfacial effects. This enforces a fixed center-of-mass frame in simulations, whereas electrophoretic NMR (eNMR) experiments [1,2] have shown that, in laboratory electrolytes, the center of mass drifts and local volume conservation is the appropriate assumption.

To mimic laboratory conditions, we introduce explicit interfaces in MD simulations and employ external fields for comparison with eNMR. As expected, we also observe a drift of the center of mass, but we do not find ideal local-volume conservation. Instead, we obtain oscillatory signals that reveal a strong dominance of acoustic effects over the intrinsic ionic dynamics. For binary electrolytes, we formulate a theoretical description that accurately incorporates the finite compressibility of the fluid. Overall, our work provides spatial and temporal insights into electrolyte dynamics in the presence of interfaces and highlights the importance of the chosen reference frame. [1] J. Phys. Chem. Lett. 2022, 13, 37, 8761-8767; [2] ACS Appl. Polym. Mater. 2025, 7, 13, 8432-8444

CPP 14.5 Mon 18:15 ZEU/LICH

Understanding electrode/electrolyte interfaces for electrocatalysis using constant potential DFT simulations — •Henrik Stooss[1], Philipp Stärk[2], and Alexander Schlaich[1] — [1]Institute for Physics of Functional Materials, Hamburg University of Technology, 21071 Hamburg — [2]Institute for Computational Physics, Universität Stuttgart, 70569 Stuttgart

This study explores the complex dynamics at electrode/electrolyte interfaces under constant potential, which is crucial for advancing electrocatalysis and designing efficient energy systems. We combine advanced computational techniques to gain insights into the mechanisms at these interfaces. Specifically, we perform Density Functional Theory (DFT) simulations of interfacial systems while maintaining a constant electrode potential. Despite the associated challenges and computational costs, these simulations provide valuable insights into the electronic structure and behavior of electrode surfaces. We calculate IR spectra of water in front of a gold electrode at different applied potentials and compare the results with experimental ATR-SEIRAS data, thereby strengthening the connection between first-principles calculations and experimental observations for material design.

CPP 14.6 Mon 18:30 ZEU/LICH

Atomistic modeling of azopolymers: light-induced deformation — •Dmitry Ryndyk[1,2], Olga Guskova[1], and Marina Saphiannikova[1,2] — [1]Leibnitz Institute of Polymer Research Dresden, Germany — [2]Technische Universität Dresden, Germany

In our recent study [1], we employ, for the first time, a fully atomistic force-field approach to model light-induced deformations in side-chain azopolymers. To mimic sample illumination, we introduce an orientation potential that reorients the azo chromophores perpendicular to the light polarization direction. This strategy enables us to capture both the microscopic details of chromophore behavior and the collective, anisotropic response of the polymer matrix. The atomistic simulations show a clear correlation between chromophore reorientation and sample contraction, as well as between backbone alignment and sample elongation. The separation of time scales between these two processes is controlled by the relative distance to the glass-transition temperature. Furthermore, the simulations elucidate a role of the flexible spacer in transferring the light-induced torque to the polymer backbone.

CPP 14.7 Mon 18:45 ZEU/LICH

Self-Assembly of Porphyrin-Based Monomers into Supramolecular Polymers — •Mira Mors[1], Hanna Rieger[2], Oliver Stach[2], Thomas Speck[1], and Pol Besenius[2] — [1]Institute for Theoretical Physics IV, University of Stuttgart, Germany — [2]Department of Chemistry, Johannes Gutenberg-University Mainz, Germany

Through a combination of computational modeling and experiments, we investigate the assembly pathways of water-soluble supramolecular porphyrin-peptide amphiphiles. Our computational approach employs a coarse-grained, nine-bead planar model that captures the essential molecular interactions. Simulations show that stronger interactions promote polymerization, whereas increased monomer flexibility hinders it, consistent with experiments in which an additional glycine is introduced into the peptide arms. The observed power-law dependence of the polymerization half-time suggests a nucleation-elongation-aggregation pathway; however, experiments show no concentration-dependent aggregation. To probe oligomer stability, we apply a simplified free energy model and enhance sampling by generating a grand canonical system to map free energies across cluster sizes. Aggregation kinetics are additionally studied by solving the rate equations explicitly and using moment-based approaches. These analyses reproduce the dynamics from low to high interaction strengths, highlighting the vital role of recombination in the polymerization regime. Overall, our results provide a framework for a better understanding of supramolecular polymerization under varying conditions.

CPP 15: Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods II

CPP 15.1 Mon 17:15 ZEU/0255

Deep Learning-Driven Grazing Incidence Small-Angle X-ray Scattering Data Processing for Nanostructure Characterization — •Yufeng Zhai[1], Jungui Zhou[1], Shachar Dan[1], Julian Heger[2], Benedikt Sochor[1,3], Arno Jeromin[4], Wenbo Wang[5], Wolfgang Parak[5], Sarathlal Koyiloth Vayalil[1,6], Thomas Keller[4,5], Andreas Sitierle[4,5], Alexander Hexemer[3], Peter Müller-Buschbaum[2], and Stephan V. Roth[1,7] — [1]DESY, Hamburg, Germany — [2]TUM, Garching, Germany — [3]ALS/LBNL, California, United States — [4]CXNS, Hamburg, Germany — [5]UHH, Hamburg, Germany — [6]UPES, Dehradun, India — [7]KTH Stockholm, Sweden

Nanostructured thin films formed via nanoparticle deposition or self-assembly exhibit diverse morphologies that are crucial for their functional properties. Grazing-incidence small-angle X-ray scattering (GISAXS) provides detailed structural information on such systems, but conventional model-based fitting remains limited by simplified assumptions and convergence difficulties. We employ the distorted wave Born approximation (DWBA) to simulate a wide range of two-dimensional GISAXS patterns, which are used to train convolutional neural networks (CNNs) for predicting nanoparticle size distributions. The trained models demonstrate robust performance on both simulated and experimental data, providing a faster and more flexible alternative to traditional fitting. In ad-

dition, we have developed a graphical user interface (GUI) that integrates conventional fitting routines with our deep learning framework, providing a user-friendly platform for rapid GISAXS analysis.

CPP 15.2 Mon 17:30 ZEU/0255

Chirp-DMA for expanded frequency and reduced aging — •Juan Pablo Segovia Gutiérrez[1], José Alberto Rodríguez Agudo[2], Jan Haeberle[2], Dominic Oppen[2], Jörg Läuger[2], and Natalie Germann[1] — [1]University of Stuttgart, Stuttgart, Germany — [2]Anton Paar Germany GmbH, Ostfildern, Germany

Optimal Fourier Rheometry (OFR), or Chirp rheometry, is an advanced technique that uses a continuous, sine wave-shaped stress/strain signal characterized by an exponential frequency increase. This approach is important for measuring rapidly time-evolving soft materials, where conventional frequency sweeps are impractical; their slow, sequential data acquisition often fails to capture fast structural changes before the material itself mutates. A key advantage of Chirp is its ability to drastically reduce measurement time, making it highly effective at low and very low frequencies. This speed is essential to circumvent undesirable material aging, for instance in the dehydration observed in hydrogels, which modifies properties during long acquisition times. Conventionally, Chirp has been implemented using standard plate-plate geometries. The novelty of this study is the implementation of Chirp within a Dynamic Mechanical Analysis (DMA) setup utilizing extension and torsion modes. This permits the characterization of soft, fragile materials outside the typical rheometer configuration. By combining this novel Chirp-DMA approach with conventional sweeps on gellan gum/alginate hydrogels, we extend the practical frequency range and prove that Chirp recovers true viscoelastic moduli, thereby eliminating dehydration-induced effects.

CPP 15.3 Mon 17:45 ZEU/0255

PIERS-Based Mechanistic Insights into PVC Micro- and Nanoplastics Degradation on Ag Nanoflake-TiO2 Platform — •Olugbenga Ayeni[1], Josiah Ngenev Shondo[2], Tim Tjardts[3], Sinan Şen[4], Franz Faupel[3], Salih Veziroglu[3], Oral Cenk Aktas[3,4], and Tayebeh Ameri[1] — [1]Chair for Composite Materials, Department of Materials Science, Kiel University, Germany. — [2]Department of Energy Conversion and Storage, Technical University of Denmark, Denmark. — [3]Chair for Multicomponent Materials, Department of Materials Science, Kiel University, Germany. — [4]Department of Orthodontics, University Hospital of Schleswig-Holstein (UKSH), Kiel, Germany.

Conventional characterization techniques such as FTIR and SERS have been applied to Polyvinyl chloride (PVC) micro- and nanoplastics (MNPs) degradation, but they lack the combined real-time sensitivity and photocatalytic functionality needed to probe early-stage PVC-MNPs degradation. In this work, we report the use of Photo-induced enhanced Raman spectroscopy (PIERS) technique under continuous UV illumination to monitor the degradation of PVC-MNPs in real time on a highly active photocatalytic platform based on Ag nanoflakes (Ag NFs) grown on TiO2 thin films. Our PIERS-based approach reveals the chemical transformations and structural disorder occurring in the PVC-MNPs backbone within 10 min of UV irradiation. Our results establish PIERS as a promising mechanistic probe for tracking real-time PVC degradation pathways at the nanoscale. This study advances the mechanistic understanding of plastic degradation at the nanoscale.

CPP 15.4 Mon 18:00 ZEU/0255

Exploring Colloidal Kinetics Using DLS — •Mohit Agarwal and Jiaxing Sun — Swabian Instruments GmbH, Stuttgart, Germany

The kinetic behavior of colloidal and soft matter systems arises from particle diffusion, aggregation, and structural rearrangement, which collectively determine how microstructures evolve over time. Accurate characterization of these dynamics is crucial for understanding nonequilibrium phenomena such as gelation, crystallization, and phase separation in complex fluids. Conventional experimental techniques often lack the temporal and angular resolution needed to resolve these fast and heterogeneous processes in their native state, especially when multiple relaxation mechanisms coexist. We present a time-resolved, multi-angle Dynamic Light Scattering (DLS) technique that records individual photon arrival events in real-time across multiple scattering angles. This configuration enables angle-dependent temporal correlation analysis with improved sensitivity to both short-time diffusive motions and long-time relaxation processes that reflect evolving particle interactions. By employing complete photon statistics rather than time-averaged intensity correlations, the method captures transient fluctuations and kinetic transitions in colloidal suspensions. Measurements on well-defined colloidal dispersions reveal subtle temporal variations in particle dynamics and aggregation behavior that remain inaccessible with conventional single- or multi-angle goniometer-based DLS. The technique establishes a robust framework for real-time, multi-scale investigation of kinetic processes in colloidal and soft matter systems.

CPP 15.5 Mon 18:15 ZEU/0255

The Power of One Oxygen: How a Single Atom Alters the Field Evaporation of Liquid Crystals — •Kuan Meng, Sebastian Eich, and Guido Schmitz — University of Stuttgart, Institute for Materials Science, Heisenbergstr. 3, 70569 Stuttgart, Germany

In this study, we established a cryo-atom probe tomography (cryo-APT) workflow to investigate how the presence of a single oxygen atom alters the field evaporation behavior of two structurally similar liquid crystals: 8CB and 8OCB. Both compounds exhibited over 70% intact molecular retention and comparable fragmentation patterns.

Mass spectra revealed that the oxygen in 8OCB hinders the formation of extended cyanobiphenyl fragments across the linkage and promotes full cleavage of the alkyl chain. In contrast, 8CB allows the formation of longer backbone fragments. Spatially, 8CB evaporated mainly as intact molecules across both crystalline and smectic domains. 8OCB, however, evaporated predominantly as small fragments in low volume-density domains while as larger fragments or intact molecules in the high volume-density regions, which are suspected to crystalline and smectic phases, respectively. Further structural validation is required.

This work illustrates how cryo-APT enables the characterization of the molecular structure of organic liquid systems and demonstrates that even a single oxygen atom can fundamentally alter their field evaporation pathways. It further proposes a tunable fragmentation strategy to investigate molecular orientation in soft matter at an unprecedented resolution.

CPP 15.6 Mon 18:30 ZEU/0255

Depth-resolved cathodoluminescence for mapping exciton diffusion in rubrene thin film polymorphs — •Heiner Thiersch[1,2], Jonas Schröder[1], Anna-Lena Hofmann[1], Wooik Jang[1], Nora Engelmann[1], Fritz Henke[1], Maximilian F. X. Dorfner[3], Shu-Jen Wang[4], Frank Ortmann[3], Johannes Benduhn[1,2], Ellen Hieckmann[1], and Karl Leo[1] — [1]IAPP, TU Dresden, Germany — [2]DZA Görlitz, Germany — [3]Dep. of. Chem., TU München, Germany — [4]Dep. of. Phys., HKBU, China

The exciton diffusion length (L_D) is a key parameter in opto-electronic devices, as it governs the transport and recombination of photo-generated excitons. However, accurately measuring L_D remains challenging due to the limited penetration depth and lateral resolution of conventional techniques such as photoluminescence quenching and transient absorption spectroscopy. Here, we will introduce a novel approach for L_D determination based on quenching processes observed by depth-resolved cathodoluminescence (CL) measurements with highly localized excitation. The method combines CL experiments with kinetic Monte Carlo simulations and a diffusion model derived from Fick's second law. Applied to the organic semiconductor rubrene- renowned for its high hole mobility in single crystals- the technique yields L_D values ranging from 50 to 100 nm across different thin-film polymorphs. The results provide new insights into the exciton dynamics of rubrene and present a new methodological tool for accurate L_D characterization in semiconductors.

CPP 15.7 Mon 18:45 ZEU/0255

Towards Theoretical UV/Vis Spectra with Experimental Accuracy - Functional Errors and Thermal Broadening — •Robert Strothmann[1], Johannes T. Margraf[2], and Karsten Reuter[1] — [1]Fritz-Haber-Institut, Berlin, Germany — [2]University of Bayreuth, Bayreuth, Germany

First principles methods like time-dependent density-functional theory (TD-DFT) can be used to predict molecular UV/Vis spectra relying on a number of approximations such as the choice of functionals, the description of solvation, as well as the treatment of thermal broadening. For the latter, simple (smeared) line spectra or structural ensembles obtained within the harmonic approximation are the most common choices. With the rise of machine learning interatomic potentials (MLIP) prohibitively costly *ab initio* molecular dynamics (MD) simulations can be replaced with similarly accurate MLIP MDs. This allows a detailed comparison of these approaches for a large number of systems for the first time.

In this talk, we benchmark predicted UV/Vis spectra against experimental references. To this end, the agreement with a curated set of literature reported spectra for diverse organic molecules in various solvents is assessed in terms of full spectral overlap, beyond a "peak to peak" comparison. We emphasize the influence of functional choice and thermal sampling approaches (e.g. harmonic vs. anharmonic), as well as the role of different conformers. How important each of these effects is and how it affects computational cost will be studied with the goal of providing best practise guidelines.

CPP 16: Energy Storage Materials and Devices II

Time: Monday 17:15–19:00 Location: ZEU/0260

Invited Talk CPP 16.1 Mon 17:15 ZEU/0260

Understanding the Passivation Properties of Solid Electrolyte Interphases (SEIs) in Batteries: Generator-Collector Experiments combined with a Transport and Reaction Model — •Bernhard Roling, Falk Krauss, Annalena Duncker, and Isabel Pantenburg — Department of Chemistry, University of Marburg, Germany

The solid electrolyte interphase (SEI) is a passivation layer in lithium-ion batteries, which has a strong impact on the battery lifetime. The SEI is formed by reductive decomposition of the electrolyte at the graphite particles of the anode during the first charging of the battery. The passivation of the SEI is not perfect, which leads to battery aging and to a reduced battery lifetime. The transport and reaction mechanism in the SEI governing the passivation properties are not well understood. Here, we elucidate transport and reaction processes during the formation of model-type SEIs by combining generator-collector experiments with a transport and reaction model. In the generator-collector experiments, we use a four-electrode-based setup to compare the electrolyte reduction current with a redox molecule reduction current at the SEI-covered electrode. We find that the current ratio depends on the SEI formation potential as well as on the formation time. The experimental results are compared to a transport and reaction model predicting four distinct transport and reaction regimes depending on the rate constant for the molecule-electron reaction. Using this combined approach, we obtain good estimates for the transport coefficients of both electrons and molecules inside the SEI.

CPP 16.2 Mon 17:45 ZEU/0260

Insight into SEI formation and dendrite growth in all-solid-state lithium metal batteries by Operando nWAXS — •Yingying Yan[1], Liangzhen Liu[2], Yuxin Liang[1], Lyuyang Cheng[1], Fabian A.C. Apfelbeck[1], Guangjiu Pan[1], Anton Davydok[3], Christina Krywka[3], Roland A. Fischer[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]TUM School of Natural Sciences, Chair of Inorganic and Metal-Organic Chemistry, Garching, Germany — [3]Helmholtz-Zentrum Hereon, Max-Planck-Str. 1, Geesthacht, Germany

Composite solid polymer electrolytes (CSPEs) have emerged as promising candidates for next-generation all-solid-state lithium batteries (ASSLBs). However, the limited ionic conductivity and poor interphase stability have seriously hindered their practical application. Herein, the anion-trapping layered double hydroxide (LDH) was introduced to enhance ionic conductivity and interfacial compatibility in poly(ethylene oxide) (PEO)-based CSPEs for stabilizing lithium metal anodes. Importantly, operando nano-focus Wide-angle X-ray scattering (nWAXS) was employed to spatially map the distribution of both the solid electrolyte interphase (SEI) layer and lithium dendrites across micron-scale lateral and vertical dimensions. Therefore, this study provides a novel strategy for designing high-performance CSPEs with stabilized interfaces and establishes an innovative approach for real-time visualization of SEI evaluation and dendrite growth in ASSLBs.

CPP 16.3 Mon 18:00 ZEU/0260

Temperature effects on the electrochemical behavior of graphite cathodes for aluminium-polymer batteries — •Mohammad Mostafizar Rahman, Mohammad Jony Rana, Shuvrodev Biswas, Amir Mohammad, Hartmut Stöcker, and Dirk C. Meyer — Institute of Experimental Physics, TU Bergakademie Freiberg, Leipziger Str. 23, Freiberg, 09599, Germany

This study assesses the performance of Aluminium-polymer batteries at variable temperatures between −20 °C and 80 °C. Pouch cells were constructed utilizing a solid polymer electrolyte (SPE) coupled with two different types of graphite cathode: mesocarbon microbeads (MCMB) and spherical graphite (SpG). Cyclic voltammetry and galvanostatic cycling with potential limitation measurements were conducted at different temperatures combined with variable current densities (25...100 mA/g). The results reveal that the resistance degradation below 0 °C is reversible, with performance being recovered when returning to positive temperatures. However, at moderately high temperatures above 60 °C, the degradation becomes permanent. MCMB cells operate effectively between −10 °C and 40 °C, while SpG cells function from 0 °C to 60 °C. The capacity of MCMB cells peaks at 20 °C at all current densities and then drops significantly at 60 °C. In contrast, SpG cells exhibit their highest capacities at 40 °C or 60 °C, followed by a rapid decline. Together with the good Coulombic efficiencies > 95 % both types of cells are proven suitable for varying environmental conditions.

CPP 16.4 Mon 18:15 ZEU/0260

X-Ray Absorption Near-Edge and Photoemission Spectroscopy of Deintercalation and Redox Reactions in Alluaudite-Type Na-Ion Cathodes — •Neama Imam[1], Karsten Henkel[1], Stephan Werner[2], Christoph Pratsch[2], Anna Milewska[3], Janina Molenda[3], Jan Ingo Flege[1], and Ehrenfried Zschech[1] — [1]Brandenburg University of Technology Cottbus - Senftenberg, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, BESSY II, Germany — [3]AGH University of Science and Technology, Krakow, Poland

We have investigated alluaudite-type $Na_{2.5-x}Fe_{1.75}(SO_4)_3$ cathodes that exhibit a three-dimensional open-channel framework with multiple Na sites. Using spatially resolved X-ray absorption near-edge spectroscopy (XANES), performed within a transmission X-ray microscope (TXM), and lab-based X-ray photoelectron spectroscopy (XPS), we have examined Na^+ deintercalation and Fe^{2+}/Fe^{3+} charge compensation at different selected charging states. This combination of bulk- and surface-sensitive methods allows correlating Na^+ depletion with Fe^{3+} formation, potentially identifying nanoscale redox heterogeneities and tracking changes in the local Na chemical environment. Our study builds on a broader investigation [1] that includes theoretical calculations as well as structural and electrochemical analyses.

[1] J. Molenda *et al.*, *Acta Mater.* **301**, 121582 (2025).

CPP 16.5 Mon 18:30 ZEU/0260

Understanding the Impedance Spectra of Composite Materials using a 3D Electrical Network Model — •Felix Schug[1,2], Sascha Kremer[2,3], Christian Heiliger[1,2], and Janis K. Eckhardt[1,2,3] — [1]Institute for Theoretical Physics, Justus-Liebig-University Giessen, Germany — [2]Center for Materials Research (ZfM), Justus-Liebig-University Giessen, Germany — [3]Institute of Physical Chemistry, Justus-Liebig-University Giessen, Germany

All-solid-state batteries (ASSBs) are promising candidates for next-generation energy storage systems, offering enhanced energy density and safety compared to conventional lithium-ion batteries. Electrochemical Impedance Spectroscopy (EIS) is a powerful method for determining charge transport characteristics in these systems. However, the presence of multiple phases, each with distinct transport processes, as well as complex microstructures result in complex impedance spectra that are challenging to interpret.

To address this challenge, we use a microstructure-resolved 3D electrical network model to simulate charge transport on microscopic length scales. This approach enables us to disentangle the contributions of different transport processes and microstructural features to the impedance response. Our model offers insights into the local potential and current distributions influenced by material heterogeneities, directly connecting them to impedance signals. We provide insights into the impedance of composite materials, identifying the key factors that dominate the impedance signal.

CPP 16.6 Mon 18:45 ZEU/0260

Dual-Ion $AlCl_4^-$ / $AlCl_2^+$ Charge Storage Mechanism in Composite Cathode for Aluminum-Polymer Batteries — •Shuvrodev Biswas, Thomas Köhler, Amir Mohammad, Hartmut Stöcker, and Dirk C. Meyer — Institute of Experimental Physics, TU Bergakademie Freiberg, Leipziger Str. 23 09599 Freiberg, Germany

Rechargeable aluminum batteries have emerged as a promising post-lithium-ion technology. Graphite, the most widely used cathode that relies on $AlCl_4^-$ intercalation, offers limited capacity, whereas organic cathodes, such as phenanthrenequinone (PQ), coordinate with $AlCl_2^+$ but suffer from limited cycling stability. Here, we design a composite (SPGPQ) consisting of spherical graphite (SPG) and PQ through melt diffusion, enabling dual-ion charge storage by coupling $AlCl_4^-$ intercalation with $AlCl_2^+$ coordination. FTIR, XPS, *in situ* XRD, and cyclic voltammetry using polyamide-6 (PA6) electrolytes (SPE) provide clear evidence of this synergistic mechanism. Whereas the PA6-SPE limits capacity due to low ionic conductivity, the higher-conductivity polyacrylonitrile (PAN)-based SPE delivers improved capacity but shows limited cycling stability. To enhance stability, we further developed an ACPQ+SPG composite through solvent-assisted impregnation using activated carbon (AC). This composite features an identical mechanism to SPGPQ, while offering significantly enhanced capacity and stable long-term cycling.

CPP 17: Poster I

Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates; Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics; Energy Storage Materials and Devices; French-German Session: 2D Materials, Thin Films and Interfaces; Wetting, Fluidics and Liquids at Interfaces and Surfaces

Time: Monday 19:00–21:00 Location: P5

CPP 17.1 Mon 19:00 P5

How do interfaces shape molecular conformations in condensates? — •Nora-Elen Giesinger[1] and Arash Nikoubashman[1,2] — [1]Leibnitz-Institut für Polymerforschung, Dresden, Germany — [2]Technische Universität Dresden, Dresden, Germany

The interface between biomolecular condensates and their surrounding environment plays an important role for, e.g., regulating the condensate's stability and interactions with other cellular components. These interfacial properties are primarily dictated by the density and conformation of the constituent biomolecules, but it remains experientially challenging to resolve interfacial properties on the molecular level. Further, the conformations of the constituent biomolecules are influenced by many intertwined factors like sequence patterning, electrostatics, and chain-length diversity. To understand how polymer conformations evolve from the dense condensate interior through the interfacial region into the surrounding dilute phase, we use a minimal model of fully flexible homopolymers. To disentangle effects arising from chain ends, we examine condensates formed from both linear and ring polymers. Molecular dynamics simulation show that polymers gradually collapse as they transition from the bulk-like interior of the condensate to the surrounding dilute aqueous phase. Notably, the condensate interface induces a highly non-monotonic structural crossover between the dense and dilute regions, irrespective of the polymer architecture: the side facing the interface flattens, while the inward-facing side is also compressed. As a result, the monomer cloud loses its spherical symmetry, and chains tend to align tangentially along the interface.

CPP 17.2 Mon 19:00 P5

Effects of Activity on Polymeric Condensates — •Rahul Yadav[1] and Arash Nikoubashman[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., 01069 Dresden, Germany — [2]Institut für Theoretische Physik, Technische Universität Dresden, 01069 Dresden, Germany

Biological systems are inherently out of equilibrium as external sources of energy are constantly consumed; for example, microtubules and filamentous actin seemingly move through the cytoplasmic matrix via the continuous addition and removal of subunits. At the same time, equilibrium thermodynamic properties, governed by the interactions and length scales of the (macro)molecular constituents, play a central role in phenomena such as the formation of biomolecular condensates. A central open question is whether such non-equilibrium activity enhances phase separation or, conversely, hinders it. To answer this, we performed molecular dynamics simulations of a bead-spring polymer model, systematically varying both the attrac- tion strength and activity. When the active forces act along the contour of the polymer, the miscibility gap narrows and the critical temperature decreases with increasing activity, indicat- ing that this form of activity opposes phase separation. Based on these observations, we expect that contractile active forces will instead broaden the miscibility gap and increase the critical temperature, and we plan to test this prediction in future work.

CPP 17.3 Mon 19:00 P5

Using the Patchy Particle Model to simulate Biomolecular Condensates — •Mubarrat Mursalin[1,2], Simon Dannenberg[1], and Stefan Klumpp[1,2] — [1]Georg August University Göttingen — [2]Max Planck School of Matter to Life

Biomolecular condensates are formed through liquid-liquid phase separation (LLPS) of proteins, often together with nucleic acids, typically driven by low-affinity interactions. Phase separation allows biological systems to spatially organize molecules for biological functions. Theoretical studies of LLPS are usually based on continuum descriptions of fluids, which allows access to the biologically relevant time and length scales, but neglects all molecular details of the interactions, which implements their genetic programmability and determines the local structure of the condensates. Here, we use the coarse grained patchy particles to simulate LLPS, which provides an intermediate level of description between atomistic MD and continuum descriptions, thus allowing to access systems large enough to describe droplets and still retain a coarse-grained picture of the local structure inside the condensate. We look at the effects of repulsive crowding particles on the critical values, dynamics and structures of biomolecular condensates formed by three patch patchy particles. Using NVT simulations, combined with the direct coexistance method, we study the effects of crowder concentration and size, and recreate the known depletion and excluded volume effects.

CPP 17.4 Mon 19:00 P5

Partial demixing of RNA Polymerase II condensates in transcription regulation — Arya Changiarath[1], Rosa Herrera Rodriguez[1], Jasper Michels[3], Friederike Schmid[1], Jan Padeken[2], and •Lukas Stelzl[1,2] — [1]Johannes Gutenberg University Mainz — [2]Institute of Molecular Biology (IMB) — [3]Max Planck Insitute for Polymer Research

Phase-separated condensates may spatio-temporally regulate RNA polymerase II (Pol II) during the transcription of genes. Distinct condensates may underpin the two key stages of transcription, initiation and elongation. However, it remains unclear whether these condensates mix or maintain distinct chemical environments. To investigate this, we combined multi-scale molecular dynamics simulations with experiments in C. elegans. We identified a lower critical solution temperature (LCST) behavior for Pol II, where higher temperatures promote condensation. This behavior correlates with an incremental transcriptional response to temperature but is largely uncoupled from the classical heat stress response. Our simulations demonstrate that the phosphorylation state of the disordered CTD controls the demixing of CTD and pCTD, resulting in full or partial engulfment depending on composition. Remarkably, we observe such partially-demixed of RNA polymerase II condensates by super resolution microscopy of C. elegans embryos. Overall, our results suggest that partially demixed condensates provide distinct chemical environments and binding platforms to facilitate transcription initiation and elongation.

CPP 17.5 Mon 19:00 P5

Optimization of Slot-Die Printed Organic Solar Cells — •Dinusha M. Egalla, Christoph G. Lindenmeir, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany

Organic solar cells (OSCs) are promising candidates for lightweight, flexible, and low-cost photovoltaic technologies due to their solution processability and compatibility with large-area printing. The performance and stability of printed OSCs, however, are highly influenced by the morphology and uniformity of the active layer, which are sensitive to changes in coating and processing conditions. In this work, we investigate the optimization of printed donor-acceptor active layers by systematically varying key fabrication parameters, including coating temperature, printing speed, and solution preparation. The resulting thin films are characterized using UV-Vis spectroscopy to evaluate optical absorption, and microscopy to investigate the film homogeneity, while X-ray reflectivity (XRR) is used to determine film thickness and roughness. Full devices are built and assessed through current-voltage (J-V) measurements under standard illumination to establish how different printing conditions affect active-layer morphology and overall photovoltaic performance.

CPP 17.6 Mon 19:00 P5

Tuning Two-Photon Absorption Cross Sections in Azaacene Diradicals — •Gabriel Sauter[1], Antonia Papapostolou[2], Julia Weyandt[1], Pascal Merten[3], Kerstin Brödner[3], Uwe H. F. Bunz[3], Andreas Dreuw[2], and Petra Tegeder[1] — [1]Physikalisch-Chemisches Institut — [2]Interdisziplinäres Zentrum für Wissenschaftliches Rechnen — [3]Organisch-Chemisches Institut, Universität Heidelberg

Diradical bithiophene azaacenes have been shown as an outstanding class of nonlinear optical (NLO) materials with potential applications in bioimaging, photodynamic therapy, and 3D nanoprinting, while exhibiting exceptionally high two-photon absorption (2PA) cross sections exceeding 53000 GM [1]. Using a combined approach of experimental z-scan measurements and theoretical modeling, we analyzed the structure-property relationships governing NLO efficiency and tuning. Here especially the influence of diradical character, molecular extension, and sulfur substitution on the 2PA response was investigated. The results reveal fundamental insights into the synergy between molecular symmetry and electronic structure for optimizing the NLO responses. This enables a more targeted design of near-infrared active materials for photonic applications.

CPP 17.7 Mon 19:00 P5

Long Chain, Strong Gain: How SubPC side chains control the pseudoferroelectric bulk photovoltaic effect — •Kaspar Haas[1], Sophia Klubertz[1], Victor Rodriguez[2], David González-Rodríguez[3], Miguel García Iglesias[2], and Martijn Kemerink[1] — [1]Universität Heidelberg, Heidelberg — [2]Universidad de Cantabria, Santander — [3]Universidad Autónoma de Madrid, Madrid

While most studies of the bulk photovoltaic effect (BPE) in recent years have focused on inorganic materials, this fascinating effect should also be observable in organics. In contrast to the conventional photovoltaic effect, the BPE voids the need for doping by utilizing an intrinsic symmetry breaking and could allow for wider absorption spectra while theoretically overcoming the Shockley-Queisser limit. Going organic holds the additional promise of lightweight, low-fabrication- and low-energy-cost devices, and, particularly, of a much greater tunability of the active material.

Here, we investigate organic molecules of the semiconducting π-conjugated SubPC-F family with the purpose of finding and quantifying a bulk photovoltaic effect. Combining electrical measurements with polarization optical microscopy (POM), XRD and AFM, we investigate the dipole alignment in these liquid crystalline materials, before assessing their photovoltaic performance under irradiation. We further build our own liquid crystal cells for measuring in out-of-plane structures to draw a connection between device thickness and performance. We also aim to quantify the influence of different side chain lengths on material properties like open-circuit voltage and photocurrent.

CPP 17.8 Mon 19:00 P5

Thin Films of Substituted Imidazoquinolines as Emitters for Blue OLED Devices — •Lasse Freitag[1], Pascal Schweitzer[1], Carina Rössiger[2], Thomas Oel[2], Richard Göttlich[2], and Derck Schlettwein[1] — [1]Justus-Liebig-Universität Gießen, Institut für Angewandte Physik, Heinrich-Buff-Ring 16, D-35392 Gießen — [2]Justus-Liebig-Universität Gießen, Institut für Organische Chemie, Heinrich-Buff-Ring 17, D-35392 Gießen

Organic semiconductors are routinely applied in microelectronics. Still challenging is the field of organic blue light emitting diodes (OLED), due to degradation of the emitters. We study the application of imidazoquinolines such as 4EstPhPh(iso)IC as emitters. Different substitutional patterns allow for tuning of their opto-electronic properties. We achieved thin films of 4EstPhPh(iso)IC via physical vapor deposition (PVD). Promising blue photo- and electroluminescence was found in solid state. Film formation at interfaces with contact materials was studied by in-situ Kelvin-probe force microscopy (KPFM). On the p-conducting poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) we found a Stranski-Krastanov (SK) growth of the emitter. X-ray diffraction (GI-XRD) confirmed a crystalline structure in these films, in line with single crystal data. Further, the growth of n-conducting bathocuproine (BCP) on the emitter layer was monitored by KPFM, revealing SK growth followed by formation of 3D crystalline islands. As a fundamental prerequisite, morphological stability at air was confirmed by microscopy. Therefore, we built OLED with varying thickness to find the best-performing layer stack.

CPP 17.9 Mon 19:00 P5

The aggregation of DPND dyes in the solid state studied by nuclear magnetic resonance spectroscopy — •Sascha Bartosch[1], Mohamed Bouajhine[2], Łukasz Kielesiński[3], Marieta Levichkova[4], Eva Bittrich[1], Petra Uhlmann[1], Patrick Brocorens[2], Martin Pfeiffer[4], Daniel T. Gryko[3], David Beljonne[2], and Ulrich Scheler[1] — [1]Leibniz-Institut für Polymerforschung Dresden e. V. - Dresden, Germany — [2]Laboratory for Chemistry of Novel Materials, University of Mons - Mons, Belgium — [3]The Institute of Organic Chemistry of the Polish Academy of Sciences - Warsaw, Poland — [4]Heliatek GmbH - Dresden, Germany

Dipyrrolonaphthyridinediones (DNPDs) have recently been introduced as a novel class of cross-conjugated dyes. Their promising photophysical properties make them a potential candidate for various applications. Although the packing type is expected to have an influence on the performance, their aggregation remains to be studied.

Solid-state NMR 1H-1H double-quantum-single-quantum correlation experiments are suitable to probe the spatial proximity of functional groups since it is based on short-range dipolar interactions between the spins. The proximity information is used for the understanding of the packing of molecules. Signals have been assigned by comparison of the experimental to simulated chemical shifts. Strong up-field shifts of aromatic protons induced by packing effects like pi-pi-interactions were observed, consistent with predicted crystal structures. Intermolecular homo couplings were used to identify different aggregation patterns.

CPP 17.10 Mon 19:00 P5

Influence of antisolvents and interfacial layers on charge carrier dynamics of hybrid perovskite films — •Leon Weintz[1], Patrick Dörflinger[1], Volodymyr Vasylkovskyi[1], Junmo Park[2], Hobeom Kim[2], and Vladimir Dyakonov[1] — [1]Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany — [2]Department of Materials Science and Engineering, Gwangju Institute of Science and Technology, 61005, Gwang-ju, Republic of Korea

Charge carrier behavior in perovskite thin films is crucial to their optoelectronic performance; yet, the impact of antisolvents and self-assembled monolayers (SAMs) on their basic charge carrier transport properties remains not fully understood. In this work, $FAPbI_3$ and $FAMACsPbBr_3$ perovskite systems are investigated to gain a more comprehensive understanding of how processing additives influence charge generation, transport, and recombination. The mobility and lifetime of photogenerated charge carriers in perovskite layers are determined in a non-contact way using Time-Resolved Microwave conductivity (TRMC), where the interaction of an applied electro-magnetic field with the charge carriers results in a time-dependent change in conductance. Complementary time-resolved photoluminescence (trPL) measurements support the interpretation of TRMC-derived carrier dynamics. Together, TRMC and trPL provide insight into how processing additives influence charge-carrier dynamics in perovskite materials.

CPP 17.11 Mon 19:00 P5

Comparative Analysis of Excited-State Dynamics in Thiophene based D-A-Polymers — Tobias Reiker[1], Marek K Charyton[2], Liu Zitong[3], Deqing Zhang[3], Nicolas D. Boscher[2], and •Helmut Zacharias[1] — [1]Center for Soft Nanoscience, University of Münster, Germany — [2]Materials Research and Technology Department, Luxembourg Institute of Science and Technology, Esch-sur-Alzette, Luxembourg — [3]Institute of Chemistry, Chinese Academy of Science, Beijing, China

We investigate the excited state dynamics of conjugated thiophen based polymers using several kinetic models commonly discussed in the literature. These models describe scenarios in which a short lived excited state acts as a precursor for one or more long lived states and are formulated through coupled rate equations. Four representative models were fitted to the dynamics of DPP4T-1 and subsequently applied to pDPP4T, DPP DTT, pF8T2 and pTDPP to identify trends linked to structural variations within the polymer series. This analysis provides a coherent framework for comparing relaxation pathways and for assessing how precursor states influence the formation of long lived excited state populations.

CPP 17.12 Mon 19:00 P5

Tuning the switching response of purely organic photonic devices by polymer blending — •Jinghan Lin, Sebastian Schellhammer, and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics, Technische Universität Dresden, Dresden, Germany

Programmable luminescent tags (PLTs) provide a promising photonic technology for UV sensing by utilizing the oxygen-sensitivity of room-temperature phosphorescence (RTP) from purely organic emitters [1]. In the emissive layer, the emitter molecules are diluted at low concentration in a rigid polymer host, like Polystyrene (PS) or Poly(methyl methacrylate (PMMA), to reduce photonic loss mechanisms, e.g. triplet-triplet annihilation and non-radiative relaxation. Here, we tailor the microenvironment of RTP emitters and, thus, the photophysical characteristics of the emissive layer by blending different polymers. While the blending of PMMA550k with PS350k led to inhomogeneous films with insufficient photophysical properties, mixing of PS350k with PS40k allows the finetuning of the UV dose required to activate the RTP emission in the PLTs. By combining polymers with different physical characteristics, the local matrix rigidity, oxygen permeability, and intermolecular interactions can be varied in a controlled manner. The study demonstrates how polymer-host engineering provides a systematic route to modulate the characteristics of PLTs while maintaining their key characteristics.

CPP 17.13 Mon 19:00 P5

Unraveling biodegradable phosphorescent emitters by combining quantum chemical simulations with photophysical spectroscopy — •Philipp Wieland, Iuliia Malakhova, Sebastian Reineke, and Sebastian Schellhammer — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics, Technische Universität Dresden

Naturally derived organic emitters are required for the design of efficient biodegradable photonic devices. For instance, quinoline alkaloids exhibit sufficient emission via room-temperature phosphorescence (RTP), enabling their successful application in programmable luminescent tags for sustainable information storage [1]. Despite minimal structural differences between specific emitters of this quinoline alkaloid material family, they result in very different device performances.

In this work we present a combined experimental and computational characterization of RTP-active quinoline alkaloids, aiming to improve the understanding of their structure-property relationship. Photoluminescence analysis of quinine and cinchonine shows that phosphorescence dominates as the radiation process in cinchonine, whereas fluorescence is much more pronounced in quinine. To understand the origin of these differences, Density Functional Theory simulations are conducted. Conventional modelling approaches typically rely on static descriptions, which, while efficient, fail to capture the behavior of highly dynamic molecules. To overcome this limitation, we explicitly incorporate Molecular Dynamics into the screening of excited state properties. [1] Thomas et al. Adv. Mater. 2024, 36, 2310674.

CPP 17.14 Mon 19:00 P5

Stabilization via Confinement of Halide Perovskites — •Marius Kaiser[1], Osama Alsheika[2], Helen Grüninger[2], and Eva M. Herzig[1] — [1]Dynamik- und Strukturbildung - Herzig Group, University of Bayreuth, Germany — [2]Bavarian Center for Battery Technology (BayBatt) and Inorganic Chemistry, University of Bayreuth

The practical use of halide perovskites (HPs) for optoelectronic applications is severely limited by degradation caused by intense light exposure, heat, and unintended ion transport under external electric fields [1]. Key challenges in this field include understanding the underlying mechanisms, stabilizing the semiconductor, and achieving controlled electron and ion transport.

Methylammonium lead bromide (MAPbBr3) is used as a model system, and its lattice parameters are systematically investigated in both bulk form and when confined within SBA-15 silica nanopores (average diameter ~8.4 nm), across a range of temperatures and pore loadings.

Furthermore, we examine thermal expansion behaviour of the materials and evaluate the effect of surface functionalization.

These results provide valuable insights for the development of more stable HP-based optoelectronic devices with directionally controlled charge transport.

CPP 17.15 Mon 19:00 P5

Early-Stage Growth and Morphological Evolution of Ag Electrodes during Sputter Deposition on PDINN — •Doan Duy Ky Le[1], Kristian Reck[2], Benedikt Sochor[3], Thomas Strunskus[2], Jungui Zhou[3], Anuragk Keloth[3], Lyuyang Cheng[1], Sarathal Koyiloth Vayalil[3], Stephan V. Roth[3], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]CAU, Kiel, Germany — [3]DESY, Hamburg, Germany

The integration of sputtered metal electrodes with organic interlayers remains a key challenge for the scalable fabrication of organic solar cells (OSCs). PDINN is an efficient cathode interlayer, yet its behavior under sputter deposition is not well understood. Here, we use *in situ* GISAXS to resolve the nanoscale morphological evolution of Ag during direct-current magnetron sputtering (DCMS) onto PDINN thin films. Time-resolved scattering reveals distinct early-stage growth regimes, including the nucleation of small Ag clusters, their coalescence into medium-sized species, and the formation of laterally connected domains. Compared to thermally evaporated Ag, sputtered Ag achieves continuous coverage at significantly reduced thickness. These findings confirm the feasibility of sputter-deposited Ag/PDINN interfaces and establish a foundation for scalable electrode fabrication in next-generation OSCs.

CPP 17.16 Mon 19:00 P5

Spin-Sensitive Spectroscopy of TADF OLEDs — •Andreas Kohrmann, Ahmed Mohamed, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

The performance of the blue emitter *ν*-DABNA in thermally activated delayed fluorescence (TADF) organic light-emitting diodes (OLEDs) is closely related to the dynamics of triplet excitons. In optically excited host-guest thin films, triplet states are generated and evolve through the intricate interplay of triplet diffusion, triplet recombination, and triplet-triplet annihilation (TTA). Thereby TTA and triplet diffusion are inherently host-dependent. Consequently, the host environment exerts a pivotal influence on exciton loss and delayed emission pathways. We used spin-sensitive optical spectroscopy, specifically photoluminescence-detected magnetic resonance (PLDMR) to examine the spin nature of the singlet-triplet interaction in optically excited host-guest thin films. Correlating these with exciton kinetics from transient photoluminescence (trPL) yields insights on the luminescence as well as the formation, diffusion, and annihilation of triplet excitons. The findings of this study offer a more profound understanding of the triplet harvesting mechanisms in TADF emitters. Additionally, they offer guidance for host selection strategies that are intended to enhance the efficiency and stability of the devices.

CPP 17.17 Mon 19:00 P5

Excimers in carbazole-substituted 4NICz TADF emitters: from frozen solution to films. — •Anatolii Kuimov[1], Oliver Lee[2], Eli Zysman-Colman[2], and Anna Köhler[1] — [1]Soft Matter Optoelectronics, University of Bayreuth, 95440 Bayreuth, Germany. — [2]Organic Semiconductor Centre, EaStCHEM School of Chemistry, University of St Andrews, St Andrews, UK, KY16 9ST

To obtain high brightnesses in OLEDs, emitters need to be packed sufficiently densely for good charge transport. However, too close a proximity between chromophores can lead to the formation of excimers. We investigate under which conditions such excimers are formed in carbazole-substituted 4NICz blue emitters and how this formation can be controlled. In dilute solution at room temperature, we see only emission from non-interacting molecules, whereas in frozen glass a weak red-shifted emission band appears that grows with laser intensity. A similar increase is observed in films. We attribute excimer formation in the glass and in films to structural reorganization after local heating that results from the absorption of the laser pulses.

CPP 17.18 Mon 19:00 P5

Bulk-Heterojunction Morphology Engineering in D18:Y6 Solar Cells — •Dennis Straub, Lixing Li, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

Organic solar cells based on non-fullerene acceptors have attracted considerable interest due to their favourable optoelectronic properties and compatibility with low-temperature solution processing. In this work, the D18 polymer donor and the non-fullerene acceptor Y6 (BTP-4F) are used as the active layer materials. The study investigates how variations in fabrication parameters influence the evolution of the bulk-heterojunction morphology and the resulting photovoltaic behaviour. Key factors examined include solvent choice, wet-film formation, drying kinetics, and thermal treatment, which govern phase separation, domain purity, and molecular ordering within the active layer.

To further explore morphology control, selected additives are introduced that may affect miscibility, aggregation, and domain formation. Their influence on the structural organisation of the D18:Y6 blend is analysed to determine how additive-induced morphological changes impact charge generation, transport pathways, and recombination processes. By correlating structural characteristics with device performance, this work aims to clarify how processing and material modification shape the efficiency and reproducibility of D18:Y6 organic solar cells and to provide guidance for future optimisation.

CPP 17.19 Mon 19:00 P5

Spray Engineering for High-Efficiency Organic Solar Cells — •Xinyu Jiang[1], Kang An[2], Nadja Koelpin[1], Ning Li[2], and Stephan V. Roth[1,3] — [1]Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, 22607 Hamburg — [2]Institute of PolymerOptoelectronic Materials and Devices, State Key Laboratory of Luminescent Materials and Devices, South China University of Technology (SCUT), Guangzhou, Guangdong 510641, China — [3]Department of Fibre and Polymer Technology, KTH Royal Institute of Technology,Teknikringen 56-58, SE-100 44 Stockholm, Sweden

Spray coating has emerged as a powerful and scalable technique for fabricating high-performance organic solar cells (OSCs), offering precise control over ink deposition and rapid compatibility with large-area manufacturing. Compared with conventional solution-processing methods, spray deposition enables fine tuning of droplet dynamics, solvent evaporation, and wet-film thickness, which are critical for achieving optimal phase separation and molecular ordering in the active layer. In this work, we demonstrate that rational engineering of spray parameters such as atomization rate, nozzle substrate distance, carrier-gas flow, and solvent volatility significantly improves film uniformity and reduces morphological defects, leading to enhanced charge transport and suppressed recombination losses. By integrating these optimized spray processes, the resulting OSCs exhibit markedly improved device efficiency and excellent reproducibility across enlarged areas. These results highlight spray coating as a highly efficient and industry-ready pathway for the scalable integration of organic solar cells.

CPP 17.20 Mon 19:00 P5

Narrowband organic Photodetectors with J-Aggregate materials — •Angelina Stoer[1], Jakob Wolansky[1], Matthias Stolte[2], Frank Würthner[2], Karl Leo[1], and Johannes Benduhn[1] — [1]Institut für Angewandte Physik und Photonik, TU Dresden — [2]Institut für Organische Chemie, Universität Würzburg

With the development of organic photodetectors, new opportunities for narrowband photodetection have emerged. Instead of relying on costly and unwieldy optical filters, the molecular structure of organic materials can be chemically tailored to tune their absorption range. Recently, the material class of merocyanine dyes has been investigated as a promising candidate for this purpose, exhibiting favorable absorption properties. By post-annealing these dyes, the molecules can rearrange and form J-aggregated thin films, resulting in a narrowband absorption spectrum due to the intermolecular interactions.

In this work, the merocyanine dye 1(Hex) is used in fully vapor-deposited organic photodetectors. Narrowband detection with a FWHM as low as 15 nm could be realized at a center wavelength of 755 nm. Through careful optimization of the heating conditions and device structure, a notable external quantum efficiency was achieved, accompanied by very low noise at zero voltage. Based on this, the resulting specific detectivity exceeds 10^{12} Jones. The comprehensive photodetector characterization is complemented by an in-depth analysis of changes in the thin film's morphology and energetics induced by the J-aggregation formation process.

CPP 17.21 Mon 19:00 P5

Nanoscale Structural and Electronic Characterization of the DTDCPB:C70 donor-acceptor system for vacuum-deposited organic solar cells — •Milena Merkel[1,2], Jan ter Glane[1,2], and Harry Mönig[1,2] — [1]Institute of Physics, University of Münster, Münster, Germany — [2]Center for Nanotechnology (CeNTech), Münster, Germany

The active layer of organic solar cells is produced either by solution-processing or vacuum thermal evaporation. While solution-processed cells have achieved

higher efficiencies to date, vacuum-deposited cells exhibit higher morphological stability and thus a longer durability. For a future commercialization of organic solar cells, where both efficiency and durability are crucial, understanding the current limitations of vacuum-deposited cells is thus of major interest.

Cells based on an active layer made of the DTDCPB:C70 donor-acceptor system have so far achieved one of the highest efficiencies in the group of vacuum-deposited organic solar cells, while also exhibiting high durability [1,2]. We used a combined approach of high-resolution scanning tunneling microscopy and spectroscopy to investigate the structural and electronic properties of assemblies of these donor and acceptor molecules deposited on single-crystalline substrates, as well as of their lateral and vertical interfaces.

CPP 17.22 Mon 19:00 P5

Interfacial modification of transport layers for enhancing the performance and stability of organic solar cells — •Saib Jahan Qazi[1,2], Md. Moidul Islam[1,2], Md. Zobaer Ahmed Rahat[1,2], Md. Farhatul Hassan[1,2], Ulrich S. Schubert[1,2], and Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry (IOMC Jena), Friedrich Schiller- University Jena, Jena, Germany — [2]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich-Schiller-University Jena, Jena, Germany

Organic solar cells are emerging as promising prospects in the field of solar energy technology due to their low-cost, lightweight and simple roll to roll fabrication properties. A record power conversion efficiency above 19% has already been reported. However, long-term stability is still the main obstacle for commercialization due to inherent instability particularly at the interfaces. In this study, we demonstrate solution processed interfacial modification of zinc oxide (ZnO). ZnO is widely used in organic solar cells for electron extraction, but it brings performance and lifetime limitations due to surface defects and photochemical reactions under UV exposure, which generates radicals resulting into accelerated degradation of the photoactive layer in the device. Here we compare approaches using organic acids with polysilazane, for successful ZnO passivation.

CPP 17.23 Mon 19:00 P5

Simulation of Pump-Probe Spectra Including Linear Vibronic Coupling – A Study on Naphthalene Diimide — •Matthias Knechtges, Maximilian F. X. Dorfner, and Frank Ortmann — Department of Chemistry, TUM School of Natural Sciences, and Atomistic Modeling Center, Munich Data Science Institute, Technical University of Munich, München, Germany

Non-linear optical techniques such as pump-probe spectroscopy provide insight into the dynamical processes governing excited-state evolution, which are often influenced by electron-vibrational interactions.

The theoretical computation of pump-probe spectra remains an open research field [1] due to the complicated treatment of coupled electronic and nuclear dynamics, which require feasible but accurate approximations [2]. In particular, including the full quantum nature of the nuclei remains a major challenge.

In this contribution, we present a framework for calculating pump-probe spectra of molecules based on an analytic linear electron-vibrational coupling model. Evaluating the third-order response function in the Franck-Condon approximation and including vibrational transitions enables us to predict the pump-probe signal in the infrared region as well. We apply this to the Naphthalene Diimide molecule, a building block for a prospective solar cell material.

CPP 17.24 Mon 19:00 P5

QD-based hybrid organic photo detectors for narrowband IR sensing — •Johann Demel[1], Louis Conrad Winkler[1,3], Andrey Iodchik[2], Moritz Flemming[1], Tobias Antrack[1], Karl Leo[1], and Johannes Benduhn[1,3] — [1]IAP, TU Dresden — [2]Chemistry, TU Dresden — [3]German Center for Astrophysics

The ability to detect infrared radiation is relevant across a multitude of fields. Autonomous driving and deep space exploration utilize its ability to propagate long distances with little absorption losses. While, e.g., medical diagnostics can profit from its penetration depth into biological tissue. Organic materials have proven to be a viable platform for photo detection, with advantages such as low-cost fabrication, flexible devices, and tunable absorption; however, their IR absorption capabilities are limited.

This work presents a hybrid structure combining organic transport layers and PbS nanoparticles into optical microcavities. Based on transfer-matrix simulations, the resonance wavelength of the stack can be precisely predicted and tuned by adjusting the thickness of the organic transport layers. By combining precise thermal evaporation of the organic layers with interface assembly to incorporate nanoparticle layers into the stack, wavelength-selective devices are achieved whose resonance feature can be tuned from 750 nm up to 1800 nm. This expands the advantageous properties of the organic device framework by the wavelength-tunable IR absorption capabilities of semiconductor nanoparticles, leading to devices with specific detectivity values D^* of $10^{11}\ cm \cdot \sqrt{Hz} \cdot W^{-1}$ (based on noise measurements).

CPP 17.25 Mon 19:00 P5

Heat induced morphological changes in P3HT:PCBM solar cells — •Jose Prince Madalaimuthu[1,2], Edward Wijaya[1,2,3], Ulrich S Schubert[1,2], and Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry (IOMC Jena), Friedrich-Schiller-Universität Jena, Germany — [2]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich-Schiller-Universität Jena, Germany — [3]Department of Chemical Engineering, Swiss German University, 15143 Tangerang, Indonesia

Organic solar cells are becoming an important technology for next-generation energy applications since they can be made into flexible and lightweight devices. However, attaining thermal stability remains a significant challenge for its actual deployment. Heat-induced morphological alterations within the photoactive layer typically led to considerable performance reductions. It's interesting to note that this effect may be reversed in some circumstances. Our investigations on P3HT:PCBM solar cells show that devices subjected to high-temperature exposure (up to 250°C) demonstrated substantial performance recovery upon cooling. Thermally driven and reversible morphological change in the active layer was demonstrated by photoluminescence analysis.

CPP 17.26 Mon 19:00 P5

Trace Intrinsically Microporous Polymer Additives Induce LiF-Rich SEI for Enhanced Performance of Silicon-Based Lithium-Ion Batteries — •Ming Yang[1], Ruoxuan Qi[1], Ya-Jun Cheng[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]College of Renewable Energy, Hohai University, Changzhou, Jiangsu Province, P. R. China

Silicon-carbon (Si/C) composite anodes are promising candidates for high-energy-density lithium-ion batteries due to the high theoretical capacity of silicon. However, their practical application is hindered by severe volume expansion and unstable solid electrolyte interphase (SEI) formation during cycling. Fluoroethylene carbonate (FEC) is commonly used to improve interfacial stability, but its effectiveness is limited by concentration sensitivity and uncontrollable side reactions. This study introduced carboxyl-functionalised intrinsically microporous polymer (PIM-COOH) as a functional additive, achieving dual regulation of electrode structural evolution and interfacial chemistry. Only 0.5wt% PIM-COOH is required to achieve these effects. The Si/C@PIM||Li half-cell retains 90% of its capacity after 300 cycles at 1.0 C, demonstrating excellent long-term stability. The utilisation of 1Ah NCM811-Si/C pouch cells demonstrates its commercial potential. These results demonstrate a scalable and effective strategy for stabilizing silicon-based anodes, offering valuable insight into the design of next-generation lithium-ion batteries with both high energy density and long cycle life.

CPP 17.27 Mon 19:00 P5

In-situ WAXS observation of 3D porous electrodeposition Cu in lithium-metal batteries — •Lyuyang Cheng[1], Zhuijun Xu[1], Yingying Yan[1], Fabian Apfelbeck[1], Yuxin Liang[1], Anton Davydok[3], Christina Krywka[3], Yajun Cheng[2], and Peter Müller-buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany — [2]Hohai University, 213022 Changzhou, China — [3]Helmholtz-Zentrum Hereon, 21502 Geesthacht, Germany

Lithium (Li) metal is the ultimate anode for rechargeable batteries. Its high specific capacity (3860 mAh/kg) and low voltage warrant optimal cell energy density. However, these anodes rely on repeated plating and stripping of Li, which leads to consumption of Li and the growth of dendrites that can lead to self-discharge and safety issues. To address these issues and problems, a number of different porous conductive scaffolds have been reported to create high surface area electrodes on which Li can be plated reliably. While impressive results have been reported in literature, current processes typically rely on either expensive or poorly scalable techniques. Herein, we report a scalable fabrication method to create porous Cu anodes using a one-step electrodeposition process. The areal loading, pore structure, and electrode thickness can be tuned by changing the electrodeposition parameters, and we illustrate the in-situ nano WAXS images with lithium growth, which can help to explain the mechanism. We also provide a feasible method to fabricate the porous Cu cathodes with different electrodeposition solution concentrations.

CPP 17.28 Mon 19:00 P5

Ionic-Liquid-Regulated PVC-Based Solid Polymer Electrolyte for High-Performance Lithium Metal Batteries — •Jiaqi Ding and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany

Lithium metal batteries (LMBs) are regarded as one of the most promising next-generation energy-storage systems owing to their ultrahigh theoretical capacity. However, the safety issues associated with conventional liquid electrolytes, including dendrite-induced short circuits and interfacial instability, severely hin-

der their practical application. Solid polymer electrolytes (SPEs) offer a potential pathway to address these challenges. In this work, we develop a poly(vinyl carbonate) (PVC)-based solid polymer electrolyte incorporating the ionic liquid [EMI][TFSI] to enhance both ion transport and mechanical integrity. Structural and electrochemical characterizations show that the ionic liquid effectively regulates ion transport within the polymer matrix, enabling the formation of continuous Li ion conduction pathways and improving the compatibility of the electrolyte with lithium metal. This tailored ion-transport behavior leads to enhanced ionic conductivity, mitigated interfacial degradation, and significantly extended cycling stability in LMBs. The results highlight the critical role of ionic-liquid modification in tuning transport properties of polymer electrolytes and provide a viable materials strategy for high-performance lithium metal batteries.

CPP 17.29 Mon 19:00 P5

Investigation of the Effects of LiDFOB Salt Concentration on the Fast-Charging Performance of LiCoO2 Cathodes — •Yifeng Liu, Ming Yang, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany

Fast-charging lithium-ion batteries have drawn increasing interest, yet lithium cobalt oxide ($LiCoO_2$) paired with commercial electrolytes generally suffers from severe capacity fading and limited cycle life at high charging rates. This study aims to explore strategies for improving capacity retention of $LiCoO_2$-based lithium-ion batteries under fast-charging conditions. We employ boron-containing lithium salt LiDFOB as an electrolyte additive and systematically investigate its concentration-dependent effects on the capacity retention of LCO cells under fast-charging operation. Interfacial stability and charge-transfer kinetics associated with different LiDFOB levels are evaluated through cyclic voltammetry (CV), linear sweep voltammetry (LSV), Tafel analysis, and chronoamperometry (CA). The results show that the concentration of LiDFOB has a pronounced influence on the cycling performance. In particular, the optimized LiDFOB concentration enables the LCO cells to stably cycle for over 1000 cycles at 1C and 3C, benefiting from the improved interfacial stability and enhanced Li^+ transference number. Morphological and material characterizations further reveal that different LiDFOB concentrations generate SEI films with distinct compositions and structures, which account for the disparities in fast-charging capacity retention.

CPP 17.30 Mon 19:00 P5

High-Power Continuous Laser-Guided Synthesis of Bimetallic Metal-Organic Framework (NiCoMOF) Structures and Their Composites: Photophysical, Photochemical, and Electrical Characterization — •Saliha MUTLU[1,2], Bülend ORTAÇ[2], Ali KARATUTLU[2,3], Nergis ARSU[4], and Sevil SAVAŞKAN YILMAZ[1,2] — [1]Karadeniz Technical University Chemistry Department, Trabzon, Türkiye — [2]Bilkent University, Institute of Materials Science Nanotechnology and National Nanotechnology Research Center (UNAM), Ankara, 06800 Turkey — [3]Sivas University of Science and Technology, Department of Engineering Basic Sciences, Sivas, 58100 Turkey — [4]Department of Chemistry, Yildiz Technical University, Davutpasa Campus, Istanbul 34210, Turkey;

Metal-organic frameworks (MOFs) are among the most innovative breakthroughs in chemistry and materials science. In this study, the first bimetallic synthesis of MOFs was achieved using the high-power laser-induced rapid synthesis (LIRS) method via two different ligand and metal salt combinations with different π-conjugated linkers. The synthesis of NiCo-MOF structures (in 1:2 and 2:1 ratios) was completed in just 70 minutes using the LIRS method. Furthermore, the synthesis of MOF composites (rGO/MOF) containing reduced graphene oxide (rGO) was also achieved for the first time. On top of these, the electrical properties of the epoxy acrylate-based MOF and rGO@MOF composites prepared by in situ photopolymerization were investigated in detail. This study was supported by TÜBITAK-BIDEB 2211-A National PhD Scholarship Programs.

CPP 17.31 Mon 19:00 P5

A gel polymer electrolyte interface layer-amphiphilic polymer/salt composite nanoarray for lithium metal batteries — •Thomas Bullinger, Ming Yang, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany

Research on lithium-ion batteries has been focused on improving energy density, which is mainly limited by conventional graphite anodes. Therefore, lithium metal has emerged as a desirable anode material due to its high energy density. However, it easily reacts during cycling, thus forming lithium dendrites, which can lead to short-circuiting of the battery. As liquid electrolytes cannot solve this problem, solid-state polymer electrolytes have shown promise as an alternative, but their ionic conductivity at room temperature limits their practical use, leading to the compromise of gel polymer electrolytes. In this project the block copolymer P2VP-b-PEO together with the lithium salt lithium nitrate, both dissolved in tetrahydrofuran (THF), surprisingly lead to the solvent phase changing to a gel polymer, which was then used as the electrolyte in coin cells. For the cycling and rate performance tests, Li||LFP batteries were investigated. Further experiments include cycling voltammetry (CV), linear sweep voltammetry (LSV), Tafel curves and impedance spectroscopy.

CPP 17.32 Mon 19:00 P5

In-situ interface film forming on the high-voltage LiCoO2 cathode by a tiny amount of nanoporous polymer additives — •Ruoxuan Qi[1], Ming Yang[1], Tianle Zheng[1], Xingchen Liu[2], Yonggao Xia[2], Ya-Jun Cheng[2,3], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]NIMTE, CAS, Zhejiang Province, P. R. China — [3]College of Renewable Energy, Hohai University, Jiangsu Province, P. R. China

The LiCoO2 (LCO) cathode has been foreseen for extensive commercial applications owing to its high specific capacity and stability. Therefore, there has been considerable interest in further enhancing its specific capacity by increasing the charging voltage. However, single-crystal LCO suffers from a significant capacity degradation when charged to 4.5 V due to the irreversible phase transition and unstable structure. Herein, an ultra-small amount (0.5 wt% in the electrode) of multi-functional PIM-1 (a polymer with intrinsic microporosity) additive is utilized to prepare a kind of binder-free electrode. PIM-1 modulates the solvation structure of LiPF6 due to its unique structure, which helps to form a stable, robust, and inorganic-rich CEI layer on the surface of LCO at a high voltage of 4.5 V. This reduces the irreversible phase transition of LCO, thereby enhancing the cyclic stability and improving the rate performance, providing new perspectives for the electrodes fabrication and improving LCO-based high-energy-density cathodes.

CPP 17.33 Mon 19:00 P5

Effects of differently sized and shaped active and passive Filler for PVDF-HFP CPEs in All Solid-State Lithium-Ion Batteries — •Daniel Karlinger, Yuxin Liang, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, Graching, Germany

All-solid-state lithium-ion batteries are regarded as highly promising due to their enhanced safety and potentially higher energy density compared to conventional cells with liquid electrolytes. In this project, solid polymer electrolytes based on PVDF-HFP are investigated with the aim of improving ionic conductivity and overall electrochemical performance. The approach is to incorporate combinations of ac tive and passive fillers to tailor the material properties. Conductivity and mechanical stability will be systematically examined with cyclic voltammetry (CV), electrochemical impedance spectroscopy (EIS), X ray diffraction (XRD) and other methods, in order to identify opti mized compositions for solid-state battery applications.

CPP 17.34 Mon 19:00 P5

Tracing the Path from Solvation to Transport in Lithium and Sodium Electrolytes — •Chinwendu Nancy Anabaraonye[1,2], Diddo Diddens[3], and Andreas Heuer[1,2] — [1]Institute of Physical Chemistry, University of Münster, Corrensstraße 28/30, 48149 Münster, Germany — [2]International Graduate School for Battery Chemistry, Characterization, Analysis, Recycling and Application (BACCARA), University of Münster, Corrensstr. 40, 48149 Münster, Germany — [3]Forschungszentrum Jülich GmbH, Helmholtz-Institute Münster (IMD-4), Corrensstraße 48, 48149 Münster, Germany

Advancing technology continues to increase demands on energy storage devices and their performance requirements. Over the years, lithium-ion batteries have consistently remained the market leader. However, their long-term sustainability remains questionable due to the limited lithium reserves. Therefore, there is need for increased research toward alternative battery chemistries, among which are sodium-ion batteries. The present work is a comparative study of the transport properties of lithium hexafluorophosphate (LiPF6) and sodium hexafluorophosphate (NaPF6) in carbonate electrolytes consisting of ethylene carbonate (EC) and ethyl methyl carbonate (EMC). Based on molecular dynamics simulations, we analyse the influence of EC ratio and salt concentrations on the solvation structure with particular focus on the formation of contact ion pairs (CIP), solvent-seperated ion pairs (SSIP) and ion aggregates and how this correlates with the ionic transports within the systems.

CPP 17.35 Mon 19:00 P5

Modeling Electron Transfer at Electrode-Electrolyte Interfaces — •Joshua Krieger[1,2,3], Johannes Tölle[4,5,3], Diddo Diddens[2,6], and Andreas Heuer[2,6] — [1]International Graduate School BACCARA, University of Münster, 48149 Münster, Germany — [2]Institute for Physical Chemistry, University of Münster, Münster, Germany, 48149 Münster, Germany — [3]Center for Multiscale Theory and Computation (CMTC), University of Münster, 48149 Münster, Germany — [4]Department of Chemistry, University of Hamburg, 22761 Hamburg, Germany — [5]The Hamburg Centre for Ultrafast Imaging (CUI), 22761 Hamburg, Germany — [6]Helmholtz Institute Münster - Forschungszentrum Jülich GmbH (IEK 12), 48149 Münster, Germany

The solid electrolyte interphase (SEI) is an important component in rechargeable battery performance and lifetime, but the complex mechanisms behind its for-

mation are still not yet fully understood. Accurate electron-transfer (ET) rates are important for simulating SEI growth, e.g. using reactive molecular dynamics simulations that require electrolyte reduction rates. To obtain the ET rates, we investigate a simplified Anderson impurity-type model designed to describe non-equilibrium electron transfer between an electrode and the redox-active species under an applied potential. This framework enables systematic exploration of how molecular distance, electronic coupling, as well as solvent interactions and reorganization effects influence electron-transfer dynamics. The resulting insights provide a foundation for constructing more reliable, physics-based rate expressions that can be integrated into large-scale SEI formation simulations.

CPP 17.36 Mon 19:00 P5

Toward Improved Lithium Batteries: Performance of Magnetron-Sputtered Silicon Anodes — •Thomas Köhler[1], Christian Ludt[1], Tina Weigel[1], Marc Ferch[2], Robert Hahn[2], Annekatrin Delan[3], Charaf Cherkouk[4], Hartmut Stöcker[1], and Dirk C. Meyer[1] — [1]TU Bergakademie Freiberg, 09599 Freiberg, Germany — [2]Fraunhofer IZM, 13355 Berlin, Germany — [3]Fraunhofer IZM-ASSID, 01468 Moritzburg, Germany — [4]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

Silicon is considered one of the most promising anode materials for lithium-ion batteries due to its high theoretical specific capacity of 3590 mAh/g in the $Li_{3.73}Si$ phase at room temperature and its broad availability. However, its practical application remains limited because i) significant volume changes occur during cycling, ii) its intrinsic electronic conductivity is low, and iii) the stability of the solid-electrolyte interphase is insufficient.

In this work, silicon thin-film anodes were fabricated by magnetron sputtering onto copper foil. The electrodes were thoroughly characterized regarding their chemical composition and surface morphology. Scanning electron microscopy was used to evaluate the structural stability of the silicon layers in contact with a polymer-based solid electrolyte and to compare their degradation behavior with that in conventional liquid electrolyte. Electrochemical testing with the polymer electrolyte shows promising cycling performance; the reduced surface degradation observed in SEM correlates with improved long-term stability of the cell system.

CPP 17.37 Mon 19:00 P5

Structural and Ionic Transport Properties of Li3-3xDy1+xCl6 Solid Electrolytes — •Francesco Falsina[1,2], Peter Müller-Buschbaum[1], and Anatoliy Senyshyn[2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]MLZ, TUM, Garching, Germany

Ternary lithium lanthanide chlorides, Li_3RCl_6 (R = rare earth), have recently emerged as promising solid electrolytes. Although initially thought to exhibit low ionic conductivity, later studies showed that ball milling synthesis, by leading to microstructure modification, can raise conductivity to $\sim 10^{-3}$ S·cm^{-1}. In this work we studied the $Li_{3-3x}Dy_{1+x}Cl_6$ system (x = −0.1 to 0.1). For $x = 0$, we assessed how annealing conditions affect structure and conductivity. Ionic transport was measured using isostatically pressed, gold-sputtered pellets and broadband impedance spectroscopy. XRD, DSC, and EIS analyses of as-milled, annealed, and melt-synthesized samples show that conductivity decreases by nearly an order of magnitude after annealing, while over-lithiated compositions consistently display higher conductivity, highlighting the impact of lithium retention. DSC and XRD also reveal an orthorhombic-to-trigonal transition with increasing lithium content. Overall, these results clarify how composition and disorder govern ionic transport in the Li_3MCl_6 electrolyte family.

CPP 17.38 Mon 19:00 P5

Investigating the Interfacial Impedance Characteristics of Composite Materials — •Janne Mattis König[1,2], Felix Schug[1,2], Christian Heiliger[1,2], and Janis K. Eckhardt[1,2,3] — [1]Institute of Theoretical Physics, Justus-Liebig-University Giessen, 35392 Giessen, Germany — [2]Center of Material Research (ZfM), Justus-Liebig-University Giessen, 35392 Giessen, Germany — [3]Institute of Physical Chemistry, Justus-Liebig-University Giessen, 35392 Giessen, Germany

All-solid-state batteries (ASSBs) are a promising alternative to conventional lithium-ion batteries, offering high energy and power densities, long-term stability, and fast-charging capability. Consequently, significant effort is focused on identifying suitable materials. Electrochemical impedance spectroscopy (EIS) is a key characterization technique, but interpreting spectra from realistic composite systems remains challenging. In this work, we investigate interfacial impedance in simplified composite microstructures using a 3D electrical network model. The simulations reveal that high charge-transfer resistances lead to geometric constriction effects, producing an impedance signature that closely resembles a migration process or a charge-transfer reaction. This constriction impedance is strongly influenced by the composite microstructure. Furthermore, increased conductivity along the interface introduces a characteristic deformation in the impedance spectrum shape. Overall, these findings clarify the origin of interfacial impedance features in composite materials and support more informed interpretation of EIS measurements in ASSB research.

CPP 17.39 Mon 19:00 P5

Aluminium-Polymer Batteries as a viable Post-Lithium Technology — •Oliver Schmidt[1,2], Amir Mohammad[1,2], Shuvrodev Biswas[1,2], Mostafizar Rahman[1,2], Nathan Leubner[1,2], Thomas Köhler[1,2], Hartmut Stöcker[1,2], and Dirk C. Meyer[1,2] — [1]TU Bergakademie Freiberg, Institute of Experimental Physics, Leipziger Str. 23, 09599 Freiberg — [2]Zentrum für effiziente Hochtemperatur-Stoffwandlung, Winklerstr. 5, 09599 Freiberg

One of the key challenges of the energy transition is the rising demand for lithium. In the future, there will be a supply gap, even taking into account recycling and the development of new mining areas. In addition to the limited availability, safety risks such as fire hazards make lithium-ion batteries less suitable for the long-term requirements of the energy transition.

Here, we present the aluminium-polymer battery as a novel technology adressing these issues. Aluminium is the most abundant metal in the Earth's crust and therefore inexpensive. It is available in Europe and is highly recyclable. The battery cells are free of toxic or critical raw materials and eliminate the risk of fire.

Pouch cells consisting of a simple 3-layer setup have been developed: aluminium anode, polymer electrolyte (consisting of $AlCl_3$, Et_3NHCl and PAN) and graphite cathode. Capacity, safety and recycling tests show promising results. Remaining challenges are tackling the self-discharge and scaling up the cell fabrication. The future goal is making large-scale storage systems cost-effective, efficient and safe.

CPP 17.40 Mon 19:00 P5

Microstructure-Resolved Impedance Modeling of Cathode Composite Electrodes for Solid-State Batteries — •Matthias Braun[1,2], Felix Schug[1,2], Christian Heiliger[1,2], and Janis K. Eckhardt[1,2,3] — [1]Institute for Theoretical Physics, Justus-Liebig-University Giessen, Germany — [2]Center for Materials Research (ZfM), Justus-Liebig-University Giessen, Germany — [3]Institute of Physical Chemistry, Justus-Liebig-University Giessen, Germany

Solid-state batteries (SSBs) rely on composite cathodes whose complex microstructures critically influence ionic and electronic transport. Electrochemical impedance spectroscopy (EIS) is widely used to probe these transport processes. The impedance behavior of mixed ionic electronic conductors is commonly interpreted using transmission-line models (TLMs). However, the extent to which composite microstructure governs impedance features and the validity of TLM-based interpretations remains insufficiently understood. In this work, we employ microstructure-resolved impedance simulations to investigate how key structural characteristics of cathode composites shape their impedance response. We demonstrate that interface morphology and porosity significantly modulate the spectra, giving rise to microstructure-specific features that conventional TLMs fail to capture. In particular, geometric current-constriction effects at the cathode active material/solid-electrolyte interface emerge as dominant contributors to impedance behavior. These findings provide a deeper mechanistic understanding of microstructure-induced impedance signatures and offer practical guidance for interpreting EIS data in composite electrodes for SSBs.

CPP 17.41 Mon 19:00 P5

Optimization in Fabrication Process and Understanding the Impact of Crystal Size and Growth in RbCsMAFA Perovskite Solar Cells — •Bashudev Bhandari[1,2,3], Sai Durga Prasad Sudana[1,2], Chikezie Williams Ugokwe[1,2], Ulrich S Schubert[1,2], and Harald Hoppe[1,2] — [1]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich-Schiller-University Jena, Germany — [2]Laboratory of Organic and Macromolecular Chemistry (IOMC Jena), Friedrich-Schiller- University Jena, Germany — [3]Faculty of Physics and Astronomy, Friedrich-Schiller- University Jena, Germany

Perovskite solar cells (PSCs) emerged as remarkable and promising cutting-edge clean and green energy sources. Recent breakthroughs in their performance attract researcher's interest. Despite its promising performance, degradation issues and defects are critical obstacles to overcome. Our work explores different mechanisms to suppress defects and improve stability via improved crystallization. We have systematically optimized different processing parameters such as annealing time, antisolvent dropping time, hot casting, etc., and introduced additives like different phosphonium salts and PEAI for passivation and seeding for perovskite growth. Different Characterization and imaging techniques illustrate improved crystalline and opto-electronic properties of the perovskite film and solar cells.

CPP 17.42 Mon 19:00 P5

In Situ Investigation of Ag Sputter Deposition on a Zwitterionic Polymer Film — •Georgios Panagiotidis[1], Christoph Lindenmeir[1], Grace Leone[2], Lixing Li[1], Lyuyang Cheng[1], Doan Le[1], Yufeng Zhai[3], Kristian Reck[4], Benedikt Sochor[3], Matthias Schwartzkorpf[3], Anurag Keloth[5], Sarathlal Vayalil[3,5], Todd Emrick[2], Thomas Russell[2,6], Stephan V. Roth[3,7], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]UMass Amherst, Massachusetts, United States — [3]DESY, Hamburg — [4]CAU, Kiel, Germany — [5]UPES, Dehradun, India — [6]LBNL, Berkeley — [7]KTH, Stockholm, Sweden

While organic electronic devices mainly use organic or organic-inorganic hybrid materials, many electrodes still rely on pure metals due to their unparalleled electrical conductivity. Thus, the polymer-metal interface is crucial to device performance. Studies have demonstrated the use of ultrathin metal electrodes for (semi)transparent organic solar cells, and the quality of the interface influences the formation of structural defects, which can increase resistance and the likelihood of a short circuit. These metal contacts are typically deposited through lab-scale methods such as thermal evaporation, while industrial manufacturing prefers large-scale sputter deposition. Moreover, zwitterionic polymers can reduce the work function of metals and serve as interlayers in inverted organic solar cells. Therefore, understanding the growth behavior of sputtered silver on zwitterionic polymer surfaces is critical.

CPP 17.43 Mon 19:00 P5

Probing the Distribution of Residual Stresses in Thin Polymer Films Using Mechanochromic Molecular Springs — •Meirui Fu[1], Raphael Hertel[2], Bence Dajka[3], Michael Walter[3], Michael Sommer[2], and Günter Reiter[1] — [1]Institute of Physics, University of Freiburg, Germany — [2]Institute for Chemistry, Chemnitz University of Technology, Germany — [3]FIT Freiburg, University of Freiburg, Germany

Polymer thin films prepared rapidly from solution by spin coating often retain residual stresses originating on a molecular level. However, typically these stresses are probed on a macroscopic level, yielding spatially averaged responses, but do not resolve forces acting on individual chains. Here, we employed mechanochromophores, covalently integrated along the backbone of a glassy polymer, as optical reporters whose emission response varies continuously with the applied force. By combining optical microscopy and spectroscopy, we were able to measure the sum of the forces acting on individual chains with high spatial resolution. In particular, we investigated the distribution of forces acting on non-equilibrated polymer chains. Samples prepared under different spin coating conditions exhibited systematic variations in the emission spectra, which reflect differences in the distribution of the sum of forces acting on individual chains. We distinguish contributions from polymers experiencing low and high forces, respectively, which exhibited opposite trends with preparation conditions. We tentatively relate the heterogeneity of the acting forces to differences in conformation of the non-equilibrated polymer chains.

CPP 17.44 Mon 19:00 P5

Real Time Spectroscopy of Plasmonic Core-Shell Microgels during Compression at Air/Water Interfaces — •Matthias Karg and Déborah Feller — Martin Luther University Halle-Wittenberg, Halle, Germany

Plasmon resonance coupling is strongly distance-dependent. In contrast to near-field coupling of plasmonic nanoparticles in close proximity, periodic superstructures support plasmonic-diffractive coupling. The resulting surface lattice resonances are interesting for their narrow linewidth and sensitivity to refractive index environment and lattice periodicity. Typically studied periodic arrays are (solid) substrate-supported and thus structurally fixed unless elastic substrates are used. Seeking an alternative approach, we demonstrate the large dynamic control of periodic plasmonic lattices using soft and deformable core-shell microgels self-assembled at air/water interfaces. Using microgels with gold cores and sufficiently thick microgel shells, we realized periodic monolayers where the periodicity can be controlled by compression using a Langmuir trough. The implementation of an extinction spectrometer setup was used to probe the optical response of the monolayer in situ during continuous reduction of the available area, in real time. We monitor plasmon resonance coupling with a never before reported stepsize in interparticle spacing by following peak position, width and intensity. The observed spectral changes support recent findings that confined microgel monolayers at fluid interfaces show a continuous reduction in spacing when uniaxially compressed opposed to the cluster formation that is observed after drying on solid substrates.

CPP 17.45 Mon 19:00 P5

In-situ FTIR spectroscopy on organic semiconductor electric double-layer transistors — •Marvin Schmidt[1], Pushi Wang[2], Jun Takeya[2,3], and Martin Dressel[1] — [1]1. Physikalisches Institut, Universität Stuttgart, Germany — [2]Graduate School of Frontier Sciences, The University of Tokyo, Kashiwa, Japan — [3]Research Center for Materials Nanoarchitectonics, National Institute for Materials Science, Tsukuba, Japan

The field of organic electronics is ever-growing due to the enormous range of unique properties and possible applications exhibited by organic molecules. Electric double-layer transistors (EDLTs) consisting of the organic semiconductor 3,11-dinonyldiaphtho[2,3-*d*:2′,3′-*d*′]benzo[1,2-*b*:4,5-*b*′]dithiophene (C_9-DNBDT-NW) have recently attracted attention because they are highly processable and, thus, allow for the fabrication of large-scale single-crystal transistors with excellent crystallinity and high mobility. Furthermore, Hall effect measurements indicate the emergence of a metallic phase with strong correlations upon doping.

Here, we performed, for the first time, in-situ Fourier-transform infrared spectroscopy on EDLTs composed of C_9-DNBDT-NW single crystals for different sheet conductivities and temperatures down to 6K in the mid and far infrared regions. Our results give insights into how thermal fluctuations are suppressed with decreasing temperature and increasing electrostatic doping concentration, which manifests itself in the behavior of the displaced Drude peak.

CPP 17.46 Mon 19:00 P5

Measurement of photon antibunching of organic molecules by substrate scanning — •Janne Oskar Becker, Robert Schmidt, Steffen Michaelis de Vasconcellos, and Rudolf Bratschitsch — Institute of Physics, University of Münster

Single-molecule photoluminescence spectroscopy is often performed in solution, with molecules drifting in and out of a stationary focus. To immobilize single molecules, they are typically diluted in a solvent and spin-coated on a substrate. However, bleaching processes lead to decreasing photoluminescence count rates when illuminating isolated single-molecules over time, making photon antibunching measurements extremely challenging. To circumvent this, we measure multiple molecules sequentially by spatially scanning the spin-coated surface and accumulating photons of multiple single-molecules. In that way, we are able to measure photon antibunching Si/SiO_2 substrate.

CPP 17.47 Mon 19:00 P5

Large-Area Semiconducting 2D Imine-COF Polymer Films on Dielectric Glass for Electronic Applications — •Diksha Srivastava[1], Vipin Mishra[2], Showkat H. Mir[3], Jyotirban Dey[1], Jayant K. Singh[1], Manabendra Chandra[1], and Thiruvancheril G. Gopakumar[1] — [1]Indian Institute of Technology Kanpur, Kanpur 208016, India — [2]Vellore Institute of Technology, Vellore, Tamil Nadu 632014, India — [3]University of Kashmir, Hazratbal, Srinagar 190006, Jammu and Kashmir, India

Two-dimensional imine-based covalent organic frameworks (2D COFs) are a growing class of crystalline π-conjugated organic polymers with strong potential in thin-film electronics and optoelectronics. We present a scalable and reproducible strategy for producing 2D imine-COF-based polymer thin films through a quasi-equilibrium Schiff-base reaction between p-phenylenediamine (PDA) and benzene-1,3,5-tricarboxaldehyde (TCA). This method enables the growth of large-area polymer films (up to 2 cm) on dielectric substrates with controlled thickness. SEM, TEM, and AFM confirmed the layered and crystalline morphology of the films. Optical absorption and scattering measurements revealed a semiconducting band gap consistent with the DFT-calculated band structures, indicating the presence of delocalized states suitable for charge transport. To probe intrinsic electrical behaviour, COF polymer films were integrated into Ag/COF/Glass devices. The I-V curves revealed semiconducting behaviour with low current density and field-assisted conduction limited by electrode-COF injection barriers.

CPP 17.48 Mon 19:00 P5

Designing functional polymer surfaces by initiated chemical vapor deposition — •Stefan Schröder, Lynn Schwäke, Tobias Giez, Thomas Strunskus, Franz Faupel, and Tayebeh Ameri — Kiel University, Kiel, Germany

Polymer thin films and organic surfaces have attracted significant interest across diverse application areas, ranging from wearable electronics to biomedicine and encapsulation. The demand for new functional surfaces, combined with ongoing device miniaturization, requires defect-free nanoscale polymer films with precise control over thickness and chemistry. Chemical vapor deposition (CVD) of polymer surfaces addresses these challenges by eliminating the dewetting and surface tension effects commonly encountered in conventional solution-based thin film fabrication. In particular, initiated chemical vapor deposition (iCVD) enables the fabrication of conformal polymer coatings with nanoscale precision on large-area substrates as well as on complex geometries. Moreover, iCVD allows for room-temperature deposition on delicate substrates, including flexible organic materials, copy paper, and biomedical patches. This contribution presents the fundamentals of the iCVD process and highlights selected application examples.

CPP 17.49 Mon 19:00 P5

Controlling Surface Wetting through Light- and Electric-Fields — •Billura Shakhayeva[1], Bas ter Beest[2], Frieder Mugele[2], and Björn Braunschweig[1] — [1]University of Münster, Institute of Physical Chemistry, Germany — [2]University of Twente, Physics of Complex Fluids

Electro-dewetting (EDeW) enables reversible control of surface wettability using ionic surfactants. Using dodecyl tetraethyl ammonium bromide (DTAB) as a cationic surfactant, previous studies achieved a change in the apparent contact angle (CA) of up to 30°. We used vibrational sum-frequency generation (SFG) spectroscopy and ellipsometry to probe the molecular structure close to the three-phase contact line under initial and EDeW conditions. Using 0.15 mM DTAB we observed the largest changes in contact angle and observed spreading of surfactant even at larger distances from the contact line. Further, we extended this approach from DTAB to photoswitchable arylazopyrazole triethylammonium bromide (AAP-TB) surfactants. AAP-TB can undergo E/Z photoisomerization and allows to change the surface activity through the choice of the configurational isomer with the Z being less surface active compared to the E. We demonstrate that EDeW with AAP-TB surfactants is possible similar to DTAB,

but with a smaller maximum change in contact of about 13° once a potential of +3 V is applied. In addition, photo-isomerization of AAP-TB allows to further finetune the CA reversibly by about 4°.

CPP 17.50 Mon 19:00 P5

Dynamic wetting of mixed rod-sphere suspensions and its relation to the suspension rheology — •Reza Azizmalayeri and Günter Auernhammer — Leibniz-Institut für Polymerforschung Dresden e. V.

In this study, we examine dynamic wetting of mixed rod-sphere suspensions near the advancing contact line. We compare pure spherical suspensions with 98:2 sphere-rod mixtures. Using a pinned droplet and moving substrate geometry on an inverted microscope, we achieve a locally stable contact line. Astigmatism Particle Tracking Velocimetry (APTV) measures the trajectories of tracer particles within the refractive index-matched suspension. Pinch-off experiments conducted via the Dripping-onto-Substrate (DoS) method provide Protorheology insights into shear and extensional viscosities. We analyse rod dynamics and orientation as they approach the advancing contact line, interact with the substrate, and re-enter the bulk suspension. In purely spherical suspensions, tracer trajectories near the advancing contact line deviate significantly from hydrodynamic model predictions. Conversely, mixed rod-sphere suspensions exhibit minimal deviations. Rod inclusion reduces effective viscosity during pinch-off, promoting deformation and thread thinning. This effect is amplified by rod-induced polydispersity and the disruption of spherical contact structures, weakening resistance to flow and altering rheology. Visualizations reveal that rods align parallel to the contact line, then rotate 90 degrees to align with the substrate.

CPP 17.51 Mon 19:00 P5

Statics and dynamics of drops on liquid infused surfaces — Hossein Abdolnezhad[1], •Martin Brinkmann[2], Ralf Seemann[2], and Ciro Semprebon[1] — [1]Department of Mathematics, Physics and Electrical Engineering, Northumbria University, Newcastle, UK — [2]Zentrum für Biophysik, Universität des Saarlandes, Saarbrücken, Germany

Slippery liquid-infused porous surfaces (SLIPS), inspired by the slippery properties of the Nepenthes pitcher plant, have been introduced to increase the mobility of wetting drops by minimizing the liquid-solid contact. Preparation of these surfaces involves infusing a lubricating liquid into a porous or textured surface, creating a thin liquid layer on top of the surface resulting in high drop mobility as well as unique properties such as anti-corrosion, self-cleaning, heat transfer enhancing, anti-fouling and anti-icing, water harvesting properties with a broad potential for application in industry.

The complex relationship between lubricant properties and retention mechanisms in liquid-infused surface, particularly the role of the lubrication ridge forming around the drop causing depletion of the lubricant over time brings up the questions of whether the lubricant ridge can be effectively controlled as well as whether there is an optimal size in relation to the volume of the drop sliding over liquid-infused surface. Recent experiments elucidate the role of the lubricant ridge in the dynamics of drops on liquid-infused surfaces, and led to the development of a theoretical understanding of the experimental observations combining finite-element and analytical modeling approaches.

CPP 18: Active Matter III (joint session BP/CPP/DY)

Time: Tuesday 9:30–12:45 Location: BAR/SCHÖ

CPP 18.1 Tue 9:30 BAR/SCHÖ

inertia-driven re-entrant coil-Globule transition of active ring polymers — •Sunil P Singh[1], Roland G Winkler[2], Rakesh Palariya[1], and Arindam Panda[1] — [1]Indian Institute of Science Education and Research Bhopal, India — [2]Theoretical Physics of Living Matter, Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Germany

The role of inertia in the collective dynamics of active systems has been a subject of increasing interest in recent studies. The present study investigates the inertial effects on active agents. We present the conformational and dynamical characteristics of an active Brownian ring polymer using Langevin dynamics simulations. We show that a long active ring polymer shrinks into globular-like structures even in the absence of attractive interactions. This transition becomes sharper and the structures more compressed as the reduced moment of inertia of the monomers increases, particularly in the intermediate range of activity. We demonstrate that the ring polymer undergoes a coil-globule-coil transition, which is modulated by both activity and rotational inertia. The coil-to-globule transition is mapped in the inertial parameter space (J-M) using the radius of gyration. Additional physical quantities, including bond-bond correlations, scaling behavior in the compressed state, monomer contact probability, geometric distances, coordination number, and effective temperature, further elucidate the physical mechanism driving the collapse. Finally, we show that the effective diffusivity of the ring polymer increases with the reduced moment of inertia as $D_p \sim \sqrt{J}$.

CPP 18.2 Tue 9:45 BAR/SCHÖ

Shape selectivity by complex buckling dynamics in poroelastic active gels — •Kinjal Dasbiswas[1], Subhaya Bose[1], Arnab Roy[1], Michael Vennettilli[1], and Anne Bernheim[2] — [1]University of California, Merced, USA — [2]Ben Gurion University, Israel

Shape change in animal cells is prototypically driven by active forces, generated by myosin molecular motors bound to the actin cytoskeleton. Inspired by experiments on disc-shaped extracts of crosslinked actomyosin gels, we aim to show how a family of 3D shapes can arise from buckling caused by non-uniform active stresses. Although synthesized with identical composition of actin, myosin and the crossliker fascin, these gels contract and buckle into different shapes depending on the initial aspect ratio of the disc: thinner gels tend to wrinkle, while thicker gels tend to form domes. By incorporating active stresses, actin alignment, and stress-dependent myosin binding kinetics into a 2D poroelastic gel model, we qualitatively capture trends in gel contraction dynamics observed from quantitative particle image velocimetry (PIV). Next, we carry out numeric simulations of a geometric elastic model for thin sheets to obtain 3D buckled shapes from the strain rates predicted by the poroelastic model. Our results show that the coupling of elasticity to solvent flow, motor binding and fiber alignment play an important role in shape changes in living matter. Our studies have implications for shape changes during tissue morphogenesis and cell migration.

CPP 18.3 Tue 10:00 BAR/SCHÖ

The energy cost to build a spindle — •Dongliang Zhang[1], Xingbo Yang[4], Jan Brugués[2,1,3,4], and Frank Jülicher[1,3,4] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [3]Center for Systems Biology Dresden, Dresden, Germany — [4]Physics of Life, Cluster of Excellence, TU Dresden, Dresden, Germany

Spindle is a structure actively build from microtubules (MTs), and plays an important role for chromosome segregation during cell cycle. It's observed in experiments that the spindle size and shape depends on the cell level metabolic rate. In this work, we developed a minimal model that captures the active, energy-consuming processes such as MT turnover and active stress generation, which shows the energy cost for spindle mass maintenance and spindle-shape formation. We show that a spindle can be self-organized through these active processes. We aim to predict how the size and shape of the spindle depends on the energy input, and explain relative experimental phenomena, e.g. spindle shrinkage when the metabolism level is reduced.

CPP 18.4 Tue 10:15 BAR/SCHÖ

Cytoskeletal oscillations drive large-scale flows and nuclear organization in early embryonic systems. — •Lara Koehler, Elissavet Sandaltzopoulou, and Jan Brugués — Physics Of Life, TU Dresden

Synchronization drives early embryonic development, enabling simultaneous cell divisions and the spatial organization of nuclei within the embryo. In organisms such as Xenopus, Drosophila, and zebrafish, mitotic waves coordinate cell cycles across distances that exceed diffusion limits, guided by a chemical oscillator. At the same time, global cytoplasmic flows in these syncytial tissues contribute to the large-scale self-organization of nuclei, yet the coupling between biochemical signaling and cytoskeletal mechanics that underlies these directed flows remains poorly understood. Here, we relax the geometric constraints of the embryo and investigate nuclear dynamics in Xenopus egg extracts and complementary simulations. We show that the periodic polymerization and depolymerization of microtubule asters are sufficient to generate robust large-scale directed flows, even though the asters are intrinsically isotropic. Furthermore, we demonstrate that cell division stabilizes short-range order in a global synchronized system. Together, these findings reveal a minimal physical mechanism by which cytoskeletal dynamics and biochemical oscillations jointly organize flows and patterns, with implications for understanding the emergent principles that shape early development across species.

CPP 18.5 Tue 10:30 BAR/SCHÖ

Geometric control of cell migration in disordered porous media — •Laeschkir Würthner[1] and Frederik Graw[2] — [1]European Molecular Biology Laboratory, Heidelberg, Germany — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany

Cell migration is a dynamic process that plays a central role in development, wound healing, and immune responses. Active cell movement is controlled by

several biochemical and mechanical cues, including chemokine gradients and the mechanical properties of the extracellular matrix (ECM). Although the biochemical pathways underlying directed cell motion are increasingly well understood, the influence of the porous structure of the ECM on active cell motion remains largely unexplored. Using a combination of computational modeling and theory, we investigate how active cells move through 3D disordered porous environments. We show that cell migration in disordered porous media can be understood as a generalized random walk among "traps", with the effective diffusivity determined by the geometry of the microenvironment. A key implication of our work is that spatial heterogeneities in porosity effectively direct cell motion, revealing a guidance mechanism that we refer to as porotaxis. Overall, our work connects geometry with cell motility and underscores the microenvironment as a key regulator of cell migration.

CPP 18.6 Tue 10:45 BAR/SCHÖ

Motility-induced mixing transition in exponentially growing multicellular spheroids — •Torben Sunkel[1,2], Lukas Hupe[1,2], and Philip Bittihn[1,2] — [1]MPI for Dynamics and Self-Organization, Göttingen, Germany — [2]Institute for the Dynamics of Complex Systems, University of Göttingen, Germany

Growth drives cellular dynamics in various dense aggregates, but its effects on other relevant activities have only received limited attention. Here, we investigate the interplay of unconstrained growth, steric repulsion and motility in a minimal agent-based model of exponentially growing, three-dimensional spheroids. Our results reveal a diverging mixing time scale at a critical motility threshold, below which mixing of cells is completely suppressed. Above the threshold, large-scale mixing is enabled. Using an effective phenomenological model parameterized from full simulations, we identify two fundamental mechanisms governing this transition: On the cell scale, weak motility-induced active motion is locally suppressed by growth-induced steric repulsion, consistent with an Active Brownian Particle type description of single-cell dynamics. Beyond this, the expanding nature of the system inhibits global mixing purely geometrically by limiting the exploration range of diffusive cell motion. Both mechanisms naturally scale with the growth rate, highlighting the nature of the transition as an interplay between proliferation and motility. The results provide a baseline for identifying additional biological mechanisms in experiments and could be relevant for competition, heterogeneous tumor evolution and other manifestations of motile proliferating active matter.

15 min. break

CPP 18.7 Tue 11:15 BAR/SCHÖ

Fluctuation-Response Theory of Non-Equilibrium Complex Fluids — •Ryota Takaki[1] and Frank Jülicher[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Center for Systems Biology Dresden, Dresden, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, Dresden, Germany

Active soft materials such as cytoplasm and tissues are constantly driven by chemical reactions and often retain long-lived mechanical memory. In this work, we develop a generalized hydrodynamic framework applicable to non-equilibrium fluids with memory at finite wavevectors and frequencies. Our approach is based on exact correlation-function identities, leading to a fluctuation-response relation for steady states, including non-equilibrium. Applying the theory to chemically driven active fluids, we uncover Active Viscoelastic Memory, in which reaction cycles dynamically renormalize the viscous response and can generate negative storage moduli at finite frequency, absent in conventional viscoelastic materials. Our results provide a first-principles basis for modeling memory-dependent dynamics in a broad class of biological and synthetic active systems, and suggest concrete rheological signatures of chemical driving that can be tested experimentally.

CPP 18.8 Tue 11:30 BAR/SCHÖ

Chemically Active Liquid Bridges Generate Repulsive Forces — •Noah Ziethen — DAMTP, University of Cambridge, UK

Intracellular droplets help organize cells by compartmentalizing biomolecules and mediating mechanical interactions. When such droplets bridge two structures, they generate capillary forces that depend on the surface properties and the separation between the structures. While the forces exerted by passive liquid bridges are well understood, the impact of active chemical reactions, ubiquitous in biological condensates, remains unclear.

Here, we investigate a single liquid bridge with continuous chemical turnover, in which the production and degradation of droplet material maintain a non-equilibrium steady state. In this active bridge, the reactions dynamically set the bridge radius, thereby controlling the force-distance relation. In striking contrast to passive systems, we find that activity can generate purely repulsive forces over a broad range of separations. These results show that chemical activity can qualitatively alter capillary forces generated by liquid bridges, suggesting a potential route for cells to actively regulate mechanical coupling via droplets.

CPP 18.9 Tue 11:45 BAR/SCHÖ

Shared Laws of Pattern Formation in Reaction-Diffusion and Phase Separation — •Daniel Zhou[1] and Erwin Frey[1,2] — [1]Arnold Sommerfeld Center for Theoretical Physics — [2]Max Planck School Matter to Life

Many nonlinear field theories generate a strikingly similar repertoire of patterns: arrested coarsening, traveling waves, and spatiotemporal chaos appear both in phase-separating systems and in classical reaction-diffusion models. These descriptions have different physical origins, yet recent studies on Turing mixtures and foams in protein systems [1] and on chemotaxis-driven phase separation in cell populations [2] have already highlighted unexpected connections between these ostensibly different mechanisms, linking foam-like, phase-separating, and reaction-diffusion-type patterns. The present work revisits the relation between kinetic and phase-separating descriptions from a more general viewpoint. A unifying perspective is developed that places different modeling frameworks on comparable footing, identifies the conditions under which they yield effectively equivalent patterns, and suggests how stability criteria and design principles can be translated between them. This points toward a more systematic classification of pattern-forming dynamics that cuts across traditional divides between reaction-diffusion, chemotactic, and phase-separating systems.

CPP 18.10 Tue 12:00 BAR/SCHÖ

Spatial self-organization of enzymes in complex reaction networks — •Vincent Ouazan-Reboul[1,2], Ramin Golestanian[2,3], and Jaime Agudo-Canalejo[2,4] — [1]LPTMS, CNRS, Université Paris-Sud, 91400, Orsay, France — [2]Max Planck Institute for Dynamics and Self-Organization, Am Fassberg 17, D-37077, Göttingen, Germany — [3]Rudolf Peierls Centre for Theoretical Physics, University of Oxford, OX1 3PU, Oxford, UK — [4]Department of Physics and Astronomy, University College London, WC1E 6BT, London, UK

Living systems contain intricate biochemical networks whose structure is closely related to their function and allows them to exhibit robust behavior in the presence of external stimuli. Such networks typically involve catalytic enzymes, which can have non-trivial transport properties, in particular chemotaxis-like directed motion along gradients of substrates and products. Here, we find that taking into account enzyme chemotaxis in models of catalyzed reaction networks can lead to their spatial self-organization in a process similar to biomolecular condensate formation. We develop a general theory for arbitrary reaction networks, and systematically study all closed unimolecular reaction networks involving up to six chemicals. Importantly, we find that network-wide propagation of concentration perturbations can be key to enabling self-organization, in a manner which is highly sensitive on the global network structure.

CPP 18.11 Tue 12:15 BAR/SCHÖ

Spatial organisation of the cell's metabolic power plant via phase separation — •Kathrin S. Laxhuber[1,2] and Frank Jülicher[1,2] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck School Matter to Life

Cell metabolism is the power plant that fuels the active processes essential to life. Recent experimental results show that glycolytic enzymes, central to sugar metabolism, phase-separate to form foci under energetic stress and can localise to sites of demand. To understand this phenomenon, we build and study a minimal theoretical model. We show that droplet formation can act as a metabolic switch that enables the system to maintain energetic homeostasis at higher output power. Notably, the metabolic droplets that emerge from this switch can self-organise to colocalise with demand. We discuss the non-equilibrium features and spatial energetic profiles in this system.

CPP 18.12 Tue 12:30 BAR/SCHÖ

Emergent interactions lead to collective frustration in robotic matter — •Onurcan Bektas[1,3], Adolfo Alsina[2,3], and Steffen Rulands[1,3] — [1]Arnold-Sommerfeld-Center for Theoretical Physics and Center for NanoSciences, Ludwig-Maximilians-Universität München, Theresienstr. 37, 80333 München, Germany — [2]GISC, Universidad Rey Juan Carlos, Tulipán, 28933, Móstoles, Spain — [3]Max-Planck-Institute for the Physics of Complex Systems, Noethnitzer Str. 38, 01187 Dresden, Germany

Current artificial intelligence systems show near-human-level capabilities when deployed in isolation. Systems with intelligent agents are deployed to perform tasks collectively. This raises the question of whether robotic matter, where many learning and intelligent agents interact, shows emergence of collective behaviour. And if so, what kind of phenomena would such systems exhibit? Here, we study a paradigmatic model for robotic matter: a system composed of a large collection of stochastic interacting particles where each particle is endowed with a deep neural network that optimizes its transitions based on the particles' environments. For a 1D model, robotic matter exhibits complex phenomena arising from emergent interactions, including transitions between long-lived learning regimes, the emergence of particle species, and frustration. We also find an

abrupt, density-dependent change in the behaviour of particles. Using active matter theory, we show that this phenomenon is a reflection of a phase transition with signatures of criticality. Our model captures key phenomena observed in more complex forms of robotic systems.

CPP 19: Focus Session: Water – from Atmosphere to Space I (joint session CPP/DY)

Water plays a vital role in diverse Earth processes across multiple scales, from atmospheric cycles and aerosol chemistry to geological porous media and nanoscale biological functions of hydrated proteins. Despite its fundamental importance and numerous anomalous properties, such as the diverging heat capacity of supercooled water, pure bulk water remains poorly understood. Key phenomena like evaporation and crystallization are relevant not only on Earth but also in extraterrestrial environments. In Germany, molecular water research is flourishing across prestigious centers, exemplified by the new BlueMat cluster at Hamburg University of Technology, the renewed RESOLV cluster at Ruhr-University Bochum, and the Max Planck Society's expanding Liquid Initiative in Mainz. The 2025 inauguration of the Centre for Molecular Water Science (CMWS) at Hamburg's DESY campus further strengthens a Europe-wide interdisciplinary network, uniting 47 founding members from 12 countries to advance water science across disciplines and methods. Within this focus session the state of molecular water research shall be discussed and interactions between the physical sub-fields shall be fostered.

Organized by Alexander Schlaich, Katrin Amann-Winkel, Mischa Bonn.

Time: Tuesday 9:30–11:00 Location: ZEU/LICH

Topical Talk CPP 19.1 Tue 9:30 ZEU/LICH

Surface adsorption and protonation equilibrium of atmospheric organics at the aqueous surface — •Nønne Prisle — Center for Molecular Water Science, Deutsches Elektronen-Synchrotron DESY, Notkestrasse 85, D-22607 Hamburg, Germany — Institute of Inorganic and Applied Chemistry, University of Hamburg, Martin-Luther-King-Platz 6, D-20146 Hamburg, Germany — Center for Atmospheric Research, University of Oulu, P.O. Box 4500, FI-90014, Oulu, Finland

Atmospheric aerosols comprise a significant fraction of organic species which frequently exhibit both surface activity and Brönsted acidity or basicity in aqueous solutions. The high surface area to bulk volume ratios of nano- and microscopic aerosols and droplets further favor surface-specific states, affecting both bulk-phase and heterogeneous chemistry.

We used X-ray Photoelectron Spectroscopy (XPS) in combination with high-brilliance synchrotron radiation to directly observe the protonation state of atmospheric acids and bases at the surfaces of aqueous aerosol and droplet models. We found that for each acid-base pair, the neutral species is enhanced in the surface, consistent with its higher surface activity, compared to the charged conjugate. This introduces a shift in the protonation equilibrium at the aqueous surface corresponding to an apparent change in pKa of 1-2 pH units, depending on the concentration, acidity, and surface activity of the conjugate acidic and basic species.

CPP 19.2 Tue 10:00 ZEU/LICH

The Effect of pH on the Structure of Model Sea Spray Aerosol Surfaces — •Clara M. Saak, Lars Höhner, and Ellen H.G. Backus — Institute of Physical Chemistry, Faculty of Chemistry, University of Vienna, Währinger Straße 42, 1090 Vienna, Austria

Aerosols play a key role in the global climate due to their ability to scatter and reflect solar radiation and to act as cloud condensation nuclei (CCN), exerting a pronounced cooling influence on the global climate. In particular, the surface availability of ions and organic compounds is known to affect the hygroscopicity of the particle and thereby its ability to act as a CCN [1]. While the surface propensity of individual compounds has been studied widely, much less is known about more complex systems. Here we focus on the impact of bulk pH on the architecture of mixed aqueous interfaces. In atmospheric systems the pH has been shown to range from roughly pH 8 to 2 [2]. Using sum-frequency-generation (SFG) spectroscopy in conjunction with surface tension data we study the surface composition and structure of short and long chain organic acids at different protonation stages, obtained by varying the pH. Using this approach, we find pronounced changes in the structuring of the aqueous sub-surface layers depending on the specific composition and pH, and in the Gibbs free energy of adsorption of the studied organics. Our results show that it is feasible for subtle environmental changes to considerably affect structure and composition of the aqueous interface, which is known to play a key role in aerosol hygroscopicity. CPP 19.3 Tue 10:15 ZEU/LICH

Crystallization behaviour of nanoparticle suspensions — •Isabell Zick[1,2], Eduard Edel[2], and Katrin Amann-Winkel[1,2] — [1]Institut für Physik, Johannes Gutenberg-Universität, Staudinger Weg 7, 55128 Mainz, Germany — [2]Max-Planck-Institut für Polymerforschung, Ackermannweg 10, 55128 Mainz, Germany

Water is one of the most abundant substances in the world and due to this in close contact with many materials including micro- and nanoplastic particles. Those have been detected not only in sea but also in the atmosphere, where the particles can interact with water and act as cloud condensation nuclei or ice-nucleating particles. Emerging evidence suggests that nanoparticles with increased surface roughness or chemical functionalities may promote heterogeneous ice nucleation through different processes like, e.g., contact- and immersion-freezing. Such a behaviour affects cloud properties with significant implications for Earth*s radiative balance and the hydrological cycle.

We investigate atmospherically relevant nanoparticles dispersed in water to investigate their influence on the ice crystallization. Our experiments include calorimetry (DSC) as well as X-ray diffraction measurements (XRD). Our measurements show that the crystallization temperature depends on the particle size, concentration, and the chemical surface of the particles. Using XRD, we investigate the restructuring of the water molecules during supercooling, observed by a shift in the characteristic main diffraction peak of water and the subsequent crystallization process.

CPP 19.4 Tue 10:30 ZEU/LICH

Laser-Excited X-ray Reflectivity of Aqueous SrCl2 at the Air-Water Interface — •Ali Ashtiani Abdi[1,2], Julia Kobus[1,2], Svenja C. Hövelmann[1,2], Philipp Jordt[1,2], Nicolas Hayen[1,2], Prashant Hitaishi[1,2], Ajay Ajay[1,2], Rabia Qamar[1,2], Otto Lippmann[1,2], Chen Shen[3], Florian Bertram[3], and Bridget M. Murphy[1,2] — [1]IEAP, CAU Kiel University, Kiel, Germany — [2]Ruprecht Haensel Laboratory, DESY, Hamburg, Germany — [3]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

Understanding aqueous interfaces is essential for describing chemical processes in atmospheric, marine, and geochemical environments. While monovalent salts have been widely studied, the interfacial behavior of divalent ions is less understood, despite their relevance in seawater aerosols and reactive brines. SrCl2 is a representative divalent electrolyte whose interfacial structure may show alteration by laser illumination.

We investigate aqueous SrCl2 solutions at different concentrations using X-ray reflectivity (XRR) at the liquid-air interface. Measurements were performed at the LISA setup at beamline P08, PETRA III (DESY), where controlled laser illumination can be applied directly to the X-ray footprint, following the instrumentation concept of Warias and Hovelmann et al. (J. Synchrotron Rad. 2024). Reflectivity curves were recorded with and without laser exposure. The data demonstrate the suitability of SrCl2 surfaces for laser-assisted XRR and the sensitivity of the method to potential changes in interfacial structure, including indications of near-surface layering.

CPP 19.5 Tue 10:45 ZEU/LICH

Monitoring Uptake, Release and Reaction of Gases at the Liquid-Vapor Interface — •Tillmann Buttersack[1], Shirin Gholami[1], Clemens Richter[1], Daniela Torres-Diaz[1], Bernd Winter[1], Pavel Jungwirth[2], Stephen Bradforth[3], Markus Ammann[4], Ruth Signorell[5], Ivan Gladich[6], Remi Dupuy[7], Philip Mason[2], and Hendrik Bluhm[1] — [1]Fritz Haber Institute, Max Planck Society, Berlin, GER — [2]IOCB, Czech Academy of Sciences, Prague, CZ — [3]University of Southern California, Los Angeles, USA — [4]Paul Scherrer Institut, Villigen, CH — [5]EZH Zürich, CH — [6]University of Urbino, Urbino, I — [7]Sorbonne Université, Paris, F

Multiphase reactions are omnipresent in nature, industrial applications. The direct observation of reactions at the liquid-vapor interface requires spectroscopic

techniques that are surface specific and chemically sensitive to detect low concentrations, e.g., photoelectron spectroscopy (XPS). Furthermore, the sample delivery method must allow sufficient time for an interface reaction to proceed. These complex challenges require individual approaches for each system of interest. One example for a multiphase process is the reaction between liquid alkali metal and water vapor, which is extremely fast. We used a slow droplet train of NaK in a wet atmosphere and observed the formation of golden aqueous solutions with metallic properties with XPS. An example with relevance for atmospheric chemistry is the formation and the release of sulfur dioxide (SO2) from aqueous sulfite solutions due to acidification. We demonstrated that dissolved gases can be detected with XPS even though their concentration is only about 1 mM.

Process-Directed Self-Assembly of Copolymer Blends: Micro- and Macrophase Separation — •Jiayu Xie and Marcus Müller — Institute for Theoretical Physics, Georg August University Göttingen, Germany

The equilibrium phase behavior of binary diblock copolymer blends involves a complex interplay between microphase and macrophase separation. We investigate blends of linear diblock copolymers, A_1B_1 (cylinder-forming) and A_2B_2 (cylinder- or lamella-forming), using a combination of self-consistent field theory (SCFT) and single-chain-in-mean-field (SCMF) simulations. When the chain-length asymmetry between the A_1B_1 and A_2B_2 copolymers becomes large, the equilibrium phase diagram exhibits a wide macrophase-separation channel. Strikingly, our simulations reveal a strong pathway dependence within this region: rapid quenching yields a spatially homogeneous structure with narrow cylinder-size distributions and strong hexagonal order, whereas gradual annealing promotes local demixing, resulting in bimodal domain sizes and weaker order. We demonstrate that this process-dependent nonequilibrium behavior can be explained by the distinct evolutions of the system state and free-energy landscape of the blends under quenching or annealing. These findings highlight how different processing conditions can direct nanostructure formation in block copolymer blends, and establish a mechanistic link between processing pathway and the final morphology, thus offering insights into rational design of targeted nanostructured materials.

CPP 20.2 Tue 9:45 ZEU/0160

Topological defect engineering enables size and shape control in self- assembly — Lara Koehler[1,3], Markus Eder[2], Vincent Ouzan-Reboul[3], Christoph Karfusehr[2], Andrey Zelenskiy[3], Pierre Ronceray[4], Friedrich Simmel[2], and •Martin Lenz[3] — [1]MIPPKS, Dresden, Germany — [2]TU Munich, Germany — [3]U. Paris-Saclay, Orsay, France — [4]Aix-Marseille-Université, Marseille, France

Equilibrium self-assembly is a powerful way to build nano- and microscale structures out of interacting subunits. The size and shape of such structures must be controlled in many biological and technological functions, posing significant practical challenges as current strategies require multiple subunit types or the precise control of their shape and mechanics. Here we introduce an alternative approach that circumvents these obstacles. Our method uses subunits whose interactions promote crystals, but also favor crystalline defects. We show theoretically that the magnitude of these interactions, which is well controlled in experiments, governs the self-assembly through topological restrictions on the scope of the defects. Using DNA origami, we demonstrate both size and shape control in two-dimensional disk- and fiber-like assemblies. Our basic concept of defect engineering operates well beyond these examples, and provides a broadly applicable framework to control self-assembly.

CPP 20.3 Tue 10:00 ZEU/0160

Soft colloidal monolayers under drying conditions — •Kai Luca Spanheimer[1], Maret Ickler[2], Julian Ringling[3], Nicolas Vogel[2], Matthias Karg[4], and Hartmut Löwen[1] — [1]Insitut für Theoretische Physik II, Heinrich-Heine-Universität, 40225 Düsseldorf, Germany — [2]Institute of Interfaces and Particle Technology, Friedrich-Alexander University, Erlangen, Germany — [3]Physikalische Chemie I: Kolloide und Nanooptik Heinrich-Heine-Universität, 40225 Düsseldorf, Germany — [4]Institut für Chemie, Martin-Luther-Universität Halle-Wittenberg, 06099 Halle, Germany

Langmuir-Blodgett deposition is a well established technique in research and industry. Even though, there still are effects in this process that are not yet explored from a theoretical standpoint. It is usually assumed that the deposited pattern is identical with the one appearing at the water-air interface. In recent experimental studies, strong reorganization during the drying of soft colloidal monolayers has been observed [1]. Capillary forces during drying are known to change nanoscopic structures, sometimes even leading to their destruction. To model these processes we propose a combination of overdamped particle dynamics coupled to dewetting dynamics of an evaporating liquid film. The patterns produced by this model fit those observed in experiment. This theoretical approach allows exploration of the drying dynamics. Thereby we gain new insights into the drying process and makes experimental results produced with Langmuir-Blodgett deposition more reliable.

CPP 20.4 Tue 10:15 ZEU/0160

Mechanical assessment of microfluidically-generated poroelastic microgel particles — Aude Sagnimorte[1,2], Anke Lindner[2], and •Joshua McGraw[1] — [1]Gulliver-CNRS, ESPCI-PSL, 10 rue Vaquelin, 75005 Paris — [2]PMMH-CNRS, ESPCI-PSL, 10 rue Vaquelin, 75005 Paris

Soft microgels have numerous applications in diverse fields,such as tissue engineering, drug delivery systems, soft robotics, or as model systems for suspensions or colloids. Among these, photopolymerized hydrogels such as poly(ethylene glycol) diacrylate (PEGDA) are commonly used due to their highly tunable mechanical properties. However, proper characterisation of these properties is challenging, in part due to their small scale, on the order of tens of microns, and in particular the lack of assessment of their time-dependent properties. Here we provide a comprehensive mechanical characterisation of individual photopolymerised microgels particles using atomic force microscopy (AFM) for precise local measurements. In particular, we performed indentation-relaxation tests on PEGDA microdisks immersed in water. By varying indentation depth and probe diameter, we changed the contact area and observed relaxation responses which are indicative of poroelastic behaviour. In particular, larger contact areas resulted in longer relaxation times. Our results also show that increasing the amount of solvent increased the relaxation time. Our collected results are consistent with a simple, Herzian poroelastic model giving good agreement with both the approach and relaxation phases of the experiments.

CPP 20.5 Tue 10:30 ZEU/0160

Nonlinear Viscoelastic Response and Stress Shielding in Driven Bistable Spring Chains — •Sven Pattloch[1,2] and Joachim Dzubiella[1,2] — [1]Applied Theoretical Physics-Computational Physics, Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Germany. — [2]Cluster of Excellence livMatS@FIT-Freiburg Center for Interactive Materials and Bioinspired Technologies, Albert-Ludwigs-Universität Freiburg, Germany

Bistable micromodules are a promising route to design adaptive mechanical metamaterials with tunable viscoelastic response. Here, a driven one-dimensional chain of bistable springs is studied in which both the mechanical deformation and the internal excitation states evolve dynamically under time-dependent forcing. Their coupling produces rich nonlinear viscoelastic behaviour, including frequency-dependent susceptibilities, delayed deformation, and pronounced hysteresis in cyclic loading.

Using analytical linear response theory complemented by numerical simulations, the model quantifies how microscopic parameters and driving protocols control effective stiffness, loss, and phase lags. A key result is a strong attenuation ('shielding') of stress propagation along the chain that is already present for monostable springs but is markedly amplified by excitation switching in bistable modules. These findings provide simple design principles for tailoring nonlinear viscoelasticity, hysteresis, and stress shielding in driven soft matter and mechanical metamaterial systems.

CPP 20.6 Tue 10:45 ZEU/0160

Euler buckling on curved surfaces — •Shiheng Zhao[1,2,3] and Pierre A. Haas[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems — [2]Max Planck Institute of Molecular Cell Biology and Genetics — [3]Center for Systems Biology Dresden

Nearly three hundred years ago, Euler showed that an inextensible straight elastic line in the plane buckles under compression when the compressive force F reaches a critical value $F_* > 0$. But how does such an elastic line buckle within a general curved surface? Here [1], we reveal that the classical instability changes fundamentally: By weakly nonlinear analysis of the buckling of an asymptotically short elastic line, we show that the critical force for the lowest buckling mode is $F_* = 0$ and discover a new bifurcation structure in which the modes of classical Euler buckling split into pairs. For long elastic lines, we numerically find an additional bifurcation by which the second of these new modes becomes the lowest mode and show that, at sufficiently large F, they undergo discontinuous snap-through to higher end-to-end compression. We explain these bifurcations in terms of the general unfolding of a pitchfork. This constitutes the foundations for a class of mechanical instabilities within curved surfaces from which, for example, biological shape emerges in development.

Linking molecular dynamics and experimental FORCs in multicore magnetic nanoparticles — Ekaterina Novak[1], •Malika Khelfallah[2], Andrey Kuznetsov[3], Deniz Mostarac[4], Claire Carvallo[2], Amélie Juhin[2], and Sofia Kantorovich[3] — [1]Ekaterinburg, Russia — [2]Sorbonne Université, Paris, France — [3]University of Vienna, Vienna, Austria — [4]University of Edinburgh, Edinburgh, United Kingdom

Multicore magnetic nanoparticles - clusters of several magnetic grains embedded in a nonmagnetic matrix - exhibit collective behaviour distinct from single-core particles and are promising candidates fro drug targeting and magnetic hyperthermia. Their magnetic cores possess finite anisotropy, and the multicore assemblies range from near-spherical to elongated ellipsoids, features that strongly affect their response to external fields. To study these effects, we use molecular dynamics simulations [1] to model internal structure, anisotropy distribution, and collective switching. As a key diagnostic, we employ First Order Reversal Curves [2], which experimentalists routinely measure for immobilised multicore particles, enabling direct comparison between simulations and experiments. FORC diagrams reveal coercivity distributions and magnetic interactions between grains, offering detailed insight into interaction mechanisms and domain processes.

The work was financially supported by the RSF grant No. 25-22-00762.

Hydrodynamics substantially affects induced structure formation in magnetic fluids — •Henning Reinken and Andreas M. Menzel — Otto-von-Guericke-Universität Magdeburg, Germany

Magnetorheological fluids consist of micrometer-sized magnetic particles suspended in a carrier liquid [1]. Sufficiently strong external magnetic fields lead to the formation of string-like particle aggregates, which results in complex magnetorheological behavior. This mechanism can further be used in the production of magnetic elastomers during the polymerization process when the carrier medium is still fluid and particulate structure formation still possible [2]. Using numerical simulations that spatially resolve both fluid flows and magnetization, we demonstrate that hydrodynamic interactions play a substantial role during structure formation. Hydrodynamics supports the emergence of string-like aggregates, while magnetic interactions align them. Considering besides this fundamental insight the enormous technical importance and potential of magnetic fluids, our results are substantial also from an application perspective.

CPP 20.9 Tue 11:45 ZEU/0160

Near-surface colloidal dynamics in jammed and slipping microgel suspensions — •Masoodah Gunny[1], Frédérick Caetano[2], Matilde Bureau[2], Alexandre Vilquin[1], Marie Le Merrer[2], Catherine Barentin[2], and Joshua McGraw[1] — [1]Gulliver - CNRS, ESPCI-PSL 10 Rue Vauquelin 75005 Paris, France — [2]ILM - CNRS, Claude Bernard University, 16 Enrico Fermi 69100 Villeurbanne, France

Jammed suspensions of soft microgel particles exhibit wall slip along smooth boundaries. The direct observation of dynamics within a supposed depletion layer near the wall were difficult to achieve as a result of the layers' supposed sub-micrometric dimensions. We use total internal reflection fluorescence microscopy (TIRFM) to observe colloidal-particle dynamics near the interface between glass and microgel suspensions. Remarkably, microgel suspensions display nanoscale velocity profiles with a slope rupture; particle velocity increases with distance near the wall, and tends to a constant beyond a distance which is characteristic of the ones predicted previously. Beyond velocimetry, we also study the statistical particle altitude distributions near the wall in TIRFM measurements. These distributions are strongly pressure dependent, with nanoparticles more likely found near the solid/liquid interface when the fluid is transported faster near the wall. This high-velocity particle enrichment, not seen for the Newtonian case, is consistent with the development of a depletion layer under such conditions. Taken together, our observations give strong support for the existence of a depletion layer being responsible for wall slip.

CPP 20.10 Tue 12:00 ZEU/0160

Random close packing as a conserved directed percolation transition — •Thomas Axmann and Michael Schmiedeberg — Theoretical Physics: Lab for Emergent Phenomena, Soft Matter Theory Group, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

In studying quenches in soft sphere systems O'Hern et al. related the onset of overlaps to isostaticity [1], and consequently to the random close packing scenario. The conditions that lead to the avoidance of overlaps between spheres can be studied with the random organization model [2], which was initially introduced to investigate self organization in sheared colloids. Modifications of this model, which dynamically reduce interparticle overlaps, were used to characterize the random close packing problem as the critical point of a dynamic absorbing state transition in the $d + 1$ dimensional conserved directed percolation universality [3,4].

We aim to deepen the understanding of this connection by demonstrating that the configuration change at each time step can be chosen with a fully deterministic strategy while retaining the features of the transition. We clarify difficulties in the treatment of percolating clusters and find that the median overlap depth proves to be a more useful order parameter.

Rescaled mode-coupling scheme for dynamics in binary mixtures of highly charged colloids — •Daniel Weidig and Joachim Wagner — University of Rostock, Rostock, Germany

We investigate dynamic processes in binary mixtures of highly charged colloidal particles by means of Brownian dynamics and multi-component mode-coupling theory (MCT). As input for MCT, thermodynamically consistent, static structure factors from integral equations with Rogers-Young closure are used which are in quantitative agreement to Fourier transforms of static pair correlation functions resulting from simulations.

MCT based on partial structure factors in many-particle systems predicts dynamic properties such as long-time self-diffusion coefficients in qualitative agreement to simulation trajectories. Using instead structure factors from systems with slightly reduced number of effective charges as input, a quantitative agreement of MCT with simulations is achieved. In mixtures of identically charged particles with different short-time mobilities, this rescaled MCT scheme accurately predicts coupling effects in long-time dynamics observed in Brownian dynamics simulations.

CPP 20.12 Tue 12:30 ZEU/0160

Electric double layers - the software package capDFT — Fabienne Dressler and •Andreas Härtel — Institute of Physics, University of Freiburg

Electric Double Layers are used to store electric energy, they can be utilized to harvest energy from waste heat or steps in concentrations, and they stabilize colloidal systems. In all cases, mobile ions arrange themselves to screen surface charges, resulting in sometimes densely packed regions of microscopic particles far from bulk states that dominate the macroscopic physical properties of the system. Modeling these complex systems has theoretical and numerical limitations, but good although expensive solutions exist. We present an open-source software package to treat the described modeling utilizing classical density functional theory [1]. The package has been used successfully in studies of underscreening [2] and allows to go beyond the standard mean-field approximation of primitive models [3]. We will demonstrate the package by discussing an example, where we study capacities of structured electrodes.

Molecular modelling of gas solubility and free volume trends in Si-functionalized ionic liquids — •Kateryna Goloviznina[1,2], Eduards Bakis[3], Inês C. M. Vaz[2,4], Agilio Padua[2], and Margarida Costa Gomes[2] — [1]ICSM, University of Montpellier, CEA, CNRS, ENSCM, 30207 Bagnols-sur-Ceze, France — [2]Laboratoire de Chimie, ENS de Lyon and CNRS, 46 allée d'Italie, 69364 Lyon, France. — [3]Faculty of Chemistry, University of Latvia, Jelgavas 1, Riga, LV-1004, Latvia. — [4]CICECO, Aveiro Institute of Materials,

Department of Chemistry, University of Aveiro, 3810-193 Aveiro, Portugal

Molecular dynamics (MD) simulation is a powerful technique that provides insight into the nanoscale structure and transport properties of liquids in bulk and at interfaces, explaining experimentally observed phenomena and contributing to the rational design. In the present work, we explored Si-functionalized imidazolium-based ionic liquids—low-density, low-viscosity systems—that are promising for gas capture and separation due to their enhanced free volume. [1] Using classical MD simulations with the CL&Pol polarizable force field, [2] we proposed a way to estimate free-volume trends and solubilities of simple gases (e.g., argon) without the need to perform costly experiments. The work was further extended to unsaturated C_2 hydrocarbons, for which we rationalized solubility trends via local structural analysis and estimated the contributions of van der Waals, electrostatic, and polarization terms to the solvation free energy.

Classical DFT compared to AFM measurement of structural forces from confined electrolyte containing charged nanoparticles — •Simone Riva[1], Michael Ludwig[2], Regine von Kltizing[2], and Ofer Manor[1] — [1]Technion, Haifa, Israel — [2]Technische Universität Darmstadt, Darmstadt, Germany

We use classical density functional theory (DFT) to model colloidal-probe atomic force microscopy (AFM) force curves across an aqueous electrolyte containing charged solid nanoparticles. The charged AFM probe and substrate interact through a suspension of silica nanoparticles. The probe experiences oscillatory forces driven by the structuring of the charged nanoparticles, which can enhance the stability of the film. Structural forces are characterized by an alternation of repulsion due to steric and electrostatic nanoparticle interactions, and depletion attraction. We present a self-consistent theory of oscillatory forces in ionic systems. Moreover, we compare different DFT approaches and validate them against AFM measurements, to develop a theory that best fits the rich physics of experiments. We calculate structural and EDL forces by minimizing dedicated functionals. We adopt two types of weighted density functionals, disclosing their applicability in different concentration conditions. We propose a way to include electrostatic interactions between nanoparticles in an effective hard-sphere functional. We further confirm a general scaling law of the oscillation wavelength observed in experiments and connect it to nanoparticle packing structures. The theory agrees well with measurement in the absence of fitting parameters. Riva et al., JCIS 2026, 702, 138901.

CPP 21.3 Tue 10:15 ZEU/0255

Sc-cDFT: A Single-Chain Simulation Framework with Classical Density Functional Theory for Polymers — •Raju Lunkad[1], Alejandro Gallegos[2], Jianzhong Wu[3], and Marcus Müller[1] — [1]Institute for Theoretical Physics, Georg-August University, 37077 Göttingen, Germany — [2]Department of Chemical and Materials Engineering, New Mexico State University, Las Cruces, New Mexico 88001, United State of America — [3]Department of Chemical and Environmental Engineering, University of California, Riverside, CA, United States of America

We present Sc-cDFT, a combination of Single-Chain Simulation with classical Density-Functional Theory (cDFT), for modeling polymer solutions and brushes. In this approach, intramolecular correlations are explicitly treated using Monte-Carlo (MC) simulations, while intermolecular correlations are extracted from cDFT. In this way, we capture structural properties and thermodynamics of multi-chain systems while providing a segment-level description of the dynamic behavior. Importantly, this framework substantially reduces computational cost, enabling the simulation of significantly longer polymer chains that are often inaccessible to fully explicit particle-based simulations. We validate the Sc-cDFT framework for hard-sphere polymer solutions and brushes by comparing polymer configurations and the segmental density profiles with fully explicit particle-based simulations, showing quantitative agreement.

CPP 21.4 Tue 10:30 ZEU/0255

Adsorption Thermodynamics and Kinetics of Complex Fluids: Physical Modeling of Surface Saturation, Reservoir Depletion, Lateral Interactions, and Collective Effects — •Nada Ben Amor[1,2], Daniela Bauer[1], Benjamin Braconnier[1], and Benoit Coasne[2,3] — [1]IFP Energies nouvelles, 92852 Rueil-Malmaison, France — [2]Université Grenoble Alpes, CNRS, LIPhy, F-38000 Grenoble, France — [3]Institut Laue Langevin, F-38042 Grenoble, France

Adsorption at solid surfaces is considered a promising technique to capture and remove emerging pollutants such as PFAS from water. However, a major gap in the literature remains in modeling complex adsorption mechanisms. Three key factors were identified for modeling adsorption thermodynamics and kinetics: surface saturation, reservoir depletion, and lateral interactions. While the first is captured by the celebrated Langmuir model, reservoir depletion, which is crucial for assessing adsorption in batch and dynamic experiments, is often neglected in classical kinetic models. Lateral interactions are also important for pollutants like PFAS as they undergo cooperative adsorption. A 2D lattice gas model with two- and three-body lateral interactions is solved using mean-field and quasi-chemical approximations. The resulting thermodynamics lead to a phase diagram predicting complex adsorption isotherms in agreement with available experiments as well as a first-order dilute to dense phase transition. A mixed-order kinetic model including all three factors is proposed and both thermodynamic and kinetic models are successfully applied to experimental data.

CPP 21.5 Tue 10:45 ZEU/0255

Molecular Dynamics Insights into Thermodynamic and Structural Properties of Water Adsorbed Poly(Heptazine Imide) Zeolites — •Youssef Mabrouk[1], Akshey Suresh[2], Yizak Tzegazab[2], Lingli Ni[2], Martin Oschatz[2], Alexander Croy[1], and Stefanie Gräfe[1] — [1]Friedrich Schiller University of Jena, Insitute of Physical Chemistry, Lessingstraße 4, 07743 Jena, Germany — [2]Friedrich Schiller University of Jena, Institute for Technical Chemistry and Environmental Chemistry, Philosophenweg 7a, 7743 Jena, Germany

The recently reported reversible water adsorption of porous layered carbon nitrogen frameworks suggests their high potential as functional materials for energy storage and conversion applications specifically in view of the controlled crystallinity and polarity and water binding motifs these frameworks offer. Based on molecular dynamics simulations of pressure-controlled solid/gas equilibrium isotherms, the framework structure-dependent adsorption of water in poly(heptazine imides) is here investigated. Using minimal motifs of heptazine sheets in pressure-controlled water vapor environments, the load-dependent transition from monomolecular to condensation-limited adsorption is furthermore investigated. The hydrophilicity characterized by the isotherms agree with physiosorption experiments. The layer planarity and pore geometry-dependent crystallinity characterized by the structure factor and normal modes agree with x-ray diffraction and infrared spectroscopy experiments. Overall, our results contribute to identifying the relevance of each structural motif to adsorption.

CPP 21.6 Tue 11:00 ZEU/0255

Insights into phenylalanine self-assembly and its modulation by nucleotides from molecular dynamics simulations. — •Mattia Borriello — Ruhr-Universität Bochum

Phenylalanine (Phe) can aggregate in water into various fibrillar structures, which is relevant to diseases like phenylketonuria. The precise molecular structure of these aggregates is still unknown, and although they dissolve in the presence of nucleotides such as ATP, the mechanism behind this disassembly remains unclear. We use molecular dynamics simulations to gain new insights on Phe cluster structure, understand which interactions drive this process and how nucleotides can modulate it.

Parallel tempering simulations of Phe in water in zwitterionic form have been performed varying concentration and temperature. Analysis of the trajectories revealed a strong tendency to aggregate in two ordered structures. One is characterized by a tubular shape, while the other by an alternating motif. Cluster stabilization is mainly electrostatic for smaller aggregates, while apolar interactions become significant as the size of the clusters grows.

The same computational approach has been extended to systems containing Phe and NaCl or different nucleotides, such as ATP, ADP and AMP. While NaCl showed a limited influence on aggregation, nucleotides can inhibit cluster formation and disrupt pre-existing aggregates. Our findings provide molecular-level insight into both the structural organization of Phe assemblies and into the mechanisms through which nucleotides modulate their stability.

From Solution to Thin Films: Structure Formation Pathways in Organic Photovoltaic Films — •Eva M. Herzig — Dynamik- und Strukturbildung - Herzig Group, University of Bayreuth, Germany

The performance of organic solar cells is governed by a delicate interplay between molecular packing, phase separation, and mesoscale connectivity in donor-acceptor blends. It is therefore highly desirable to control structure formation; however, this remains a non-trivial task. Several factors contribute simultaneously: the initial aggregation state in solution [1,2], the rapid structure formation during solution processing [2], and subsequent temperature- or solvent-annealing steps [3,4]. In this talk, I will discuss and illustrate with selected examples at which of these stages the final thin-film morphology can be controlled.

Using time-resolved and multimodal characterization methods, including grazing-incidence X-ray scattering and optical spectroscopy, we resolve the evolving structures during and after film deposition. These measurements reveal how subtle variations in processing conditions translate into distinct nanoscale morphologies.

CPP 22.2 Tue 10:00 ZEU/0260

DBTTF:HATCN Cocrystals – experimental details on influence of crystal solvents on crystal structure and on charge transfer — •Andreas Opitz[1], Ana M. Valencia[2], Lisa Schraut-May[3], Marie Siegert[3], Sebastian Hammer[3], Beatrice Cula[4], Alexandra Friedrich[5], Holger Helten[5], Jens Pflaum[3], and Caterina Cochi[6] — [1]Institut für Physik, Humboldt-Universität zu Berlin — [2]Institute of Physics, Carl-von-Ossietzky Universität Oldenburg — [3]Experimental Physics VI, Julius-Maximilians-Universität Würzburg — [4]Department of Chemistry, Humboldt-Universität zu Berlin — [5]Institute of Inorganic Chemistry & Institute for Sustainable Chemistry and Catalysis with Boron, Julius-Maximilians-Universität Würzburg — [6]Institute of Condensed Matter Theory and Optics, Friedrich-Schiller-Universität Jena

Donor-acceptor (D:A) cocrystals offer a promising platform for next-generation optoelectronic applications, but the impact of residual solvent molecules on their properties remains an open question. We investigate six novel D:A cocrystals of dibenzotetrathiafulvalene (DBTTF) and 1,4,5,8,9,11-hexaazatriphenylenehexacarbonitrile (HATCN), prepared via solvent evaporation, yielding 1:1 molar D:A ratios with solvent molecules in the structure, and horizontal vapor deposition, resulting in solvent-free 3:2 cocrystals. Optical properties of these materials are largely unaffected by solvent inclusion. The vibrational energy of the cyano mode depends on the dipole moment of the incorporated solvent molecules, but the degree of charge transfer is consistent across all analyzed cocrystals.

CPP 22.3 Tue 10:15 ZEU/0260

Reassessing Mobility Imbalance in Organic Photodetectors for High-Speed Applications — •Felix Hergenhan, Tianyi Zhang, Karl Leo, and Johannes Benduhn — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics, Technische Universität Dresden

Organic photodetectors (OPDs) are emerging candidates for diverse optoelectronic applications, yet their use in high-speed technologies such as optical communication remains largely believed to be restricted by low effective charge carrier mobilities. To address this challenge, we investigated how the transient behavior of OPDs depends on the mobilities of the respective charge carriers. This relationship is examined through drift-diffusion simulations and experiments across various material systems, under varied bias and illumination conditions. We show, contrary to common assumptions, that obtaining only one fast charge carrier mobility is sufficient to achieve high response speed. Likewise, in systems with pronounced mobility imbalance, the slower carriers do not necessarily govern the maximum operation speed of the device. Leveraging these insights, we demonstrate an OPD tailored for optical communication that achieves data transmission rates up to 170 Mbps, representing one of the highest reported transmission rates for organic-based optical communication systems. These findings establish a refined design framework for ultrafast OPDs, providing guidance on material selection, device design, and operation regimes.

CPP 22.4 Tue 10:30 ZEU/0260

Rational Design of Donor-Acceptor Oligomers for Enhanced Charge Separation — •Jannik Theile[1], Michele Guerrini[2], Surender Kumar[2], and Caterina Cocchi[2] — [1]Physics Department and Center for Nanoscale Dynamics, Carl von Ossietzky Universität Oldenburg, Germany — [2]Physics Department for Solid-State Physics and Optics, Friedrich-Schiller Universität Jena, Germany

Intramolecular charge transfer (ICT) in donor-acceptor (D-A) oligomers is central to organic optoelectronics, yet symmetric D-A-D and A-D-A systems often suffer from delocalized frontier molecular orbitals (FMOs) that hinder efficient photoinduced charge separation. To address this, we present a first-principles study based on (time-dependent) density functional theory of 22 dithieno[3,2-b:2',3'-d]pyrrole oligomers, exploring the interplay between structural asymmetry and site-selective fluorination. Donor fluorination widens the electronic gap, while acceptor fluorination enhances charge imbalance and promotes confinement and spatial segregation of FMOs onto distinct molecular segments. The resulting optical properties reveal asymmetric, acceptor-fluorinated systems as optimal for ICT due to strong charge-transfer excitations with large oscillator strengths in the visible region. This work establishes rational design rules for conjugated D-A oligomers, showing that combining asymmetry with targeted halogenation is key to achieving robust, directional ICT and enabling high-performance organic semiconductors.

CPP 22.5 Tue 10:45 ZEU/0260

Substituted Benzo[*b*]fluorenes as Emitters for OLED With Tunable Electroluminescence in the Full Visible Range — •Pascal Schweitzer[1], Christopher M. Leonhardt[2], Cazibe Arslan[1], Hermann A. Wegner[2], and Derck Schlettwein[1] — [1]Justus-Liebig-Universität Gießen, Institut für Angewandte Physik, Heinrich-Buff-Ring 16, D-35392 Gießen — [2]Justus-Liebig-Universität Gießen, Institut für Organische Chemie, Heinrich-Buff-Ring 17, D-35392 Gießen

Organic light emitting diodes (OLED), despite widespread application in displays, still exhibit major challenges. The search for stable and efficient emitting molecules continues, especially in the blue range. Substituted benzo[*b*]fluorenes (BF) show high stability of photoluminescence in solution over months. By exchanging the substitutional pattern, we show that this group of molecules allows for preparation of OLED with tunable emission bands in the full range of the visible spectrum. Thin films of BF can be prepared by solution-based methods or physical vapor deposition, allowing for easy integration into different layer stacks. Photoluminescence spectroscopy of showcase BFs revealed a multi-band emission that is found in line with electroluminescence spectra of the corresponding devices. Contact formation at relevant device interfaces was studied by in-situ Kelvin-probe force microscopy and gave insight into details of film growth and alignment of transport levels. Based on these findings we demonstrate working OLED devices with intense blue or red emission, respectively.

CPP 22.6 Tue 11:00 ZEU/0260

Electrically switchable chiroptical responses in organic ferroelectric thin films — •Lorenz Friedrich Meier[1], Sophia Klubertz[1], Victor Rodriguez[2], Miguel García-Iglesias[2], David González-Rodríguez[3], and Martijn Kemerink[1] — [1]Heidelberg University, Germany — [2]Universidad de Cantabria, Spain — [3]Universidad Autónoma de Madrid, Spain

Organic ferroelectrics potentially allow to introduce switchable polarization into an easily processable material, enabling their integration into next-generation electronic devices. We investigate a liquid-crystalline organic ferroelectric that additionally can exhibit electrically controlled chiroptical responses, relevant for optical data storage, photonic components, and chiroptical sensing. We investigate thin films of trialkylbenzene-1,3,5-tricarboxamide (BTA). These molecules self-assemble into supramolecular columns by forming a triple helix of dipoles connected via hydrogen bonds. By incorporating chirally-biased sidechains, the handedness of the supramolecular helix can be defined. We experimentally show ferroelectric behavior in both in-plane and out-of-plane geometries by double wave and CV measurements. We demonstrate how the unpractically high coercive fields for pure chiral BTA can be reduced by mixing with achiral BTA. Previous simulations show that the energetically preferred mechanism of polarization reversal of a supramolecular column will simultaneously change its chirality. Thus, an electrically switchable chirality is possible. We present an experimental investigation of this mechanism, discussing the challenges including the need for dipole pre-alignment.

CPP 23: Focus Session: Water – from Atmosphere to Space II (joint session CPP/DY)

Time: Tuesday 11:15–12:45 Location: ZEU/LICH

CPP 23.1 Tue 11:15 ZEU/LICH

Microscopic diffusion and reactivity in aqueous solutions: photogenerated nascent halogen atoms, solvated electrons and subsequent dihalide formation — •Zhangatay Nurekeyev[1,2], Hyein Hwang[1,2], Fernando Rodriguez Diaz[1], Mei Bai[3], Michael Thorwart[3], Michaela Schäfer[4], Carmen Herrmann[4], and Christian Bressler[1,2,5] — [1]Institute of Experimental Physics, Universität Hamburg — [2]The Hamburg Centre of Ultrafast Imaging (CUI) — [3]I. Institute of Theoretical Physics, Universität Hamburg — [4]Department of Chemistry, Universität Hamburg — [5]European XFEL, Schenefeld

The solvent plays an important role in the assembly, stability and reactivity of (bio)chemical molecules. Small changes of the caging solvent can alter the reaction outcome, but little is known about the atomic-scale solvation shell dynamics. Our approach utilizes aqueous mono-atomic halide solutes, which are transformed into nascent neutral halogen atoms upon femtosecond optical ex-

citation together with a separated solvated electron. Combining X-ray absorption with transient optical absorption spectroscopies we monitor the subsequent diffusion-driven atom-electron recombination, each focusing on the halogen atom and on the solvated electron, respectively. We also monitor the appearance of dihalides on the tens of picosecond time scale. Using all x-ray and laser observables we deliver a new picture of the ensuing dynamics, for which the existence of the long-lived (X:e) contact pair is not required. Next steps aim to trace more complex guest-host scenarios towards functional proteins in solution.

CPP 23.2 Tue 11:30 ZEU/LICH

Surface Propensity of Halide Ions in Water: New Evidence from LJ-XPS — •Daniela Torres-Díaz[1], Shirin Golami[1], Tillmann Buttersack[1], Qi Zhou[1], Rémi Dupuy[2], Bernd Winter[1], Chistophe Nicolas[3], and Hendrik Bluhm[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Laboratoire de Chimie Physique - Matière et Rayonnement (Sorbonne Université, CNRS), Paris, France — [3]Synchrotron SOLEIL, Saint-Aubin, France

The surface propensity of halide ions in water is still a matter of debate. While the famous Onsager&Samaras model indicates that charged species should avoid the interface, more recent Molecular Dynamics simulations that take into account the polarizability of the ions indicate notably that iodide and bromide prefer the interface while chloride and fluoride avoid it. Different models, however, differ in how strong this effect is, while experimental studies have reported contradictory results. Here I will discuss recent results obtained using Liquid-Jet X-Ray Photoemission Spectroscopy on water interfaces for potassium halide solutions. In particular, the measurement of the photoelectron angular distributions allow for a higher spatial resolution than classic XPS measurements.

CPP 23.3 Tue 11:45 ZEU/LICH

Ion Correlations Drive Collective Adsorption of Hydronium Ions at the Air-Electrolyte Interface — •Elena Köhler Ruiz, Maximilian Becker, Louis Lehmann, and Roland Netz — Fachbereich Physik, Freie Universität Berlin, Germany

Acids exhibit distinct interfacial behavior at the air-water interface compared to simple monoatomic salts. While monoatomic ions are largely repelled from the interface, hydronium ions preferentially reside at the interface due to formation of an interfacial hydrogen-bond network. To investigate these contrasting behaviors, we perform molecular-dynamics simulations with thermodynamically optimized force fields, analyzing ionic distributions at the interface as well as resulting surface tensions and potentials. The simulated surface potentials reproduce the concentration-dependent trends observed in SFG experiments: At high concentrations, interfacial hydronium promotes co-adsorption of counterions, which results in a decrease of the surface potential with rising concentration, consistent with experimental observations. These findings highlight the critical role of ion-ion correlations at interfaces, which are not accounted for by modified Poisson-Boltzmann models.

CPP 23.4 Tue 12:00 ZEU/LICH

Calcium-amino acid complexation in water probed by Intermolecular Coulombic Decay — •Michele Pugini, Nicolas Velasquez, Harmanjot Kaur, Florian Trinter, Qi Zhou, Lukas Tomaník, Uwe Hergenhahn, and Bernd Winter — Fritz-Haber-Institut, Berlin

The Ca2+ ion is the most abundant metal ion in the human body, playing essential roles in numerous biological processes, many of which involve interactions with proteins. Gaining molecular-level insight into the nature of the interaction between Ca2+ ions and solvated amino acids is therefore crucial for understanding calcium's biological function. Intermolecular Coulombic decay (ICD), a non-local autoionization process, offers unique sensitivity to the local chemical environment and can selectively probe interactions within the first solvation shell of solvated Ca2+ ions.

Here, we demonstrate the sensitivity of resonant ICD3 to the chemical composition of the solvation shell, enabling the identification of Ca2+ associations with specific amino acids. Our model system is the amino acid proline. The interaction, if present, is revealed via the ICD electrons resulting from the ionization of the biomolecule upon the 2p to 3d excitation of Ca2+.

Our results unequivocally identify Ca2+-proline interactions, indicating substitution of water molecules in the ion's coordination shell by proline. These findings establish ICD as a sensitive probe of metal-biomolecule interactions and highlight its potential as a powerful spectroscopic tool for investigating biomolecular structure in solution.

CPP 23.5 Tue 12:15 ZEU/LICH

Distinguishing cavity and non-cavity solvation structures of the hydrated electron — •Sy Dat Ho and Benjamin Philipp Fingerhut — Department of Chemistry and Centre for NanoScience, Ludwig-Maximilians-Universität München, 81377 München, Germany

Solvated electrons in water are prototypical low-dimensional quantum systems that are coupled to a fluctuating, many-body environment. However, their hydration structure is still a matter of debate, with both cavity and non-cavity models having been suggested. First-principles molecular dynamics simulations are performed of excess-electron localization in liquid water, using hybrid-meta-GGA and hybrid-GGA density functionals that accurately reproduce bulk water structure. Perturbations to the local hydrogen bond structure of water due to interaction with the excess charge are identified, giving rise to specific signatures in transient radial distribution functions. These patterns are then compared with preliminary liquid-phase MeV-UED data obtained during an early science campaign at SLAC. In order to distinguish the structural changes induced by excess electrons in the diffraction patterns, long-time simulations at an unprecedented level of theory are required in order to minimise statistical noise. Our results clarify the coupling of hydrated electrons to solvent fluctuations and provide microscopic insight into polaron formation in disordered condensed phases.

CPP 23.6 Tue 12:30 ZEU/LICH

Mesoscopic Structures in Water/HFIP based Electrolytes — •Sophie Zeilinger[1,2] and Markus Mezger[1] — [1]Center for Nano Structure Research, Faculty of Physics, University of Vienna, AT-1090 Vienna — [2]Institute of Physical Chemistry, Faculty of Chemistry, University of Vienna, AT-1090 Vienna

Previous studies have shown that binary water/hexafluoroisopropanol (HFIP) mixtures exhibit nanoscale heterogeneties that strongly affect properties such as reaction rates. The complex hydrogen bonding network of the binary mixture together with the amphiphilic character of the HFIP molecule provides a sensitive environment in which subtle changes in interactions can generate nanoscale heterogeneties. Here, we study the structure formation in water/HFIP under the influence of hydrophilic and hydrophobic ions by Small Angle X-Ray Scattering (SAXS). Depending on water content, pH, salt concentration and temperature we observe monotonous and oscillatory density correlations with structural parameter on the nanometer length scale. These structures are explained by the coupling of coulombic interactions between charged hydrophilic and hydrophobic ions vs. local fluctuations in water/HFIP concentrations.

CPP 24: French-German Session: Simulation Methods and Modeling of Soft Matter IV

Time: Tuesday 11:30–12:45 Location: ZEU/0255

CPP 24.1 Tue 11:30 ZEU/0255

Systematic coarse-graining with density dependent potential: Application to small organic molecules, multicomponent mixtures and polymers — •Sayan Dutta[1,2,3], Maria C. Lesniewski[4], W. G. Noid[4], Denis Andrienko[5], and Arash Nikoubashman[2,3] — [1]Leibniz-Institut für Polymerforschung — [2]Technische Universität Dresden — [3]Johannes Gutenberg-Universität Mainz — [4]Pennsylvania State University, University Park, PA, USA — [5]Max-Planck Institut für Polymerforschung Mainz

Conventional coarse-graining (CG) approaches approximate the underlying many body interactions through effective pair potentials. Although this strategy works well for reproducing structural and thermodynamic properties in bulk systems, it often fails in heterogeneous systems, such as droplets or films, due to the inherently strong density fluctuations in those systems. To address this issue, we incorporated local-density-dependent potentials (LDPs) that treat these many-body contributions explicitly within a mean-field formalism. We develop a CG force-field framework that integrates LDPs, enabling accurate simulation of conjugated organic molecules, organic liquid mixtures, and polymeric systems. This approach provides a more accurate description of thermodynamic and interfacial properties of these systems. Further, it facilitates the establishment of structure-function description that helps in rational designing of functional materials.

CPP 24.2 Tue 11:45 ZEU/0255

A data-driven decoupled multiscale scheme for anisotropic finite strain magneto-elasticity — •Heinrich T. Roth, Philipp Gebhart, Karl A. Kalina, Thomas Wallmersperger, and Markus Kästner — TU Dresden, Dresden, Germany

Structured magnetorheological elastomers (MREs) are composite materials exhibiting magneto-mechanical coupling effects, such as the magnetostrictive and magnetorheological effect. They consist of magnetizable particles arranged in chain-like structures within a soft elastomer matrix. As explicitly resolving their microstructure in real-world samples is infeasible, a multiscale modeling approach is required.

In this work, we present a framework for the macroscale modeling of structured MREs using physics-augmented neural networks (PANNs) [1,2]. The framework begins with data generation, where a representative volume ele-

ment (RVE) undergoes macroscopic magneto-mechanical loadings in Finite Element (FE) simulations. The resulting homogenized microscale variables form a macroscale dataset for the training and testing of the PANN macromodel, which satisfies key physical principles [1]. Finally, the trained PANN model is used in a decoupled multiscale scheme as the material model for a macroscale FE simulation to examine the magnetostriction of a spherical sample.

We acknowledge support by the German Research Foundation DFG through Research Unit FOR 5599 on structured magnetic elastomers.

CPP 24.3 Tue 12:00 ZEU/0255

In Silico Self-Assembly of Magnetic Colloidal Polymers with Magnetization Dynamics — •Deniz Mostarac[1], Sofia Kantorovich[2], and Philip J. Camp[1] — [1]School of Chemistry, University of Edingburgh, EH9 3FJ Edinburgh , United Kingdom — [2]Computational and Soft Matter Physics, University of Vienna, Vienna, Austria

Polymer-like mesostructures formed by crosslinked magnetic nanoparticles (MNPs) have created a new class of stimuli-responsive materials magnetic colloidal polymers (MCPs) that show enhanced optical, thermal, mechanical, rheological, and adsorption properties compared to conventional magnetic fluids. The interplay between magnetic interactions and solvophilic/solvophobic forces produces complex, field-tunable self-assembly. In our previous work, we investigated isolated MCPs and showed that solvophobicity drives compact, magnetically frustrated conformations, with structural features determined by crosslink type and MNP properties. These distinctions strongly affect MCP dynamics under shear and external fields. In this contribution we study the self-assembly of solvophobic MCPs while explicitly modeling MNP magnetodynamics with finite anisotropy. Our simulations capture internal magnetization dynamics over long times and at system sizes sufficient for bulk behavior. We show that coupling between Brownian and Néel relaxation, together with nonlinear magnetization, yields distinct structural, magnetic, and dynamical features in MCP suspensions governed by solvophobicity and intrinsic NP magnetism.

CPP 24.4 Tue 12:15 ZEU/0255

Pulling knotted polymer rings and concatenated knotted polymer rings in order to understand the effects of entanglement on the mechanical properties of polymers materials — •Franco Ferrari[1], Neda Abbasi Taklimi[1], Marcin Piatek[1], and Luca Tubiana[2] — [1]CASA* and Institute of Physics, University of Szczecin, Szczecin, Poland — [2]Physics Department, University of Trento, Via Sommarive 14, Trento I-38123, Italy

The topological structure of polymers is expected to produce relevant effects on the mechanical properties of polymer systems. However, to assess the contribution of topology by experiment is difficult, mainly due to technical obstacles in controlling the entanglement during the synthesis process, in particular the formation of knots and concatenations. In this contribution presented are the results of numerical simulations focusing on the mechanical properties of topologically entangled polymer systems. First, the case of single knotted polymers pulled by an external force are discussed. Next, the stress-strain curves of a few concatenated knots with forces applied at different locations are shown. To check the validity of our simulations based on the Wang-Landau algorythm, two different methods are employed and their consistency is verified. The final goal of this research is to understand the mechanical properties of more complex polymer materials characterized by an uniform distribution of knots or concatenated knots of a given topological type.

CPP 24.5 Tue 12:30 ZEU/0255

Prediction of Ultra-Long Time-Scale Dynamics from Picoseconds to Seconds: Integral of First-Passage Times — •Qiyun Tang — School of Physics, Southeast University, Nanjing, China

The dynamics of non-equilibrium nanostructure formation span over 13 orders of magnitude in time, from molecular vibrations at picoseconds to macroscopic processes at seconds or longer. Predicting such ultra-long time-scale dynamics poses significant challenges for conventional molecular simulation methods. We recently proposed a new approach-Integral of first-passage times (IFS)-to predict the evolution of non-equilibrium nanostructures, and the resulting structural distributions align well with experimental observations [1]. Furthermore, we have verified that the dynamics predicted by IFS are consistent with direct simulations in cases of low free energy barriers, while under high free energy barriers, the ultra-long time-scale dynamics predicted by IFS agree with experimental measurements [2]. Utilizing this method, we have also systematically investigated the relationship between polymer adsorption dynamics and surface curvature [3,4]. The IFS method bridges microscopic picosecond-scale dynamics with macroscopic growth kinetics of nanostructures, offering an effective approach for designing and controlling non-equilibrium nanostructures.

CPP 25: Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics II

Time: Tuesday 11:30–12:45 Location: ZEU/0260

CPP 25.1 Tue 11:30 ZEU/0260

Transiently Delocalised Hybrid Quantum States are the Gateways for Efficient Exciton Dissociation at Organic Donor-Acceptor Interfaces — •Filip Ivanovic[1], Samuele Giannini[2], Wei-Tao Peng[3], and Jochen Blumberger[1] — [1]Department of Physics and Astronomy, University College London, London, United Kingdom — [2]Department of Chemistry and Industrial Chemistry, University of Pisa, Pisa, Italy — [3]Department of Chemistry, Tunghai University, Taichung City, Taiwan

Organic solar cells (OSCs) have long been the subject of intensive research. Following the absorption of sunlight, localised excitations (excitons) are able to dissociate into separated charges at the interface between donor and acceptor components. Whilst this separation has been leveraged to achieve cell efficiencies above 20%, the exact mechanism by which this occurs remains without consensus.

Theoretical research has been centred on simulating such phenomena on experimentally relevant time scales, whilst sufficiently describing the underlying electronic structure. Here, we introduce our in-house non-adiabatic dynamics package, termed X-SH.

We elucidate the mechanism of ultrafast charge separation in an atomistic OSC junction, where separation is mediated by non-local hybridised states comprising both excitons and separated charges, and in-fact accelerated by non-interfacial exciton dissociation. We then demonstrate that tuning the hybridised states' accessibilities through the density of states can be translated into design rules informing the synthesis of yet more efficient OSCs.

CPP 25.2 Tue 11:45 ZEU/0260

Temperature-Dependent Spin-Sensitive Spectroscopy of Triplet-Exciton Dynamics in TADF OLEDs — •Ahmed Mohamed, Andreas Kohrmann, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics 6, University of Würzburg, 97074 Würzburg, Germany

Thermally Activated Delayed Fluorescence (TADF) enables efficient harvesting of triplet excitons through reverse intersystem crossing (rISC) in OLEDs. Previous studies have shown that TADF device operation is dominated by triplet excitons, whose densities exceed singlet and charge carrier densities by several orders of magnitude. A major limitation to TADF efficiency is the non-radiative loss of triplet excitons. Here, we analyze the transient photoluminescence (trPL) and transient electroluminescence (trEL) decays of the blue TADF emitter ν-DABNA hosted in TDBA-Si or mCP. Temperature-dependent trPL/trEL kinetics were modeled using a rate-equation framework. Key triplet-exciton parameters, including the lifetime, diffusion coefficient, diffusion length, and activation energies were extracted by considering both 1^{st} and 2^{nd} order triplet-exciton decay pathways. The spin properties of the triplet exciton were additionally identified using photoluminescence-detected magnetic resonance (PLDMR) measurements on the organic layer stack. Together, kinetic and spin analysis of triplet excitons provide a comprehensive picture of non-radiative quenching to guide future improvements of TADF OLEDs

CPP 25.3 Tue 12:00 ZEU/0260

Modeling the ionization potential and electron affinity in organic semiconductors — •Alexey Gudovannyy and Frank Ortmann — Department of Chemistry, TUM School of Natural Sciences, and Atomistic Modeling Center, Munich Data Science Institute, Technical University of Munich, Germany

Ionization potential (IP) and electron affinity (EA) are essential quantities for characterizing and tuning transport properties of organic semiconducting materials. Computational prediction of these properties under realistic conditions of crystalline or polycrystalline forms remains challenging, as it requires a proper description of all interactions within the bulk material environment. In this work, we present an accurate protocol for computing molecular materials' IP and EA values, using computed gas-phase molecular values corrected via an improved multilevel scheme for describing the materials' environment, where an electronic structure is treated explicitly at the microscopic level, while at larger scales, a continuum model is applied. Special significance will be dedicated to the requirement of accurate reference gas-phase calculations, which we carried out within the GW framework and to demonstrating limitations of prevalent

Density Functional Theory (DFT) methods, while preserving feasible computational time demands. The main bottleneck of this approach is the need for an experimental or predicted crystal structure. We will also show how to incorporate reliable structure prediction into it, which opens up possibilities for purely in silico materials design.

CPP 25.4 Tue 12:15 ZEU/0260

Morphological Insights into Spray-Coated Organic Semiconductors — •Shuxian Xiong[1,2], Marie Betker[2,3], Simon Schraad[1,2], Yufeng Zhai[2], Benedikt Sochor[2], Sarathlal Koyiloth Vayalil[2,4], Peter Müller-Buschbaum[1], and Stephan V. Roth[2,3] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [3]Department of Fibre and Polymer Technology, KTH, Stockholm, Sweden — [4]Applied Sciences Cluster, University of Petroleum and Energy Studies UPES, Dehradun, Uttarakhand, 248007, India

Ultrasonic spray coating offers improved scalability for large-scale applications, reduced material waste, and enhanced compatibility with various substrates, making it a more cost-effective solution for the mass production of photovoltaic devices. However, how to simply and efficiently build ordered structural networks is still a critical issue. We investigate the morphological transition of organic semiconductors and their effect on device performance using grazing incidence wide-angle X-ray scattering in traditional fullerene systems. By systematically optimizing spray flow rate and substrate temperature, we effectively tailored the film morphology, enhancing molecular crystallization of PTB7-Th and PCBM, resulting in an improvement in device performance of 9% in air, which is one of the highest device efficiencies currently achieved for spray-coated fullerene acceptor-based organic solar cells, and is equivalent to the device efficiencies of spin-coated fullerene acceptor-based organic solar cells.

CPP 25.5 Tue 12:30 ZEU/0260

Enhancing device performance parameters of organic photodiodes by understanding the thickness dependence of the reverse dark current — •Fred Kretschmer[1], Tianyi Zhang[1], Oskar J. Sandberg[2], Mathias Nyman[2], Karl Leo[1], and Johannes Benduhn[1] — [1]Institute of Applied Physics, TU Dresden, Dresden, Germany — [2]Faculty of Science and Engineering, Åbo Akademi University, Turku, Finland

In recent years, organic photodetectors (OPDs) have attracted interest due to their advantageous properties and rapidly advancing performance, making them promising not only as complements to inorganic photodetectors but also for emerging applications in bioimaging, health monitoring, and high-speed optoelectronics. A key figure of merit for comparing PDs is the specific detectivity (D^*), which quantifies the detector's ability to sense weak optical signals. Achieving high D^* relies on maximizing charge carrier extraction while minimizing internal noise. Under reverse bias, OPD performance is particularly influenced by shot noise, which is proportional to the dark current (J_D).

In this work, the variation of J_D with active-layer thickness across multiple energy-gap-tuned bulk-heterojunction systems was examined. Surprisingly, the dark current exhibits a thickness-dependent minimum, contrary to the general assumption that J_D only decreases with thickness. Using sensitive, temperature-dependent current-voltage measurements together with drift-diffusion simulations, the new minimum feature was confirmed, and improvements in the specific detectivity of OPDs were achieved.

CPP 26: French-German Session: 2D Materials, Thin Films and Interfaces II

Invited Talk CPP 26.1 Tue 14:00 HÜL/S386

Investigating lignin graphitisation depending on botanical source and extraction method — Lucie Dieval[1], Phuthiphong Ouitrakoon[2], Robert Hunter[2], Sébastien Schaefer[3], Louis Hennet[3], Erik Elkaim[4], Julie Ruellou[5], Milo S. P. Shaffer[2], Agnieszka Brandt-Talbot[2], and •Pascale Launois[1] — [1]LPS, CNRS/Université Paris Saclay, France — [2]Imperial College, UK — [3]ICMN, CNRS/University of Orléans, France — [4]Synchrotron SOLEIL, France — [5]ESRF, France

Lignins, plant-derived macromolecules, are promising carbon sources from a sustainable development perspective. Here, we study the transformations of various lignins into turbostratic carbon or graphite, consisting of stacked graphene sheets.

The lignin powders were heated at temperatures between 1000 and 2730°C. Analyses were performed ex-situ using X-ray scattering (XRS) and Raman spectroscopy, which confirmed XRS results. XRS data were analysed combining analyses in reciprocal space and in direct space with Pair Distribution Function. The dimensions of the carbonaceous crystalline domains formed from lignins are determined as a function of temperature, as well as the stacking mode of their graphene sheets. We find that all studied lignins transform into turbostratic carbon, with no evidence for intermediate stackings towards graphite. Different sizes of crystalline domains are evidenced depending on the lignin form. One lignin presents relatively large sizes both for the graphene layers and in the stacking direction at a temperature as low as 1300°C, a most promising finding for future applications.

CPP 26.2 Tue 14:30 HÜL/S386

Atomistic Origin of Photoluminescence Quenching in Colloidal MoS_2 and WS_2 Nanoplatelets — •Surender Kumar[1], Markus Fröhlich[2], Stefan Velja[1], Marco Kögel[2], Onno Strolka[2,3], André Niebur[3], Samuell Ginzburg[4], Muhammad Sufyan Ramzan[1], Jannik C. Meyer[2], Jannika Lauth[2,3], and Caterina Cocchi[1] — [1]Friedrich-Schiller-Universität Jena, Germany — [2]Eberhard Karls University of Tübingen, Germany — [3]Leibniz University of Hannover, Germany — [4]University of Cambridge, UK

Large chemical tunability and strong light-matter interactions make colloidal transition metal dichalcogenide nanostructures particularly suitable for light-emitting applications. However, ultrafast exciton decay and quenched photoluminescence limit their potential. Combining femtosecond transient absorption spectroscopy with first-principles calculations on MoS_2 and WS_2 nanoplatelets, we reveal that the observed sub-picosecond exciton decay originates from edge-located optically bright hole traps [1]. These intrinsic trap states stem from the metal *d*-orbitals and persist even when the sulfur-terminated edges are hydrogen-passivated. Notably, WS_2 nanoplatelets show more localized and optically active edge states than their MoS_2 counterparts, and zigzag edges exhibit a higher trap density than armchair edges. The nanoplatelet size dictates the competition between ultrafast edge-trapping and slower core-exciton recombination, and the states responsible for exciton quenching enhance catalytic activity.

CPP 26.3 Tue 14:45 HÜL/S386

Data-driven exploration of thermal and elastic properties in covalent organic framekworks — •Aleksander Szewczyk[1], Leonardo Medrano Sandonas[1], David Bodesheim[1], Bohayra Mortazavi[2], and Gianaurelio Cuniberti[1] — [1]TUD Dresden University of Technology, 01062 Dresden, Germany — [2]Leibniz Universität Hannover, Welfengarten 1A, 30167 Hannover

Covalent organic frameworks (COFs) are a class of advanced materials that can be precisely engineered for diverse applications, including catalysis, flexible electronics, and sensors. However, COFs synthesised experimentally often exhibit a variety of structural defects and grain boundaries, which affect their properties. Because of their large and complex structure, COFs pose a considerable challenge for traditional *ab-initio* methods. Machine learning interatomic potentials (MLIPs) can be used to significantly accelerate property calculations, while retaining near *ab-initio* accuracy. Our team have parametrised an MLIP using the MACE architecture and a dataset of non-equilibrium confirmations of 2D COFs. We assessed the transferability of the MACE model computing atomic forces and phonon dispersions of unseen COFs, and compared these results to ReaxFF and reference data by Density Functional Theory using VASP code. Using the parametrised model, we explore the effect of defects and grain boundaries on thermal and elastic properties of COFs.

CPP 26.4 Tue 15:00 HÜL/S386

PNIPAM Microgel-Stabilized Foam Films: Effect of Crosslinking Content — •Luca Mirau, Joanne Zimmer, Kevin Gräff, Matthias Kühnhammer, and Regine von Klitzing — Institute for Condensed Matter Physics, TU Darmstadt, Germany

Aqueous foams find widespread application in fields such as cosmetics, the food industry, oil recovery and fire-fighting. Their stabilization requires the presence of surface-active molecules or colloidal particles. In this study, thermoresponsive microgels (MGs) composed of poly(N-isopropylacrylamide) (PNIPAM) with varying crosslinker contents are applied as foam stabilizers, resulting in temperature-sensitive foams. Foam films serve as the fundamental building blocks of foams. The structuring of MGs within these films is analyzed using the Thin Film Pressure Balance (TFPB) technique. Foam films are formed within a pressure chamber, and their thickness is determined through interferometric methods under a light microscope. The foam films display an inhomogeneous structure, characterized by network-like, several 100nm thick regions containing MGs, interspersed with thin MG-depleted zones less than 100nm thick. We show how the cross-linker density of the microgels affect the MG layering within these thick network regions, influencing the film thickness. Another question we answer is how the MG-free areas are stabilized.

CPP 26.5 Tue 15:15 HÜL/S386

Irreversible protein adsorption on mobile surfaces: control and modelling of surface density and in-plane mobility through molecular crowding — Wanchung Chiang[1], Lionel Bureau[1], Ralf Richter[2], Galina Dubacheva[1], and •Delphine Debarre[1] — [1]Grenoble-Alpes University, France — [2]University of Leeds, UK

Adsorption of proteins onto surfaces has been the focus of a wealth of experimental, theoretical and numerical studies but surprisingly little is known on the dynamics of protein adsorption on fluid surfaces.

In this study, we consider irreversible adsorption of streptavidin, a protein with a very strong affinity for its ligand biotin, onto a lipid bilayer incorporating biotin-terminated lipids, a widely-used model to build biomimetic surfaces. We show that after the initial, rapid adsorption phase, a slower, logarithmic continuous adsorption can lead to surface densities much larger than in the absence of surface diffusion. Simultaneously, we quantify the lateral diffusion of the adsorbed proteins, which drops sharply and can be tuned continuously over two orders of magnitude depending on surface density.

We then adapt free-volume theories to two dimensions to rationalize our findings and bridge the gap between in-plane diffusion and adsorption dynamics. Beyond a better understanding of adsorption onto mobile surfaces, our data paves the way towards biomimetic surfaces incorporating mobility control of functional groups.

CPP 27: Focus Session: Water – from Atmosphere to Space III (joint session CPP/DY)

Time: Tuesday 14:00–15:30 Location: ZEU/LICH

Topical Talk CPP 27.1 Tue 14:00 ZEU/LICH

Why water in plants survives negative pressure — Marin Šako[1,2], Emanuel Schneck[3], Roland Netz[4], and •Matej Kanduč[1] — [1]Jožef Stefan Institute, Ljubljana, Slovenia — [2]University of Ljubljana, Faculty of Mathematics and Physics, Ljubljana, Slovenia — [3]Physics Department, Technische Universität Darmstadt, Darmstadt, Germany — [4]Fachbereich Physik, Freie Universität Berlin, Berlin, Germany

It may seem surprising that we can lower the pressure in a liquid to negative values, far below the saturated vapor pressure at which a vapor phase should form. In water, such deeply metastable states are possible only when it is exceptionally pure and free of nucleation sites. It is therefore even more striking that plants transport water at negative pressures down to −100 atm without cavitation, even though xylem sap is anything but pure: it contains dissolved ions, sugars, lipids, and other organic molecules. How is this possible?

In this talk, I will show how molecular simulations and theory can explain this surprising behavior. We find that amphiphilic molecules such as lipids can adsorb onto hydrophobic surface crevices — places that would normally trap nanobubbles. Once coated, these surface defects can no longer stabilize bubbles, which allows water to stay intact even under strong tension. This mechanism offers a molecular-level explanation for how trees transport water to heights of over 100 meters without cavitation. More broadly, it illustrates how soft-matter physics and interfacial molecular organization can control the mechanical stability of liquids under extreme conditions.

CPP 27.2 Tue 14:30 ZEU/LICH

Cholesterol Controlled Photo-Switching Activity of Azobenzene Glycoconjugates in Lipid Membranes — •Prashant Hitaishi[1,2], Svenja C. Hövelmann[1,2], Michael Röhrl[3], Nicolas Hayen[1], Ella Diebell[1], Ali Ashtiani[1], Carlotta Mager[1], Thisbe Lindhorst[3], and Bridget M. Murphy[1,2] — [1]Institute of Experimental and Applied Physics, Kiel University, Leibnizstraße 19, Kiel, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, Hamburg, Germany — [3]Otto Diels-Institut für Organische Chemie, University of Kiel, Germany

Reversible photo-switchable molecules enable precise optical control of soft interfaces and are attractive for smart surfaces and light-triggered drug delivery. Azobenzene glycoconjugates (Azo) undergo reversible trans-cis isomerization under alternating UV and visible illumination, thereby modulating their conformation and interactions with lipid membranes. Here, Azo is incorporated into DPPC monolayers containing 0, 15, or 30 mol% cholesterol to mimic biologically relevant membrane compositions. Langmuir monolayer isotherm studies combined with time-resolved illumination cycles and X-ray measurements are used to quantify Azo-induced changes in membrane structure and relaxation kinetics. Increasing cholesterol slows Azo photo-switching, indicating a more constrained, rigid nanoenvironment, and shows that membrane composition can be used to tune light responsiveness in lipid interfaces for designing azobenzene-based responsive biomaterials.

CPP 27.3 Tue 14:45 ZEU/LICH

Photoelectron Angular Distributions of Ions Influenced by Surfactants at the Solution-Vapor Interface — •Shirin Gholami[1], Tillmann Buttersack[1], Clemens Richter[2], Rémi Dupuy[3], Daniela Torres-Díaz[1], Christophe Nicolas[4], Uwe Hergenhahn[1], and Hendrik Bluhm[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]SPECS Surface Nano Analysis GmbH, Berlin, Germany — [3]Sorbonne Université, CNRS, Paris, France — [4]Synchrotron SOLEIL, Paris, France

Aqueous liquid-vapor interfaces play key roles in atmospheric and oceanic processes. The ocean-air boundary forms the largest aqueous-vapor interface, covering over 70 % of Earth's surface. In addition to Na^+ and Cl^-, Mg^{2+} and SO_4^{2-} are the most abundant ions in ocean water.

Here, we investigate how Mg^{2+} and SO_4^{2-} ions behave at the aqueous solution-vapor interface in the presence of charged surfactants. Using sub-monolayer coverages of octylamine $-CNH_3^+$ and octanoate $-COO^-$, we examine how these surfactants modify the distance of the ions from the interface. Liquid-jet X-ray photoelectron spectroscopy in combination with photoelectron angular distributions provides Å-scale depth sensitivity, enabling us to quantify ion-surfactant interactions.

Our results show that differently charged surfactants shift the interfacial positioning of Mg^{2+} and SO_4^{2-}, and that specific ion-ion interactions influence their interfacial propensity.These findings reveal how surfactants govern the depth distribution of ions, providing insight into oceanic and atmospheric processes.

CPP 27.4 Tue 15:00 ZEU/LICH

Contact line dynamics on moving fibers measured by X-ray holography — •Louisa E. Kraft[1,2], Jens Lucht[3], Fiona Berner[1,2], Hannes P. Hoeppe[3], Tobias Eklund[1,2], Yizhi Liu[1], Markus Osterhoff[3], Tim Salditt[3], Hans-Jürgen Butt[1], and Katrin Amann-Winkel[1,2] — [1]Max Planck Institute for Polymer Research, Mainz, Germany — [2]Johannes Gutenberg University, Institute for Physics, Mainz, Germany — [3]Georg-August-University, Institute of X-ray Physics, Göttingen, Germany

The wetting properties of solid surfaces are important for many natural and industrial processes, especially with respect to dynamic wetting. The wetting dynamic of solid surfaces, in particular the quantitative description of the dynamic contact angles, is still under debate. Dynamic contact angle variations connect macroscopically measured quantities with microscopic processes. Most studies rely on optical or confocal microscopy which limits the experimental access to the sub-microscopic region where these processes take place. We present data from X-ray holography experiments, imaging the three-phase contact line on moving glass fibers with an improved spatial resolution of about 450 nm combined with a temporal resolution of 10 Hz. We used the GINIX nanofocusing setup at the P10 beamline at PETRA III (DESY, Hamburg). The used glass fibers were pulled out of a liquid bath filled with varying aqueous solutions while changing the lateral velocity. We could clearly observe a decrease of the receding dynamic contact angle with increasing fiber velocity confirming the predictions of dynamic wetting theory.

CPP 27.5 Tue 15:15 ZEU/LICH

Properties of micrometre-sized supercooled water droplets — Claudia Goy[1], •Frédéric Caupin[2], Felix Lehmkühler[1], and Robert E. Grisenti[3,4] — [1]Deutsches Elektronen Synchrotron DESY, Hamburg, Germany — [2]Université Claude Bernard Lyon 1, Villeurbanne, France — [3]GSI, Darmstadt, Germany — [4]J. W. Goethe-Universität, Frankfurt am Main, Germany

Water displays a wide range of anomalous behaviors, many of which become particularly pronounced in the supercooled state, where its properties deviate strongly from those of other liquids. A prevailing hypothesis suggests that, at low temperatures, water may locally adopt two distinct structural motifs. This presentation will discuss results from temperature-dependent experiments that probe the physical and chemical properties of liquid water. The studies employ evaporatively cooled liquid jets in vacuum, investigated with techniques such as Raman spectroscopy and X-ray spectroscopy. These approaches enable a detailed examination of inter- and intramolecular vibrational modes, providing insight into the molecular dynamics of cooling water and optical properties, including the refractive index. Together, these experimental methods offer a comprehensive view of the temperature-dependent behavior of water, shedding light on the complex interactions that drive its anomalies. Through these studies, we aim to elucidate the mechanisms governing water's unique behavior in the supercooled regime and contribute to a deeper understanding of its structural transformations and physical properties.

CPP 28: Active Matter IV (joint session DY/BP/CPP)

Time: Tuesday 14:00–15:30 Location: ZEU/0160

CPP 28.1 Tue 14:00 ZEU/0160

Automated decision-making by chemical echolocation in active droplets — •Aritra K. Mukhopadhyay[1], Ran Niu[2], Linhui Fu[2], Kai Feng[2], Christopher Fujta[1], Qiang Zhao[2], Jinping Qu[2], and Benno Liebchen[1] — [1]Technische Universität Darmstadt, Darmstadt, Germany. — [2]Huazhong University of Science and Technology, Wuhan, China.

Motile microorganisms like bacteria and algae combine self-propulsion, cooperation, and decision-making at the micron scale. Inspired by these biological systems, synthetic microswimmers are emerging as human-made counterparts capable of self-propulsion. Recent breakthroughs provide a platform to integrate additional functionalities, bridging the gap between biology and synthetic systems. We propose and experimentally demonstrate a mechanism that enables synthetic microswimmers, including autophoretic colloids, droplet swimmers, and ion-exchange-driven modular swimmers, to make autonomous navigational decisions. These swimmers generate chemo-hydrodynamic signals that interact with boundaries, producing echoes that encode structural information about the environment. These echoes trigger automatic responses, such as synthetic chemotaxis, allowing swimmers to avoid dead ends and autonomously find paths through complex mazes. We show the mechanism remains robust across different maze geometries, ensuring reliable navigation without external cues. Our findings illustrate how simple physical principles can endow synthetic systems with advanced navigation functionalities.

CPP 28.2 Tue 14:15 ZEU/0160

Dead or alive?—Probing scale-dependent liveliness in multiscale active matter — •Joscha Mecke[1] and Klaus Kroy[2] — [1]Institute for Advanced Study, Shenzhen University, Shenzhen, China — [2]Institut für Theoretische Physik, Universität Leipzig, Leipzig, Germany

If you have ever watched live and dead trouts swimming upstream, side by side, you may have wondered how closer inspection of their mesoscale activity might help to tell them apart. But probing spatially heterogeneous activity in living matter is a major challenge. We demonstrate the emergence of multiple effective ("active") temperatures in nonequilibrium molecular- and Brownian-dynamics simulations of an active polymer. Energy injection at different length scales leads to mode coupling, inter-modal energy transfer, and entropy production. We put forward a generalised Langevin equation for a labelled monomer, which, by application of a harmonic potential, can serve as a spectroscopic device. Upon varying the trap stiffness, we can selectively scan through the emergent effective temperatures and thereby resolve the scale-dependent activity. Our approach thus provides a minimally invasive spectroscopic tool to generate quantitative maps of liveliness, across multiple scales.

CPP 28.3 Tue 14:30 ZEU/0160

Tuning the velocity of thermophoretic microswimmers with thermo-sensitive polymers — Franziska M. Braun, Aritra K. Mukhopadhyay, Samad Mahmoudi, Benno Liebchen, and •Regine von Klitzing — Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstrasse 8, 64289 Darmstadt

Understanding and controlling the motion of self-propelled particles in complex fluids is crucial for applications in targeted drug delivery, microfluidic transport, and the broader field of active matter. Here, we investigate the thermophoretic self-propulsion of partially gold-coated polystyrene Janus particles (Au-PS) in temperature-responsive linear Poly(N-isopropyl acrylamide) (PNIPAM) solutions across various PNIPAM concentrations and temperatures. Particle velocities are examined at three representative temperatures: far below, near but below and above the LCST. In pure water, Au-PS Janus particles propel with the PS hemisphere leading, driven by their intrinsic thermophoretic response. Conversely, the positive Soret coefficient of PNIPAM results in depletion forces that induce motion of the Janus particle towards the hot Au side. The experiments reveal a non-monotonic dependence of particle velocity on temperature, with a maximum near the LCST. Interfacial processes like ion movement in the electric double layer and PNIPAM adsorption at the Au-PS particles are separated from processes that are coupled to the bulk solution. Theoretical calculations are in good agreement with the experimental findings and are essential for the understanding of the complex interplay of microswimmers with thermoresponsive polymers.

CPP 28.4 Tue 14:45 ZEU/0160

Non-reciprocal multifarious self-organization — •Saeed Osat[1] and Ramin Golestanian[2] — [1]Institute for Theoretical Physics IV, University of Stuttgart, Heisenbergstraße 3, 70569 Stuttgart, Germany — [2]Max Planck Institute for Dynamics and Self-Organization (MPI-DS), 37077 Goettingen, Germany

Biological systems exhibit a unique ability to design diverse structures from a shared set of building blocks, with a plethora of proteins made from a limited set of amino acids as a prime example. Furthermore, these systems often use building blocks efficiently by introducing transformations between different structures. A structure might undergo structural transformations to form a new structure with different functional purposes, without the need to discard the current structure and start anew. To unravel this mystery, one must examine the underlying non-equilibrium processes that make this shape-shifting behavior feasible.

Here, we leverage non-reciprocal interactions between building blocks to provide a foundation for designing dynamic structures. We used a multifarious self-assembly (MSA) model, which is the molecular counterpart of the Hopfield associative memory. By upgrading the MSA model to its non-equilibrium counterpart with non-reciprocal interactions, we introduce the ability to not only self-assemble different structures on demand but also facilitate shifts and transformations that lead to shape-shifting behavior.

Invited Talk CPP 28.5 Tue 15:00 ZEU/0160

Designing topological edge states in bacterial active matter — Yoshihito Uchida[1], Daiki Nishiguchi[2,1], and •Kazumasa A. Takeuchi[1] — [1]The University of Tokyo, Tokyo, Japan — [2]Institute of Science Tokyo, Tokyo, Japan

Besides its potential relevance to the life sciences, active matter also manifests as a novel, intrinsically non-equilibrium kind of matter, endowed with characteristic transport properties distinguished from conventional matter. A challenge is how to control and design transport in active matter. A potentially useful, emerging concept here is topological transport developed in condensed matter physics, which was extended to active matter successfully, but experimental realizations have thus far relied on the chirality of the active particles, which limits design capabilities.

Here we report a controlled realization of topological edge states in dense bacterial suspension, induced by microfabricated geometry instead of the bacteria's chirality. First we demonstrate that we can rectify bacterial collective motion by a channel with asymmetric shape. Then we construct networks made of asymmetric channels and show that we can control the emergence of topological edge states through the network design. Through modelling and experiments, we discuss what properties of the network and the bacterial flow are crucial to the observed topological phenomenon. We expect our results may pave the way for establishing a control and design principle of topological transport in such active matter systems.

CPP 29: Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods III

Time: Tuesday 14:00–15:30 Location: ZEU/0255

CPP 29.1 Tue 14:00 ZEU/0255

Towards Evolved Sensing Applications for Organic Photonic Devices Utilizing Room-Temperature Phosphorescence — •Sebastian Kaiser, Sebastian Schellhammer, and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics (IAP), Technische Universität Dresden

Photonic devices function through the absorption and emission of light, making them independent of electricity or other influences. This trait is vital for sustainable advances in imaging, sensing, information storage, and anticounterfeiting. Programmable luminescent tags (PLTs) exemplify this by utilizing the oxygen-sensitivity of organic room-temperature phosphorescence (RTP) for controllable switching of the device's light output under UV illumination. [1, 2] Optimizing the homogeneity and reproducibility of photonic thin-film devices, paired with use-case-tailored layer compositions, allowed us to develop a new, advanced UV light-sensing application. The thin-film nature of PLTs, especially their flexibility and transparency, combined with a freely scalable sensor area, enables a broader range of use cases than common detectors can achieve. The combination of these unique device characteristics opens the way for new sensing applications for purely photonic devices.

CPP 29.2 Tue 14:15 ZEU/0255

Synergistic and unique information reveals multicentre bonding and geometry — •Kyunghoon Han, Miguel Galleogos Gonzalez, and Alexandre Tkatchenko — University of Luxembourg, Luxembourg, Luxembourg

Classical bonding measures and entropy maps are mostly pairwise, obscuring cooperative effects. We introduce a Partial Information Decomposition of bond character built from standard density-functional and coupled-cluster data. Fragment electron- and spin-number distributions along a coordinate define a simple label (covalent, ionic, multicenter), and information about that label is separated into redundant (shared), unique (single-fragment), and synergistic (joint-only) parts. Treating bond character as a geometric response, small perturbations yield a synergy profile that pinpoints where cooperation emerges and how it evolves. The profile rises at the onset of sharing in diatomic hydrogen, is maximal for the central bond of bicyclo[1.1.1]propellane only when the bridgeheads and the three methylene groups are taken together, and peaks at the square geometry of cyclobutadiene before dropping with bond alternation. Benchmarks against density, orbital, energy, and machine-learning descriptors show where PID adds explanatory power and, for ordinary two-center bonds far from dissociation, why it is near-zero with detectable exceptions only when the two atoms are the same.

CPP 29.3 Tue 14:30 ZEU/0255

Utilizing Immediate Phosphorescence in Organic Photonic Devices for Rewritable Information Storage and Oxygen Sensing — •Lucy Winkler, Sebastian Schellhammer, and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics (IAP), Technische Universität Dresden

Programmable luminescent tags (PLTs) are photonic devices that offer simple and versatile solutions for reversible information storage and food labeling by using the oxygen-sensitive phosphorescent emission from organic emitters embedded in polymer matrices [1]. Conventional PLTs fabricated by spin-coating under ambient conditions exhibit oxygen-quenched phosphorescence in their initial state, requiring photoactivation to consume oxygen in the active layer and switch on emission. However, these PLTs show inconsistent activation between the initial and subsequent writing processes, significantly limiting their controlled reusability for practical applications [2]. To better understand activation cycles and identify potential improvements, different fabrication workflows in oxygen-free environments were tested. While activation behavior remains similar to conventional devices, these fabrication approaches enable creation of activated PLTs with an initial switched-on state that could serve as simple oxygen detectors, for example, in vacuum packaging integrity monitoring.

Solution to the current paradox of anomalous underscreening in electrolytes — •Esther Ohnesorge, Thomas Tilger, Michalis Tsintsaris, Hayden Robertson, and Regine von Klitzing — Department of Physics, Technische Universität Darmstadt, Darmstadt, 64289, Germany

Since colloidal dispersions have a significant importance in our daily life, it is of special interest to get a deeper understanding of which interfacial forces govern their stability and how this stability can be tailored.

For aqueous electrolyte solutions, DLVO theory is a powerful and well-established framework to describe these interactions at low and intermediate ionic strengths. In contrast, the situation at high ionic strength is less understood and the main methods for direct force measurements give inconsistent results. Whilst the surface force apparatus (SFA) provides clear evidence for a re-entrance of repulsion in the highly concentrated regime (termed underscreening) for a wide range of different electrolytes [1], similar observations were not possible with the atomic force microscope (AFM) to date [2]. In this presentation we will examine the reason of these fundamental differences. Specifically, in an attempt to explore experimental screening lengths across a wide suite of electrolyte concentrations, we demonstrate the experimental parameters dominating the occurrence of anomalous underscreening and a comprehensive understanding of this long-debated phenomenon. [1] DOI: 10.1103/PhysRevLett.119.026002 [2] DOI: 10.1016/j.jcis.2022.05.004

CPP 29.5 Tue 15:00 ZEU/0255

Thermal properties of a knotted diblock copolymer ring — •Neda Abbasi Taklimi[1], Franco Ferrari[1], Marcin Radoslaw Piatek[1], and Luca Tubiana[2] — [1]Institute of Physics, University of Szczecin, Wielkopolska15, 70-451 Szczecin, Poland — [2]INFN-TIFPA, Trento Institute for Fundamental Physics and Applications, Via Sommarive 14, I-38123 Trento, Italy

The phase transitions and geometrical properties of diblock copolymers have been studied extensively; however, few studies have addressed knotted structures under varying monomer distributions and solvent quality. Here, we present a computational study of how topological constraints and block lengths affect the behavior of a single diblock copolymer ring. We used the Wang-Landau Monte Carlo algorithm and a coarse-grained model on a simple cubic lattice with an implicit solvent to explore thermal and structural properties. In the AB model, A-type monomers are self-repulsive, B-type monomers are self-attractive, and AB interactions are neutral; the solvent is good for A-type and poor for B-type monomers at low temperatures.

We computed key properties, including heat capacity, radius of gyration of individual blocks and the whole ring, number of contacts (AA, BB, AB), and knot length. Our results reveal several phase transitions for specific monomer distributions and topologies. Subtle changes in monomer distribution lead to transitions between knotlocalization and delocalization at low temperatures, driven by the competition between entropic and energetic contributions to the free energy.

CPP 29.6 Tue 15:15 ZEU/0255

A Systematic Multiscale Study of Bio-Based Polymers for Novel Food Packaging Systems — •Andoni Ugartemendia, Alessandro Mossa, and Giorgia Brancolini — Institute of Nanoscience, CNR-NANO S3, via G. Campi 213/A, 41125 Modena, Italy

Recently, monolayer materials of bio-based polymers have gained increased attention to develop more sustainable packaging systems.[1] In this regard, rational in silico design has become essential to predict novel polymers and reduce experimental workload. However, the computational modeling of these materials poses a great challenge since their dynamics span over different time scales.[2] To bypass this issue, in this work we propose a modular multiscale computational protocol to study linear polymers from ab initio to coarse grained (CG) dynamics. In the first part, we derive a full atomistic force field (FA-FF) from DFT data and carry out FA-MD simulations for its validation. In the second step, all structural properties are passed to a database to parametrize a CG-FF with the iterative Boltzmann inversion (IBI).[3] Lastly, large scale CG-MD simulations are run for a final validation of the CG-FF. This methodology is applied first to PET, a polymer widely used in the packaging industry, as well as to emerging bio-based polymers such as PEF and PLLA.

Solvent effects on amphiphile self-assembly in Deep Eutectic Solvents — •Karen Edler — Centre for Analysis and Synthesis, Chemistry Department, Lund University, Sweden

Deep eutectic solvents (DES) are mixtures of hydrogen bond donors and acceptors that form strongly hydrogen-bonded room temperature liquids. These mixtures are straightforward to prepare, using cheap, bioderived components, with lower volatility than most organic solvents, so are potential new green solvents for applications from drug delivery to battery electrolytes. We are interested in micelle templating of inorganic nanomaterials and formulations for delivery of actives, using these versatile solvents.

Changing the H-bonding components and their ratios alters the physicochemical properties of DES, leading to changes in solubility of other species in these solvents. This also alters the self-organisation of surfactants in these mixtures. We have investigated how specific DES components and their molar ratios impact upon solubility and structuring in surfactant solutions, using small angle X-ray and neutron scattering and rheology. Factors such as polarity, the presence of water, and the intermolecular interactions, both between solvent components and with the surfactant headgroups, play a role in the size and morphology of the micelles formed. We aim to develop design rules for novel complex solutions with applications in templating, rheology control and encapsulation using these interesting new solvent systems.

CPP 30.2 Tue 14:30 ZEU/0260

Brick by Brick - Magnetic Particle Transport — •Margaret Rosenberg[1], Jonas Bugase[2], Christian Janzen[2], Rico Huhnstock[2], Arno Ehresmann[2], and Hartmut Löwen[1] — [1]Heinrich-Heine University Düsseldorf, Universitätsstraße 1, Düsseldorf — [2]Institute of Physics , University of Kassel, Kassel

Facilitated by advances in particle synthesis, anisotropic and anisometric magnetic micro- and nanoparticles have been intensely studied in recent years, as the

particles' lack of symmetry can give rise to unique, tailor-able interactions. However, the modeling of off-equilibrium processes in non-trivial magnetic landscapes is still relatively under-explored. This contribution will seek to understand the ratchet-like transport process of a magnetically coated polymer block ("brick") across a stripe-patterned magnetic surface via a sequence of time-dependent external magnetic fields, from a simulation perspective. In particular, we explore the rotational behavior unlocked by the anisotropic particle shape, and discuss the connection to ongoing experiments.

CPP 30.3 Tue 14:45 ZEU/0260

Role of acids in stabilizing Reverse Micelles: the case of Dodecyl Sulfate — •Qixuan Li and Marialore Sulpizi — Faculty of Physics and Astronomy, Ruhr-University Bochum

The anionic surfactant Sodium dodecyl sulfate (SDS) can form reverse micelles (RMs) in two non-miscible components above the critical micelle concentration [1]. Although the RMs in salt or alkali solution has been investigated in previous studies [2,3], less is known on the working mechanism of acids in SDS RMs. Here, we employ all-atom (AA) and coarse-grained (CG) molecular dynamics to investigate the effects of chloroauric acid (HAuCl4), fluoroboric acid (HBF4) and phosphoric acid (H3PO4) solutions on the stability of the RMs through spontaneous self-assembly in toluene. We find that investigated acids can stabilize micellar structure, particularly H3PO4 due to the stable hydrogen-bonds it forms with the SDS headgroups. In addition, HAuCl4 can significantly influence micelle shape because of its strong polarizability at the water-toluene interface, while HBF4 causes the highest interfacial tension as a result of its significant hydrophilicity. Moreover, scission free energy calculations from CG simulations [4,5] reveal important differences, which along with the viscosity can explain how different acids affect the size of RMs. Our findings can help to rationalize the impact of different acids on the RMs stability and morphology and, in turn, on the metallic nanoparticles synthesis where the RMs are used as nanoreactors.

CPP 30.4 Tue 15:00 ZEU/0260

Microsecond-Resolved Tracking of Ultrasound-Responsive Colloids: From Rigid Silica Probes to Acousto-Responsive Microgels — Parsa Kassaiyan, Regine von Klitzing, and •Amin Rahimzadeh — Technische Universität Darmstadt, Hochschulstrasse 8, 64289 Darmstadt, Germany

Dynamic Light Scattering (DLS) is a powerful tool for characterizing dispersed particles, providing access to their size, size distribution, and dynamical behavior. Here, we integrate high-frequency ultrasound excitation into a conventional DLS setup to resolve the microsecond-scale motion of colloidal particles subjected to intense acoustic fields. This enables simultaneous extraction of particle size and ultrasound-induced oscillation parameters such as vibration frequency, amplitude, and acoustic response, through analysis of the scattered-light intensity correlation function. Compact silica particles serve as robust reference probes: their size remains unaffected by ultrasound, allowing us to map local acoustic energy dissipation by tracking their oscillatory motion at varying distances from the ultrasound source. Building on this reference system, we investigate acousto-responsive PNIPAM microgels. We find that microgels undergo a pronounced ultrasound-induced volume phase transition, shrinking due to rapid dehydration driven by absorption of high-frequency acoustic energy. Our approach thus provides both microsecond-resolved characterization of particle dynamics and a direct pathway to understanding, and exploiting, the acousto-responsiveness of microgels.

CPP 30.5 Tue 15:15 ZEU/0260

Influence of End Groups on the Aggregation of Polymers: A Neutron Scattering Study — •Jonathan Linus Samuel Garthe[1,2], Sylvain Prévost[3], and Matthias Karg[1] — [1]Physical Chemistry of Functional Polymers, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany — [2]Physical Chemistry: Colloids and Nanooptics, Heinrich Heine University Düsseldorf, Düsseldorf, Germany — [3]Large Scale Structures, Institut Laue-Langevin, Grenoble, France

The solution structure of polymers depends strongly on polymer concentration, solvent quality, and molecular weight. Additionally the nature of chemically different terminal groups influences the phase behavior of polymers with strong differences depending on the average chain length. We investigated the solution behavior and the occurrence of micelle-like structures for (semi)-dilute solutions. We synthesized PNIPAM homopolymers that are hydrophobically terminated. Via aminolysis we also cleaved the hydrophobic end groups allowing for direct comparison of the same homopolymers with and without hydrophobic end group. Small-angle neutron scattering was used to study the structure of the polymers in solution. Our studies demonstrated that a subdominant micelle formation occurs for samples with molecular weights below 100 kDa. The aggregation number of these micelles scales inverse with the molecular weight. At low concentrations, these micelles exist as individual structures. Upon increasing the concentration micelles aggregate, leading to a distinct structure factor contribution in the scattering profile.

CPP 31: Responsive and Adaptive Systems

Time: Wednesday 9:30–11:30 Location: ZEU/0255

Invited Talk CPP 31.1 Wed 9:30 ZEU/0255

Hydrogels with a Pinch of Embodied Intelligence — •Andreas Walther — Department Chemie, JGU Mainz

Smart is good, but intelligent is better. The next frontier in soft matter research is to design life-like materials with embodied intelligence, featuring the integrated sensor-processor-actuator paradigm. Our work explores how hydrogels and soft robotic systems can be endowed with autonomous operation and decision-making capacity by embedding chemical reaction networks, enzymatic feedback loops, and mechanical gating principles. Such metagels and metamaterials are capable of self-strengthening behavior, strain-gated responses, and non-reciprocal motion, moving far beyond the limits of traditional responsive materials. By intertwining chemical, mechanical, and structural information, these systems provide a blueprint for programmable, adaptive matter that approaches the complexity and functionality of biological tissues.

CPP 31.2 Wed 10:00 ZEU/0255

Secondary crosslinking of thermoresponsive microgels for smart microgel-based membranes — •Jonas Runge[1,2], Stefanie Uredat[1,2], Aditi Gujare[1,2], Domenico Truzzolillo[2], Julian Oberdisse[2], and Thomas Hellweg[1] — [1]Physical and Biophysical Chemistry, Bielefeld University, Germany — [2]Laboratoire Charles Coulomb, Université Montpellier, France

Responsive microgels are crosslinked polymer networks of colloidal size, which undergo a so-called volume phase transition induced by a certain stimulus like e.g. temperature or pH. Temperature sensitive microgels undergo a strong decrease in size at the volume phase transition temperature (VPTT). Smart membranes are based on responsive polymers and allow to open pores triggered by an external stimulus [1]. Our project on smart microgel-based membranes (SmartBRANE) aims to incorporate an UV-crosslinker and form membranes by activating the UV-crosslinker [2]. The working temperature of low-temperature fuel cells is in the range of 80-100 °C. Since the VPTT of common acrylamides is close to the physiological temperature, we synthesized a hydrophilic acrylamide monomer (NIPMAMol) with an extrapolated VPTT of 85°C. In this work, we copolymerize NIPMAMol with NIPAM and the UV-crosslinker HMABP to increase the VPTT of the then formed membrane. The thermoresponsive properties of the microgels are characterized with PCS. The distribution of the UV-crosslinker within the microgels particles and the formed membrane is investigated with contrast-matching SANS experiments. [1]Runge,Gujare,Uredat, PCCP, 2024, 26, 2732.[2]Dirksen, RSC Advances, 2021, 11(36), 22014.

CPP 31.3 Wed 10:15 ZEU/0255

Photoresponsive Control of Fullerene Diffusion in Azo-BT Nanotraps — Dmitry A. Ryndyk[1,2] and •Olga Guskova[1] — [1]IPF Dresden, Dresden, Germany — [2]TU Dresden, Dresden, Germany

We present a light-switchable azobenzene-bithiophene (Azo-BT) self-assembled monolayer (SAM) on Au(111) that operates as a reversible nanotrap for C60. Using density-functional theory and QM molecular dynamics, we quantify C60 adsorption on planar layers and diffusion on the SAM and within a fixed 12 A slit-like pore. Direct adsorption on the cis layer is about twice as favorable as on the trans layer due to stronger dispersion interactions with exposed thiophene rings, whereas the densely packed trans layer presents mainly hydrogen contacts and weaker binding. In the slit geometry, the trans (and mixed) layers provide an open pore that captures C60, while photoisomerization to cis closes the slit and prevents release. Diffusion analysis shows that specific interaction sites along the slit walls and the effective degree of confinement - arising from local potential variations within the fixed 12 A slit - govern diffusion pathways and escape barriers. External electric fields or charging of the Au/Azo-BT/C60 complex enable active expulsion, offering design principles for light- and field-responsive nanocarbon trapping interfaces. The financial support from DFG (grant number 509039598) is highly appreciated.

CPP 31.4 Wed 10:30 ZEU/0255

Reversible Photoswitching of Arylazopyrazole-functionalized Polyacrylamide Thin Films under Water Vapor — •David P. Kosbahn[1], Morgan P. Le Dû[1], Simon A. Wegener[1], Feifei Zheng[2], Robert Cubitt[3], René Steinbrecher[4], André Laschewsky[4,5], Christine M. Papadakis[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for

Functional Materials, Garching, Germany — [2]TUM School of Natural Sciences, Soft Matter Physics Group, Garching, Germany — [3]Institut Laue-Langevin, Grenoble, France — [4]Institut für Chemie, Universität Potsdam, Potsdam-Golm, Germany — [5]Fraunhofer Institut für Angewandte Polymerforschung, Potsdam-Golm, Germany

This study investigates the swelling behavior of p(AAPEAm-co-DMAm) films in both isomeric states of the novel photoswitchable molecule arylazopyrazole (AAP). The impact of reversible switching using two different wavelengths on swelling of the polymer in water vapor is examined, with the aim of controlling water uptake, expansion, and nanoscale morphology. This material shows potential for applications in reversible light sensors, photo-actuators, and drug delivery systems. We use time-resolved FTIR spectroscopy to monitor group vibrations during switching, gaining insights into molecular interactions throughout the isomerization processes. Additionally, in situ time-of-flight neutron reflectometry on a thin film provides time- and depth-resolved data on the water distribution along the surface normal. The results shed light on the influence of arylazopyrazole moieties on the polymer's microscopic properties.

CPP 31.5 Wed 10:45 ZEU/0255

Modeling the Viscoplastic Deformation of Azopolymers Under the Influence of Structured Light — •Nikolai Liubimtsev and Marina Saphiannikova — Leibniz Institute of Polymer Research Dresden, Germany

A distinctive feature of side-chain azopolymers is their ability to convert structured light into a well-defined stress field [1]. This field results from the alignment and elongation of polymer backbones along the light-polarization direction, which acts as a nematic director. Linearly or elliptically polarized irradiation induces uniaxial or biaxial chain orientation, and the stress tensor is proportional to the rate of change of the second-order orientation tensor, predicted from the spatial distribution of light intensity and polarization [1]. Using viscoplastic photoalignment modeling, we achieve excellent agreement with experimentally observed reshaping of azopolymer microstructures. Three-dimensional light fields - such as tightly focused Gaussian beams or q-plate patterns - produce directional photodeformations. These fields are incorporated into ANSYS either analytically or by directly mapping intensity, polarization, and ellipticity at each material point, the latter being especially useful for arbitrary SLM-generated patterns. Financial support from DFG grant GR 3725/10-1 is gratefully acknowledged.

CPP 31.6 Wed 11:00 ZEU/0255

Impact of surface chemistry on the adsorption and dynamics of stimuli-responsive polymers — Baptiste Chabaud[1], Wanchung Chiang[1], Lionel Bureau[1], Ralf Richter[2], Rachel Auzély[1], Delphine Debarre[1], and •Galina Dubacheva[1] — [1]Université Grenoble Alpes, Grenoble, France — [2]University of Leeds, Leeds, UK

Stimuli-responsive polymers at interfaces underpin smart coatings, sensors and bioinspired materials, yet how surface chemistry controls their binding and dynamics remains poorly understood. We probe the interfacial behavior of redox- and thermosensitive polymers on well-defined model surfaces using QCM-D, SPR, ellipsometry, electrochemistry and fluorescence microscopy. For redox-active host/guest systems, we show that grafting strategy, linker flexibility and host/guest density govern the stability, specificity and reversibility of polymer assemblies. Kinetic analysis further reveals that small changes in surface chemistry, such as linker design or dilution with inert molecules, strongly tune multivalent superselectivity, enabling sharp discrimination of receptor densities. Using supported lipid bilayers as fluid interfaces, we correlate lateral mobility with contraction, dehydration and 2D aggregation of thermoresponsive polymer brushes. Overall, we identify interfacial density, mobility and flexibility as key parameters for controlling stimuli-responsive polymer assemblies and outline design rules for supramolecular and bio-inspired systems with high specificity and precision.

CPP 31.7 Wed 11:15 ZEU/0255

Modeling of magnetic hysteresis in magneto-active elastomers — •Pawan Patel[1,2], Dirk Romeis[1], and Marina Saphiannikova[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden e.V, Hohe Straße 6, 01069, Dresden, Germany — [2]Faculty of Mechanical Science and Engineering, Dresden University of Technology, 01062, Dresden, Germany

Magneto-active elastomers (MAEs) are soft polymer composites containing magnetizable microparticles. MAEs exhibit field-dependent mechanical and magnetic properties. When subjected to an external magnetic field, MAEs display magneto-mechanical coupling effects such as tunable stiffness and reversible shape changes. This study presents a multiscale theoretical model to describe the magnetic hysteresis behavior of MAEs, focusing on the role of microstructure evolution during magnetization and demagnetization of microparticles. The total energy of the system is formulated as the sum of magnetic and micromechanical contributions, while macroscopic deformation of the cylindrical sample is constrained. The model incorporates both pure dipole–dipole interactions and near field effect to account for multipole higher-order particle interactions. The results reveal that magnetic hysteresis in soft magnetic MAEs arises primarily from microstructural rearrangements, where the spatial configuration of particles differs between increasing and decreasing magnetic fields. Simulations demonstrate that parameters such as particle volume fraction, sample geometry, and micromechanical stiffness significantly influence the hysteresis loop width.

CPP 32: Focus Session: Water – from Atmosphere to Space IV (joint session CPP/DY)

Time: Wednesday 9:30–10:45 Location: ZEU/0260

Topical Talk CPP 32.1 Wed 9:30 ZEU/0260

Synchrotron X-Ray Studies on Structural Transitions in Water and Alcohol containing Ice Analogues — •Christina M. Tonauer — Institute of Physical Chemistry, University of Innsbruck, Austria — Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany

To this date, 21 different crystalline and at least 3 distinct amorphous forms of water ice have been discovered. In addition to the structural versatility of pure water ice phases, water forms solid guest-host systems, so-called 'clathrate hydrates' where water builds cage-like structures around guest molecules of various sizes (e.g., Ar, CO2, methane, ethanol).

Ices in space are exposed to various forms of (external) stress, e.g., impacts, cosmic rays, UV/Vis radiation as well as endogenous thermal fluctuations, thereby undergoing structural changes. By studying such structural transitions in ice analogues upon heating (and/or radiation), conclusions can be drawn about the conditions at various extraterrestrial environments.

Therefore, we here present temperature-resolved wide- and small-angle synchrotron X-ray scattering data of vapor-deposited water-ethanol mixtures of various concentrations, collected at PETRA 3/DESY. While the SAXS data allows for monitoring of changes of the morphology of the microporous sample, the WAXS data reveals the formation sequence of two different hydrates, offering new insights into the crystallisation of astrophysical ices.

CPP 32.2 Wed 10:00 ZEU/0260

Water in exoplanetary atmospheres: from molecular spectra to Water Worlds — •Sergey Yurchenko — Department of Physics and Astronomy, University College London, Gower Street, WC1E 6BT London, United Kingdom

Water vapour is one of the key tracers of atmospheric physics and chemistry on exoplanets, from hot Jupiters to temperate sub-Neptunes and so-called Water Worlds. In this contribution I will give an overview of the role of H_2O across this diversity of atmospheres, focusing on how we infer its presence from transmission and emission spectra. I will review both low-resolution transit spectroscopy and high-resolution cross-correlation techniques, and show how they are applied to data from space- and ground-based facilities, including JWST, Hubble and VLT, as well as future observations with the ELT and ESA's Ariel mission. Special emphasis will be placed on the way clouds and hazes imprint themselves on the observed spectra.

I will summarise the current observational status of water detections and non-detections – including recent and sometimes controversial claims for habitable-zone planets. A central theme of the talk will be the importance of accurate laboratory and theoretical data for water and related species. I will highlight how comprehensive molecular line lists and cross sections from the ExoMol and HITRAN databases, together with other laboratory measurements, underpin the modelling and retrieval of exoplanet spectra over a wide range of temperatures, pressures and compositions, thereby linking detailed molecular physics to the emerging picture of water in exoplanetary atmospheres.

CPP 32.3 Wed 10:15 ZEU/0260

Structures of Ices by Quantum Crystallography and PDF — Krzysztof Wozniak[1], •W. Sławiński[1], G. Łach[2], R. Gajda[1], M. Chodkiewicz[1], P. Rejnhardt[1], M. Arhangelskis[1], Ch. Ridley[3,4], and C. L. Bull[3,5] — [1]Deptm. of Chem., Univ. of Warsaw,Poland — [2]Deptm. of Phys., Univ. of Warsaw, Poland — [3]ISIS Neutron and Muon Source, STFC, RAL, Harwell Campus, UK. — [4]Spallation Neutron Source, Oak Ridge Nat. Lab., Oak Ridge, Tennessee 37830, USA — [5]Univ. of Edinburgh, UK.

Ice is the solid form of water (H*O). The most familiar form of ice is the hexagonally structured ice Ih. However, water can crystallize into at least 21 distinct

phases, unique in structure, depending on T and P and route of formation. In this contribution, will present details of structures of ices (VI[3], VII[1,2], Ih [4]) obtained with quantum-crystallographic Hirshfeld Atom Refinement against single crystal X-ray and electron diffraction data. We will also present the first quantitative characterisation of disorder in D2O ice VII and VI obtained through a combination of Pair Distribution Function (PDF) analysis, Reverse Monte Carlo (RMC) modelling, and high-pressure neutron scattering. Our results provide a detailed decomposition of both the average and local atomic structures of Ice VII, revealing a previously unquantified level of structural disorder. References [1] R. Gajda et al., IUCRJ, 12(3) (2025) 288-294; [2] W. A. Sławiński et al., Hidden complexity in D2O Ice VII, Acta Mat., (2025) submitted; [3] M. L. Chodkiewicz et al., IUCRJ, 9 (2022) 573-579; [4] M. L. Chodkiewicz et al., IUCRJ, 11(5) (2024) 730-736.

CPP 32.4 Wed 10:30 ZEU/0260

Water dynamics in conductive PEDOT:PSS/cellulose nanocomposite films in dependence of relative humidity and temperature — •Lucas Kreuzer[1], Marie Betker[2], Marcell Wolf[1], Jacques Ollivier[3], Daniel Söderberg[4], and Stephan V. Roth[2,4] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), TUM, Garching, Germany — [2]Deutsches Elektronen Synchrotron, Hamburg, Germany — [3]Institut Laue-Langevin, Grenoble, France — [4]Department of Engineering Mechanics, Royal Institute of Technology KTH, Stockholm, Sweden

PEDOT:PSS is a conductive and water-soluble polymer blend widely used in organic electronics. However, pure PEDOT:PSS films absorb significant amounts of water, causing swelling, degradation, and eventually a decrease in conductivity. Integrating PEDOT:PSS with cellulose nanofibrils (CNFs) overcomes these issues by limiting water absorption and enhancing mechanical stability. However, a minor amount of water is still absorbed, leading to a change in film morphology: high humidity induces de-wetting of PEDOT:PSS from the CNFs, reducing conductivity, whereas drying generally leads to a re-wetting of PEDOT:PSS, thereby restoring conductivity. To investigate further the role of water, quasi-elastic neutron scattering is applied, which reveals two water species in the films: mobile bulk water and slower hydration water. Upon drying, bulk water is released completely, while hydration water remains in the films, supporting the re-wetting of PEDOT:PSS. Moreover, at higher temperatures, different diffusive behavior was found for bulk and hydration water.

CPP 33: Complex Fluids, Colloids, Micelles and Vesicles II

Invited Talk CPP 33.1 Wed 10:00 ZEU/LICH

Shape-induced superstructure formation in concentrated ferrofluids — •Sabrina Disch — University of Duisburg-Essen, Essen, Germany

The response of magnetic nanoparticles to applied static and dynamic magnetic fields is the subject of intense research in view of its fundamental technological importance [1]. The field-assisted self-organization of shape-anisotropic nanoparticles in dispersions is particularly desired for liquid crystalline or optically anisotropic materials and as a prerequisite for self-organization into long range ordered arrangements [2]. A strong structure-directing influence of the particle shape on the symmetry of mesocrystalline arrangements has been established for nanocubes with a varying degree of cubicity [3].

In this contribution, we give a detailed account on the impact of nanoparticle shape and size on the interparticle correlations in colloidal dispersions of maghemite nanoparticles. Despite the similar particle size, magnetic moment, and volume concentration (>5 vol-%), we observe a significantly distinct aggregation behavior of nanospheres and nanocubes using small-angle neutron scattering [4]. The field-dependent arrangement of cuboidal nanoparticles into mesocrystalline assemblies and their geometric orientation will be discussed as observed by field-dependent small-angle scattering experiments.

CPP 33.2 Wed 10:30 ZEU/LICH

Modeling artificial cells to control the local chemical environment — •Nils Göth and Joachim Dzubiella — Applied Theoretical Physics—Computational Physics, Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, 79104 Freiburg, Germany

Living cells change and respond to their environment. Synthesized artificial cells (hollow microgels) show in experiments pH-responsive behavior by a pH-dependent membrane permeability and change their pH-environment by a chemical reaction [1]. Here, we report a simple model for such artificial cells based on the feedback mechanism between permeability and pH. We introduce the model on the basis of recent experiments [1] and study the effects of experimentally tunable parameters. The model captures not only the effects observed in the experiments, but further predicts the behavior of mixtures of two different kinds of artificial cells. Thus, we provide guidance for future experiments in the field of collective behavior of artificial cells.

CPP 33.3 Wed 10:45 ZEU/LICH

Evaporation-driven assembly of colloidal monolayers and multilayers — •Qingguang Xie[1] and Jens Harting[1,2] — [1]Helmholtz-Institut Erlangen-Nürnberg for Renewable Energy (IET-2), Forschungszentrum Jülich, Erlangen, Germany — [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

Drying of colloidal suspension films is a common approach to synthesize colloidal monolayers and multilayers for applications such as photovoltaics and catalysis. The fundamental understanding of the complex processes involved in film drying is essential for controlling and optimizing the deposition structure. We numerically investigate the drying dynamics of both thin and thick colloidal suspension films. For thin films, we focus on the influence of substrate and particle wettability on assembled monolayers. High substrate wettability promotes hexagonally packed monolayers, while low wettability leads to droplet formation and particle clustering. Furthermore, we reveal that higher particle wettability can mitigate the impact of substrate wettability and facilitate the formation of highly ordered monolayers. We propose theoretical models predicting the surface coverage fraction dependent on particle volume fraction, initial film thickness, particle radius, as well as substrate and particle wettability, and validate these models with simulations. In a further step, we investigate the drying of thick films with different particle-particle interactions. Weak interactions led to densely packed structures, while strong interactions led to more porous structures due to aggregation.

CPP 33.4 Wed 11:00 ZEU/LICH

Microscopic liquid marbles for force sensing using AFM — •Tomas P. Corrales[1], Constanza Rodriguez[1], Catalina Navarrete[1], Diego Cortés[2], Michael Kappl[2], and Syuji Fujii[3] — [1]Universidad Tecnica Federico Santa Maria — [2]Max-Planck-Institut für Polymerforschung, Mainz, Germany — [3]Osaka Institute of Technology, Osaka, Japan

An AFM cantilever is an exceptional tool for measuring friction and adhesion forces at the nanoscale. We have recently shown the possibility of fixing microscopic liquid droplets on the end of a tipless AFM cantilever, which was used to measure friction forces of a Teflon surface (D. Cortes et al., Physical Review Letters 135, 048203, 2025). In this new work, we have set out to extend this approach by fixing microscopic liquid marbles at the end of an AFM cantilever. Liquid marbles are prepared from hydrophobic nanoparticles of CaCO3. We first spray a mixture of water glycerol over a powder of these CaCO3 nanoparticles, which creates a collection of microscopic liquid marbles. Afterwards, we attach these droplets to a hydrophobic tipless AFM cantilever with a hydrophilic sticky point. With this system we explore liquid marble friction, adhesion and stability.

CPP 34: Focus Session: Water – from Atmosphere to Space V (joint session CPP/DY)

CPP 34.1 Wed 11:00 ZEU/0260

Scalable Machine Learning Model for Energy Decomposition Analysis in Aqueous Systems — •Thomas Kühne — CASUS/HZDR, Görlitz, Germany

Energy decomposition analysis (EDA) based on absolutely localized molecular orbitals provides detailed insights into intermolecular bonding by decomposing the total molecular binding energy into physically meaningful components. Here, we develop a neural network EDA model capable of predicting the electron delocalization energy component of water molecules, which captures the stabilization arising from charge transfer between occupied absolutely localized molecular orbitals of one molecule and the virtual orbitals of another. Exploiting

the locality assumption of the electronic structure, our model enables accurate prediction of electron delocalization energies for molecular systems far beyond the size accessible to conventional density functional theory calculations, while maintaining its accuracy. We demonstrate the applicability of our approach by modeling hydration effects in large molecular complexes, specifically in metal-organic frameworks.

CPP 34.2 Wed 11:15 ZEU/0260

Advances in absolute-scale electronic structure measurements of liquid water and aqueous solutions — •Florian Trinter — Fritz-Haber-Institut, Berlin, Germany

Recent advances in liquid-jet photoelectron spectroscopy (LJ-PES) have enabled the precise determination of absolute electronic energetics of liquid water and aqueous solutions, both in the bulk and at interfaces. By implementing refined vacuum and Fermi-level referencing procedures, rooted in condensed-matter concepts, vertical ionization energies (VIEs) and solution work functions can now be measured with high accuracy. We show that binding energy determinations near the ionization threshold are strongly influenced by quasi elastic electron scattering and indirect ionization processes. Vibrational excitation and autoionization via super-excited states lead to spectral distortions at electron kinetic energies below ~14 eV, necessitating careful data interpretation to extract intrinsic properties. Applying these methods to neat water and aqueous solutions of sodium iodide (NaI) and tetrabutylammonium iodide (TBAI), we reveal solute-specific effects: NaI primarily alters water's bulk structure, increasing the $1b_1$ binding energy with concentration, while TBAI affects surface potentials through interfacial dipole formation, leading to an apparent binding energy decrease. Additionally, we determine the work function of neat water as 4.73 ± 0.09 eV and quantify its reduction in TBAI solutions. These findings establish a framework for quantitative studies of molecular interactions and electronic-structure modifications in aqueous systems, with implications for electrochemical and interfacial science.

CPP 34.3 Wed 11:30 ZEU/0260

Liquid-vapor critical behavior of the TIP4P/2005 water model: Effects of NaCl solutes and hydrophobic confinement — •Mayank Sharma and Peter Virnau — Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany

The liquid-vapor critical behavior of water is strongly influenced by both ionic solutes and confinement. Molecular dynamics simulations of aqueous NaCl solutions using the TIP4P/2005 water model and the Madrid-2019 ion parameters reveal a systematic increase in the liquid-vapor critical temperature and pressure with salt concentration, consistent with experimental trends. In contrast, confinement between parallel hydrophobic plates leads to a depression of the critical point. The critical temperature was determined using the Binder cumulant crossing in the NVT ensemble, based on a recently developed method originally applied to an active Brownian particle system [1]. The reliability of this approach was verified through complementary NPT simulations using histogram reweighting. We further demonstrate the pronounced sensitivity of the estimated critical point to the van der Waals cutoff distance, underscoring the importance of properly accounting for long-range interactions. The present results capture qualitative shifts in the critical point of water arising from ionic interactions and confinement, and the Binder-cumulant framework used here is readily extendable to other critical phenomena, including the putative liquid-liquid critical point of water.

CPP 34.4 Wed 11:45 ZEU/0260

Cooperative molecular dynamics and nuclear quantum effects in bulk water — •Margarita Russina — Helmholtz-Zentrum Berlin for Materials and Energy, Berlin, Germany

The cooperative dynamics in water remain difficult to access due to the lack of long-range order and the short lifetimes of molecular correlations. Neutron scattering is well suited to probe such phenomena on the nanoscale but has been hindered by the weak coherent signal of H2O. Using a novel neutron polarization-analysis approach, we directly measure the coherent scattering in H2O and D2O with high accuracy [1]. Beyond self-diffusion and molecular rotation, we identify a picosecond cooperative process in liquid water, likely associated with rearrangements of several neighboring molecules and the reorganization of hydrogen bonds. This process may act as a precursor to large-scale molecular transport. In the intermediate wave-vector range Q < 1 1/Å, the coherent signal in H2O is enhanced compared to the expectation for rigid, noninteracting, randomly oriented molecules. Since this Q-range corresponds to distances of several molecular spacings, our results provide evidence that intermolecular correlations in water extend beyond short-range correlations and involve more distant neighbors, giving rise to cooperative dynamical fluctuations. Such an enhancement can be rationalized by correlated preferential molecular orientations, hydrogen-bond rearrangements, and nuclear quantum effects. In contrast, D2O follows a more hydrodynamic behavior consistent with reported differences in the molecular bonding and symmetry of H2O and D2O. [1] M. Russina et al., J. Phys. Chem. Lett. (2025).

CPP 35: Glasses and Glass Transition (joint session DY/CPP)

Time: Wednesday 11:15–12:45 Location: ZEU/0118

Invited Talk CPP 35.1 Wed 11:15 ZEU/0118

Topological defects in 2D amorphous ensembles — •Peter Keim — Heinrich-Heine-Universität Düsseldorf

Topological defects are key to understand melting of crystals in two dimensions. A dilute gas of bound thus virtual pairs of dislocations cause the softening of a crystal in the vicinity of melting. If thermal energy is high enough to unbind dislocation pairs, translational order is destroyed and the crystal to melts due to the lack of shear resistance. In an amorphous solid, the concept of topology seems useless for the first glance due to the absence of order. Here, we discuss, how the definition of virtual dislocations can be generalized for a two-dimensional glass. Based on positional data of a binary colloidal monolayer we determine the fugazity of generalized virtual dislocations and measure elasticity close to the glass transition: Youngs modulus gets 16π at melting in surprisingly close analogy to Kosterlitz-Thouless-Halperin-Nelson-Young (KTHNY) - theory for melting of 2D crystals.

CPP 35.2 Wed 11:45 ZEU/0118

Glass transition and universal scaling in ultra-low crosslinked microgels — Alessandro Martinelli[1], Rajam Elancheliyan[1], Andrea Scotti[2], Alexander V. Petrunin[3], •Domenico Truzzolillo[1], and Luca Cipelletti[1,4] — [1]Laboratoire Charles Coulomb (L2C), UMR 5221 CNRS-Universitè de Montpellier, F-34095 Montpellier,France — [2]Division of Physical Chemistry, Lund University, SE-22100 Lund, Sweden — [3]Institute of Physical Chemistry, RWTH Aachen University, Landoltweg 2, 52074 Aachen,Germany — [4]Institut Universitaire de France, F-75231 Paris, France

We investigate the glassy dynamics of Ultra-Low Crosslinked (ULC) poly(N-isopropylacrylamide) (PNIPAM) microgels. The glass transition is reached by varying either the temperature (modulating microgel swelling) or the colloidal number density. Our Dynamic Light Scattering (DLS) measurements confirm that the dynamic slowdown is solely governed by the effective volume fraction (φ), with ULC microgels behaving as fragile glass formers. Small-Angle X-ray Scattering data further indicates that the center-to-center inter-microgel distance is insensitive to temperature, scaling geometrically with mass fraction, while the height of the first peak of the static structure factor decreases with increasing concentration, suggesting structural melting above glass transition. We finally we report on the striking emergence of a universal dynamic behavior for the relaxation time (τ_α) dependence on the scattering vector (q) across the entire supercooled and glass regimes, allowing the data to collapse onto a master curve, whose features will be discussed.

CPP 35.3 Wed 12:00 ZEU/0118

Strain-rate dependent rheological memory in a model glass former — •Monoj Adhikari and Jürgen Horbach — Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, 40225 Düsseldorf, Germany

We investigate the shear response of deeply supercooled liquids far below the mode coupling critical temperature of a model glass former. Our system is based on the Kob-Andersen binary Lennard-Jones mixture (KABLJM) model but incorporates polydispersity, allowing us to combine SWAP Monte Carlo (MC) with Molecular Dynamics (MD) simulations. This hybrid approach enables equilibration at temperatures far below the Mode-Coupling critical temperature, T_{MCT}, while maintaining an equation of state similar to the original binary KABLJM model. We examine the response of these equilibrated samples to shear deformation at finite temperature and strain rate. By combining MD with SWAP MC during shear, we demonstrate that states with stress far below the yield stress can be accessed, making Newtonian fluid behavior observable even at temperatures well below T_{MCT}. To characterize the Newtonian fluid states obtained from this hybrid approach, as well as the solid-like states from standard MD, we employ a strain-rate switching protocol on the steady states. When applying this protocol to the stationary states, we observe intriguing memory effects. In the transient regime, stress overshoots appear when increasing the strain rate, whereas a striking stress undershoot emerges when decreasing it, mirroring recent experimental observations in polymer glasses.

CPP 35.4 Wed 12:15 ZEU/0118

An Analytical Relation between Thermodynamics and Dynamics in a Trap-like Model of Supercooled Liquids — •Simon G. Kellers, Anshul D. S. Parmar, and Andreas Heuer — Institute of Physical Chemistry, University of Münster, Corrensstraße 28/30, 48149 Münster, Germany

Recent studies on 2D non-network glass formers, enabled by the million-fold acceleration of Swap Monte Carlo, have revealed clear deviations from Gaussian behavior in the inherent-structure (IS) density of states and linked these features to the fragile-to-strong crossover (FSC) and the emergence of a low-energy depletion regime.

Here, we establish such a connection by introducing a direct analytical relation between thermodynamic PEL statistics and dynamical properties within a trap-like description of supercooled liquids. We illustrate this relation using a binomial distribution of IS states and show that it naturally yields a characteristic trap size for polydisperse systems. This trap size reflects the effective number of degrees of freedom that collectively determine the depth and barrier of a metabasin participating in an activated relaxation event, thereby offering a physically transparent measure of cooperativity.

By combining this analytical framework with simulation data for a polydisperse 2D glass former, we obtain a coherent and quantitatively consistent landscape-based interpretation of the FSC.

Single particle vs. collective diffusion dynamics in a glassforming ternary Lennard-Jones mixture — •Anna Pini and Jürgen Horbach — Institut für Theoretische Physik II: Soft Matter, Heinrich Heine-Universität Düsseldorf, Universitätsstraße 1, 40225 Düsseldorf

Ternary fluid mixtures exhibit a rather complicated diffusion dynamics compared to their binary counterparts. Apart from three self-diffusion coefficient, there are three interdiffusion coefficients. In this work, we study a ternary ABC Lennard-Jones mixture using molecular dynamics computer simulation. It is based on the Kob Andersen binary Lennard-Jones mixture (KABLJM) [1] to which we have added a third C component. While C-C and A-C interactions are respectively identical to A-A and A-B interactions, B-C interactions are different from those between A and B particles. We study the glassy dynamics of this system at a high density of $\rho = 1.2$ and compare it to that of the original KABLM. While the self-diffusion coefficient show a similar temperature dependence for the binary and the ternary system, the behavior of the interdiffusion coefficients in the ternary system is significantly different from that in the binary one; in particular, unlike the binary system, the Darken equation does not hold in the ternary one. [1] W. Kob and H. C. Andersen, Phys. Rev. Lett. **73**, 1376 (1994).

CPP 36: Round Table Discussion: The Future of Neutrons in France and Germany (joint session CPP/BP)

Organized by Benoit Coasne and Christine M. Papadakis.

Time: Wednesday 11:45–12:45 Location: ZEU/LICH

Discussion CPP 36.1 Wed 11:45 ZEU/LICH

Round Table: Novel Opportunities for France/Germany Cooperation in Neutron Science — •Julian Oberdisse[1], •Frank Schreiber[2], •Arnaud Desmedt[3], •Stephan Förster[4], •Jacques Jestin[5], •Pascale Launois[6], •Christian Pfleiderer[7], and •Sabrina Disch[8] — [1]Laboratoire Charles Coulomb, U Montpellier, France — [2]Institut für Angewandte Physik, Universität Tübingen, Germany — [3]Laboratoire Léon Brillouin (LLB), Gif-sur-Yvette, France, — [4]Jülich Centre for Neutron Science (JCNS), FZ Jülich, Germany — [5]Institut Laue-Langevin (ILL), Grenoble — [6]Laboratoire de Physique des Solides d'Orsay, France — [7]Heinz Maier-Leibnitz Zentrum (MLZ), Garching, German — [8]University of Duisburg-Essen, Germany

With current and upcoming major changes in European neutron science and facilities, Germany and France are expected to play a strong role. This emerging new landscape for neutron science offers opportunities to reshape and reinvent the traditionally strong bonds between our two countries – both in terms of science cooperation and technical collaboration. The hosts Julian Oberdisse and Frank Schreiber look forward to a diverse panel discussion with the directors of the French and German neutron facilities as well as the chairs of the French and German neutron associations.

CPP 37: Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics III

Predicting molecular ordering in deposited molecular films — •Denis Adrienko — Max Planck Institute for Polymer Research, Mainz, Germany

Thin films of molecular materials are commonly employed in organic light-emitting diodes, field-effect transistors, and solar cells. The morphology of these organic films is shown to depend heavily on the processing used during manufacturing, such as vapor co-deposition. However, the prediction of processing-dependent morphologies has until now posed a significant challenge, particularly in cases where self-assembly and ordering are involved. In this work, a method is developed based on coarse-graining that is capable of predicting molecular ordering in vapor-deposited films of organic materials. The method is tested on an extensive database of novel and known organic semiconductors. A good agreement between the anisotropy of the refractive indices of the simulated and experimental vapor-deposited films suggests that the method is quantitative and can predict the molecular orientations in organic films at an atomistic resolution [1]. The methodology can be readily utilized for screening materials for organic light-emitting diodes.

CPP 37.2 Wed 15:30 ZEU/LICH

A Universal Soft Upper Limit to the Seebeck Coefficient in Organic Thermoelectrics — •Dorothea Scheunemann[1], Zelong Li[2], Dennis Derewjanko[1], Yuqian Liu[2], Martijn Kemerink[1], and Guangzheng Zuo[2] — [1]Heidelberg University, Germany — [2]Fudan University, Shanghai, P.R. China

Organic thermoelectrics have the potential to convert waste heat into electricity by utilizing lightweight and flexible polymers. Despite over a decade of intensive research, significant progress remains limited. A key factor is the trade-off between conductivity (σ) and Seebeck coefficient (S), which dictates the extent to which the power factor ($PF = \sigma S^2$) can be optimized. Here, we combine an experimental data set for different polymers at variable doping levels to show that the S vs. σ curve is universal up to the maximum PF, followed by a material-dependent roll-off, when S and σ are normalized to their values at maximum PF. Furthermore, it is demonstrated that there is a soft upper limit for S ($\sim$200μV/K), at which the optimal power factor is achieved. Combining tight-binding and kinetic Monte-Carlo modeling, we quantitatively explain this behavior in terms of quasi-free charges moving in a renormalized density of states of Gaussian shape, where the renormalization accounts for the screened interaction with the ionized dopants. These findings suggest that the trade-off only exists at the single-material level, which subsequently gives rise to practical design rules.

CPP 37.3 Wed 15:45 ZEU/LICH

Nanoscale Dry-Processed Phosphorescent Films for Programmable Photonic Applications — •Yana Bui Thi, Sebastian Schellhammer, and Sebastian Reineke — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics, Technische Universität Dresden

Room-temperature phosphorescence (RTP) of organic materials provides a versatile basis for applications in environmental detection, security features, and optical data storage. Many of these concepts, including programmable luminescent tags (PLTs) [1], rely on precise control of triplet states, which poses certain challenges in terms of stability and processing. While polymer matrices are commonly used to suppress non-radiative decay, their processing limitations have restricted the miniaturization and control of devices. Here, we introduce ultra-thin RTP tags that are produced entirely solvent-free and use organic materials as active layer. These nm-sized stacks exhibit higher efficiency and can be more than twenty times thinner than polymer-based structures. We characterize the

resulting activation dynamics, stability, and reusability and discuss how the processing enables improved uniformity and the possible integration with structuring techniques. These results demonstrate a path toward compact, low-energy, and precisely controllable luminescent tags for future photonic technologies.

CPP 37.4 Wed 16:00 ZEU/LICH

Probing the percolating charge transport network in organic semiconductors by noise spectroscopy — •Sebastian Klein, Priya Viji, Constantin Tormann, Clemens Göhler, and Martijn Kemerink — IMSEAM, Heidelberg University, Germany

In disordered organic semiconductors (OSCs), a suppression of shot noise is expected due to the internal charge carrier transport mechanisms, which is relevant for, e.g., their application in photodetectors. The charge transport in OSCs, which occurs by hopping between localized sites, can be described by percolation theory, from which it follows that so-called hard hops form the bottleneck that charge carriers have to overcome to progress through the device. The tunneling through one singular hard hop is a random uncorrelated poissonian process which leads to OSCs displaying shot noise. Since multiple hard hops sit in series in the charge transport path in macroscopic OSCs, it is expected that shot noise in OSC is suppressed, inversely proportional to the number of hard hops, which in turn depends on disorder, temperature and thickness of the OSC. This suppression is quantified by the Fano factor, which we directly measure by current cross-correlation noise spectroscopy. Temperature- and current-bias-dependent Fano factor measurement results are compared with kinetic Monte Carlo simulations. From the measurements and simulations, it can consistently be concluded that Fano factor measurements give direct and otherwise inaccessible insight into the internal structure as well as the disorder and correlation length of OSC.

CPP 37.5 Wed 16:15 ZEU/LICH

Charge transfer dynamics in PBDB-T blends studied by time-resolved optical spectroscopy — Beatriz Molinaro Guerra[1], Federico Cilento[2], Maria Luiza Miranda Rocco[1], and •Wibke Bronsch[2] — [1]Institute of Chemistry, Federal University of Rio de Janeiro, 21941-909, Rio de Janeiro-RJ, Brazil — [2]Elettra-Sincrotrone Trieste S.C.p.A., 34149 Basovizza, Trieste, Italy

Charge transport processes in conjugated polymers are an important key for the production of more efficient organic optoelectronic devices, such as organic solar cells. Specially, the study of electron charge transfer dynamics in excited states may help us to understand charge transport properties in these materials. We studied the ultrafast response of different blends of PBDB-T polymers with small molecules after NIR excitation. Time-resolved optical spectroscopy measurements with broad-band probe pulses performed in the T-ReX facility at Elettra reveal clear changes in the ultrafast response when comparing the results for the pure molecule films and the blends, suggesting that charges are transferred between the two components of the blend on the femto- to picosecond timescale. After exciting the HOMO-LUMO transition of the ITIC molecule, the exciton population decay time drastically reduces due to the presence of the PBDB-T polymer, while the decay constant at photon energies in the range corresponding to the PBDB-T HOMO-1-LUMO transition increases. This behavior indicates hole injections in PBDB-T after primary excitation of ITIC, as it was also discussed for PBBF:ITIC blends [1]. [1] Liu et al. Advanced Science 6, 1802103 (2019).

CPP 37.6 Wed 16:30 ZEU/LICH

Analysis of Charge Carrier Dynamics in Organic Solar Cells via Optical Impedance Spectroscopy — •Elias Wassmer, Jan Phillip Ott, Brian Hinz, Clemens Göhler, and Martijn Kemerink — IMSEAM, Heidelberg University, Germany

Understanding the complex dynamics of charge carriers in organic solar cells (OSCs) is essential to identify the mechanisms that lead to voltage, current and fill factor losses. In this work, we investigate these dynamics by combining conventional electrical impedance spectroscopy (EIS) with the newly implemented optical impedance spectroscopy (OIS). In OIS, in addition to a constant background illumination, a small alternating light signal is applied to investigate the photogenerated charge carriers under quasi-steady-state conditions. The results of both EIS and OIS of PM6:Y6 OSCs across a range of operating conditions are used to compare the two methods and allow us to track changes during device degradation. To interpret the measured impedance spectra, two established models are applied: an equivalent-circuit model, which maps the behaviour of the OSC onto a network of resistances and capacitances, and a rate-equation model that describes carrier generation, recombination and extraction through differential equations. Comparing these modelling approaches allows us to evaluate how well the charge-carrier dynamics are captured by each model and how this relates to the physical processes inside the OSCs. Our results show that the equivalent-circuit model is insufficient for describing OIS, indicating that a more physically motivated rate-equation model is needed to reproduce photogenerated carrier dynamics.

CPP 38: Biopolymers, Biomaterials and Bioinspired Functional Materials I (joint session CPP/BP)

Invited Talk CPP 38.1 Wed 15:00 ZEU/0255

Engineering, processing and application of recombinant spider silk proteins — •Thomas Scheibel — Universität Bayreuth, Lehrstuhl Biomaterialien, Prof.-Rüdiger-Bormann-Str. 1, 95440 Bayreuth

Proteins reflect one fascinating class of natural polymers with huge potential for technical as well as biomedical applications. One well-known example is spider silk, a protein fiber with excellent mechanical properties such as strength and toughness. We have developed biotechnological methods using bacteria as production hosts which produce structural proteins mimicking the natural ones. We employ silk proteins in application forms such as fibers, hydrogels, particles or films with tailored properties, which can be employed especially for biomaterials applications. In case of implants or catheters cell adhesion plays a crucial role for the overall function of the to-be-used material. To change the properties of in-use polymers and to adopt their biocompatibility, we established coatings based on engineered spider silk proteins. Spider silk hydrogels can be employed as new bioinks for biofabrication. Their elastic behavior dominates over the viscous behavior over the whole angular frequency range with a low viscosity flow behavior and good form stability. Cell-loaded spider silk constructs can be easily printed without the need of additional cross-linkers or thickeners for mechanical stabilization. Our bio-inspired approach serves as a basis for new materials in a variety of medical, biological, or technical applications.

CPP 38.2 Wed 15:30 ZEU/0255

Inferring Structure-Property Relationships with Artificial Intelligence: A Lignin Case Study — •Matthias Stosiek and Patrick Rinke — Department of Physics, Atomistic Modelling Center, Munich Data Science Institute, Technical University of Munich

The potential of lignin as an abundant, underutilized biopolymer is increasingly being realized. A key challenge for the targeted production of lignins remains the poorly understood relation between lignin properties and its complex structure. Artificial intelligence (AI) methods could reveal such structure-function relationships but remain elusive in biomaterials research.

95 structurally diverse lignins are extracted from birch wood combining the Aqua Solv Omni (AqSO) biorefinery process and AI-guided data acquisition [1, 2]. Each lignin sample is characterized with 2D NMR spectroscopy and complemented with measurements of key lignin properties such as antioxidant activity.

To establish structure-function relationships, we correlate regions of the NMR spectra with corresponding property measurements. With a feature importance analysis, we identify structural relevant features for each property and provide a chemical interpretation. For instance, we find that more β-O-4 bonds lead to lower surface tension in water indicating a more linear lignin structure. Our structure-inference approach is designed to be general and applicable to a wide range of materials and characterization data.

CPP 38.3 Wed 15:45 ZEU/0255

A minimalist view on biopolymer phase separation and aging — •Jasper Michels — Max Planck Institute for Polymer Research, Mainz, Germany

Phase separation of proteins is a ubiquitous process by which cells regulate biological processes. In aberrant cases, such as encountered in neurodegeneration, initially liquid condensates age to become more solid-like. Understanding the interplay between phase separation and aging seems essential in the development of new therapeutic strategies. We apply minimal models that aim to capture the essence of biological transitions in terms of driving forces and thermodynamics. Models discriminating between mono- and multivalent directed association on the one hand and non-specific interactions on the other appear surprisingly versatile in reproducing and predicting biopolymer phase behavior, while at the same time providing essential mechanistic insight. We will review our efforts, combining theory with experiments and demonstrating how relatively simple descriptions can (re)produce complex multi-component phase behavior. We will also present a dynamic version of the model, which provides for a thermodynamically fully consistent and intuitive description of the experimentally observed

changes in viscoelasticity during aging. Our calculations explain how the stickiness of the proteins changes with time and concentration and how the coupling between association and solvation determines condensate viscoelasticity.

CPP 38.4 Wed 16:00 ZEU/0255

Cellulose-colloid hybrid materials for refractive index tuning — •Stephan V. Roth — Deutsches Elektronen-Synchrotron DESY, Hamburg, Sweden — KTH Royal Institute of Technology, Stockholm, Sweden

Cellulose nanofibrils (CNF) with tailored (negative) surface charge are ideal for stable, nanoporous, structure-guiding network for thin film composite materials. Colloid materials offer the possibility for tunable structural colors, templates for metamaterials, and refractive index tuning. Here, core-shell-colloids with a hydrophobic core and positively charged, hydrophilic shell are used as additive in CNF thin films to tune their refractive index. The imbibition and self-assembly of the colloids as a function of colloid diameter in the CNF network was quantified, with colloids smaller than the pores in the CNF network penetrating into the thin film. Subsequent heat treatment allows for nanoscale composite formation on the level of the ~ 10 nm sized CNF bundles, while humidity treatment homogenizes the colloid distribution. Furthermore, the influence of the colloid size on the CNF structure inside the thin film was investigated and related to the mechanical properties of the colloid-CNF composite.

CPP 38.5 Wed 16:15 ZEU/0255

A universal material basis for biocompatible printed electrolytes in Organic Electrochemical Transistors (OECTs) — •Moritz Flemming, Paul Zechel, Rakesh Nair, Laura Teuerle, Hans Kleemann, and Karl Leo — Institute of Applied Physics, Technische Universität Dresden

Organic Electrochemical Transistors (OECTs) stand out for their interplay between ionic and electronic conduction, making them ideal analogues to biological synapses for neuromorphic computing or biosensors. Furthermore, they can be printed into integrated circuits on flexible substrates, allowing for low-cost and high throughput fabrication of full electronic systems. However, most OECT electrolytes for integrated circuits still lack biocompatibility and suffer from rheology-related printing challenges. This talk presents a novel material basis that can be combined with an ionic liquid to fabricate a biocompatible electrolyte for OECTs. It allows rheological adjustments to enable the use of electrolyte in both inkjet and screen printing. Furthermore, the electrolyte is UV-curable, enabling it to transition into solid-state structures after printing. Extended ink and device lifetimes for screen-printed structures enable the fabrication of state-of-the-art OECTs that can operate in ambient air more than 30 days after fabrication. Ultimately, a fully biocompatible and screen-printed OECT on a leaf substrate is demonstrated.

CPP 38.6 Wed 16:30 ZEU/0255

Nonequilibrium dynamics of the helix-coil transition in polyalanine — •Maximilian Conradi[1], Fabio Müller[1], Suman Majumder[2], and Wolfhard Janke[1] — [1]Institut für Theoretische Physik, Universität Leipzig, IPF 231101, 04081 Leipzig, Germany — [2]Amity Institute of Applied Sciences, Amity University Uttar Pradesh, Noida 201313, India

As a continuation of our previous work, the nonequilibrium pathways of the collapse of the helix-forming biopolymer polyalanine are investigated in an explicit solvent. To this end, the full time evolution of the helix-coil transition is simulated using molecular dynamics simulations. We compare the phenomenology of the transition between the two studies and investigate the dynamics.

CPP 39: French-German Session: Nanomaterials, Composites and Hybrids I

Time: Wednesday 15:00–16:45 Location: ZEU/0260

Invited Talk CPP 39.1 Wed 15:00 ZEU/0260

A polarizable model for atomistic simulations of metals and graphitic material/ liquid interfaces — Krishan Kanhaiya[1], Hendrik Heinz[2], and •Marialore Sulpizi[1] — [1]Department of Physics and Astronomy, Ruhr-University Bochum, Universitätsstraße 150, 44801 Bochum, Germany — [2]Department of Chemical and Biological Engineering, University of Colorado at Boulder, Boulder, CO 80301

Polarization significantly affects the interaction and adsorption energy of molecules on metal surfaces. The ability to describe at a metal surface the classical "image charge" potential is a direct result of its polarizability, which needs to be modelled correctly to accurately simulate interfacial phenomena e.g. in electrochemistry or catalysis. Recently, we have introduced a polarizable model for metals which permits to describe also electrified interfaces. Here we extend the idea to graphitic material introducing flexible dummy electrons to represent the polarizable π-electron cloud. The model accurately predicts surface and hydration energy, water contact angle as well as experimental and DFT data on molecular adsorption on surfaces. A considerable improvement is obtained in the prediction of water-graphite interfacial friction, which is obtained at the level of electronic structure calculations.

CPP 39.2 Wed 15:30 ZEU/0260

Lamellar Domain Spacing of Copolymers with Nonlinear Block Architectures — Andrzej Grzyb[1], Jarosław S. Kłos[2], Aykut Erbaş[3], Michael Lang[4], and •Jarosław Paturej[1] — [1]Institute of Physics, University of Silesia, Katowice, Poland — [2]Faculty of Physics, A. Mickiewicz University, Poznań, Poland — [3]UNAM, Bilkent University, Ankara, Turkey — [4]Leibniz-Institut für Polymerforschung Dresden e.V., Germany

Topological modification of block copolymer (BCP) conformations offers a promising approach for developing self-assembled periodic nanostructured materials with smaller domain sizes, which are essential for a range of technological applications. Cyclic polymers, with their inherently more compact conformations, present an effective strategy for achieving this miniaturization. In this work, through a combination of analytical theory and coarse-grained molecular dynamics simulations, we establish a relationship between different nonlinear topologies and the corresponding domain size of lamella-forming BCPs. Our investigations includes BCP architectures with one or two cyclic segments such as tadpoles, diblock and triblock 8-shaped polymers, and diblock nonconcatenated and concatenated rings. We demonstrate that the primary reduction in lamellar domain size is driven by the more compact arrangement of monomers in the cyclic architectures, with an additional contribution from the nonconcatenation of cyclic segments. This is corroborated by theoretical predictions for both domain size reduction and BCP conformations across different architectures.

CPP 39.3 Wed 15:45 ZEU/0260

Self-Healing Composite Structures for Aerospace Applications — •Merve Ozkutlu Demirel[1], Eray Kostur[1,2], Yigitalp Okumus[1], Bilal Altin[1], Melih Seckin[1], and Yahya Oz[1] — [1]Turkish Aerospace, R&D and Advanced Technologies Directorate, 06980 Ankara, Turkiye — [2]Cukurova University, Department of Mechanical Engineering, 01330 Adana, Turkiye

Self-healing composite structures offer a promising solution for enhancing durability and reducing maintenance costs in aerospace platforms. In this study, a self-healing mechanism based on a microvascular channel network was developed. Composite laminates were fabricated using carbon fabric and epoxy resin. Polyamide monofilaments with a diameter of 450 um were integrated into a hand lay-up process by placing them between composite layers. After curing, these fibers were removed to create hollow channels. Various channel configurations were manufactured and evaluated through bending tests. 5-Ethylidene-2-norbornene was selected as healing agent because its operating temperature range is similar to flight temperature conditions. The healing agent was injected into the channels, while the Grubbs catalyst that would start the polymerization reaction was uniformly dispersed within the polymer matrix. Upon crack formation, the healing agent is expected to flow into the damaged region and polymerize upon contact with the catalyst, thereby filling the crack. Compact tension tests were performed to analyse the healing performance. The results demonstrated that the microvascular channel approach exhibits strong potential for aerospace applications.

CPP 39.4 Wed 16:00 ZEU/0260

Increasing the Mechanical Stability of Carbon Nanomembranes Using a Holey Carbon Interlayer — •Luzie Lina Heinrichs, Zhen Yao, Yang Yang, and Armin Gölzhäuser — Faculty of Physics, Bielefeld University, 33615 Bielefeld, Germany

Carbon nanomembranes (CNMs) are atomically thin, with sub-nanometre pores that enable strong gas selectivity and fast, efficient water transport. However, their limited mechanical robustness has constrained their integration into practical filtration technologies.

In this study, we introduce a reinforced CNM architecture that incorporates an intermediate holey support layer. We fabricate and compare single-layer, double-layer, and holey film reinforced composite CNMs. Water permeation measurements using a cup test, combined with nanoindentation characterisation, show that the reinforced architecture preserves high water permeability while markedly improving mechanical stability. The effective Young's modulus reaches ~25 GPa, approximately five times higher than that of an unreinforced double layer.

By combining mechanical robustness with efficient single-file water transport and precise selectivity, the holey-layer-reinforced CNMs provide a promising route toward real-world applications, especially in seawater desalination.

CPP 39.5 Wed 16:15 ZEU/0260

Particle distribution and thermoresponsive properties of PNIPAM brush/gold nanoparticle composite films — •Elias Hallenbach, Marvin Glock, Hayden Robertson, and Regine von Klitzing — TU Darmstadt, Institute for Condensed Matter Physics, 64289 Darmstadt, Germany

Metal/polymer nanocomposites are versatile hybrid materials and find use in many fields such as photonics, biomedical engineering and catalysis. A promising realization of this type of hybrid material is the controlled self-assembly of gold nanoparticles (AuNPs) inside a polymer brush, which induces color changes upon exposure to environmental changes, enabling sensor applications. Polymer brushes can serve as a matrix for the immobilization of AuNPs. Particle uptake into the brush matrix is affected by parameters such as thickness, particle size and grafting density [1]. Nanoparticle uptake has proven to be highest at intermediate grafting densities [2]. In the present study thermoresponsive Poly(*N*-Isopropylacrylamide) brushes with varying grafting densities were synthesized directly from a silicon substrate. Nanocomposite materials were fabricated by dip-coating of polymer brushes into an AuNP suspension. Characterization of nanocomposites was performed by (in situ) spectroscopic ellipsometry, atomic force microscopy and (in situ) X-ray reflectometry. The relation between particle distribution and temperature-induced structural changes will be discussed.

CPP 39.6 Wed 16:30 ZEU/0260

Morphology-controlled electrical and thermal conductivity of filled diblock copolymers: effect of filler shape. — •Alexander Chervanyov — University of Münster, Münster, Germany

We investigate the electrical and thermal conductivity of an electrically insulating diblock copolymer (DBC) matrix filled with conductive cylindrical and spherical nanofillers modeling carbon nanotubes (CNTs) and carbon black (CB), respectively. The composite transport properties are examined as functions of the underlying DBC morphology, the selective affinities of CNTs and CB for the dissimilar DBC blocks, and inter-filler interactions that determine the positional and, for CNTs, orientational correlations. Using a combined phase-field description of the DBC host and Monte Carlo simulations of anisotropic CNT fillers, we show that the localization and alignment of CNTs within the microphase-separated domains are highly sensitive to the above parameters. The simulated CNT and CB network structures are used to compute the electrical and thermal response of the composite. We quantitatively elucidate how the morphological transitions in the DBC correlate with structural rearrangements of the filler networks. Furthermore, we demonstrate that both the order-disorder transition and the order-order transitions between distinct DBC morphologies lead to pronounced changes in composite conductivity, driven by morphology-induced restructuring and alignment of the conductive pathways formed by CNT and CB.

Financial support of Deutsche Forschungsgemeinschaft (DFG) through Grant No. CH 845/2-3, is gratefully acknowledged.

CPP 40: Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics IV

Time: Wednesday 17:00–18:30 Location: ZEU/LICH

CPP 40.1 Wed 17:00 ZEU/LICH

Morphological Disorder Boosts Charge Separation in Single-Component OPDs — •Michel Panhans[1], Jakob Wolansky[2,3], Karl Leo[2], Johannes Benduhn[2,3], and Frank Ortmann[1] — [1]TUM School of Natural Sciences and Atomistic Modeling Center, Munich Data Science Institute, Technische Universität München, 85748 Garching b. München, Germany — [2]Dresden Integrated Center for Applied Physics and Photonic Materials, Technische Universität Dresden, 01069 Dresden, Germany — [3]DZA, Görlitz, Germany

Single-component organic photodetectors (OPDs) provide a simplified alternative to donor-acceptor heterojunctions, yet their operation mechanisms remain theoretically underexplored. We investigate the molecular origin of charge generation in vapor-deposited DCV2-5T by modeling the excitonic density of states with an effective exciton Hamiltonian that incorporates electronic coupling, Coulomb interaction, and structural disorder. Disorder is introduced through lateral shifts between π-stacked molecules, which notably modulates electronic and excitonic couplings. Simulations show that intermediate disorder reproduces the experimental external quantum efficiency, while strong disorder enhances hybridization between excitonic states. This hybridization enables exciton delocalization via a superexchange-like mechanism, increasing the probability of charge separation. Counterintuitively, disordered domains exhibit stronger coupling than crystalline ones, suggesting that reduced structural order can facilitate charge generation. These insights highlight morphology-dependent excitonic interactions as a design principle for self-driven OPDs.

CPP 40.2 Wed 17:15 ZEU/LICH

Limiting factors to free charge generation in low-bandgap organic blends for photovoltaic applications and beyond — •Manasi Pranav[1], Atul Shukla[1,2], and Dieter Neher[1] — [1]University of Potsdam, Potsdam, Germany — [2]University of Queensland, Brisbane, Australia

Despite possessing similar theoretical limits, state-of-the-art organic solar cells outshine low-bandgap organic blends (absorption edge beyond 1000 nm) in their exciton harvesting efficiency. An understanding of these free charge generation mechanisms is needed to tap into the potential of such low-bandgap non-fullerene acceptors (NFAs) for photovoltaic and photodetector applications. To this end, we probe the pathways of exciton dissociation and charge-transfer state separation in multiple D:NFA systems with varying absorption edges, and varying extents of energy-transfer or charge-transfer prior to free charge generation. This is done by combining transient and steady-state optoelectronic techniques, to resolve the losses incurred between photon absorption and carrier extraction. For some of these systems, namely in blends using Y6 derivatives with extended pi-conjugation, we find that the kinetic competition between geminate charge-transfer state decay and its separation is a major limiting role in the overall photon harvesting capability of the devices. As part of ongoing work, these investigations aim to reveal the underlying geminate loss pathways, which limit overall internal quantum efficiency of the blends and, in turn, limit the figures of merit of the resulting devices.

CPP 40.3 Wed 17:30 ZEU/LICH

Consistency of Electron-Vibrational Coupling Across Methods? A Comparative Study — •Maximilian F. X. Dorfner, Konrand Merkel, and Frank Ortmann — Department of Chemistry, TUM School of Natural Sciences, and Atomistic Modeling Center, Munich Data Science Institute, Technical University of Munich, München, Germany

Characterizing electron-vibrational interaction in materials is a non-trivial theoretical task, owing to the differing definitions of coupling constants and the variety of available methods for computing these. This diversity naturally raises questions about the consistency and reliability of the methods used and their interrelation.

To address this issue, this contribution presents a systematic comparison of electron-vibrational coupling calculations. We summarize our findings on the relationship between density functional theory approaches and quasi-particle methods [1], study the influence of different exchange and correlation functionals, and investigate the impact of various ab initio methodologies [2] on the resulting electron-vibrational coupling constants.

Our findings provide guidelines and data for validating methodologies and estimating theoretical errors in coupling constant calculations.

CPP 40.4 Wed 17:45 ZEU/LICH

Enhanced Photo-multiplication Effect through Synergistic Hole Blocking and Traps Engineering in OPDs — •Awais Sarwar[1], Louis Conrad Winkler[1,2], Karl Leo[1], and Johannes Benduhn[1,2] — [1]IAPP, TU Dresden, Germany — [2]DZA, Görlitz, Germany

Photomultiplication-type organic photodetectors (PM-OPDs) are highly effective for detecting weak light. However, they often face a significant trade-off: high gain usually results in excessive noise and slow response times. To overcome these limitations, we introduce a vacuum-deposited broadband photodetector architecture that utilizes the synergistic integration of hole-blocking layers and precise traps engineering. By strategically controlling the charge injection barriers and trap distribution, this design effectively separates the gain mechanism from the noise floor. The resulting device achieves a peak external quantum efficiency (EQE) exceeding 1100 per cent, while maintaining a specific detectivity of 4.4*10e12 Jones at a bias of -2 V. Unlike slow trap-dominated systems, our optimised architecture keeps a cutoff above 25 kHz. Vacuum-deposited PM-OPDs offer high sensitivity and fast response, ideal for real-time sensing.

CPP 40.5 Wed 18:00 ZEU/LICH

Wavelength-dependent charge carrier extraction of organic solar cells under operational conditions — •Lara Bartnick, Martijn Kemerink, and Clemens Göhler — IMSEAM, Heidelberg University, Germany

Organic solar cells (OSCs) have recently achieved power-conversion efficiencies of about 20%, making them increasingly promising for renewable energy ap-

plications despite still falling behind silicon photovoltaics. To understand the mechanisms that limit their performance, highly sensitive external quantum efficiency (EQE) measurements are essential, as they show how efficiently photons of different energies generate extractable charge carriers across the UV- to near-infrared spectrum.

We have measured the EQE of current standard PM6:Y6 OSCs under different initial conditions including bias voltage in both reverse and forward direction, bias illumination, and temperature, to investigate how open-circuit voltage- and fill-factor losses can be attributed to wavelength-dependent charge carrier generation efficiencies. These measurements reveal that the spectral shape of the EQE is highly sensitive to biasing conditions. By relating the voltage dependent EQE to collection fields, we have been able to identify charge carrier extraction losses under typical working conditions, which are dependent on the incident photon energy. These findings, as well as wavelength- and voltage-dependent exciton generation and recombination rates, contribute to understanding the loss mechanisms and charge extraction behaviour of OSCs.

CPP 40.6 Wed 18:15 ZEU/LICH

Current Generation in Photomultiplication-type Organic Photodetectors — •Louis Conrad Winkler[1,2], Jonas Kublitski[1,3], Awais Sarwar[1], Hrisheekesh Thachoth Chandran[1], Wolfgang Tress[4], Urs Aeberhard[5], Karl Leo[1], and Johannes Benduhn[1,2] — [1]IAPP, TU Dresden, Germany — [2]DZA, Görlitz, Germany — [3]Departamento de Fisica, UTFPR, Curitiba, Brazil — [4]ZHAW, Winterthur, Switzerland — [5]FLUXiM, Winterthur, Switzerland

Organic photodetectors (OPDs) utilizing intrinsic gain promise enhanced performance in regard to faint light detection. While this gain mechanism boosts the external quantum efficiency (EQE), the associated noise often negates the net improvement of the specific detectivity D*. Nonetheless, the simplified readout circuitry and associated cost savings hold high potential for the market. Crucially, the origin of this photomultiplication (PM) effect is currently attributed to tunnel injection of charge carriers, driven by internal band bending due to trapped charge carriers. Here, we challenge this prevailing tunnel injection model based on comprehensive experimental evidence. We propose an alternative mechanism that offers a unified explanation for the gain observed across diode-like OPD architectures and validate it by drift-diffusion simulations. This model successfully provides general predictive capabilities regarding the magnitude and dependencies of the photocurrent gain. We rigorously tested this proposed mechanism across 29 diverse material systems, including both vacuum-processed and solution-processed devices.

CPP 41: Biopolymers, Biomaterials and Bioinspired Functional Materials II (joint session CPP/BP)

Time: Wednesday 17:00–18:45 Location: ZEU/0255

CPP 41.1 Wed 17:00 ZEU/0255

Coarse-grained simulations of network-forming DNA nanostructures — •Takahiro Yokoyama[1,2] and Arash Nikoubashman[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden, Dresden, Germany — [2]Technische Universität Dresden, Dresden, Germany

DNA nanotechnology offers exceptional nanoscale designability through precise control of DNA sequences. These individual DNA strands can form predetermined building blocks, which then hierarchically assemble into super-structures such as nanotubes, nanocapsules, or nanostars. The latter can assemble further into (percolated) networks, where sequence-level design enables systematic control of the rheological and mechanical network properties. This multi-scale self-assembly can lead to cascading effects, where even a single unpaired nucleotide on the building block level can act as a highly flexible hinge that dramatically alters the network mechanics. To understand how such variations on the nucleotide-scale affect the network properties, we designed a series of DNA networks by systematically altering the arm number and junction flexibility of the star-shaped building blocks using coarse-grained molecular simulations of the oxDNA model. Our study revealed that the bulk modulus of the network decreased with increasing number of DNA arms; this counter-intuitive behavior stems from the addition of flexible junctions on the single-star level, which preferentially absorb deformation and soften the overall network. This result highlights the importance of precise nanoscopic design on the order of one nucleotide to obtain optimal network properties.

CPP 41.2 Wed 17:15 ZEU/0255

Characterizing interactions between glycoproteins and RNA at the lipid membrane interface — •Horacio V. Guzman[1] and Viviana Monje[2] — [1]Biophysics & Intelligent Matter Lab, Material Science Institute of Barcelona, CSIC, Spain — [2]Department of Chemical and Biological Engineering, State University of New York at Buffalo, 308 Furnas Hall, Buffalo, USA

Biological membrane interfaces interacting with proteins, nucleic acids, and glycans are integral to many cellular processes. The interplay between membrane lipids and biopolymers is highly sensitive to their flexibility grade, secondary structure, and electrostatics. Consequently, the cell membrane interface experiences changes in local lipid distribution and fluctuation in local properties. Projecting biophysical and structural membrane and biopolymer properties onto a two-dimensional plane simplifies the quantification of molecular signatures by reducing the dimensional space and identifying relevant entropic and short-range interactions at the interface of interest, as well as, characterizing interaction patterns and spatial correlations of complex lipid bilayers as they interact with biopolymers. We compare lipid-lipid interaction patterns in membrane-only systems to the corresponding systems containing small proteins and RNA fragments, respectively. These analyses quantify the effect of peripheral biopolymers on local lipid composition, structure, packing, deformation ratio of the biopolymer, and surface topology of the membrane upon adsorption. Such characterization is crucial for starting with the next-generation rational design of lipid vesicles and lipid-coated RNA drug delivery systems.

CPP 41.3 Wed 17:30 ZEU/0255

Nanoscale characterization of piezoelectric nanofibers blended with Salmon Gelatin — •Martín Chavarría-Vidal[1], Dragica Bezjak[2], María Saavedra-Fredes[1], Benjamín Schleyer-Thiers[1], Ilka Hermes[3], and Tomás P. Corrales[1] — [1]Universidad Técnica Federico Santa María, Valparaíso, Chile — [2]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — [3]Leibniz Institute of Polymer Research, Dresden, Germany

We electrospin salmon gelatin (SG) mixed in a polyvinyl alcohol (PVA) matrix containing chitosan (Ch). Furthermore, we used a coaxial electrospinning approach to blend these nanofibers together with polyvinylidene fluoride (PVDF). Such biomaterials could lead to the potential development of biocompatible and piezoelectric heart patches. After electrospinning our polymers, we observe by SEM two size distributions. Mechanical characterization of the large nanofibers obtained by AFM reveals two Youngs moduli peaks, centered at 1.77 GPa and 209 MPa. Small nanofibers also show a two component mechanical moduli distribution with peaks at 565 MPa and 1.33 GPa (10.1016/j.bbadva.2025.100168). EDS shows that both distributions contain Fluor. However, complimentary PFM measurements indicate that large nanofibers have a piezoelectric response comparable to pure electrospun PVDF, while the small ones do not exhibit such response. These measurements lead us to believe that the large nanofibers are mainly β-phase PVDF, while the smaller ones are composed of PVA/SG/Ch with α-phase PVDF (10.1177/15589250221125437).

CPP 41.4 Wed 17:45 ZEU/0255

Structural investigations using in situ SAXS on flexible bio-based vitrimeric carbon nanocomposites — •Sarathlal Koyiloth Vayalil[1,2], Vaishnav B[2], Viranchika Bijalwan[2], Sravendra Rana[2], and Ajay Gupta[2] — [1]Deutsches Elektronen Synchrotron DESY, Hamburg, Germany — [2]Applied Science Cluster, UPES, Dehradun, India

In this work, in situ small- and ultra-small-angle X-ray scattering has been employed to investigate the real-time structural evolution of 3D-printed vitrimeric thiol-acrylate photopolymers and their carbon-based nanocomposites designed for healable strain-sensing and soft-robotic applications. Flexible bio-acrylate based vitrimers reinforced with graphene/CNT fillers at varying concentrations are examined to elucidate temperature-dependent phase segregation and enable direct visualization of nano- and microscale filler morphologies, their spatial distribution, and their evolution across key thermal transitions (Tg and Tv of the polymer matrix). The effects of the stress/strain and cyclic-thermal cycles on the filler aggregates affecting the composites conductivity in carbon-filled samples are also evaluated. These insights into nano- and microscale morphology, reinforcement, and conductive behavior help us understand the dynamic structure-property relationships governing vitrimer-based conductive networks

CPP 41.5 Wed 18:00 ZEU/0255

Nanomechanical testing of suspended single nanofibers and humidity-induced glass transition — •Benjamin Schleyer-Thiers[1], Diego Benavente[2], Yusser Olguin[2,3], and Tomas P. Corrales[1,3] — [1]Physics department of Universidad Tecnica Federico Santa Maria, Valparaiso, Chile — [2]Technological and Scientific Center (CCTVal), Valparaiso, Chile — [3]Biotechnology Center Daniel Alkalay Lowitt

In this work we will study the interaction of water molecules with polymeric nanofibers made from hygroscopic biopolymers and contrast them in environ-

ments with variable relative humidity. For this, we will suspend single nanofibers over micropatterns etched on silicon. In this suspended configuration, we shall perform three-point bending tests utilizing the environmental Atomic Force Microscope (AFM) and detect bending forces of the nanofiber, at different relative humidities. As bending tests are performed over the suspended nanofiber, the position-dependent stiffness can be plotted to find its mechanical modulus through bending models. The stiffness of single nanofibers drops with the increase in relative humidity, hinting a glass transition induced by this environmental condition. To test this behavior, we attempt to perform fracture experiments on a micro structured grid made by photolithography.

CPP 41.6 Wed 18:15 ZEU/0255

Probing light-induced drug release to lipid monolayers — •Ipsita Pani, Michael Hardt, and Björn Braunschweig — Institute of Physical Chemistry, University of Münster, Corrensstraße 28-30, Münster 48149, Germany

Light-induced drug release using photoresponsive nanocarriers is increasingly explored for targeted therapeutic applications. While most studies characterize release in bulk aqueous environments, drug release across aqueous-organic interfaces is equally important, as these interfaces represent the entry point into cells. We recently demonstrated light-induced drug release to air-water interface.[1] In cancer therapeutics, passive diffusion of anticancer drugs across lipid membranes is a key transport mechanism, yet direct quantitative data on drug-lipid interactions and their effect on release remain limited. Here, using arylazopyrazole photosurfactant nanocarriers and doxorubicin as a representative anticancer drug, we investigate how interfacial lipid composition governs light-induced drug release. By combining Langmuir monolayers with interface-specific vibrational sum frequency generation (SFG) spectroscopy, we quantitatively estimate drug release at lipid-adsorbed interfaces as a model membrane. To systematically probe headgroup effects, we employ four dimyristoyl lipids-DMPC, DMPG, DMPS, and DMPE which share identical acyl chains but differ in charge and polarity. These results elucidate how lipid-drug interactions modulate release efficiencies at membrane-like interfaces, providing insights key to the design of photoresponsive nanocarriers for targeted drug delivery. [1] Pani et al. Chem. Sci., 2024, 15, 18865-18871.

CPP 41.7 Wed 18:30 ZEU/0255

Hetero-aggregation of microplastic particles — Thomas Witzmann[1], Anja F. R. M. Ramsperger[2], Hao Liu[2], Yifan Lu[3], Holger Schmalz[2], Lucas Kurzweg[4], Tom C. D. Börner[4], Kathrin Harre[4], Andreas Greiner[2], Christian Laforsch[2], Holger Kress[2], Christina Bogner[3], Stephan Geckle[2], Andreas Fery[1], and •Günter K. Auernhammer[1] — [1]Leibniz-Institut für Polymerforschung Dresden, Germany — [2]Universität Bayreuth, Germany — [3]Universität zu Köln, Germany — [4]Hochschule für Technik und Wirtschaft Dresden, Dresden

Microplastic particles (MPP) in the environment are surrounded by a layer known as an 'eco-corona'. This is made up of natural organic matter (NOM), such as biomolecules, humic substances, and other natural molecules. NOM substantially alters the surface properties of MP particles, thereby influencing their interaction with other surfaces in an aqueous environment and their aggregation behaviour. We studied the interactions of eco-corona-covered MP particles on the nanoscale using colloidal probe-AFM. Measurements were performed at different ionic concentrations to mimic changing environmental conditions. We found that the eco-corona can pull on the silica colloidal probe via polymer bridging. This mechanism leads to aggregation and, consequently, sedimentation in the environment. By comparing our AFM results with experiments and simulations at different length scales, we consistently found that this type of heteroaggregation is conducive to stable aggregate formation and retains MPPs in sediments.

CPP 42: French-German Session: Nanomaterials, Composites and Hybrids II

Time: Wednesday 17:00–18:45 Location: ZEU/0260

Invited Talk CPP 42.1 Wed 17:00 ZEU/0260

Mesopores filled with (poly)ionic liquids: phase transitions under confinement, and structure seen by SAXS and SANS — •Julian Oberdisse and Anne-Caroline Genix — Laboratoire Charles Coulomb, U Montpellier France

Understanding the molecular structure of mesoporous solid ionic systems is crucial for optimizing macroscopic properties, in particular ionic transport for energy applications, as well as mechanical flexibility. These systems can be synthesized efficiently under "one-pot" conditions, which rely on mesopore formation through microphase separation of templating ionic liquids.

In the present study, the phase transitions of the embedded ionic liquid have been studied by wide-angle scattering, QENS, DSC, and BDS, as a function of confinement. Then, poly(ionic liquid)s have been added in order to incorporate both connectivity and modify mechanical strength. We report on the structural analysis of ionic liquid and poly(ionic liquid) embedded in ionosilica matrices, employing a combination of small-angle scattering of neutrons and X-rays, isotopic substitution, and physico-chemical solvent-based extraction methods. Data analysis is based on molecular modelling with an original, quantitative comparison of the scattering curves under different contrasts. In agreement with NMR, it is shown that these mesoporous systems have an unexpected molecular structure, with the ionic liquid counterions penetrating the ionosilica matrix surrounding the mesopores. The poly(ionic liquid) forms patches decorating the pore walls, with tunable conformation sensitive to solvent conditions.

CPP 42.2 Wed 17:30 ZEU/0260

Plasmonic core-shell microgels: The role of the core size — •Déborah Feller[1,2], Julian Oberdisse[3], Sylvain Prévost[4], and Matthias Karg[1] — [1]Physical Chemistry of Functional Polymers, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany — [2]Physical Chemistry: Colloids and Nanooptics, Heinrich Heine University Düsseldorf, Düsseldorf, Germany — [3]Laboratoire Charles Coulomb (L2C), Université de Montpellier, CNRS, Montpellier, France — [4]Large Scale Structures, Institut Laue-Langevin, Grenoble, France

Gold-poly-N-isopropylacrylamide (Au PNIPAM) core-shell microgels are interesting due to the localized surface plasmon resonance (LSPR) of the cores. The LSPR position strongly depends on the core size. Compared to other core-shell microgels, Au cores can be precisely overgrown in the shell in situ. Although cores grow in size, the overall hydrodynamic diameter of the microgels does not change. It is not known how the structure of the shell changes during the overgrowth.

Here, we are analyzing Au-PNIPAM microgels with two crosslinker densities. The cores are overgrown from 14 nm in diameter to nearly 100 nm. We perform small-angle X-ray and neutron scattering (SAXS/SANS) to study the respective form factors. SAXS provides information about the cores and SANS about the shell. We also investigate temperature-dependent changes in the microgel by SANS. Additionally, extinction spectra are recorded to study the optical properties. We perform simulations of the different microgels to get information on the internal structure of the shell and the polymer distribution.

CPP 42.3 Wed 17:45 ZEU/0260

Consequences of the near-field effect in highly filled magneto-active elastomers — •Dirk Romeis and Marina Saphiannikova — Leibniz-Institut für Polymerforschung Dresden

In many theoretical models for magneto-active elastomers (MAEs) the interactions among magnetic/magnetizable particles are approximated via dipole models. In highly filled samples, as well as in structured MAEs, the particles are often very close to each other. In such situation the dipole approximation largely underestimates the interactions among magnetizable particles. Yet, for only 2 spherical particles the analytic solution is quite complex, resulting in a slowly converging series expansion. When considering many particle systems only computationally elaborate methods like a finite element approach can provide numerical solutions. Based on a compact fitting function for the 2-body problem, we suggest an accurate approximation for many-body systems including the near-field effect beyond dipole interactions. Considering these corrections due to the near-field effect in comparison to the dipole approximation, we further investigate the role of cluster formation and dispersion of particles in MAEs when an external magnetic field is applied or switched off.

CPP 42.4 Wed 18:00 ZEU/0260

Magneto-active elastomers with magnetically hard vs soft particles: molecular dynamics simulations — •Júlio P. A. Santos and Sofia Kantorovich — University of Vienna, Faculty of Physics, Kolingasse 14-16, 1090 Vienna, Austria

Magneto-active elastomers (MAEs) [1-2], or magnetorheological elastomers (MREs), are composite materials whose properties - such as stiffness, surface roughness (wettability), and shape - can be controlled by low-energy magnetic fields, making them ideal for soft robotics. MAEs consist of an elastic matrix embedded with magnetic micro- or nanoparticles, magnetically either hard (MH) or soft (MS). For high concentrations of MH particles, one can use a complex arrangement of springs that randomly bond nearby MH particles [3]. However, this model oversimplifies particle behavior (as permanent point dipoles) - critical for modeling physically relevant MAEs.

We address these issues in ESPResSo [4], employing molecular dynamics to study the impact of MS particles on the surface relief of a MAE layer and to provide a critical comparison between MH- and MS-based MAEs. At zero field, MS particles do not interact magnetically, whereas MH particles form long chains within the layer. Increasing the field slowly promotes dipolar interactions between the MS particles and rapidly promotes Zeeman interactions with the ap-

plied field, leading to chains that preferentially align parallel to it. In contrast, MH chains must break before reorienting in the direction of the magnetic field, due to the greater importance of dipolar interactions relative to Zeeman, requiring larger applied fields for signficant surface structural changes.

CPP 42.5 Wed 18:15 ZEU/0260

Microstructure analysis of intermediate states in the structure formation process of magnetorheological elastomers — •Nils Magin and Stefan Odenbach — TU Dresden

A composite of magnetic particles and an elastic polymer matrix is referred to as a magnetorheological elastomer. The size and concentration of magnetic particles, as well as the elasticity of the matrix, are the determining factors in the magnetorheological (MR) effect of such materials. Materials exhibiting significant MR properties are commonly referred to as MR elastomers. The application of an external homogeneous magnetic field during the polymerisation process enables the structuring of particles in the initially liquid polymer matrix, resulting in the fabrication of an anisotropic (or structured) material. In order to facilitate a more profound comprehension of the structural formation, the application of the magnetic field is initiated at discrete phases of the polymerisation process. This process gives rise to intermediate states in the structuring that can be observed. The microstructure is examined using computer X-ray tomography and image processing. Furthermore, the influence of the magnetic field, particle concentration, and sample height on the microstructure is discussed. We acknowledge support by the German Research Foundation DFG through Research Unit FOR 5599 on structured magnetic elastomers.

CPP 42.6 Wed 18:30 ZEU/0260

Approximate doubling of the magnitude of maximized magnetorheological effects — Lukas Fischer[1,2] and •Andreas M. Menzel[1] — [1]Otto von Guericke University Magdeburg, Magdeburg, Germany — [2]The University of Osaka, Osaka, Japan

In its static limit, the magnetorheological effect of magnetic elastomers implies changes of elastic moduli by external magnetic fields. Induced magnetic interactions between magnetizable inclusions in a soft, elastic, polymeric matrix affect the overall mechanical stiffness.

First, we optimized the spatial arrangement of the magnetizable inclusions to achieve the strongest change in overall elastic moduli, either for maximized overall stiffening or softening [1]. We focused on both, Young and shear moduli.

Second, in combination, we simultaneously optimized the structural organization to achieve maximized stiffening when an external magnetic field is applied in one direction, but maximized softening when the field is applied along a perpendicular direction [2]. In our case, switching between these two field directions can approximately double the magnitude in overall change of elastic moduli.

Once experimental realizations of prescribed structuring become possible, our strategy provides a direct route to further extend the potential of the materials.

We acknowledge support by the German Research Foundation DFG through Research Unit FOR 5599 on structured magnetic elastomers.

CPP 43: Biomaterials and Biopolymers (joint session BP/CPP)

Time: Thursday 9:30–12:45 Location: BAR/SCHÖ

CPP 43.1 Thu 9:30 BAR/SCHÖ

Characterization and Application of Honey-PVA Electrospun Scaffolds in Tissue Engineering — •Catalina Navarrete-Vera[1], Karen Yáñez[2], Cristian Acevedo[2], and Tomas Corrales[1,2] — [1]Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile — [2]Centro de Biotecnología Daniel Alkalay Lowitt, Universidad Técnica Federico Santa María, Chile

Tissue engineering seeks to develop functional biomaterials that integrate seamlessly with biological systems. Electrospinning with static collectors enables the production of nanostructured scaffolds suitable for cell regeneration (10.1021/acsomega.3c06436). Incorporating natural components, such as honey, valued for its regenerative, anti-inflammatory, and antimicrobial properties, offers a route to bioactive wound-dressing alternatives (10.1016/j.carbpol.2019.05.004).

In this study, Manuka and Ulmo honeys were each combined with PVA to generate nanofibers and scaffolds via electrospinning. AFM force spectroscopy was used to assess individual fiber mechanics, and SEM and cell-culture assays were employed to evaluate morphology and biocompatibility. Both formulations produced fibers of similar diameter (100-300 nm) and nanomechanical stiffness (~200 MPa), while honey-containing scaffolds improved cell growth over controls. These results indicate that Ulmo honey is a promising alternative to Manuka honey for tissue-engineering applications.

CPP 43.2 Thu 9:45 BAR/SCHÖ

Additive Manufacturing in Wound Care Innovation from Sugarcane Bagasse — •Ahmed El-Hussein Elnewishy[1], Muhammad Mounir[1], Mona Tarek[1], and Ita Junkar[2] — [1]Biotechnology Program, Faculty of Science, Galala University — [2]Department of Surface Engineering, Jožef Stephan Institute, Ljubljana, Slovenia

Three-dimensional (3D) printing technology is capable of creating highly complex, customizable objects, offering unique advantages for various biomedical applications through methods such as inkjet-based, extrusion-based, and light-assisted techniques. This study focuses on using direct ink writing for additive manufacturing to print antibacterial wound dressings, addressing a critical gap in the current wound care market. The management of chronic and acute wounds presents significant challenges facing human health and overall wellness. Current wound dressing fails to meet patients needs in terms of high adhesion, poor gas exchange, low moisture retention, and the use of systemic and synthetic antibiotics. Additionally, the presence of unused agricultural waste and weak waste management increase greenhouse gas emissions, thus contributing to global warming. To address these issues, we utilized agricultural waste, specifically sugarcane bagasse, to create biopolymer 3D printing ink for wound dressings. We extracted cellulose from sugarcane bagasse and antibacterial bioactive compounds from plant extracts. The synthesized ink was then printed and post treated to enhance mechanical properties. We evaluated the cytotoxicity, antibacterial activity, and morphological structure of the patches using scanning electron microscopy.

CPP 43.3 Thu 10:00 BAR/SCHÖ

FCS-Based RNA Payload Quantification and FLIM Analysis of pH-Dependent Lipid Phase Transitions in Lipid Nanoparticless — •Bernhard Kirchmair[1], Judith Müller[1], Thomas Kellerer[2], Ekaterina Kostyurina[1], and Joachim Rädler[1] — [1]Ludwig-Maximilians-Universität München, Germany — [2]Max Planck-Institut für Biochemie, Martinsried, Germany

Lipid nanoparticles (LNPs) emerged as one of the most promising delivery systems for transfecting mammalian cells with synthetic messenger RNA (mRNA). However, LNPs show a substantial heterogeneity both in shape and cargo and the precise mRNA payload and stoichiometric ratios in multi-component nucleic acid delivery remain poorly quantified. In this project we investigate how mRNA payload depends on LNP size and surface composition using fluorescence correlation spectroscopy (FCS) supported by dynamic light scattering, enabling estimation of particle concentration and RNA copies per LNP. Fluorescence cross-correlation spectroscopy further allows measurement of siRNA/mRNA ratios in mixed cargos. To link payload properties to endosomal escape rates and hence delivery efficiency, we probed pH-dependent lipid phase transitions using fluorescence lifetime imaging (FLIM) and fluorescence anisotropy, capturing changes both in bulk lipid phases and in intact LNPs. These measurements build a framework to monitor structural changes relevant to endosomal escape and can be applied to other LNP formulations and cargo types. Quantitative knowledge about content and ratios will ultimately support the delivery of genetic programs for regulated gene expression.

CPP 43.4 Thu 10:15 BAR/SCHÖ

pH-dependent phase transitions in ionizable lipid mesophases — •Ekaterina Kostyurina[1], Susanne Liese[2], Akhil Sudarsan[2], Julian Philipp[1], and Joachim Rädler[1] — [1]Faculty of Physics, Ludwig-Maximilians University, 80539 Munich, Germany — [2]Faculty of Mathematics, Natural Science, and Materials Engineering, Institute of Physics, University of Augsburg, 86159 Augsburg, Germany

Lipid Nanoparticles (LNPs) have proven valuable in modern medicine as a medium for RNA delivery. Nanoparticles containing cationic ionizable lipid (CIL), cholesterol and structural lipids complex with nucleic acids into size-controlled particles that transport nucleic acid molecules across cell membranes via the endocytic uptake pathway. The delivery efficiency of a drug or vaccine is directly related to the efficiency of the endosomal release. Here, we study pH-dependent structural transitions of the CIL core phase which are believed to play an essential role in this process. We use bulk phases of ionizable lipid/cholesterol as a model system of the LNP core which allows us to study the structure of the lipid phases with high precision using X-ray diffraction. We show that the commonly used ionizable lipids overcome the inverted micellar-inverted hexagonal phase transition within the pH range typical for endosomal life cycle, and connect structural properties of the phases with LNP efficacy. Furthermore, we are aiming to understand the thermodynamics of these phase transitions by combining experimental measurements with theoretical modeling. This will help to

better understand the structure-activity relation of LNPs and to increase the delivery efficiency in clinically relevant LNP delivery systems.

CPP 43.5 Thu 10:30 BAR/SCHÖ

To gel or not to gel? Assembly phase changes of engineered spidroin proteins induced by temperature and time — •Isabell Tunn[1,2,3], Dmitry Tolmachev[2,4], Adam L. Harmat[2,4], Nea B. Möttönen[1,2], Alberto Scacchi[2,4,5], Maria Sammalkorpi[2,4], and Markus B. Linder[1,4] — [1]Department of Bioproducts and Biosystems, Aalto University, Finland — [2]Academy of Finland Center of Excellence in Life-Inspired Hybrid Materials (LIBER), Aalto University, Finland — [3]Fraunhofer Institute for Applied Polymer Research (IAP), Germany — [4]Department of Chemistry and Materials Science, Aalto University, Finland — [5]Department of Mechanical and Materials Engineering, University of Turku, Finland

Bioinspired silk-like proteins offer exciting possibilities for developing the next generation of advanced materials - from medicine to food packaging. Here, we investigate the temperature- and time-dependent assembly behaviour of engineered silk-like proteins into hydrogels conducting experiments and molecular dynamics simulations.* Phase transitions are controlled by entropic changes in flexible glycine-rich regions and hydrophobic interactions of alanine-rich α-helical regions. High-temperature gelation proceeds through interactions between alanine-rich domains, leading to β-sheet formation while time-induced gelation occurs via protein percolation mainly driven by dimerization of terminal domains. These findings provide guidelines for engineering protein-based materials with tailored assembly properties and gel characteristics, advancing the rational design of biomimetic soft materials. *https://doi.org/10.1016/j.ijbiomac.2025.147712

CPP 43.6 Thu 10:45 BAR/SCHÖ

Power-Law Analysis of Force Relaxation and Creep Compliance in Nanoindentation of Glassy Gelatin in Humid Air — Paul Zech, Martin Dehnert, Mario Zerson, and •Robert Magerle — Fakultät für Naturwissenschaften, TU Chemnitz

Gelatin-based materials are widely used in food technology, drug delivery systems, and tissue engineering. Water acts as a plasticizer, softening gelatin and reducing its glass transition temperature. Using AFM-based nanoindentation experiments, we examined the mechanical response of a gelatin film to nanoindentations under constant strain (force relaxation) or constant stress (creep compliance) at a wide range of tip approach velocities and relative humidity levels. Scaling analysis using a fractional rheology model reveals that force relaxation and creep compliance exhibit universal power-law behavior. Temporal evolution depends only on the tip indentation time, which defines the externally imposed timescale of the process, and the power-law exponent α, which characterizes the degree of viscoelasticity. At relative humidity > 85%, the α values differ between the force relaxation and creep compliance data. This indicates differences in the underlying molecular processes.

Invited Talk CPP 43.7 Thu 11:15 BAR/SCHÖ

Directed evolution of material-producing bacteria — •André Studart — Complex Materials, Department of Materials, ETH Zürich

Engineers often use high temperatures, pressures and polluting chemicals to make synthetic materials. By contrast, biology produces remarkable materials like wood and bone using widely available chemicals in water and at ambient temperature. The ability of organisms to create materials under mild conditions relies on the intricate biological machinery of living cells. Notably, natural selection processes have evolved such machinery for hundreds of millions of years to fulfill the demands of biological environments. Can we harness the machinery and evolutionary processes of biology to create materials more sustainably while still meeting engineering needs ? To explore this question, we utilized a microfluidic platform to evolve material-forming microorganisms towards cell mutants that meet the high productivity needed in industrial processes. Using cellulose-producing bacteria as an example, we show that this directed evolution approach enabled the isolation of a bacterial mutant that produces up to 70% more cellulose than its native counterpart. The overproducing bacterial strain offers an attractive alternative to wood to meet the growing demand for cellulose in the textile, medical and packaging industries. Beyond cellulose, the proposed technology offers a compelling approach to isolate bacteria for the bio-fabrication of other sustainable materials, such as silk, polyesters and clay-based bricks.

CPP 43.8 Thu 11:45 BAR/SCHÖ

Controlling Axonal Outgrowth of Organoids by 3D Nanoprinted Scaffolds — •Tobias Müller[1], Malte Siegmund[1], Emma Wollesen[1], Kim Krieg[2], Ole Pless[2], Jan Hahn[3], Robert Zierold[1], and Robert Blick[1] — [1]Center for Hybrid Nanostructures, University of Hamburg, 22761 Germany — [2]Fraunhofer ITMP, Discovery Research Screening Port, 22525 Germany — [3]Section Facility Mass Spectrometry and Proteomics, University Medical Center Hamburg-Eppendorf, 20246 Germany

Cortical organoids are promising models for neurodegenerative disease research, yet their integration into defined neural networks remains challenging. We use two-photon polymerization (2PP) to fabricate three-dimensional scaffolds that direct axonal outgrowth and support organoid integration into engineered circuits.

Scaling structures from single neurons to millimeter-scale organoids introduces adhesion and imaging challenges. We address this by combining tailored scaffold geometries with a polydimethylsiloxane (PDMS)-based anchoring strategy, critical-point drying and quantitative analysis of electron microscopy images. Walls, stairs and microwires enhance organoid-scaffold interactions, promoting axonal outgrowth along intended paths and reducing extension into non-target regions.

These results demonstrate that 2PP-fabricated microarchitectures can guide axon growth and stabilize organoid-substrate contact, enabling more controlled organoid-based neuronal networks and advancing brain-on-a-chip approaches.

CPP 43.9 Thu 12:00 BAR/SCHÖ

Stimulus-induced biomechanical perturbations via smart hydrogel microstructures — •Katja Zieske — Max Planck Institute for the Science of Light, Erlangen, Germany

Cells reside within complex three-dimensional extracellular matrices, where mechanical interactions play essential roles in tissue development, and disease progression. To mimic these interactions, we developed a lab-on-a-chip platform that applies spatially and temporally controlled mechanical perturbations using intelligent hydrogel microstructures.

First, we optimized material composition and photopolymerization parameters and demonstrated reliable, stimulus-dependent expansion and contraction of the hydrogel microstructures within microfluidic chambers. Using these microstructures, we then applied compressive forces to Matrigel and collagen networks. Finally, we applied mechanical perturbations to cellular systems.

By mimicking cellular pushing forces with hydrogel microstructures, this lab-on-a-chip system provides a versatile tool for studying mechanical remodeling of biopolymers and cellular systems.

CPP 43.10 Thu 12:15 BAR/SCHÖ

Functionally Connecting High- and Low-Density Neuronal Networks Using 3D-Nanoprinted Structures — •Emma Wollesen, Malte Siegmund, Tobias Müller, Josephine Hoppe, Robert Zierold, and Robert Blick — Center for Hybrid Nanostructures, University of Hamburg, 22761 Hamburg, Germany

Tracing the propagation of interneural communication from high- to low-density networks is essential for exploiting information processing at the single-cell level. Given the multitude of synaptic connections, high-density networks of hiPSC-derived neurons may generate bursts of action potentials, a key communication mode that can be analyzed at the single-cell level in receiving low-density networks. Here, we move toward such a cultivation platform by evaluating 3D nanoprinted (3DN) structures fabricated by two-photon polymerization for their efficiency in facilitating connected high- and low-density networks. We demonstrate the prerequisite formation of hiPSC-derived low-density neuronal networks in tower-shaped 3DN structures. For augmentation with high-density networks, a stomach-shaped structure and connecting elements were fabricated. A minimum structure height of 30 micrometers proved critical for clear network demarcation. For future region-specific chemical stimulation, millimeter-scale structures for media reservoir separation were conceptualized, and fabrication feasibility was confirmed, requiring a 10 micrometer overlap and a suitable shear angle at structure interfaces. These results extend established 3DN platforms for low-density networks and support the integration of neural networks into Brain-on-a-Chip applications.

CPP 43.11 Thu 12:30 BAR/SCHÖ

Multiplex sensing of respiratory viruses using surface plasmon resonance spectroscopy — •Ghazaleh Eshaghi[1], David Kaiser[1], Hamid Reza Rasouli[1], Dominik Gary[2], Tobias Fischer[2], Katrin Frankenfeld[2], Abhishek Sharma[3], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, 07743 Jena — [2]Forschungszentrum für Medizintechnik und Biotechnologie (fzmb) GmbH, 99947 Bad Langensalza, Germany — [3]BioNavis Ltd., Hermiankatu 6-8H, 33720 Tampere, Finland

We present label-free and real-time biosensing of three major respiratory viruses using the Multi-Parametric Surface Plasmon Resonance (MP-SPR) technique. In this approach, MP-SPR SPR Au sensors are functionalized with ultrathin (~1 nm) azide-terminated carbon nanomembranes (N3-CNMs), enabling covalent attachment of virus-specific antibodies and thereby providing selective immobilization of target antigens on the sensor surface. We demonstrate specific detection of SARS-CoV-2, Influenza A, and Respiratory Syncytial Virus (RSV) antigens with negligible cross-reactivity and high reproducibility in both PBS-P buffer (physiological pH) and clinically relevant nasopharyngeal swab matrices. For SARS-CoV-2, Influenza A, and RSV antigens, we determine dissociation constants (KD) of 7.0 * 0.5 nM, 86 * 4 pM, and 3.0 * 0.2 pM, respectively, with corresponding limits of detection (LOD) of ~65 pM, ~80 pM, and ~2 pM.

CPP 44: Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics V

Time: Thursday 9:30–11:15 Location: ZEU/LICH

Invited Talk CPP 44.1 Thu 9:30 ZEU/LICH

Shedding light on wide bandgap perovskites — •Michael Saliba — Institute for Photovoltaics (ipv), University of Stuttgart, Germany

Low bandgap perovskite solar cells are approaching the Shockley-Queisser limit for single-junction solar cells. Less progress, however, was made for wider bandgap perovskites, which are of interest, e.g., for multijunction photovoltaics. These wide bandgap perovskites are often comprised of fully inorganic components, which are hard to dissolve in conventional solvent systems and require more sophisticated synthesis as well as crystallisation techniques. In this talk, I will discuss strategies to address these challenges by providing a library of hitherto unexplored wider bandgap perovskites using combinatorics.

Unfortunately, the newly formulated liquid precursors often exhibit complex crystallization behaviour struggling to expel the typically used DMSO solvent. To delay the crystallization time, two strategies are proposed to remove the strongly complexating DMSO molecules through a) modified processing of the liquid thin-film and b) a coordination solvent with a high donicity and a low vapor-pressure leading to a marked improvement in the overall film quality. Lastly, interface manipulation, especially on top of the formed perovskite, is becoming a central topic to advance further. Light annealing is introduced to modify the perovskite surface resulting in a reduced surface recombination.

CPP 44.2 Thu 10:00 ZEU/LICH

Perovskite Solar Cells under Orbit-Like Thermal Cycling — •Simon Alexander Wegener[1], Christoph Gernot Lindenmeir[1], Thomas Baier[1], Xiaojing Ci[1], Sigrid Bernstroff[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Elettra-Sincrotrone Trieste S.C.p.A., Basovizza, Trieste, Italy

Perovskite solar cells offer strong potential for space power systems due to their high visible-light absorbance, thin active layers, and efficiencies comparable to silicon. These features provide exceptional power-to-weight ratios, and solution processing reduces manufacturing and launch costs relative to multi-junction gallium arsenide cells. Initial demonstrations have confirmed their operability in space. Key challenges remain, particularly the extreme temperature swings in low Earth orbit. Our work examines these stresses using operando grazing-incidence wide-angle X-ray scattering (GIWAXS) to track structural changes in the perovskite during illumination and temperature cycling. Synchrotron radiation enables the necessary temporal resolution to study the multilayer device stack, which combines materials with differing mechanical and thermal properties. Complementary photoluminescence measurements reveal associated changes in optical and electrical behavior. Across -125°C to +100°C, the perovskite shows changes in crystal phase, anisotropic strain, and optoelectronic response. These findings clarify the coupled mechanical and electronic effects driving performance loss and enable strategies to enhance durability of perovskite solar cells for space applications.

CPP 44.3 Thu 10:15 ZEU/LICH

Depth Resolved Structural Analysis on CsPbI3 Nanocrystal Nucleation Seed Induced Pervskite Thin Films — •Altantulga Buyan-Arivjikh[1], Lukas Wolz[1], Ajeet Kumar[2], Yanan An[1], Christopher Everett[1], Guangjiu Pan[1], Jiinsheng Zhang[1], Zhuijun Xu[1], Matthias Schwartzkopf[3], Stephan V. Roth[4], Jürgen Hauer[1], Johanna Eichhorn[1], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, 85748 Garching, Germany — [2]Department of Chemical Physics, Lund University, 22100 Lund, Sweden — [3]Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [4]Department of Fibre and Polymer Technology KTH, SE-10044 Stockholm, Sweden

Lead-halide perovskites have attracted significant attention due to their favorable optoelectronic properties, simple processing, and the availability of precursor materials. Their performance is strongly governed by the crystallinity and morphology of the typically polycrystalline thin films. Among strategies to optimize these features, nanocrystal seeding has emerged as a promising route. Here, we show improved crystallographic orientation and reduced defect density in printed FAPbI3 thin films through the introduction of CsPbI3 nanocrystal nucleation seeds. Incidence-angle-varied GIWAXS enabled depth-resolved structural analysis, revealing seed incorporation and corresponding modifications of the energy landscape through the film thickness.

CPP 44.4 Thu 10:30 ZEU/LICH

***In-Situ* KPFM Growth Studies of Pentacene as a Model Hole Transport Material on 2D/3D Heterostructured $Cs_2AgBiBr_6$ for Perovskite Solar Cells** — •Tim P. Schneider and Derck Schlettwein — Justus-Liebig-Universität Gießen, Institut für Angewandte Physik, Heinrich-Buff-Ring 16, D-35392 Gießen

Forming low-dimensional perovskite interlayers in perovskite solar cells by applying ammonium salt solutions is a well-known method to improve devices. This has already been approved for the $Cs_2AgBiBr_6$ double perovskite in solar cell geometry by a 2D-modification with BABr or PEABr salts achieving respective low-dimensional phases at the interface. Using pentacene as a model hole conductor, its film growth and contact formation to the different double perovskite phases was investigated via *in-situ* growth studies using Kelvin Probe force microscopy (KPFM). Measuring the morphology and work function at intermittent steps during film deposition allowed to observe their evolution depending on the average pentacene film thickness. Image processing of the resulting KPFM images facilitated to assign different morphological features (from substrate or pentacene) present in the height images to different contributions to the work function and, especially, clearly identified the pentacene grains within other similar morphological features. A much more homogenous growth of pentacene on 2D/3D heterostructured $Cs_2AgBiBr_6$ was observed, forming evenly shaped grains or dendritic islands. This was further accompanied by a more confined work function, speaking for an enhanced contact alignment between the double perovskite and pentacene.

CPP 44.5 Thu 10:45 ZEU/LICH

Gas quenching under ambient condition for efficient and stable perovskite solar cells with surface passivation — •Zhaonan Jin[1], Xiongzhuo Jiang[1], Zerui Li[1], Xiaojing Ci[1], Guangjiu Pan[1], Lixing Li[1], Jinsheng Zhang[1], Xinyu Jiang[2], Sarathlal Koyiloth Vayalil[2,3], Kun Sun[4], Stephan V.Roth[2,5], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]DESY, Hamburg — [3]UPES, India — [4]HZB, Berlin — [5]Department of Fibre and Polymer Technology, KTH, Stockholm, Sweden

Wide-bandgap perovskite solar cells play a key role in tandem solar cells, which aim to overcome the Shockley-Queisser limit for single-junction solar cells. In this work, we develop and optimize a gas quenching method under ambient conditions for the fabrication of wide-bandgap (1.77 eV) perovskite films. To improve the performance of PSCs, three different organic spacer cations, including aromatic amino molecules (PEAI), aliphatic amino with long alkyl chain molecules (OAI), and short alkyl chain molecules (BAI), are applied and investigated as surface passivation materials. As a result, the 2D perovskite layers form on top of 3D perovskite films. The n-i-p devices with PEAI passivation exhibit a champion PCE of 16.26% along with a high Voc of 1.21 V, exceeding the control device (PCE = 13.42%, Voc = 1.15 V), and maintaining 88% of its initial PCE after 120 minutes of continuous illumination. This work offers a guide for the fabrication of wide-bandgap PSCs under ambient conditions and the choice of organic spacer cations for passivation.

CPP 44.6 Thu 11:00 ZEU/LICH

Solvated PbI2 Clusters Preceding the Crystalization of Lead Halide Perovsites - UV/VIS In Situ Study — •Maximilian Spies[1], Leonard Krapf[1], Fabian Eller[2], Eva M. Herzig[2], and Anna Köhler[1] — [1]Soft Matter Optoelectronics, University of Bayreuth — [2]Dynamics and Structure Formation, University of Bayreuth

The solution-based fabrication of reproducible, high-quality lead iodide perovskite films demands a detailed understanding of the crystallization dynamics. This dynamic is primarily determined by the precursor solution chemistry and processing conditions. We conducted a systematic in-situ study to elucidate the formation mechanism of perovskite films and the role of additives in the pre-crystallization phase. Using UV absorption spectroscopy during spin coating allows us to track the evolution of iodoplumbate complexes and a solvated pre-crystalline phase (PDS) present in the precursor solution. This PDS phase is proportional to the precursor concentration, even during spin coating. Notably, using different precursor solvents changes the PDS phase evolution substantially. However, when introducing additives we see no difference in this pre-crystalline evolution, suggesting that additives only affect the perovskite film formation at a later stage

CPP 45: Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates I (joint session CPP/BP)

Biomolecular condensates play a central role in many cellular processes and provide a fascinating example of self-organized, highly dynamic systems. Physical methods, particularly from statistical physics and soft matter, have emerged as valuable tools for understanding and predicting their fundamental properties. Conversely, the complexity and diversity of biological systems open new perspectives and challenges for physical modeling. This focus session will highlight current research at the interface of physics and biology, with an emphasis on theoretical modeling and simulation of the physics of biomolecular condensates.

Organized by Arash Nikoubashman, Tyler Harmon and Lukas Stelzl.

Time: Thursday 9:30–11:15 Location: ZEU/0260

Topical Talk CPP 45.1 Thu 9:30 ZEU/0260

Wetting transitions in biomolecular coacervates — •Susanne Liese[1], Tiemei Lu[2], Evan Spruijt[3], and Christoph Weber[1] — [1]University of Augsburg — [2]University of Oxford — [3]Radboud University

Biomolecular coacervates are liquid-like droplets that can interact with membranes and self-organize into complex structures. Understanding the principles governing their shapes and higher-order assemblies is crucial for controlling compartmentalization in biological and synthetic systems.

We present a theoretical framework describing the shape and organization of biomolecular coacervates interacting with membranes and each other. Large coacervate droplets adopt morphologies determined by the balance of surface tensions, from partial adhesion to full engulfment. Scaled membrane tension and droplet-membrane interactions predict transitions between spherical, lens-shaped, partially wrapped, and endocytosed droplets, with composition-dependent contact angles linking molecular properties to macroscopic shapes.

For multiphase coacervates, we model the impact of interfacial species on droplet organization. Enrichment of an interfacial component at phase boundaries drives partial wetting between droplets, promoting the formation of dimers and extended chains. Numerical simulations show that surface tension minimizes the contact area, straightening droplet arrangements and generating polymer-like behavior with bending stiffness and segment-length constraints.

CPP 45.2 Thu 10:00 ZEU/0260

Elastic regulation of biomolecular condensates — •Oliver Paulin and David Zwicker — Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany

In recent years, biomolecular condensates have emerged as a vital component of sub-cellular organisation. Here, we discuss the role that elastic interactions can play in regulating condensate size, count, and mechanical properties. First, we focus on the impact of 'external' elasticity that arises from a confining mesh such as the cytoskeleton. We find that the additional energetic cost of network deformations induced by condensate growth limits condensate size, and can even suppress condensate formation entirely. Additionally, when condensate size is comparable to characteristic heterogeneities of the network, non-local interactions may arrest thermodynamic coarsening and drive the formation of stable patterned states with an energetically selected length scale. Second, we study how 'internal' elasticity, resulting from the intrinsic viscoelasticity of condensate material, can inhibit condensate growth, but also impart condensates with mechanical strength. For the case in which condensate growth is driven by active incorporation of new material, we demonstrate how a delicate balance of material properties provides condensates with solid-like mechanical strength, without compromising their liquid-like ability to form and grow rapidly. For both examples, we construct dynamic continuum models that couple phase separation with elastic deformation, analysing the key parameters that control condensate form, and identifying how cells can use elasticity to fine-tune condensate behaviour to fulfil a specific function.

CPP 45.3 Thu 10:15 ZEU/0260

Phase Separation of a Nucleator in a Self Straining Active Filament Network — •Jakob Schindelwig[1], Quentin Bodini-Lefranc[1,2], and Sebastian Fürthauer[1] — [1]Institute of Applied Physics, TU Wien, Lehargasse 6, 1060 Vienna, Austria — [2]Ecole polytechnique, Institut Polytechnique de Paris, Route de Saclay, 91120 Palaiseau, France

Many membraneless compartments of cells, such as stress-granules, form via liquid-liquid phase separation. In cells many compartments of the same type and similar sizes can coexist. Since this is inconsistent with equilibrium phase separation physics, we ask if active mechanics could explain this observation. We develop a model coupling dynamics of the droplet material to an active self-straining filament network. This model shows (i) arrested coarsening , (ii) oscillations, (iii) scale selection. We establish that our model is physiologically plausible by comparing to recent work on a phase separating nucleator of actin.

CPP 45.4 Thu 10:30 ZEU/0260

Active Transport as a Mechanism of Microphase Selection in Biomolecular Condensates — •Le Qiao, Peter Gispert, and Friederike Schmid — Institut für Physik, Johannes Gutenberg-Universität Mainz, D55099 Mainz, Germany

Cells control the size and organization of biomolecular condensates formed by liquid-liquid phase separation (LLPS), yet the underlying physical principles remain incompletely understood. We propose a transport-driven mechanism in which undirected motor-mediated motion along cytoskeletal filaments redistributes phase-separating components, generating an effective non-equilibrium long-range repulsion that arrests coarsening. This is explored using a minimal reaction-diffusion-transport model that captures the interplay between binding-release kinetics, diffusion, and active transport. A linear stability analysis and three-dimensional simulations reveal a transition from macroscopic to microphase separation at remarkably low binding/release fractions, corresponding to minute fractions of motor-bound proteins. Tuning motor binding rates b or transport velocities enables sublinear control of condensate dimensions ($L \sim b^{1/4}$) from nanometers to micrometers. This mechanism provides a simple physical route for spatially programmable condensate organization in living cells and active materials.

CPP 45.5 Thu 10:45 ZEU/0260

Positive feedback in chemically active droplets — •Xi Chen[1], Jens-Uwe Sommer[1,2], and Tyler Harmon[1] — [1]Leibniz Institute of Polymer Research, Dresden, Germany — [2]Dresden University of Technology

Biomolecular condensates are dynamic compartments that can be maintained far from equilibrium by active chemical reactions. Active condensates can be driven by phase-dependent reaction fluxes, for example via localized enzymatic activity, and thereby exhibit emergent behaviors that cannot be realized in equilibrium condensates. We analyzed condensates with positive feedback between phase separation and reactions: droplets enhance reactions, and the resulting products stabilize the droplets. We show that this feedback produces pronounced hysteresis, making droplets resilient to cellular fluctuations. We show the hysteresis persists across a broad range of reaction schemes and parameter choices, indicating that it is a robust feature of droplets with positive feedback. Condensates that form to satisfy transient cellular needs may benefit from such hysteresis, because it ensures that they persist long enough to carry out their functions despite fluctuating conditions.

CPP 45.6 Thu 11:00 ZEU/0260

Chemically driven simulations of enzymatic phosphorylation in protein condensates — •Emanuele Zippo[1], Dorothee Dormann[1,2], Thomas Speck[3], and Lukas Stelzl[1,2] — [1]Johannes Gutenberg University Mainz, Mainz, Germany — [2]Institute of Molecular Biology (IMB), Mainz, Germany — [3]University of Stuttgart, Stuttgart, Germany

The condensation and aggregation of intrinsically disordered proteins (IDPs) in cells are governed by enzyme-driven, non-equilibrium processes. Kinases such as Casein kinase 1 delta (CK1d) phosphorylate proteins using ATP as chemical fuel, tuning intermolecular interactions and modulating condensate assembly. The neurodegeneration-linked protein TDP-43 undergoes CK1d-mediated hyperphosphorylation, proposed as a cytoprotective mechanism through condensate dissolution, yet the mechanisms underlying kinase-condensate interactions remain unclear. Using coarse-grained molecular dynamics simulations, we investigate how CK1d phosphorylates TDP-43 and how this reaction drives the structural reorganization and dissolution of its condensates. To ensure thermodynamic consistency in such fuel-driven simulations, we employ an automatic, generally applicable Markov state modeling framework. Post-translational modifications (PTMs), such as phosphorylation, can actively regulate condensate stability and suppress Ostwald ripening, offering a mechanism to control mesoscale structure in soft materials. Understanding such reaction-structure coupling in non-equilibrium environments is key to explaining cellular self-organization and designing biomimetic systems.

CPP 46: Poster II

Focus Session: Water - from Atmosphere to Space (with DY); French-German Session: Membranes and Porous Materials; Gels, Polymer Networks and Elastomers; Biopolymers, Biomaterials and Bioinspired Functional Materials (with BP); Complex Fluids and Colloids, Micelles and Vesicles (with DY); Charged Soft Matter, Polyelectrolytes and Ionic Liquids; Responsive and Adaptive Systems; Nanomaterials, Composites and Hybrids; Crystallization; Molecular and Polymer Dynamics, Friction and Rheology; Simulation Methods and Modeling of Soft Matter; Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods

Time: Thursday 9:30–11:30 Location: P5

CPP 46.1 Thu 9:30 P5

Pressure-induced amorphization of aqueous PEG solutions — •Leah Dorothea Schwerdtfeger[1,2], Isabell Zick[1,2], and Katrin Amann-Winkel[1,2] — [1]Institut für Physik, Johannes Gutenberg Universität, Mainz — [2]Max-Planck-Institut für Polymerforschung, Mainz

Water is a fundamental substance whose behavior under supercooled temperatures shows many anomalous properties. Among the many curiosities, water can even form different amorphous states. These amorphous states are hypothesized to be directly related to two different liquid states of water, namely high- and low-density liquid. Understanding the pressure-induced amorphization of aqueous solutions can reveal how solutes alter water's phase diagram and give further insight to the predicted liquid-liquid transition.

While the impact of small molecules is known from previous studies, the role of larger polymers remains unexplored. Here, we discuss experiments on aqueous polyethylene glycol (PEG) solutions with different molar weights, studying their effect on the pressure-induced phase transitions. Our dilatometric measurements show how solutes broaden the transition from hexagonal ice to high-density amorphous ice (HDA), depending on the molar fraction. We also investigate the polyamorphic transition between low- and high-density amorphous ice (LDA-HDA), which for pure water is known to exhibit a strong temperature-dependence. The samples are further characterized by X-Ray diffraction (XRD).

CPP 46.2 Thu 9:30 P5

Phase transition in water-glycerol solutions — •Klara Holl[1,2], Louisa Kraft[1,2], and Katrin Amann-Winkel[1,2] — [1]Institut für Physik, Johannes Gutenberg-Universität, Mainz — [2]Max-Planck-Institut für Polymerforschung, Mainz

Water is omnipresent in our daily lives with many anomalous properties and a unique phase diagram. Studies of supercooled water provides insight into the hypothesis of the coexistence of two liquid states of water and a liquid-liquid transition. This proposes two different types of supercooled liquid water in a high-density and low-density liquid state, that are separated by a first order phase transition at low temperatures and elevated pressure. But how does this hypothesis impact on aqueous solutions?

Water-glycerol mixtures are often used in pharmaceuticals and act as cryoprotectants, common in biomedicine as well as automotive antifreeze. While pure water crystallizes easily, the glass-forming agent glycerol can serve as soft confinement for water. Changing the concentration of the two components alters the liquid's physical and thermodynamic properties, including depression of the crystallisation temperature.

We investigate different water-glycerol solutions at low-temperatures and high-pressure conditions using a diamond anvil cell. This allows in situ optical observation of crystallisation and glass transition. Structural changes are studied by X-ray diffraction and differential scanning calorimetry.

CPP 46.3 Thu 9:30 P5

Photooxidation of vanillic acid at the air-water interface — •Manuel Hofmann[1,2] and Ellen H.G. Backus[1,2] — [1]Institute of Physical Chemistry, Faculty of Chemistry, University of Vienna, Währinger Str. 42, 1090 Vienna, Austria — [2]University of Vienna, Vienna Doctoral School in Chemistry (DoSChem), Währinger Str. 42, 1090 Vienna, Austria

Phenolic compounds like vanillic acid, emitted from biomass burning, can form secondary organic aerosols (SOA) through aqueous phase reactions. Photooxidation of vanillic acid is a potential source of Humic-Like Substances (HULIS), that influence atmospheric chemistry through light absorption.[1]

The air-water interface provides a distinct chemical environment where structural behavior and reactions may differ from those in bulk. To specifically probe this interface, sum-frequency generation (SFG) spectroscopy and surface tension measurements are employed, offering complementary insights into molecular behavior.[2]

This study examines vanillic acid at the air-water interface across different pH values, before and after UV/H2O2-induced photooxidation. Control experiments with vanillic acid alone separate direct photolysis from radical mediated processes. Preliminary SFG spectra reveal pH-dependent vibrational signatures of adsorbed species and significant changes upon photoreaction. The goal is to identify reaction products, structural changes, and how pH affects vanillic acid photoreactivity.

[1]S. Tang et al., ACS Earth Space Chem., 4 (2020) 862-872.[2]C.-M. Saak et al., J. Phys. Chem. Lett., 15 (2024) 4546-4559.

CPP 46.4 Thu 9:30 P5

Biophysical Interaction of Steroid Hormones with Model Lipid Membranes — •Rabia Rabia[1,2,3], Prashant Hitaishi[1,2], Bridget Murphy[1,2], and Julia Herzen[3] — [1]Institute of Experimental and Applied Physics, Kiel University, Leibnizstraße 19, Kiel, 24118, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, Notkestraße 85, Hamburg, 22607, Germany — [3]Technische Universität München

Menopause is characterized by declining 17βestradiol (E2), increased adiposity, reduced insulin sensitivity, and higher type 2 diabetes risk. Vasomotor symptoms, such as hot flushes and night sweats, significantly impair quality of life, and transdermal E2 provides effective relief at lower doses than oral therapy, with potentially fewer systemic risks. Despite its clinical benefits, the molecular mechanisms of E2 remain incompletely understood. While steroid hormones classically act via intracellular receptors to regulate gene transcription, they also interact directly with lipid membranes, influencing packing and elasticity. We studied βestradiol, progesterone, 17αethynylestradiol, and cholesterol in DPPC and POPC monolayers at the air water interface using Langmuir isotherms and surface elasticity measurements. E2 was found to expand molecular area and reduce packing density, increasing membrane elasticity. Planned X-ray measurements will further clarify how steroid-induced reorganization of lipid interfaces modulates downstream cellular signaling.

CPP 46.5 Thu 9:30 P5

The structure and orientation of ice under confinement in Periodic Mesoporous Organosilicas (PMOs) — Niels C. Giesselmann[1], Philip Lenz[2,3], Sophia-Marie Meinert[2], Robert P.C. Bauer[1,4], Nele N. Striker[1], Michael Fröba[2,3], and •Felix Lehmkühler[1,3] — [1]Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — [2]Institute for Inorganic Chemistry, University of Hamburg,Germany — [3]The Hamburg Center for Ultrafast Imaging, Hamburg, Germany — [4]Freiberg Center for Water Research, TU Bergakademie Freiberg, Germany

We studied water in periodic mesoporous organosilicas (PMOs) with pore diameters in the range of 2-5 nm. In these materials, the molecular mobility of water is influenced by the polarity of the organic moiety. We collected and analyzed X-ray scattering data of water and ice under confinement in PMOs with varying degrees of hydrophobicity and pore diameters and at varying temperature. A decrease in the density of the confined water was observed during cooling, which was strongly dependent on the organic moiety, as well as the pore diameter. We furthermore found deviations in the lattice constants of hexagonal ice in these materials compared to bulk water. In most cases, one lattice parameter was more strongly affected. This could be caused by orientational dependencies between the ice crystal and the pore. The orientation between the hexagonal crystallites in relation to the pore axis was therefore investigated using X-ray Cross Correlation Analysis (XCCA), indicating more uniformly oriented crystallites in more hydrophilic pores.

CPP 46.6 Thu 9:30 P5

Impact on snow albedo of soot aggregates inferred from their radiative properties — •Llorenc Cremonesi[1], Luca Teruzzi[1], Valentina Raspagni[2], and Marco Potenza[1] — [1]University of Milan, Milan, Italy — [2]Ca' Foscari University of Venice, Venice, Italy

Despite having a short lifespan in the atmosphere, soot aggregates are abundant and volatile enough to be found in various environments far from their sources. While suspended in the atmosphere, they influence local thermodynamic conditions and interact with water triggering cloud nucleation. These particles are also among the drivers of cryospheric degradation in climate-sensitive areas such as the Arctic and the European Alps.

The effectiveness with which soot aggregates interact with solar radiation is known to be related to their morphology as well as their composition. However, studies of their radiative properties rely on indirect or model-dependent measurements. We use a non-destructive optical technique that enables us to simultaneously measure several optical parameters on a particle-by-particle basis in situ.

Field measurements and laboratory tests show that aggregate particles exhibit exceptional scattering and absorption efficiencies relative to their mass. Directly

assessing these properties obviates the need to characterise their exceptional morphological variability. By quantifying these properties, we evaluate the impact of carbon aggregates on snow, particularly in the uppermost layers.

CPP 46.7 Thu 9:30 P5

Study of nuclear magnetization transfer between water and ice phases in nanoporous solids — •Cristina Abril Gutierrez Ortigoza and Rustem Valiullin — Felix Bloch Institute for Solid State Physics, University of Leipzig, Leipzig, Germany

NMR Cryoporometry is a promising tool for the characterization of nanoporous solids. The technique relies on introducing a probe liquid into the nanopores, where a liquid and frozen phase can coexist at low temperatures. Both phases can be easily identified using NMR due to their vastly different transverse relaxation rates. The magnetization transfer mechanism between these is not well understood, especially its dependence on various parameters such as temperature and pore size. In this contribution, the magnetization transfer between water and ice in porous silica is explored, the pore structure of which is composed of well-ordered spherical nanopores connected by micropores. The measurements are performed by using the Goldman-Shen pulse sequence, which initializes the experiments in a state where all the magnetization is contained in the liquid phase. By studying how the system re-equilibrates, parameters such as the diffusion coefficient in the ice phase and the proton volume fraction in each phase are obtained. Furthermore, the non-frozen layer thickness, which refers to the liquid-like layer that forms between the ice core and the pore wall, can be obtained by exploiting the well-defined geometries of the ice and water phases. The studies were performed at different temperatures to assess the dependence of the results on this parameter. The experimental data are also compared to theoretical models.

CPP 46.8 Thu 9:30 P5

Advanced analysis of NMR cryoporometry data — •Crina Rahause, Georgiy Baroncha, and Rustem Valiullin — Felix Bloch Institute for Solid State Physics, Leipzig University, Leipzig, Germany

NMR cryoporometry is a powerful tool for structural characterisation of multiscale nanoporous materials. It relies on probing the pore size dependent ice-liquid phase transitions of nanoconfined liquid. However, accurate interpretation of the experimental data requires a better description of phase equilibria, as well as a framework that takes into account the network topology and relaxation effects. In this contribution, we perform NMR measurement using water and octamethylcyclotetrasiloxane (OMCTS) as probe liquids inside highly ordered nanoporous alumina membranes with well-defined pore sizes ranging from 25 to 180 nanometres. OMCTS differs from water in terms of relaxation times and the thermodynamic parameters controlling phase transition suppressions; therefore, by comparing the responses of the two liquids in different porous media, we can identify key parameters which are necessary for accurately establishing an advanced cryoporometry methodology, and demonstrating the applicability of this technique to a wide range of materials.

CPP 46.9 Thu 9:30 P5

Comparison of mechanical properties and pore collapse characteristics of hyperuniform disordered anodic aluminium oxide membranes — •Rang Noh[1], Clara Twiehaus[2], Marc Thelen[1], Alexander Sprafke[3], Prerak Dhawan[3], Ralf Wehrspohn[3], Martin Steinhart[2], and Patrick Huber[1,4] — [1]Institute for Materials and X-ray Physics, Hamburg University of Technology, Hamburg, Germany — [2]Institute of Chemistry of New Materials, Osnabrück University, Osnabrück, Germany — [3]Institute of Physics, Martin Luther University of Halle-Wittenberg, Halle (Saale), Germany — [4]Center for X-ray and Nano Science CXNS, Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

We investigate how the degree of disorder in hyperuniform Porous Anodic Aluminum Oxide (AAO) membranes influences their mechanical properties and pore-collapse behavior. Elastic moduli of AAO were measured using two different methods; Laser Ultrasonics (LUS) and nanoindentation. The indented points were captured by scanning electron microscopy to observe pore collapse characteristics. The elastic moduli from LUS and nanoindentation agree well; in general, the elastic modulus increases as both porosity and the hyperuniformity index decrease. Even at similar porosity levels, enhanced hyperuniformity results a higher elastic modulus. When the pores are ordered, the pore collapse follows directional grain paths around the indented edge and propagate further in a connected herringbone like pattern. But, in the disordered state, the irregular collapse happens, producing direction-independent crack propagation within the restricted region.

CPP 46.10 Thu 9:30 P5

Microscopic mechanisms of polymer network breakage under mechanical deformation — •Fernando Martín Salamanca[1,2] and Michael Lang[1] — [1]Institute Theory of Polymers, Leibniz-Institut für Polymerforschung Dresden e.V. Kaitzer Strasse, 4 - 01069 (Dresden) — [2]Institute of Polymer Science and Technology, Spanish National Research Council. Juan de la Cierva, 3 - 28006 (Madrid)

The failure of polymer networks arises from a subtle interplay between bond rupture, chain interactions and the underlying topology of the network. In this work, Monte Carlo simulations are used to explore how these factors shape the mechanical response of crosslinked polymers subjected to mechanical stress. The main goal is to evaluate, in a controlled manner, the key elements that modify the mechanical response by computer simulations: the criteria for bond rupture, the mathematical modelling of interactions potentials and force fields, the effect of entanglements and excluded volume. Model networks are evaluated with diverse approaches to quantify the effect of each contribution to elastic modulus. The simulations yield detailed rupture statistics and stress-strain behavior across a broad parameter space, which are compared with predictions from established theoretical descriptions of network elasticity and fracture. Overall, this work provides basic information for understanding network failure and for establishing a first-principles based model for real polymer networks.

CPP 46.11 Thu 9:30 P5

Tuning Foam Kinetics and Structure: The Role of Gas Flowrate in Microgel-Stabilized Foams — •Vera Anna Nina Alina Hesse, Joanne Zimmer, and Regine von Klitzing — Soft Matter at Interfaces, Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 8, D-64289 Darmstadt

The stability and microstructure of foams are critical for their performance in various applications. In this work, aqueous foams are generated by sparging gas (nitrogen) through an aqueous dispersion of PNIPAM microgels, which are used as foam-stabilizers. In specific the effect of the gas flowrate during foam production on the foam structure and kinetics is investigated. In this regard, key parameters such as the foam half lifetime, drainage (liquid content), and bubble size evolution are examined. Our findings reveal a clear dependence: In general, lower flowrates produce smaller initial bubbles, which in turn significantly improve the overall foam stability, as their structural skeleton remains intact for longer periods. On the other hand, a stability optimum is detected, with peak stability occurring at a low flowrate; further reduction however ultimately compromising stability. These findings contribute to a deeper understanding of microgel-stabilized aqueous foams and render the potential for optimizing foam generation processes.

CPP 46.12 Thu 9:30 P5

Shape and inner structure of micelles from tetrablock terpolymers in aqueous solution — •Katarina Döbler[1], Feifei Zheng[1], Pablo A. Alvarez Herrera[1], Joachim Kohlbrecher[3], Anna P. Constantinou[2], Theoni K. Georgiou[2], and Christine M. Papadakis[1] — [1]Technical University of Munich, TUM School of Natural Sciences, Soft Matter Physics Group, Garching, Germany — [2]Imperial College London, U.K — [3]PSI, Villigen, Switzerland

Injectable hydrogels formed by LCST thermoresponsive block terpolymers consisting of thermoresponsive, hydrophilic and hydrophobic blocks are promising materials for tissue engineering by 3D bioprinting. The gel point temperature, gelation mechanism, and physical properties can be tuned by the number, sequence and length of the individual polymer blocks [1,2]. Utilizing small-angle X-ray and neutron scattering in a wide temperature range, we investigate aqueous solutions of thermoresponsive tetrablock terpolymers having different sequences of hydrophilic, hydrophobic and thermoresponsive blocks. By fitting structural models, we gain insight into the shape and size of the micelles as well as their inner structure. Moreover, the gelation mechanism is deduced from the changes of the micellar structure and correlation at the gel point.

CPP 46.13 Thu 9:30 P5

Interfacial Dilational Rheology of Microgel Layer at the air-water interface — •Jana Sänger, Atieh Razavi, Regine von Klitzing, and Amin Rahimzadeh — Soft Matter at Interfaces, Institute for condensed Matter Physics, Technical University of Darmstadt, Hochschulstraße 8, 64289 Darmstadt, Germany

Interfacial tension and dilational interfacial rheology of Poly (N-Isoprpylacrylamide) (PNIPAM) microgel layer at air-water interfaces are characterized using pendant-drop techniques. Static interfacial tension was first measured with a drop shape analyser by fitting the droplet profile to the Young-Laplace equation. To probe the interfacial elasticity of microgel dispersions, a Profile Analysis Tensiometer (PAT-1) is employed to impose controlled harmonic oscillations on pendant drops with volumes of 10 μL and microgel concentrations between 0.1 wt% and 0.015 wt%. By using a Fourier transformation, the surface dilational modulus is determined, and the elasticity modulus is then identified as the real part of the surface dilational modulus. In order to remain within the linear range of the interfacial dilational elasticity, various amplitude ratios were systematically tested, and a maximum amplitude ratio of 6% was found. Our study shows that the elastic modulus is frequency-dependent. By increasing the frequency, an increasing elastic modulus is determined. Furthermore, we observe a shift of the maximum elasticity modulus towards the lower surface pressure values by increasing the frequency.

CPP 46.14 Thu 9:30 P5

Combined TGA-MS Analysis of Actively Aged Polymers for Assessing Recycling Potential — •Judith Bünte, Inga Ennen, Karsten Rott, and Andreas Hütten — Universität Bielefeld, Universitätsstraße 25, 33615 Bielefeld, Germany

Thermogravimetric analysis (TGA) combined with mass spectrometry (MS) provides a powerful, complementary approach for characterizing the thermal stability and degradation pathways of polymers subjected to accelerated (active) aging. In this study, aged polymer samples, representing materials encountered in post-consumer recycling streams, are analyzed using simultaneous TGA-MS to monitor mass-loss events and identify evolved gaseous species. These results demonstrate that combined TGA-MS analysis can reveal chemical and structural changes that are not easily evident from bulk mechanical or spectroscopic testing alone. The findings support more accurate assessments of polymer recyclability, highlight indicators of material down-cycling, and inform optimization strategies for sorting, preprocessing, and reprocessing conditions. Ultimately, this work underscores the value of TGA-MS as a diagnostic tool for improving circular-economy approaches.

CPP 46.15 Thu 9:30 P5

Synthese und Reaktivität von Betti-Basen — •Alyona Nikulina — Mikluho-Maklaya Strasse, Moskau 117198

Diese Forschung konzentriert sich auf Naphthoxazine, eine wertvolle Gruppe von Verbindungen, die für ihre biologischen Aktivitäten bekannt sind wie antimikrobielle,antidiabetische und antidepressive Wirkungen sowie für ihr Potenzial in der Entwicklung von duroplastischen Polymeren. Die Synthese dieser Verbindungen beginnt häufig mit Betti-Basen, die Zwischenprodukte für die Bildung von kondensierten 1,3-Oxazinen darstellen.Um die notwendigen Betti-Basen zu erhalten, untersuchten wir zwei Syntheserouten. Eine Strategie war eine einfache Dreikomponenten-Reaktion von β-Naphthol, sekundären cyclischen Aminen und Aldehyden. Der andere Weg umfasste zunächst die Kondensation von 2-Hydroxy-1-naphthaldehyd mit Aminen und anschließend die Reduktion der resultierenden Iminiumsalze mit Natriumborhydrid. Nachfolgende Versuche, diese Basen durch Cyclisierung mit Standardreagenzien wie Silberoxid oder Kupferacetat in die Ziel-Naphthoxazine umzuwandeln, erwiesen sich als ineffizient und ergaben geringe Ausbeuten. Da bekannt ist, dass diese Cyclisierung die Bildung eines Iminiumsalzes beinhaltet, stellten wir die Hypothese auf, dass DIAD als wirksamer Katalysator wirken würde. Das Experiment nahm jedoch eine unerwartete Wendung: DIAD allein führte nicht zu den gewünschten Naphthoxazinen. Der entscheidende Moment kam, als wir ein katalytisches System aus Kupfer(I)-iodid und Cesiumcarbonat zugaben, das eine unvorhergesehene intramolekulare Umlagerung der Betti-Basen auslöste und stattdessen zu Diketon führte.

CPP 46.16 Thu 9:30 P5

Functional ZnPc-Polymer-Magnetic Nanocomposite Systems for Photodynamic Therapy — •Lungu Ion — Laboratory of Organic/Inorganic Materials for Optoelectronics, Institute of Applied Physics Moldova State University, 60 Al. Mateevici St., MD-2009, Chisinau, Republic of Moldova

Hybrid photosensitizing materials combining organic and magnetic components provide a promising route toward multifunctional systems for photodynamic therapy (PDT). In this work, we investigate the photophysical and magnetically induced processes in a series of functional zinc phthalocyanine (ZnPc) derivatives-ZnPc(COOH)4 and ZnPc(COOH)8 and their conjugates with dextran (Dx) and Fe3O4 nanoparticles. The systems were studied in DMSO/H2O (1:1) solutions using steady-state and time-resolved fluorescence and phosphorescence spectroscopy. All ZnPc-based compounds exhibit characteristic Q-band absorption (650-700 nm) and room-temperature phosphorescence with microsecond lifetimes, confirming efficient intersystem crossing (ISC). Dextran conjugation enhances fluorescence efficiency (ΦF = 2.37 %) and reduces aggregation, whereas Fe3O4 incorporation modifies the spin-orbit coupling, promoting magnetically assisted ISC and additional non-radiative channels. The triplet lifetimes vary between 1-9 μs, depending on molecular substitution and interfacial coupling. These results demonstrate that combining photoactive ZnPc cores with natural polymer matrices and magnetic nanoparticles enables control over excited-state dynamics and ROS generation for biomedical applications.

CPP 46.17 Thu 9:30 P5

Biopolymer-Templated Deposition of Hierarchical 3D-Structured Graphene Oxide/Gold Nanoparticle Hybrids for Surface-Enhanced Raman Scattering — •Yingjian Guo[1,2], Guangjiu Pan[2], Yusuf Bulut[1,2], Arno Jeromin[1], Thomas F. Keller[1], Andreas Stierle[1], Gergely Nemeth[3], Ferenc Borondics[3], Benedikt Sochor[1], sarathlal K. Vayali[1], Daniel Söderberg[4], Peter Müller-Buschbaum[2], and Stephan V. Roth[1,4] — [1]DESY, Hamburg — [2]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [3]Synchrotron SOLEIL, Saint-Aubin, France — [4]Department of Fibre and Polymer Technology, KTH, Stockholm, Sweden

Cellulose has emerged as a promising bio-based template for sensors, smart windows, and bioelectronics. Typically, Surface Enhanced Raman Scattering (SERS), an advantageous analytical technique, allows for the rapid detection and structural analysis of chemical compounds through their spectral patterns in nanotechnology. Crucial for SERS is fabricating the substrates with strong enhancements of the Raman signal over large areas. Herein, we present a straightforward approach utilizing the layer-by-layer spray coating method to fabricate films loaded with gold nanoparticles and graphene oxide to serve as SERS substrates. GISAXS combined with nano-FTIR spectroscopy was used to confirm a synergistic Raman enhancement mechanism of localized surface plasmon resonance and interface charge transfer. Our approach provides a reference for facile and scalable production of SERS substrates.

CPP 46.18 Thu 9:30 P5

Regulation of HUVEC Adhesion by Mechanical and Biochemical Tuning of PNIPAM Microgel Coatings — •Leonie Beer, Souraj Mandal, and Regine v. Klitzing — Soft Matter at Interfaces, Department of Physics, TU Darmstadt, Darmstadt 64289, Germany

A bioactive and stable interfacial layer favouring HUVEC cell adhesion is a key factor in artificial vascular network construction. This work investigates the impact of the mechanical and biochemical properties of PNIPAM microgel (MG) coatings on HUVEC cell adhesion and proliferation on 3D printed polymeric surfaces. MG stiffness can be varied based on cross-linking, and bioactivity can be imparted by functionalizing MG with RGD-based peptide mimicking extracellular matrix (ECM) ligands. HUVEC cell culture studies showed significant effects of MG stiffness on cell adhesion and proliferation, with further improvement due to biochemical functionalization. In addition, different spacers were used to enhance cell attachment and growth.

MG adhesion on different substrates was also evaluated, revealing significantly stronger adsorption on 3D-printed polymeric surfaces compared to inorganic substrates. AFM imaging confirmed the presence of firmly adhered MGs beneath the cells, demonstrating long-term coating integrity under biological conditions.

These results demonstrate that PNIPAM MG coatings provide a robust, tunable, and bioactive platform for controlling HUVEC behaviour and represent a promising strategy for endothelialization of 3D-printed vascular structures.

CPP 46.19 Thu 9:30 P5

Crystallization behavior of electron beam modified Polylactide acid (PLA) — •Regine Boldt[1], Elisabeth Hauschild[1], Michael Müller[1], and Markus Stommel[1,2] — [1]Leibniz Institut fuer Polymerforschung Dresden, Germany — [2]Dresden University of Technology, Germany

Polylactic acid (PLA) is a polymer synthesized from renewable raw materials. The properties of PLA are essentially determined by its chemical/physical structure, such as molar mass, molar mass distribution, D-isomer content, and the resulting morphology. The morphology can be influenced by modifying the molecular structure on the one hand, and by the process parameters during processing on the other. Since PLA crystallizes very slowly, high cooling rates, which occur in processing methods such as injection molding, usually result in amorphous components. In this work, we modified PLA using high-energy electrons in order to accelerate its crystallization without adding external additives. The resulting changes in crystallization kinetics were analyzed and correlated with the morphology after irradiation. The spherulite growth rates were determined quantitatively using hot stage experiments on a light microscope. The results show that electron-modified PLA exhibits substantially increased crystal growth rates, enabling significant reductions in cooling time during processing operations such as injection molding.

CPP 46.20 Thu 9:30 P5

Diffusion and stiffness characterization of photocrosslinked hydrogels to replicate biological tissues — •Lena Hilf[1], Dimitris Missirlis[1,2], and Kai Melde[1] — [1]Institute for Molecular Systems Engineering and Advanced Materials, Universität Heidelberg — [2]MPI for Medical Research, Heidelberg

Microphysiological systems (MPS), such as organs-on-a-chip, aiming to replicate the spatial arrangement of biological tissues found in vivo are in need of a reliable and replicable way to recreate the biophysical environment including topography and mechanical properties. One possible route is via selective photocrosslinking of hydrogel scaffolds, which can be performed in situ in microfluidic platforms.

However, we still lack reliable information about key properties of potential hydrogel candidates in these systems, which influence cell adhesion and spreading, as well as the uptake of media components.

In this work, we characterize the stiffness, mesh size and diffusion constant of a range of hydrogels created using photolithpgraphy. We employ both optical and mechanical approaches, taking into account the versatility of hydrogel responses to different measurement methods.

Our results together with cell proliferation assays allow for a more targeted choice of hydrogels to serve as artifical extracellular matrices in MPS.

CPP 46.21 Thu 9:30 P5

Characterization of bimodal PMMA-PDMS suspensions using light scattering — •Katharina Gaus and Joachim Wagner — University of Rostock, Rostock, Germany

Poly-dimethylsiloxane coated PMMA particles index matched in tetraline/decaline mixtures are well defined model systems for hard spheres with tunable particle size. Binary mixtures of these core-shell particles with slightly different sizes artificially increase the polydispersity of colloidal model systems preventing crystallization at large volume fractions and thus enabling the preparation of colloidal glasses. Using a priori knowledge of both species' topology, even in the limited range of wave vectors accessible with light scattering experiments, the reliable structural characterization of mixtures is possible. Hence, such binary mixtures are promising model systems for colloidal glasses.

CPP 46.22 Thu 9:30 P5

Cycles of buckling in gel phase giant unilamellar vesicles — •Azeline Hilaire, Antonio Stocco, Jean Farago, and Fabrice Thalmann — Institut Charles Sadron, Strasbourg, France

Buckling can be observed in giant unilamellar vesicles (GUVs) in gel phase, leading to shape deformations under external stress. Such deformations may offer functional advantages, particularly for inducing motion at low Reynolds numbers.

Recently, lipid-coated microbubbles were shown to exhibit directed motion through deformation cycles, suggesting a broader potential for soft interfaces to generate propulsion. Inspired by this, we investigate whether similar mechanisms can be used in isolated GUVs under cycles of deformation, with the goal of understanding and eventually triggering symmetry-breaking dynamics. We aim to use shape hysteresis for producing directed motion.

Gel-phase GUVs were fabricated via hydration method and characterized by their ability to transition between buckled and unbuckled states. We exposed these vesicles to cyclic fields using three distinct methods: (i) oscillatory shear flows, (ii) osmotic pressure, (iii) On/Off cycles of light applied with optical tweezers. In some of these cases, the membrane exhibited buckling.

Although directed motion has not yet been observed, the buckling response establishes a first result for future efforts to induce propulsion in vesicles. These preliminary results offer a first step towards exploring whether shape hysteresis in membranes could one day be used for active functions.

CPP 46.23 Thu 9:30 P5

Dynamics of trifunctional hybrid nanoparticle assemblies — •Thomas Dartige[1], Yinan Fan[2], Clément Marque[1], Ali Abou-Hassan[2], and Antonio Stocco[1] — [1]Institut Charles Sadron, Strasbourg, France — [2]Phenix Lab, Paris, France

Active colloids are colloidal systems able to consume energy to produce work, such as directed motion. Self-propulsion in micrometric particles can be achieved through surface asymmetries, using diffusiophoresis (via asymmetric catalytic properties) or thermophoresis (via asymmetric light absorption). However, the combining of several active properties into one single colloidal system remains poorly explored. In this work, we present a hybrid system synthesized by combining distinct nanoparticles, and investigate its ability to exhibit diffusiophoresis, thermophoresis, and respond to magnetic field gradients.

CPP 46.24 Thu 9:30 P5

Physics-Informed Neural Inference with Multilayer DWBA Modeling for Quantitative GISAXS — •Özüm Emre Asirim[1,2], Yufeng Zhai[1], Marina Tropmann-Frick[2], and Stephan V. Roth[1,3] — [1]Deutsches Elektronen-Synchrotron DESY FS-SMA Notkestr. 85 22607 Hamburg Germany — [2]HAW Hamburg Berliner Tor 7 20099 Hamburg Germany — [3]KTH Royal Institute of Technology, SE-100 44 Stockholm, Sweden

Quantitative GISAXS analysis is often constrained by the complexity of multilayer scattering, film-nanoparticle coupling, and the limited availability of physically interpretable synthetic datasets for training modern inference models. We address these challenges with a physics-informed neural framework that integrates a compact multilayer DWBA formulation with a hybrid CNN-Transformer architecture. The forward model captures essential film and nanoparticle scattering through per-layer incoherent DWBA terms, normalized form factors, structure factors, and DWBA-based field enhancement, yielding a reduced and physically coherent parameter space suitable for inversion. Measurement variability is modeled through noise, detector effects, and the ability to generate time-series data for evolving structures. Leveraging this parameterization, the CNN-Transformer network jointly extracts local scattering motifs and long-range reciprocal-space correlations, enabling accurate recovery of film- and particle-level parameters. Validated through forward reconstruction using the same physics model, the workflow provides a fast, interpretable, and physically grounded solution for high-throughput GISAXS analysis.

CPP 46.25 Thu 9:30 P5

How Polymer Architecture Shapes the Phase Behavior of Polyelectrolyte Complex Coacervates — •Lena Tarrach, David Beyer, and Christian Holm — Institute for Computational Physics, University of Stuttgart, Stuttgart, Germany

Polyelectrolyte (PE) complex coacervation is an associative liquid-liquid phase separation that can occur in mixtures of oppositely charged macromolecules. Although this phenomenon is widely studied, the effects of the polymer architecture on the phase behavior of PE complex coacervates have not been considered so far. To close this gap, in this contribution, coarse-grained molecular dynamics (MD) simulations with the ESPResSo software [1] are applied to calculate the phase diagram of branched PEs with varying numbers of arms but the same overall molecular weight. The slab method is used to establish the coexistence of the coacervate phase and the supernatant solution. The number of arms of the PEs is systematically increased to assess the influence of the PE topology on the phase behavior. The obtained phase diagrams are subsequently compared to theoretical phase diagrams calculated using the random phase approximation.

ESPResSo 4.0 - an extensible software package for simulating soft matter systems. The European Physical Journal Special Topics, 227(14):1789-1816, 2019. doi:10.1140/epjst/e2019-800186-9.

CPP 46.26 Thu 9:30 P5

Self-assembled Micelles from Charged Block Copolymers: Insights from Small-Angle X-ray Scattering (SAXS) — •Yijun Zhao[1], Varvara Chrysostomou[2], Athanasios Skandalis[2], Stefano Da Vela[3], Stergios Pispas[2], and Christine M. Papadakis[1] — [1]TUM School of Natural Sciences, Soft Matter Physics Group, Garching, Germany — [2]Theoretical and Physical Chemistry Institute, NHRF, Athens, Greece — [3]EMBL at DESY, Hamburg, Germany

Block copolymer micelles have been widely studied due to their ability to load drugs. Positively charged micelles have been proposed to complex DNA, enabling efficient gene therapy. To achieve highly tunable morphology, self-assembled micelles from the diblock copolymers PDMAEMA-b-PLMA and the triblock terpolymers PDMAEMA-b-PLMA-b-POEGMA are investigated in aqueous solution [1]. Here, PDMAEMA stands for the weak polycation poly(2-(dimethylamino)ethyl methacrylate), PLMA for the hydrophobic, but soft poly(lauryl methacrylate), and POEGMA for the hydrophilic poly(oligo(ethylene glycol) methacrylate). Small-angle X-ray scattering (SAXS) on dilute aqueous solutions revealed that PDMAEMA-b-PLMA forms ellipsoidal core-shell micelles, with their size and inner structure depending on temperature and the pH value. For the triblock terpolymers, the micellar structures depend strongly on the block lengths.

CPP 46.27 Thu 9:30 P5

Pump-probe spectroscopy on the polyelectrolyte donor polymer PTHS for solar cell applications — •Mick Gindorf[1], Anna Köhler[1], Christopher Vogt[2], and Johannes C. Brendel[2] — [1]Chair of Soft Matter Optoelectronics, University of Bayreuth — [2]Chair of Macromolecular Chemistry I, University of Bayreuth

Poly(3-hexylthiophene) (P3HT) is a well-researched donor polymer for application in organic solar cells (OSCs). Side chain modification of P3HT with sulfonate groups yields PTHS, a polyelectrolytic donor polymer with high hole transport mobility [1]. This polyelectrolyte possesses two key advantages: Firstly, exchange of the cationic counter ions enables insolubilization of the donor layer, allowing simple fabrication of donor-acceptor bilayer systems by sequential spin coating with a wide variety of acceptors, including both fullerene and non-fullerene acceptors (NFAs). Secondly, adjusting the counter ion composition enables tuning of the donor energy level and thereby the donor-acceptor energy level offset (E_{off}), which is critical for achieving high open circuit voltages (V_{oc}). These properties make PTHS an ideal model system for the investigation of exciton dissociation in OSCs with spectroscopic techniques, including time-resolved transient absorption spectroscopy. Probing the exciton dissociation dynamics as a function of E_{off} on a picosecond timescale in different donor-acceptor systems yields valuable insights into the energetic and entropic contributions that help overcome the exciton binding energy in OSCs.

CPP 46.28 Thu 9:30 P5

PEDOT Molecular Imprinting in PEDOT:PSS/PDADMA Layer-by-Layer Films — •Martin Hunger, Muhammad Khurram, and Christiane A. Helm — martin.hunger@uni-greifswald.de

PPEDOT:PSS films are widely used because they offer high conductivity & tunable electro-optical properties. We prepare PEDOT:PSS films with a thickness of up to 150 nm using Layer-by-Layer assembly. We vary the preparation conditions: flow cell, dip coating, PEDOT:PSS concentration in solution, and rinsing steps. Whenever PDADMA is the top layer, UV-vis-IR absorption spectroscopy

shows that there is significantly less PEDOT in the films than when PEDOT:PSS is the top layer. Films prepared using the flow cell have the highest electrical conductivity (approx. 200 kS/m) with PEDOT:PSS. When PEDOT is the top layer, conductivity is reduced by a factor of 100. The conductivity of films prepared with dip coating with PEDOT:PSS as the top layer is one order of magnitude lower or more. When PDADMA is the top layer, conductivity drops by an additional 4 to 5 orders of magnitude. Thus, during assembly, PEDOT can be selectively removed and subsequently rebound to the film, leaving behind well-defined molecular cavities that preserve their shape and enable reconstruction of percolative pathways.

CPP 46.29 Thu 9:30 P5

PDADMA/PSS Multilayer Buildup in NaBr Solution: Vertical PSS Diffusion and Unusual Growth — •Per-Ole Hilken, Issam Assi, and Christiane A. Helm — Institute of Physics, University of Greifswald, Germany

Polyelectrolyte multilayers form by sequential adsorption of oppositely charged polyelectrolytes. The interfaces between the adsorption layers are fuzzy; in the exponential growth regime of PDADMA/PSS (poly(diallyldimethylammonium)/polystyrene sulfonate) multilayers PSS diffuses vertically through the film. We determine its vertical diffusion coefficient D_{PSS} using a quartz crystal microbalance with dissipation (QCM-D). The scaling laws for D_{PSS} in dependence of the NaBr concentration are similar to those found with NaCl in the deposition solution (Sill et al., Macromolecules 2025), however, the diffusion coefficient is one to two orders of magnitude larger. The dependence on PSS molecular weight M_{PSS} is qualitatively the same as with NaCl in the deposition solution: Polymer diffusion dominates multilayer build-up when $M_{PSS} < 76$ kDa.; at larger M_{PSS}, site diffusion dominates; i.e. diffusion of charged repeat units with their counterions. For polyelectrolyte multilayers in the non-exponential growth regimes it is well known and also found with that an increase in the salt concentration leads to thicker multilayers. This is not the case if the NaBr concentration exceeds ≈ 0.6 M; additionally, film stability becomes an issue. To understand the unusual behavior, the dissipation during film build-up is quantified. The surface topography is investigated with AFM.

CPP 46.30 Thu 9:30 P5

Structural influences on nonlinear optical activity in the heterocubane family — •Alexander Kapp and Simone Sanna — alexander.kapp@pysik.uni-giessen.de

Recent progress in the study of molecular clusters with extreme nonlinear optical response has highlighted their potential for coherent broadband light generation. To extend the library of suitable candidate materials, we investigate the linear and nonlinear optical properties of a family of heterocubanes with the general formula $[(RM)_4Pn_4]$, where M = C, Si, Ge, Sn, Pn = N, P, As, Sb, Bi, and R = H, Me, Ph. Using *ab initio* density functional theory, we analyze their structural and electronic characteristics, including optimized geometries, symmetry features, band gaps on different theoretical levels and shape of the HOMO–LUMO orbitals. Both the linear and the nonlinear (SHG) optical responses of all systems are computed using the Yambo code. Clear trends emerge that link the optical activity to the choice of pnictogen, tetrel, and substituent. These findings help identify promising candidates for nonlinear optical applications and contribute to a deeper understanding of structure–property relations in heterocubane materials.

CPP 46.31 Thu 9:30 P5

A micellar solution from thermoresponsive block copolymers during pressure jumps — •Yandong Wang[1], Geethu P. Meledam[1], Leonardo Chiappisi[2], Cristiane Henschel[3], André Laschewsky[3,4], Alfons Schulte[5], and Christine M. Papadakis[1] — [1]TUM School of Natural Sciences, Soft Matter Physics Group, Garching, Germany — [2]ILL, Grenoble, France — [3]Universität Potsdam, Germany — [4]Fraunhofer IAP, Potsdam-Golm, Germany — [5]University of Central Florida, Orlando, U.S.A.

The diblock copolymer PMMA-b-PNIPAM, consisting of a hydrophobic poly(methyl methacrylate) and a thermoresponsive poly(N-isopropylacrylamide) block, forms core-shell micelles in dilute aqueous solution at atmospheric temperature. These micelles aggregate upon heating or applying pressure. Previous studies have shown that the micellar shell remains hydrated in the two-phase region under high pressure, in contrast to the strongly dehydrated micelles observed in the two-phase region at atmospheric pressure [1]. In this work, we analyzed the micellar transition kinetics during rapid pressure jumps using time-resolved small-angle neutron scattering (SANS). The system was driven from the one-phase region into the two-phase region at target pressures in both low- and high-pressure regimes.

CPP 46.32 Thu 9:30 P5

Photoresponsive Interfacial Behavior of Hybrid Photosensitizer-Surfactant Mixtures — •Phat Tan Pham[1], Julius Gemen[2], Frank Glorius[2], and Björn Braunschweig[1] — [1]Universität Münster, Institut für Physikalische Chemie, Corrensstr. 28/30, 48149 Münster — [2]University of Münster, Organisch-Chemisches Institut, Corrensstraße 40, 48149 Münster

Fluid interfaces that adapt to external triggers such as light or temperature are of great interest for driving changes in soft matter systems like foams and emulsions. Arylazopyrazoles (AAPs), as photo-responsive surfactants, can control surface tension and molecular organization at air-water interfaces through E/Z photoisomerization. However, light-induced switching of AAP derivatives is typically limited to UV and green light. To overcome this, we combined AAP with the water-soluble photosensitizer resazurin (Rez) and achieved pronounced interfacial changes under 625 nm red-light irradiation. By tuning the AAP/Rez molar ratio, we further introduced history-dependent, quasi-adaptive changes in surface tension and molecular structure. The latter was examined in situ with surface tensiometry and vibrational sum-frequency generation (SFG) when the samples where irradiated at 365, 520, or 625 nm. We propose that red-light activation occurs at the interface, through photoexcited Rez moieties at 625 nm and subsequent intersystem crossing to adjacent interfacial AAP molecules. These results demonstrate a new strategy to extend the optical control of photo-responsive surfactants into the red-light region.

CPP 46.33 Thu 9:30 P5

Thermoresponsive Microgel Membrane for applications in an Electrochemical Device — •Aditi Gujare[1], Stefanie Uredat[2], Jonas Runge[2], Domenico Truzzolillo[1], Julian Oberdisse[1], and Thomas Hellweg[2] — [1]Soft Matter Physics Team, Laboratoire Charles Coulomb, University of Montpellier, Montpellier, France — [2]Physical and Biophysical Chemistry, Bielefeld University, Bielefeld, Germany

Microgels based on NIPAM are thermoresponsive with a volume phase transition temperature (VPTT) of 33°C. The VPTT has been observed to shift by copolymerizing these microgels with comonomers such as N-hydroxymethyl acrylamide (HMAM).[1] Different sets of copolymers have been tested, NIPAM-co-HMAM and NIPMAM-co-HMAM. These microgels have been observed to have a VPTT up to 60°C. The copolymer microgels based on the comonomer HMAM has an alcohol group, making it prone to condensation at high temperatures (above 90°C) resulting in formation of a membrane. These thermoresponsive, chemically crosslinked membranes have been prepared by dropcasting and crosslinking at 100°C. Such membranes can be prepared in a range of thickness, of 30-800 μm. The resistance of these membranes of different thickness, comonomer content, and at different temperatures are being tested. Resistance measurements at room temperatures show that thicker membranes are more resistive in a certain concentration of an electrolyte. Correlating molecular properties of tetraphenylethylene substituted tetraphenyl heteoadamantanes to nonlinear optical activity — •Eva Westenfelder Gil and Simone Sanna — Institut für Theoretische Physik, Justus-Liebig-Universität Gießen, Germany

Recent studies have demonstrated white light generation from molecular clusters with adamantane-like cores and various substituents [1,2]. Subsequent investigations on isolated molecules revealed correlations of the structural, electronic and optical properties [3]. Building on this foundation, we focus here on further investigating structural, electronic, and (nonlinear) optical properties from first principles for isolated molecules with modified cores. In this contribution, we report on $[(PhSn)_3(TPESi)S_6]$ and $[(PhSn)_3(TPESi)Se_6]$ clusters, which are modeled within density functional theory. Distinct changes in the spectral signatures can be observed. The presented results expand on theoretical foundations for the design of tailored nonlinear optical sources.

Modeling Structural and Electronic Properties of Functional Organic Molecules — •Linda Düren and Simone Sanna — Institut für Theoretische Physik, Justus-Liebig-Universität Gießen, Germany

In this work, various organic molecules with the general composition $[(RT)_4E_6]$ are investigated using density functional theory (DFT) to model their structural, electronic, and optical properties. Ground-state geometries and energies, as well as the frequency-dependent optical parameters, are calculated for the isolated clusters. The study includes *tetraphenyladamantane* and its halogenated derivatives, as well as other heteroadamantanes with a heterogeneous ligand field of the type $(MeC)(CH_2)_3(PhSn)E_3$ with E = S, Se, Te, CH_2.

The theoretical results provide insights into the relationship between molecular structure and optical behavior, building on previous studies of nonlinear optical responses in organotetrel and (hetero)adamantane-type clusters [1] and amorphous molecular materials for directed supercontinuum generation [2]. The results are compared with experimental data where available and demonstrate the potential of these classes of molecules for applications in optics.

CPP 46.36 Thu 9:30 P5

Tuning PNIPAM Phase Transition and Interfacial Structures — •Zugeng Cong, Michael Hardt, and Björn Braunschweig — University of Münster, Institute of Physical Chemistry, Münster, Germany

In this work, we aim to introduce the concept of a self-regulating negative-feedback system in which an exothermic photochemical process would be coupled to the thermo-responsive polymer PNIPAM. In such a scheme, reaction-generated heat would raise the solution temperature, trigger PNIPAM collapse, increase turbidity, and thereby limit light penetration—providing an intrinsic mechanism to suppress further heat generation. For that, we characterize the PNIPAM phase transition through temperature-dependent turbidity measurements while varying SDS and NaCl concentrations as well as the water-ethanol co-solvent composition. To elucidate interfacial contributions, surface-specific sum-frequency generation (SFG) spectroscopy is used to probe adsorption layers at the air-water interface, taken as a model for micellar environments. These measurements reveal how surfactant loading, solvent composition, and electrolyte concentration reorganize interfacial structures below and above the PNIPAM phase-transition temperature. This provides the physicochemical basis required for designing a feedback-controlled photochemical soft matter system.

CPP 46.37 Thu 9:30 P5

Quasi-elastic neutron scattering of perdeuterated poly(N-isopropylacrylamide) and hydration changes across the demixing transition — •Alfons Schulte[1], Eric Rende[1], Marcell Wolf[2], Thomas Müller[3], Dirk Schanzenbach[4], Andre Laschewsky[4,5], and Christine M. Papadakis[6] — [1]Department of Physics and College of Optics and Photonics, University of Central Florida, Orlando, U.S.A. — [2]Heinz Maier-Leibnitz Zentrum (MLZ), TUM, Garching, Germany — [3]FZ Jülich, JCNS at MLZ, Garching, Germany — [4]Institut für Chemie, Universität Potsdam, Potsdam-Golm, Germany — [5]Fraunhofer-Institut für Angewandte Polymerforschung, Potsdam-Golm, Germany — [6]TUM School of Natural Sciences, Soft Matter Physics Group, Garching, Germany

We investigate the hydration dynamics of perdeuterated poly(N- isopropylacrylamide) (PNIPAM-d10) to elucidate the molecular mechanism of its demixing transition. Quasi-elastic neutron scattering (QENS) and Raman spectroscopy were measured in a 25 wt% PNIPAM-d10 aqueous solution over the temperature range from 298 to 325 K. There is a significant upward shift in the cloud point by about 4 degrees. Deuteration suppresses incoherent scattering from the polymer, allowing a clear view of hydration water dynamics. The dynamic susceptibilities reveal the relaxation processes for bulk and bound water, with the bound fraction decreasing sharply near the transition. The relaxation times of hydration water are consistently lower than in the protiated polymer, indicating faster local dynamics. Raman spectra show abrupt C-D band frequency shifts at the transition, reflecting side-group dehydration.

CPP 46.38 Thu 9:30 P5

Thermoresponsive Microgels with hydrophilic Monomers — •Stefanie Uredat[1], Aditi Gujare[2], Jonas Runge[1], Domenico Truzzolillo[2], Julian Oberdisse[2], and Thomas Hellweg[1] — [1]Physical and Biophysical Chemistry, University Bielefeld, Bielefeld, Germany — [2]Laboratoire Charles Coulomb (L2C), University of Montpellier, CNRS, Montpellier, France.

To develop fully smart membranes for use in low-temperature fuel cells operating at around 80-90 °C it is essential to achieve a high volume phase transition temperature (VPTT) within this range. To reach these high VPTTs, new monomers are required for microgel synthesis. The most common and researched monomers have a VPTT around the human body temperature [1]. To rise the VPTT we increased the hydrophilicity of the monomers by adding a hydroxy group to the well-known NIPAM and got HIPAM (N-(2-hydroxyisopropyl)acrylamide).

To tune the VPTT to higher Temperatures a series of microgels with two different main monomers (NIPAM and NIPMAM) with different contents of HIPAM as comonomer were synthesised. The microgels were observed by Dynamic Light Scattering and AFM. With higher HIPAM content the VPTT of the microgels increases and widens. We also observe a jump in size with increasing hydrophilic monomer content. We also investigated a second hydrophilic monomer N-(hydroxymethyl)acrylamide (HMAM). [2]

Steel Mesh-Supported SNW-1/CsPbBr3 Nanocomposite: Photocatalyst for Sustainable Ammonia Production — •Negin Khosroshahi and Vahid Safarifard — Iran University of Science and Technology, Tehran 16846-13114, Iran

The conversion of solar energy into chemical energy through photocatalysis is an important field of interest in green energy generation and environmental improvement [1]. Nevertheless, its effectiveness currently falls short of expectations, primarily due to the issue of charge recombination. To address this challenge, the photocatalytic effect has become an optimistic approach for enhancing processes [2]. In this research, we have developed a Steel Mesh-Supported SNW-1/CsPbBr3 nanocomposite by combining covalent-organic frameworks with metal halide perovskite. To gauge their effectiveness, the heterostructure was assessed by employing multiple characterization methods including XRD, IR, FESEM, DRS, EDX, VSM, PL, EIS, Zeta, and BET. After the composite's preparation and characterization, we examined its photocatalytic activity in nitrogen reduction. The SNW-1/MHP/Steel mesh nanocomposite exhibited exceptional performance in ammonia generation. These findings suggest that the SNW-1/MHP/Steel mesh nanocomposite holds promise as an environmentally friendly and cost-effective photocatalyst, capable of addressing the challenges of sustainable ammonia production. This study presents a promising method for identifying effective photocatalytic materials using mesh substrates to address environmental concerns.

CPP 46.41 Thu 9:30 P5

Engineering MOF@MOF Heterojunction for Photocatalytic N2 Reduction to NH3 — •Maedeh Atoufi Kashani, Negin Khosroshahi, and Vahid Safarifard — Iran university of science and technology, Tehran, Iran

Photocatalytic nitrogen fixation is a promising green alternative to the Haber-Bosch process, but cobalt-based MOFs typically suffer from poor stability in water. Here, two Co-terephthalate frameworks were synthesized via solvothermal routes: MOF-71 from Co(NO3)3.6H2O and ultrathin Co-BDC nanosheets from CoCl2.6H2O in the presence of triethylamine, water, and ethanol. Both materials showed high phase purity and strong visible-light absorption. To improve the limited stability of Co-BDC, a Ce-based MOF overlayer was constructed on Co-BDC and MOF-71, forming a Ce-Co MOF-on-MOF composite. The Ce shell enhanced water stability, facilitated charge separation, and promoted N2 activation at the heterointerface. As a result, the Ce-Co-BDC composite delivered markedly higher ammonia production and durability than pristine Co-BDC. This work highlights the critical roles of precursor chemistry and Ce-Co interfacial engineering in developing robust MOF photocatalysts for solar-driven nitrogen fixation. [1] S. Nabi, M.M. Bhat, A. Hamid, A.Y. Bhat, A.U. Bashir, Q. Jan, P.P. Ingole, M. Bayati, M.A.J.A.S.S. Bhat, (2025) e00112. [2] G. Song, Y. Shi, B. Yang, Y. Yang, H.J.I.C. Pang, 64 (2025) 6265-6274.

CPP 46.42 Thu 9:30 P5

Structural Insights into Supported Ionic Liquid Phases — •Yufei Wu[1], Julius Schlüter[2], Chandan K. Das[3], Zhuo Chen[1], Alexis Bordet[1], Maria Fyta[3], and Thomas Wiegand[1,2] — [1]Max Planck Institute for Chemical Energy Conversion, Mulheim an der Ruhr, Germany — [2]Institute of Technical and Macromolecular Chemistry, RWTH Aachen University, Aachen, Germany — [3]Computational Biotechnology, RWTH Aachen University, Aachen, Germany

Metal nanoparticles supported on molecularly modified surfaces (MMSs) offer significant potential for the development of advanced materials chemistry, particularly in catalysis. In this work, we focus on supported ionic liquid phases (SILPs) as a representative class of MMS materials. The SILP material was synthesized by functionalizing an amorphous silica surface with a layer of phosphonium-based ionic liquid (IL) covalently bound to the silica. The structural features of the SILP, specifically the conformation of the phosphonium IL cations, were characterized using magic-angle spinning (MAS) solid-state NMR spectroscopy. To complement the experimental findings, all-atom molecular dynamics (MD) simulations were performed on IL-modified silica surfaces. These simulations provided atomic-level insights into the structural organization and conformational dynamics of the IL molecules in the SILP materials. This combined approach paves the groundwork for future studies aimed at realizing SILP materials as efficient catalytic templates.

CPP 46.43 Thu 9:30 P5

Towards stable passivation layers on III-V-semiconductor nanowires for photoelectrochemical water splitting applications — •Chris Yannic Bohlemann, Pavithira Manoharan, Sahar Shekarabi, Peter Kleinschmidt, Thomas Hannappel, and Juliane Koch — Technische Universität Ilmenau, Fundermentals of Energy Materials, Ilmenau, Germany

The production of green hydrogen is expected to play a crucial role in achieving a sustainable, climate-neutral economy. Although III-V semiconductors offer record solar-to-hydrogen conversion efficiencies, the large-scale deployment is limited by the scarcity of the required materials. III-V nanowires (NWs) are a promising approach, as they require less material than planar films, and exhibit an enhanced optical absorption, as well as benefit from a high surface-to-volume ratio [1].

However, the instability of III-V materials in aqueous electrolytes leads to rapid corrosion and short lifetimes of photoelectrodes. To address this limitation, we investigated the growth behavior, electrical properties, and corrosion stability of GaAsP NWs and subsequently passivated with GaP(N) shells grown via metal-organic vapor-phase epitaxy. Scanning electron microscopy was used to examine the growth quality, crystal orientation, defect structures, and degradation before and after extended operation under water splitting conditions. Our results demonstrate that the application of a GaP(N) passivation layer significantly enhances the structural integrity and durability of the NWs during continuous photoelectrochemical water splitting.

CPP 46.44 Thu 9:30 P5

A Bottom-Up Coarse-Grained Model of Nanoparticles Decorated with Oppositely Solvent-Responsive Diblock Copolymers for Reversible Self-Assembly — •Daniel Otschkowski and Arash Nikoubashman — Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany

Polymer-grafted nanoparticles (PGNPs) combine the optical, magnetic, or electronic functionality of inorganic cores with the elasticity and responsiveness of polymer chains. This hybrid character offers multiple, orthogonal design parameters for controlling the structure and properties of PGNP-based materials. In this work, we study spherical NPs grafted with amphiphilic diblock copolymers composed of two blocks with opposing solvent affinities, enabling reversible transitions between assembly and disassembly states. In the assembly state, the inner polymer block is solvophilic while the outer block is solvophobic, thus collapsing into attractive patches; in the disassembly state, the inner block forms a dense polymer shell which is surrounded by a stabilizing hydrophilic polymer corona. To access device-relevant time and length scales, we develop a bottom-up coarse-grained (CG) model, where we describe the PGNPs in the assembly state as particles with flexible, spring-tethered patches. Smoothly varying the effective interactions allow the CG model to reproduce the continuous transition between both states. This approach enables efficient simulation of large PGNP systems and provides insight into their reversible, stimuli-responsive behavior.

CPP 46.45 Thu 9:30 P5

Organic cathodes based on polyaniline and cellulose for aqueous Zn-ion batteries — •Ramsha Wasi Khan[1], Meriem Boudjenane[1], Gilles Wittmann[1], Xaver Brehms[2], Simon Schraad[3], Xinyu Jiang[3], Stephan V. Roth[3], and Lucas P. Kreuzer[1] — [1]Heinz Maier Leibnitz Zentrum (MLZ), TUM, Garching, Germany — [2]CEA, Grenoble, France — [3]DESY, Hamburg, Germany

Aqueous zinc-ion batteries are promising candidates for a non-toxic and safer alternative to lithium-ion batteries, where organic cathodes provide distinct advantages of sustainability, tunability and mechanical flexibility. In this work, we investigate the role of polyaniline (PANI) as an organic cathode material, motivated by its high theoretical capacity, reversible redox chemistry, and intrinsic electrical conductivity. To enhance stability against humidity-induced degradation, cellulose derivatives are employed as green binders, enabling regulation of water uptake and improved mechanical stability. Comprehensive multiscale characterization is conducted to optimize the electrochemical performance and structural integrity of PANI-based cathodes, as well as understand the morphological changes and nanoscale water dynamics under humidity. Advanced techniques such as cyclic voltammetry, scanning electron microscopy (SEM), and quasi-elastic neutron scattering (QENS) are used to support this analysis. It was observed that the use of composite cellulose films as a binder with an optimized composition effectively triples the current density and improves peak reproducibility as well as the water uptake behaviour of the film.

CPP 46.46 Thu 9:30 P5

Integration of Ag_2S nanocrystals into flexible polymer matrices — •Dolores García de Viedma Guerra, Peijiang Wang, and Beatriz Hernández Juárez — Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), Madrid E-28049, Spain

A broad range of modern optical technologies, for instance flexible photonics, require luminophores to be embedded within mechanically versatile host materials [1]. Usually, transferring nanocrystals from colloidal dispersions into polymer networks alters their physicochemical environment, which promotes surface traps and can thus signify a loss in photoluminescence [2].

In this work we investigate Ag_2S nanocrystals integrated into flexible polymer matrices with the goal of preserving their NIR response. We assess nanocrystal dispersion and spatial homogeneity, and probe their optical performance under 808 nm laser excitation via photoluminescence measurements and infrared spectroscopy, while NIR imaging maps emission uniformity. The results yield bright, uniform nanocrystal-polymer composites suitable for optoelectronic integration.

Exploring the length limit for freestanding electrodeposited Ni nanowires — •Anneliese Wirth and Karin Leistner — Chemnitz University of Technology, Chemnitz 09107, Germany

Magnetic nanowire arrays are of interest from a fundamental and application point of view due to the shape anisotropy and high surface-to-volume ratio. This can be advantageous for 3D memory devices, micro-hard magnets and catalysis. The goal of this project is to obtain freestanding Ni nanowire arrays in order to functionalize their surface and possibly apply electrolytic gating strategies for 3D magneto-ionic materials in the future.[1] The Ni nanowire synthesis is performed by electrodepositing Ni into aluminum oxide membranes that serve as templates. Afterwards, the template is removed via dissolution of the aluminum oxide to achieve freestanding nanowires. For nanowires with high aspect ratio, this step usually leads to the collapse of the wires into agglomerated bundles.[2] This causes the loss of the nanowires' perpendicular alignment to the substrate. We show an optimized synthesis that avoids the collapse of nanowires with high aspect ratio in a large-scale array with a total size of around 0.5 cm^2. The deposition time during the electrodeposition is varied to obtain nanowires reaching up to more than 10 μm length while the diameter is fixed to 200 nm. Scanning electron microscopy indicates that the freestanding nature is related to irregularities of the nanowires which are introduced by the specific template geometry and lead to the stabilization of the array. CPP 46.48 Thu 9:30 P5

Structure and Morphology Investigations of Perovskite Nanocrystal Film — •Azam Davoodabadifarahani[1,2], Thomas Baier[1], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]University of Applied Sciences, Munich, Germany

In recent years, perovskite quantum dot solar cells with the ABX3 structure have shown great promise due to their high power conversion efficiency (PCE), high photoluminescence quantum yield (PLQY) and narrow photoluminescence (PL) peak. Within the presented work, the active layer consists of PQD thin films based on CsPbI3 and FAPbI3, which exhibit high photoelectric performance. However, CsPbI3 has a challenge with phase instability and FAPbI3 suffers from weak structural stability. To balance the performance and stability of the active layer, FAxCs1-xPbI3 PQDs are employed as the light-absorbing layer. The samples are evaluated using various optical and structural characterization techniques, such as PL spectroscopy, scanning electron microscopy (SEM), X-ray diffraction (XRD) and grazing incidence x-ray scattering (GIXS) to observe the influence of the synthesis process, temperature, and deposition techniques on the crystal size, orientation, phase, and stability, all of which determine the external quantum efficiency and optical performance.

CPP 46.49 Thu 9:30 P5

Surface-induced morphology and in-plane order in thin films of polydiketopyrrolopyrroles — •Anton Sinner and Oleksandr Dolynchuk — Martin Luther University Halle-Wittenberg, Germany

Board-like conjugated polymers are of particular interest in the context of surface-induced ordering because they often exhibit a preferred out-of-plane molecular orientation in thin films. Recent studies of ordering in conjugated polymer films have found that the free surface induces the formation of sanidic liquid crystalline (LC) mesophases with out-of-plane, smectic-like positional order between polymer chains. However, the question of whether the surface influences the in-plane order between polymer chains during ordering remained open. Here, we use atomic force microscopy to investigate the surface morphology and nanoscale structure formed on the surface of polydiketopyrrolopyrrole (PDPP) films after slow cooling and ordering from the melt. We find that the surface morphology consists of disc-like crystallites with diameters roughly equivalent to the polymer contour length and heights equivalent to several out-of-plane polymer layers. Thus, the observed LC morphology is consistent with the earlier study of out-of-plane molecular order. On a larger scale, multiple LC discs arrange into string-like morphologies, suggesting the existence of orientational order among them. Quantitative analysis of the surface morphology allows for calculating a distance-dependent orientation correlation function for six-fold symmetry, which indicates the presence of quasi-long-range order on the surface of PDPP films.

CPP 46.50 Thu 9:30 P5

Investigation of structure and transport properties in redox-active polymers — •Laura Hölzer[1] and Diddo Diddens[2] — [1]Institut für Physikalische Chemie, Universität Münster, 48149 Münster, Germany — [2]Helmholtz Institute Münster, Forschungszentrum Jülich GmbH, 48149 Münster, Germany

Organic radical batteries are seen as an alternative to traditional lithium-ion batteries. Their advantages include fast charge and discharge processes, and mechanical flexibility. However, high power densities are required for their application in the Internet of Things. To achieve this, good charge transport is essential. This transport mechanism is guided by two factors: the movement of electrons along the polymer, which is dictated by its structure, and the compensation of charge by counterions, which affects their mobility. The focus here is on a cathode material consisting of a redox-active polymer such as poly(2,2,6,6-tetramethylpiperidinyloxy-4-ylmethacrylate) (PTMA), which is in contact with a solvent. Classical molecular dynamics simulations of a PTMA cathode model are carried out. These provide insights into the structural properties and dynamics of charge transport. An outlook on the behaviour at interfaces around the cathode is given.

CPP 46.51 Thu 9:30 P5

Ex-Situ Investigation of Latex Deformation — •Simon Schraad[1,2], Shuxian Xiong[1,2], Helder Marques Salvador[3], Benedikt Sochor[1], Sarathlal Koyiloth Vayalil[1,4], Peter Müller-Buschbaum[2], and Stephan V. Roth[1,5] — [1]DESY, Hamburg, Germany — [2]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [3]CPP, Venlo/Poing, Netherlands/Germany — [4]UPES, India — [5]KTH, Department of Fibre and Polymer Technology, Stockholm, Sweden

Colloidal polymer latexes are used in ink-jet printing to form a pigment stabilizing layer on top of the cellulose layer. The latex film formation (LFF) is influenced by humidity, temperature, minimum film formation temperature (MFFT), and glass transition temperature (T_g). Exceeding MFFT polymer colloids begin to deform and further heating above the T_g polymers interdiffuse and coalesce into a homogeneous coating layer. Here we investigate cellulose nanofibrils (CNF) thin films coated with polystyrene colloids (diameters ranging from 100 to 500 nm) and commercially available polymeric colloids with different MFFT (Neocryl A639 and A1127). The samples were prepared by spray coating at temperatures below and above their T_g. Scanning electron microscopy revealed the size and shape of the colloids. Grazing incidence small angle scattering data shows contributions of spherical form factors from the colloids with respective diameters, which changes upon heating. We present a design of an experimental spray chamber to allow in-situ GISAXS and the spectral reflectance during spray deposition of latex inks to be used at synchrotron facilities.

CPP 46.52 Thu 9:30 P5

A DFTB Pseudoatom-Based Fragmentation Strategy — •Kevin Mächtel — Karlsruher Institut für Technologie, Institut für Physikalische Chemie, Karlsruhe, Germany

Theoretical investigations of charge transport mechanisms in large molecular systems often rely on efficient fragmentation strategies, to reduce computational costs. In conventional approaches, link atom fragmentation has been used for this purpose, but pseudoatom approaches offer a more versatile alternative. They enable more efficient molecular fragmentation, simplifying the overall fragmentation process. In this study, we develop a novel density functional tight-binding pseudoatom fragmentation scheme for complex molecular systems. We tested our approach on 9,10-di(quinolin-6-yl)phenanthrene and demonstrated strong agreement with the established link atom method.

CPP 46.53 Thu 9:30 P5

Benchmarking the Transferability of Machine Learning Interatomic Potentials for Polymers — •Mirko Fischer and Andreas Heuer — Institute for Physical Chemistry, University of Münster, Corrensstraße 28/30, 48149 Münster

Machine Learning Interatomic Potentials (MLIPs) enable molecular dynamics (MD) simulations with nearly quantum-chemical (QM) accuracy and have been successfully applied to various molecular systems. However, their systematic application to polymer systems has not yet been explored. A key challenge arises from the large molecular size, which makes QM reference calculations for the training data computationally demanding. Moreover, relaxation processes and diffusive behavior in polymers require long simulation times, making a direct comparison between MLIP-based and *ab initio* MD simulations infeasible.

In this study, we first train Atomic Cluster Expansion (ACE) potentials for small oligomers on MD reference data, thereby circumventing the need for expensive QM reference simulations and enabling long, cost-efficient MD trajectories. We then benchmark the transferability of the trained ACE potentials to longer polymer chains with respect to density, structural, and dynamic properties. The insights gained allow us to identify an optimal oligomer chain length that balances training cost and transferability. Based on this, we can efficiently train a QM-accurate potential for polymers on QM reference data in a second step.

CPP 46.54 Thu 9:30 P5

Fourth-Generation High-Dimensional Neural Network Potentials for Molecular Chemistry in Solution — •Djamil A. A. Maouene[1,2], Moritz R. Schäffer[1,2], Moritz Gubler[3], Stefan Goedecker[3], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany — [3]Department Physik, Universität Basel, Switzerland

Machine learning potentials have become essential tools in chemistry and materials science, offering accurate, efficient representations of high-dimensional potential energy surfaces for atomistic simulations. Here we compare two generations of high-dimensional neural network potentials (HDNNPs) 2G-HDNNPs and 4G-HDNNPs in their ability to model organic molecules in aqueous solution. 2G-HDNNPs perform well for systems dominated by local interactions because they rely on descriptors of the immediate atomic environment. However, in cases of long-range charge transfer 4G-HDNNPs provide a more reliable description by explicitly accounting for charge redistribution in the system as a function of its global structure. We illustrate these differences for organic molecules in water.

CPP 46.55 Thu 9:30 P5

Controlling porosity in supraparticles: A simulation study using spherical and rod-shaped particles — •Kritika Kritika[1,2], Mayukh Kundu[3], Michael Howard[3], and Arash Nikoubashman[1,2] — [1]Leibniz Institute of Polymer Research Dresden, Germany — [2]Institute of Theoretical Physics, TU Dresden, Germany — [3]Department of Chemical Engineering, Auburn University, Auburn, USA

Supraparticles (SPs) are large assemblies of smaller colloidal particles, whose properties can be tuned by modifying, e.g., the chemistry, shape, and size of the individual constituent particles and their arrangement within the SP. SPs can be formed through droplet drying, a process commonly observed in both everyday life and industrial applications, such as spray drying and printing. Porous SPs are of particular interest, since their high surface area and tunable pore size distribution make them ideal materials for catalysis, photonics, and adsorption applications. In this computational study, we explore the drying-induced formation of SPs made from spherical and rod-shaped particles. After drying, we selectively remove one of the particle components, leaving behind a highly porous SP. The initial volume fraction between spherical and rod-shaped particles plays a key role in shaping the porosity within the SP, while increasing the aspect ratio of the rods further amplifies the porosity of the SPs. Additionally, we observed that slower drying leads to a distinct increase in average pore size.

CPP 46.56 Thu 9:30 P5

Demystifying the decoupling of conformation and phase behavior in PNIPAM cononsolvency — •Ved Mahajan and Nico F. A. van der Vegt — Department of Chemistry, Technical University of Darmstadt

Cononsolvency describes the situation in which a polymer becomes insoluble in a mixture of two individually good solvents. PNIPAM, a widely studied thermoresponsive polymer, exhibits a strong coupling between its temperature-driven coil-globule transition and its phase behavior at low methanol concentrations; however, these two responses decouple as the methanol content increases. In this work, we use a minimal physical model, a hydrophobic polymer in water-methanol mixtures, that reproduces these key experimental observations. Despite its simplicity, the model captures both the emergence of cononsolvency and the crossover from coupled to decoupled thermal responses. At low methanol concentration, the polymer conformation remains temperature dependent, whereas at high methanol concentration, it becomes insensitive to temperature. In contrast, hydrophobic aggregation consistently strengthens with increasing temperature. Together, these results reveal a simple mechanism for the observed decoupling: the differing temperature sensitivities of polymer collapse and hydrophobic aggregation, both rooted in the hydrophobic effect.

CPP 46.57 Thu 9:30 P5

Molecular insights into the anion-dependence of the double-layer capacitance — •Richard Schömig[1], Xuqiang Xu[2], Jana Zaumseil[2], and Alexander Schlaich[1] — [1]Institute for Physics of Functional Materials, Hamburg Technical University, Hamburg — [2]Institute for Physical Chemistry, Heidelberg Universiy, Heidelberg

Mixed ionic-electronic conductors are promising candidates for organic electrochemical transistors (OECTs). Single-walled carbon nanotubes (SWCNTs), a key example, show transconductance and capacitance responses that are strongly influenced by the properties of the surrounding electrolyte [1]. To uncover the mechanisms governing this behavior, we perform molecular dynamics simulations of aqueous electrolytes containing ions of different sizes and concentrations under varying applied potentials. As a simplified model for the more complex SWCNT electronic structure, we here use graphene as the electrode material. Employing atomistic constant-potential simulations, we investigate how these electrolyte characteristics shape the interfacial structure and differential capacitance. Analysis of the hydrogen-bond network and associated free-energy

changes highlights the central role of ion size in determining interfacial behavior.

CPP 46.58 Thu 9:30 P5

Computing static and dynamic structure in colloidal models for solutions of globular proteins — •Sven Köbler — Institute of Applied Physics, University of Tübingen, Tübingen, Germany

Crowded solutions of globular proteins are commonly probed using neutron and X-ray scattering to obtain static and dynamic structure factors across a broad range of concentrations. Complementary insight can be gained from Brownian dynamics simulations based on coarse-grained colloidal models; however, extracting meaningful scattering observables particularly dynamic structure factors which requires fast and scalable trajectory analysis tools. We present an efficient computational framework for calculating both static structure factors $S(q)$ and intermediate scattering functions $F(q,t)$ directly from simulation trajectories. Our tools are highly optimized and build with CUDA compatibility to exploit computing speeds of GPUs. Its performance is demonstrated using binary colloidal models designed to mimic mixtures of bovine serum albumin (BSA) and ferritin. The resulting simulated scattering functions are compared with experimental X-ray photon correlation spectroscopy data.

CPP 46.59 Thu 9:30 P5

Dynamic properties of telechelic polyisobutylene with sticker ends: atomistic vs. coarse-grained molecular dynamics simulation — •Anastasiia Pivovarova and Viktor Ivanov — Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany

Modeling associating polymer networks, such as telechelic polyisobutylene (PIB) with barbiturate stickers, requires not only constructing accurate coarse-grained (CG) interaction potentials but also resolving the inherent problem of accelerated dynamics. This challenge becomes evident when comparing Green-Kubo viscosity calculations across different levels of resolution. Atomistic simulations of PIB with barbiturate end groups reproduce the expected rheological behavior of associating systems, yielding a viscosity of about 3.32 Pa*s. In contrast, CG simulations performed for pure PIB used as an initial step toward a full CG description of the telechelic system show a pronounced reduction in viscosity, reflecting substantially faster dynamics intrinsic to coarse-graining. These observations illustrate how dynamical acceleration can dominate the predicted viscoelastic properties even when structural features are reproduced, underscoring the need for systematic strategies to recover realistic dynamical behavior in CG models of associating polymer networks.

CPP 46.60 Thu 9:30 P5

Density of states in monodisperse and polydisperse hard disks: Concentration dependent SAMC estimation — •Viktor Ivanov, Joram Heimbold, Malte Kautzsch, and Timur Shakirov — Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany

We propose a new variant of flat-histogram Monte Carlo, where the density of particles is the control parameter for the density of states and the visiting histogram. We simulate a system of point particles with zero diameter. The square of the minimal interparticle distance, r^2_{min}, is used as the control parameter for a macrostate. The density of states and the visiting histogram depend on r^2_{min} and are updated at each step of the algorithm according to the usual SAMC rules. For a microstate (particilar configuration of particles) with a given value of the minimal distance between particles r_{min} one can replace the points with the hard disks of the diameter r_{min} or smaller, which corresponds to a system with a specific particle density. We apply this algorithm to 2d systems of monodisperse and polydisperse hard disks (with diameter distributions $1/d^2$) and study the density driven crystallization transition. For monodisperse hard disks the transition from the liquid to the hexatic phase proceeds via a first-order like pseudo-phase transition, whereas the transition from the hexatic to the crystalline phase is continuous. With increasing polydispersity, crystallization is significantly suppressed, such that no transition to the crystalline phase is observed for a 10% variation in particle radii.

CPP 46.61 Thu 9:30 P5

Benchmarking bond dissociation energies with plane-wave pseudopotential and Gaussian all-electron methods — •Yue Pan[1], Jochen Heil[2], Ali Karimi[2], and Arash Mostofi[1] — [1]Imperial College London, South Kensington Campus, London, SW7 2AZ, UK — [2]Continental Reifen Deutschland GmbH, Hanover, Germany

Accurate homolytic bond dissociation energies (BDE) are important for understanding bond breaking processes in molecules. They are also frequently used to benchmark the accuracy of different method for electronic-structure calculations. Most calculations of BDE focus on datasets of small gas-phase molecules and, accordingly, are carried out with localised-orbital methods, while systematic comparisons to periodic plane-wave DFT remain scarce. This is relevant for modelling interfacial failure processes in hybrid systems such as polymer nanocomposites, in which molecules are attached to inorganic surfaces, and it becomes less clear which method is more suitable from the perspective of accuracy and efficiency.

In this work, we benchmark the performance of two widely used approaches for DFT calculations, namely the plane-wave basis pseudopotential methods and Gaussian all-electron methods. We use C*C bond dissociation in gas phase hydrocarbons and surface-anchored molecules. We then compare our calculated BDEs with theoretical results obtained from highly accurate quantum chemistry methods and experimental values. Our work represents a step towards a better understanding of bond breaking and interfacial failure in materials.

CPP 46.62 Thu 9:30 P5

Continuum Modeling of Light-Matter Interaction in Polymer-Based Hollow-Core Optical Fibers with Different Geometrical Configurations — •Zehra Gizem Mutlay and Mustafa Ordu — UNAM - National Nanotechnology Research Center and Institute of Materials Science and Nanotechnology, Bilkent University, Ankara 06800, Türkiye

Recent studies have demonstrated that nested hollow-core optical fibers (HCFs) can achieve attenuation below 0.1 dB/km while maintaining broad transmission bandwidths. This performance demonstrates the promise of air-guided waveguides as alternatives to conventional solid-core optical fibers. In this work, we perform continuum modeling based on the finite-element method to investigate light interaction with polymer in HCFs by implementing three- and four-tube cladding structures. The analysis involves designs with and without nested elements and supporting bars. Our comparative investigation includes silica- and polymer-based structures to identify how intrinsic material properties and geometrical parameters influence mode confinement, optical loss, and transmission behavior. The findings show that even minor changes in geometry or material composition significantly influence light propagation, which underlines the sensitivity of optical guidance to light-material interaction. This study establishes a continuum-based framework for analyzing electromagnetic behavior in polymer systems and lays the groundwork for developing 3D-printed polymer-based hollow-core fibers with reduced attenuation for future applications in optical and materials physics.

CPP 46.63 Thu 9:30 P5

General Polarization Dependent Dynamic Light Scattering Using the Dynamic Mueller Matrix — •Reinhard Sigel — Independent Scientist, Markdorf, Germany

The Mueller Matrix for a general description of the polarization transfer of an optical system is combined with Dynamic Light Scattering (DLS) [1]. Azzam's procedure [2] based on two rotated quarter wave plates is combined with photo correlation measurements to detect the Dynamic Mueller Matrix, which contains all possible polarization dependent correlation functions. The related Siegert relation is derived. Applications are dynamic ellipsometric light scattering [3] experiments on soft colloidal particles and 3D correlation ellipsometry [4] experiments on soft interfaces [5].

CPP 46.64 Thu 9:30 P5

Versatile X-Ray Reflector Extension Setup for Grazing-Incidence Experiments for Liquid Surface Study at the Beamline P03/PETRA III — •Jan Rubeck, Andrei Chumakov, and Matthias Schwartzkopf — DESY, Notkestr. 85, 22607 Hamburg, Germany

Existing beamlines for in situ GISAXS on liquids are either limited in angular range or incompatible with the large sample-detector distance required for submicron resolution. We present a low-cost, easily assembled beam-tilting extension for synchrotron-based ultra-small-angle X-ray scattering (USAXS) facilities, enabling grazing-incidence (GI-) and transmitted scattering (GIUSAXS, GTUSAXS) studies on liquid surfaces. The setup is compatible with standard USAXS beamlines and requires only 0.5 m of space at the sample stage. It allows X-ray beam incidence angles of up to 0.6° at the liquid surface, equal to twice the angle of incidence on a reflector and below its critical angle of reflector materials, and provides access to a q-range of approximately 0.003-0.5 nm^{-1}. The system was tested at P03 beamline (DESY) using polystyrene nanoparticles, self-assembled at the air/water interface. The proposed scheme enables selective depth profiling and expands the research capabilities of existing SAXS synchrotron facilities for in situ studying submicron nanostructured objects at liquid surfaces under GI-geometry, combined also with GIWAXS and TXRF techniques. https://doi.org/10.1107/S1600577525003431

CPP 46.65 Thu 9:30 P5

Hybrid field coupling in nanoscale infrared spectroscopic imaging of nanostructured soft matter — •Sharon Xavi[1], Mashiat Huq[1], Matthias Zeissberger[2], Daniela Täuber[1,2], and Christin David[1,3] — [1]Friedrich Schiller University Jena, 07743 Jena — [2]Leibniz Institute of Photonic Technology, 07745 Jena — [3]University of Applied Sciences, 84036 Landshut, Germany

Anisotropic intensity distributions are frequently observed on nanostructured surfaces in the emerging field of nanoscale infrared (IR) spectroscopic imaging methods, including mid-IR scattering scanning optical nearfield microscopy (IR-sSNOM) and methods combining mid-IR illumination with mechanical detection using atomic force microscopy (AFM-IR). Such methods bridge the gap between high-resolution structural imaging in electron and atomic force microscopy and chemical imaging in conventional far-field IR spectroscopy by overcoming the limitations of optical diffraction in far-field IR spectroscopic imaging. In the mid-IR spectral region, the hybrid field coupling of the incident field with a polymer nanosphere and a metallic AFM probe is nearly as strong as the plasmonic coupling in case of a gold nanosphere [Anindo et al., J. Phys. Chem. C, 2025, 129, 4517]. We modeled this hybrid field coupling on varied nanostructured surfaces to enhance the understanding of the observed anisotropies and contribute to the development of advanced applications of these methods [Ali et al. Anal. Chem., 2025, 97, 23914].

CPP 46.66 Thu 9:30 P5

Learn how to switch off: In-silico Modelling of Thermal Ring-closing Process in Spiropyran Derivatives — •Bowen Cheng, Robert Strothmann, Hendrik Heenen, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin, Germany

Spiropyran (SP) and its derivatives undergo a ring-opening reaction via UV radiation and a ring-closing reaction in thermal conditions, making them excellent candidates for photoswitches. One key aspect that governs the sensitivity of such photoswitches is the rate of the thermal ring-closing process. A main challenge in modelling this process is the existence of various thermally accessible conformers, leading to a complex reaction network.

In this study, we highlight a combined workflow using machine-learned interatomic potential (MLIP) and a microkinetics model (MKM) to address this. With a fine-tuned MACE-OFF24 foundation model, we predict different transition state energies within the reaction network using the nudge elastic band method, and correlate these energies to experimental observations using the MKM.

Our workflow can be migrated between different SP derivatives to reveal the effect of functional group decorations. Our findings demonstrate the potential of using MLIPs to predict transition states and enable larger-scale studies of complex reaction networks. We also aim to condense our workflow as a new descriptor for *in-silico* screening in future spiropyran photoswitch design.

CPP 47: Focus Session: Controlling Microparticles and Biological Cells by Ultrasound (joint session BP/CPP/DY)

Recently ultrasound has emerged as a very promising physical modality to control the behavior of microparticles and even of biological cells, which can be moved and stimulated by sound waves. For biological cells, one can further control the effect of sound through gene expression (sonogenetics), similar to the control by light (optogenetics). However, because the wavelength of sound is much larger than the one of light, one of the challenges is to localize the effect of sound waves, e.g. by using gas bubbles. Here, we bring together experimental and theoretical researchers who currently explore the potential of ultrasound to control active and passive microsystems and to develop new applications ranging from biomedicine to soft robotics.

Mechanogenetics for Cell ImmunoTherapy — •Yingxiao Wang — 1002 childs way, Los Angeles, CA 90089

Cell-based cancer immunotherapy is a promising therapeutic intervention for cancer treatment. However, non-specific toxicity against healthy tissues (e.g. off-tumor toxicity) is a major hurdle for solid tumor treatment. We have developed controllable on-switch gene cassettes in which a specific antigen production on the target cancer cell can be remotely and mechanically induced by an external focused ultrasound (FUS). FUS was applied to stimulate the production of the synthetic and clinically validated antigen on tumor cell surface orthogonal to the endogenous proteins. SynNotch was further engineered into primary human T cells (SynNotch-CAR T) to recognize the synthetic antigen expressed on the ultrasound-induced tumor cells and activate the production of CAR, which can lead to the recognition of a native tumor specific antigen (TSA) universally expressed on the whole population of tumor cells for immunotherapy. We applied this system to treat prostate cancer cells whose locally metastasized tumors are confined in space but intermingled with vessels and nerves. Our results showed that FUS can mechanically induce the synthetic antigen production in prostate cancer cells, which results in the engagement and activation of SynNotch CAR T cells for the tumor eradication. This local activation of engineered tumor cells by FUS should allow a high precision and safety in eradicating tumors. Hence, this approach for immunotherapy should open new opportunities to integrate engineering mechanics with genetic medicine for successful translation.

CPP 47.2 Thu 10:45 BAR/0106

Shaping sound to tickle cells — •Dimitris Missirlis[1,2], Athanasios Athanassiadis[1,2], Rom Lerner[1,2], and Peer Fischer[1,2] — [1]Institute for Molecular Systems Engineering and Advanced Materials, Im Neuenheimer Feld 225, 69120 Heidelberg, Germany — [2]Max Planck Institute for Medical Research, Jahnstr. 29, 69120, Heidelberg, Germany

The ability to shape ultrasonic waves precisely is finding growing relevance in biomedical applications, where ultrasound is increasingly used to noninvasively stimulate biological tissues for therapeutic purposes. However, it remains an unsolved question how high-frequency ultrasound can interact with cells to excite biological responses. Our recent work on shaping and controlling ultrasound waves has provided us with a new tool to address the fundamental question how ultrasound interacts with and influences cells. To this end we have developed adaptable setups where we can control relevant ultrasound parameters in vitro as well as in vivo. By systematically examining the critical parameters, we discuss the role of different ultrasonic effects, including thermal effects, radiation forces, and sound-induced shear flows. Further, we discuss both physical and sonogenetic methods that can be used to enhance the coupling of ultrasound to cells.

CPP 47.3 Thu 11:00 BAR/0106

A Theoretical Model for Ultrasound-Induced Intracellular Streaming — •Niels Gieseler[1,2,3], Falko Ziebert[1,2], and Ulrich S. Schwarz[1,2] — [1]Institute for Theoretical Physics, Heidelberg University, Philosophenweg 19, Heidelberg 69120 Germany — [2]BioQuant, Heidelberg University, im Neuenheimer Feld 267, Heidelberg 69120 Germany — [3]Max Planck Institute for Medical Research, Jahnstrasse 29, Heidelberg 69120, Germany

Ultrasound is not only the basis of an essential imaging method for biomedicine, recently it has also become a promising avenue to control biological systems, for example, in sonogenetics or ultrasound neuromodulation. However, the underlying physical effects are not well understood, and a complete theoretical description is missing. In fact, many different physical effects compete, including radiation forces, streaming, cavitation, and local heating. Here, we focus on intracellular streaming, which might induce organelle movement or alter gene expression, as the steady second-order rotational flow generated by an acoustic source. As a model for the viscoelastic nature of cells and their surroundings, we use Oldroyd-B fluids. Building on existing work, we calculate the streaming flows inside and outside of a sphere sonicated with a plane wave. The streaming is treated as a second-order perturbation expansion of the Navier-Stokes equations, which is solved separately for both media and combined using suitable boundary conditions. Our work shows under which conditions intracellular streaming can be induced in biological cells.

Recent theoretical progress on sound-propelled microsystems — •Raphael Wittkowski — Department of Physics, RWTH Aachen University, 52074 Aachen, Germany — DWI – Leibniz Institute for Interactive Materials, 52074 Aachen, Germany

The research area of sound-propelled microsystems is growing fast and has a great potential for various future applications in engineering, medicine, and other fields. The progress in this area is accelerated by theoretical methods, as analytical modeling and computer simulations can provide new insights that cannot be obtained by experiments.

In this talk, I will address the theoretical investigation of sound-propelled microsystems and present examples from the recent research progress in this area. The talk will cover different types of sound-propelled microsystems including microrobots, micromachines, artificial muscles, and soft robots.

CPP 47.5 Thu 12:00 BAR/0106

Rarefaction wave amplification from non-resonant deforming bubbles — Yuzhe Fan, Saber Izak Ghasemian, and •Claus-Dieter Ohl — Otto-von-Guericke University, Magdeburg, Germany

Gas bubbles in liquids or soft matter exposed to acoustic waves behave as oscillators, with maximum response at their resonance frequency. When driven below resonance at sufficient pressure amplitudes, bubbles can collapse with strong energy focusing and even emit light; when driven near resonance, surface instabilities and fast jet flow develop during oscillation. Like other oscillators, bubbles cease to respond when driven far above resonance. Although their oscillations are minimal, bubbles in this regime act as pressure-release interfaces, can reflect high peak pressure shock into rarefaction wave, and may therefore seed cavitation when interacting with high-power therapeutic ultrasound. Yet, here we show that even diagnostic ultrasound with peak positive pressures as low as ~10 MPa can nucleate cavitation in microseconds. This is caused through the non-resonant deformation of the bubble into a concave shape that refocuses scattered waves, amplifying the tension leading to microcavitation. Our findings reveal that cavitation can be triggered by high-frequency positive pressure over a much wider amplitude range than previously recognized, offering a new perspective for current safety guidelines for ultrasound bioeffects and applications in medical ultrasound.

CPP 47.6 Thu 12:15 BAR/0106

Optimizing acoustically propelled microrobots using genetic algorithms — •Lennart Gevers[1,2,3] and Raphael Wittkowski[1,2,3] — [1]Department of Physics, RWTH Aachen University, Aachen, Germany — [2]DWI – Leibniz Institute for Interactive Materials, Aachen, Germany — [3]Institute of Theoretical Physics, Center for Soft Nanoscience, University of Münster, Münster, Germany

The promising potential applications of acoustically propelled microparticles demand methods to create particle designs that allow for targeted autonomous motion. Current methods remain largely based on experiments due to the intricate nature of the underlying dynamics. Large-scale computational studies, specifically when combined with optimization algorithms, are impeded by the cost of traditional acoustofluidic simulations.

In this talk, we present the implementation of an analytical framework describing non-Brownian motion of colloidal molecules driven by acoustic streaming. The analytical framework is combined with vectorized, GPU-accelerated, and distributed computation. This enables fast, large-scale simulations, where 10^5 trajectories over 10 s real time can be simulated on a normal personal computer within one minute. Coupling this approach with genetic algorithms reveals particle geometries, control parameters, and underlying principles for acoustically propelled particles that exhibit controllable and stable behavior over long times.

Funded by the Deutsche Forschungsgemeinschaft (DFG) – 535275785.

CPP 47.7 Thu 12:30 BAR/0106

Equations of motion for arbitrarily shaped acoustically propelled rigid microparticles — •Justus Schnermann[1,2,3] and Raphael Wittkowski[1,2,3] — [1]Department of Physics, RWTH Aachen University, Aachen, Germany — [2]DWI – Leibniz Institute for Interactive Materials, Aachen, Germany — [3]Institute of Theoretical Physics, Center for Soft Nanoscience, University of Münster, Münster, Germany

Much experimental research concerns the acoustic propulsion of microparticles, but theoretically, only axisymmetric particles with a stable orientation have been studied thus far. In this talk, we present an analytical derivation of the ordinary differential equation of motion for an arbitrarily shaped acoustically propelled rigid microparticle. This equation governs the time evolution of the orientation and position of the particle. Its parameters depend only on the particle's leading-order oscillation velocity field. Based on this equation, we classify qualitatively the possible long-term trajectories of arbitrary particles in unidirectional ultrasound.

Funded by the Deutsche Forschungsgemeinschaft (DFG) – 535275785.

CPP 48: Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics VI

Simulating Light Induced Phase Separation in Mixed Halide Perovskites — •Sebastian Schwartzkopff, Ivan Zaluzhnyy, Ekatarina Kneschaurek, Paul Zimmermann, Dmitry Lapkin, Hans Mauser, Alexander Hinderhofer, and Frank Schreiber — University of Tübingen

By varying the halide composition in mixed organic-inorganic perovskites such as $MAPbBr_{1.8}I_{1.2}$ (MA-methylammonium), one can precisely tune the band gap. This is a desirable property for solar cell design, as it allows for the production of high efficiency solar cells. However, illumination with visible light drives these materials to phase-separate into Br-rich and I-rich domains, thereby degrading the tuned bandgap. To better understand and potentially control this behavior, we employ phenomenological approaches such as Cahn-Hilliard and Monte Carlo models. While Cahn-Hilliard methods were initially explored, they proved challenging in reproducing experimentally observed dynamics. On the other hand, Monte Carlo methods have shown themselves to enable a systematic exploration of how factors such as halide ratio, charge-carrier density, temperature, and illumination intensity influence light-induced phase separation. Overall, we found that Monte Carlo simulations, with appropriately chosen parameters, can successfully reproduce key features observed in experimental diffraction measurements.

CPP 48.2 Thu 11:45 ZEU/LICH

Reorientation-driven degradation in oriented perovskite films: shifting facet engineering to thermodynamic stability — •Xiaojing Ci[1], Xiongzhuo Jiang[1], Guangjiu Pan[1], Kun Sun[1], Altantulga Buyan-Arivjikh[1], Zerui Li[1], Lixing Li[1], Thomas Baier[1], Matthias Schwartzkopf[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]DESY, Hamburg

Hybrid perovskite solar cells suffer from underexplored links between crystallographic orientation and thermal stability. We fabricate highly oriented mixed Sn-Pb perovskite films via an additive-free two-step method. Accelerated aging studies under high temperature reveal that high orientation paradoxically compromises stability and PSCs built from highly oriented perovskite films retain only 73% of their initial PCE versus 89% in less-oriented devices. Operando GIWAXS of the PSCs shows that thermal stress induces significant reorientation and lattice distortion in the oriented crystallites. Structural analyses confirm progressive crystallographic transitions, including grain reconfiguration, shifts toward isotropy, and systematic diffraction migrations. Critically, we demonstrate that metastability is an intrinsic consequence of high crystallographic order, which is why the very high alignment strategies that enhance performance induce thermodynamic vulnerability. This necessitates redesigning crystal engineering priorities where suppressing instability requires engineering thermodynamic equilibrium states over maximizing alignment for stable perovskite photovoltaics.

CPP 48.3 Thu 12:00 ZEU/LICH

Understanding the molecular origins of giant surface potential: a case study of TPBi — •Mauricio Sevilla[1], Naomi Kinaret[1], Muhammad Nawaz Qaisrani[1,2], Albin Cakaj[4], Alexander Hofmann[4], Falk May[3], Wolfgang Brütting[1], and Denis Andrienko[4] — [1]Max Planck Institute for Polymer Research, Mainz, Germany — [2]Technische Universität Ilmenau, Ilmenau, Germany — [3]Merck Electronics KGaA, Darmstadt, Germany — [4]University of Augsburg, Augsburg, Germany

In the context of organic light-emitting diodes, the molecular orientation in thin layers of organic materials plays a crucial role in charge injection, light outcoupling, and the formation of internal electrostatic fields due to the alignment of molecular dipoles. This latter phenomenon is referred to as the giant surface potential (GSP). Predicting GSP soleley from the chemical structure is challenging, as it is highly sensitive to processing conditions such as temperature and deposition rate during the physical vapor deposition process. Using both all-atom and coarse-grained simulations, we develop and test a framework capable of predicting the molecular ordering of organic materials under varying substrate temperatures and deposition rates. The framework's accuracy is validated by comparing the predicted GSP and birefringence of thin films to experimentally measured values, for a series of TPBi isomers.

CPP 48.4 Thu 12:15 ZEU/LICH

Additives to enhance efficiency and stability of PPDT2FBT:PC60BM organic solar cells — •Hassan Ismail[1,2], Jose Prince Madalaimuthu[1,2], Ulrich Schubert[1,2], and Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldtstrasse 10, 07743 Jena, Germany — [2]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany

The development of organic solar cells (OSCs) requires simultaneous optimization of photovoltaic performance and long-term thermal stability, often mediated by processing solvents and additives. This study investigates the role of small amphiphilic molecules (AMs) as surfactants in stabilizing the bulk heterojunction morphology of PPDT2FBT:PCBM-based OSCs. Our research goal is to understand how the chemical nature of AMs and their interface engineering within the device affect stability and efficiency. We demonstrate that the AM's polar headgroup chemistry is a critical determinant for operational stability, and by strategically applying interface engineering across all major interfaces, we identify optimal scenarios for enhancing both efficiency and device durability. Interface engineering not only improves charge transport and mitigates degradation but also supports large-area fabrication and practical device reliability, addressing prominent challenges for commercialization. These findings guide future molecular design and interface engineering strategies, contributing to the realization of more robust and reliable organic solar cells.

CPP 48.5 Thu 12:30 ZEU/LICH

Controlling singlet fission in diketopyrrolopyrole diner through solvent choices — •Sruthy Asa Rajan[1,2], Isaac M. Etchells[3], Jegadesan Subbiah[2], Sergey Bagnich[1], Paul E. Shaw[3], David Jones[2], and Anna Köhler[1] — [1]Universität Bayreuth — [2]University of Melbourne — [3]University of queensland

The efficiency of conventional solar cells is constrained by the Shockley-Queisser limit, which is arises from thermalisation loss. Singlet fission (SF) offers a promising pathway to surpass this efficiency limit. However, a key challenge lies in identifying SF molecules with triplet energy levels that align with the silicon band gap, enabling the efficient formation of correlated triplet pairs, 1(TT), and their separation. PDPP is a molecule with a comparable triplet energy to the silicon bandgap. But monomer molecules are not SF active in solution. We prepared PDPP-dimers with a pyrene bridge. We investigate the influence of solvent properties on the optical behaviour of these N-alkylated pyrene-bridged PDPPs. We employ temperature-dependent steady-state and time-resolved photoluminescence studies on N-alkylated pyrene-bridged PDPPs in protic polar and aprotic polar solvents to study the optical properties of the evolution of different species. At an intermediate temperature, we observed an intermediate emission, which then, on further decreasing the temperature (less than 100K), is replaced by 1(TT) emission. We also measured TA on different solvents which showed different pathway. In protic polar solvent, our molecule showed intermolecular SF whereas in aprotic polar solvent it showed intermolecular

CPP 49: Gels, Polymer Networks and Elastomers I

Time: Thursday 11:30–12:45 Location: ZEU/0255

CPP 49.1 Thu 11:30 ZEU/0255

Nanoparticle–Polymer Coupling in Magnetic Gels Studied by Means of Computer Simulations and Experiments — •Rebecca Stephan[1], Surojit Ranoo[2,4], Patrick Kreissl[1], Chinmay Pabshettiwar[1], Jessica Kubis[2], Christian Holm[1], Annette M. Schmidt[2], Regine von Klitzing[3], and Rudolf Weeber[1] — [1]Institute for Computational Physics (ICP), Universität Stuttgart — [2]Institute of Physical Chemistry, Department of Chemistry, University of Cologne — [3]Institute for Condensed Matter Physics, Technical University of Darmstadt — [4]Laboratoire Colloïdes et Matériaux Divisés, ESPCI Paris

Magnetic gels - soft hydrogels with embedded magnetic nanoparticles (MNPs) - combine the viscoelastic properties of a gel with the magnetic behavior of the MNPs. Their response to an external magnetic field enables tunable mechanical and dynamic properties such as shape, stiffness, and swelling. The microscopic coupling mechanisms between the MNPs and the surrounding polymer matrix are crucial for the material's stimuli-responsive properties. However, these mechanisms are not yet fully understood.

In this work, we juxtapose results for PAAm hydrogels with embedded cobalt ferrite nanoparticles with coarse-grained molecular dynamics simulations coupled to lattice-Boltzmann hydrodynamics. In both cases, we probe the coupling using magnetic AC susceptibility spectra. Our findings demonstrate that the local polymer environment and the surface heterogeneity of the magnetic particles - chemical or topographical - play an important role in MNP-polymer coupling.

CPP 49.2 Thu 11:45 ZEU/0255

Strain-stiffening critical exponents of fibre networks under uni-axial deformation — •Atharva Pandit[1] and Abhinav Sharma[1,2] — [1]Institut für Physik, Universität Augsburg, 86159 Augsburg, Deutschland — [2]Bereich Theorie der Polymere, Leibniz-Institut für Polymerforschung, 01069 Dresden, Deutschland

Disordered fibre networks exhibit a floppy to rigid mechanical phase transition as a function of connectivity. Sub-isostatically connected networks can undergo this transition via straining. Critical exponents governing this transition have been estimated theoretically and by numerical simulations of various types of networks. We present improved results, achieved through a combination of refined numerical simulations, larger system sizes and incorporation of theoretical predictions for better post-simulation analysis. A linear evolution of the critical strain and critical exponents is observed as the network is sheared while being subjected to non-volume-preserving uni-axial deformations.

CPP 49.3 Thu 12:00 ZEU/0255

Probing Mechanical Properties of Magnetic Gels Using Computer Simulations — •Yashas Tejaskumar Gandhi, Christian Holm, and Rudolf Weeber — Institute For Computational Physics, University of Stuttgart, Germany

Magnetic gels are liquid swollen polymer networks embedded with magnetic nanoparticles (MNPs). Their motion, shape and mechanical properties can be governed by an external magnetic field. The mechanical properties of a magnetic gel depend on both the polymer network and the embedded MNPs. They can also be heated by applying an AC magnetic field due to viscous and hysteresis losses.

There are two ways to probe the mechanical properties of magnetic gels: at the nanoscopic level using AC susceptometry, and at the macroscopic level by measuring stress under deformation. While macroscopic measurements are relatively straightforward, they are computationally demanding. The Gemant-DiMarzio-Bishop theory provides a framework for connecting magnetic AC susceptibility data to nanoscale mechanical properties. Our objective is to test this theory in computer simulations by comparing nanoscale measurements with macroscale measurements.

The polymer network is modelled as a coarse-grained bead-spring system. We also incorporate a solvent model for hydrodynamic interactions in the system. Shear deformation is applied using periodic Lees-Edwards boundary conditions. Our simulations use the 'Extensible Simulation Package for Research on Soft Matter Systems (ESPResSo)' simulation package.

CPP 49.4 Thu 12:15 ZEU/0255

Dynamic control of rigidity via geometric frustration — •Santiago Gomez Melo[1,2], Falko Ziebert[1,2], and Ulrich S. Schwarz[1,2] — [1]ITP, Philosophenweg 19, Heidelberg — [2]BioQuant, Im Neuenheimer Feld 267, Heidelberg

Recent advances in materials design and 4D-printing now allow one to realize programmable metamaterials that upon receiving a suitable stimulus dynamically change their unconventional macroscopic properties. For mechanical metamaterial, these tunable features have so far been restricted to geometric quantities, such as the Poisson ratio and the strain-to-twist ratio, but the effective elastic moduli have not been addressed yet. Here we combine central force network theory and responsive hyperelasticity to show that it is also possible to dynamically control the elastic moduli, and more specifically the shear modulus, by programming geometric frustration into a stimuli-responsive structure. This phenomenon, known as geometric incompatibility, produces a rigidity phase transition in which the elastic modulus changes by several orders of magnitude. It results from inducing a state of self-stress that eliminates the floppy modes of the system by producing second-order rigidity. The underlying physical principle seems to be also at work in biological systems, most prominently in epithelial monolayers, but here it is predicted for entirely synthetic materials, like temperature-sensitive hydrogels and nematic elastomers, opening up the perspective of designing a new class of dynamic metamaterials.

CPP 49.5 Thu 12:30 ZEU/0255

Aqueous Foams stabilized by PNIPAM Microgels: Effect of Cross-linker and Concentration — •Joanne Zimmer, Kevin Gräff, Luca Mirau, and Regine von Klitzing — Soft Matter at Interfaces, Institute for Condensed Matter Physics, TU Darmstadt, Hochschulstraße 8, D-64289 Darmstadt

Aqueous foams are abundant in everyday life, important for industrial applications and interesting from a fundamental point of view. In this work, aqueous foams are generated by sparging gas (nitrogen) through an aqueous dispersion of PNIPAM microgels, which are used as foam stabilizers. The microgel cross-linker content as well as the microgel concentration are varied and prove to significantly influence the foam formation properties (foamability) and the foam stability. A lower cross-linker content as well as a higher microgel concentration elevate the foamability, generate foams with higher liquid content and smaller

bubbles and increase the foam stability. These observations are correlated with the microgel behaviour at the single air-water interface, i.e. pendant drop measurements and Langmuir trough. Our findings highlight good agreement across both length scales: an increase in foamability correlates with a faster decrease in surface tension, and a higher foam stability with a higher surface elastic modulus of a microgel-covered single air-water interface. The ability of the microgels to form a collective polymer network seems to dominate these processes.

CPP 50: Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates II (joint session CPP/BP)

Time: Thursday 11:30–12:45 Location: ZEU/0260

CPP 50.1 Thu 11:30 ZEU/0260

Exponential Size Control in Biomolecular Condensates via Universal Scaling of Power-Law Distributions — •Yifan Huang[1], Chuan Tang[1], Haoyu Song[2], Bing Miao[3], and Qiyun Tang[1,4] — [1]Key Laboratory of Quantum Materials and Devices of Ministry of Education, School of Physics, Southeast University, Nanjng 211189, China — [2]School of Physics, Zhejiang University, Hangzhou 310058, China — [3]Center of Materials Science and Optoelectronics Engineering, College of Materials Science and Opto-Electronic Technology, University of Chinese Academy of Sciences, Beijing 100049, China — [4]Jiangsu Physical Science Research Center, Nanjing 210093, China

Power-law distributions are ubiquitous phenomena in diverse systems, whereas concomitant scale invariance hinders the exploration of precise size control for biocondensates in recent experiments. Using massive computer simulations and the kinetic theory of coalescence, we demonstrate that the cutoff volume can collapse all power-law distributions of biocondensates in different parameters onto one master curve. Remarkably, the cutoff size can increase exponentially by increasing monomer concentrations $R \sim e^{\phi}$, of which nanometer condensates in simulations can be extrapolated to micrometer droplets in experiments. The findings provide a new mechanism to rapidly tailor the biocondensates to appropriate sizes through power-law distributions, which can stimulate explorations in biological and other nonequilibrium systems

CPP 50.2 Thu 11:45 ZEU/0260

Droplet-assisted folding of long regulatory RNAs — Simon Doll[1], Lukas Pekarek[1], Fathima Ferosh[1], Jovana Vasiljević[1], Marcus Jahnel[1], and •Tyler Harmon[2] — [1]BIOTEC, Dresden, Germany — [2]IPF, Dresden Germany

Long regulatory RNA regions orchestrate complex cellular processes, including gene expression and epigenetic modifications. How these RNAs dynamically fold and refold in response to cellular signals remains poorly understood. Given that RNAs interact with ubiquitous RNA-binding proteins (RBPs) prone to form biomolecular condensates, we explore how protein droplets interacting along an RNA impact its folding process. Attached droplets prevent premature folding by competing with RNA:RNA interactions. When droplets dissolve due to cellular signals, capillary effects cause the RNA to collapse while refolding. We test this process of condensate-guided RNA folding by adapting established RNA secondary structure predictors to mimic various folding pathways and supplement this with coarse-grained simulations. We find that interactions with transient droplets robustly leads to the formation of long-range RNA contacts, which are otherwise hard to achieve. Our results compare favorably with available experimental data. We propose that this strategy, which we call droplet-assisted RNA folding, represents a previously unexplored mechanism for shaping RNA structures. Given the widespread propensity of RBPs to form condensates, this process could play a fundamental role in the structural organization, conditional reshaping, and functional regulation of long regulatory RNAs.

CPP 50.3 Thu 12:00 ZEU/0260

Simulation Insights into the Assembly of Polyplexes for RNA Delivery — •Jonas Hans Lehnen[1], Jorge Moreno Herrero[3], Heinrich Haas[3], Friederike Schmid[1], and Giovanni Settanni[1,2] — [1]Department of Physics, Johannes-Gutenberg University Mainz — [2]Faculty of Physics and Astronomy, Ruhr University Bochum — [3]BioNTech SE, Mainz

RNA-based pharmaceuticals proved successful with the COVID-19 vaccines and are now undergoing clinical trials for a broad range of therapeutic indications. Lipid-based nanoparticles (LNPs) have been used so far as delivery systems, although alternatives are still needed to meet efficacy and safety requirements across a broader range of applications. Polyplexes, formed by the self-assembly of cationic polymers with the anionic nucleic acids, constitute a valuable substitute, especially if precise control of the number and shape of the encapsulated RNA chains is possible. Here[1], we use molecular dynamics simulations of a coarse-grained polyplex model to show that the most important factors controlling it are the charge ratio between polyelectrolytes and RNA and their concentration during assembly. Close to the isoelectric point, the polyplexes are large, whereas in large excess of cationic polymer, their size decreases, allowing one RNA copy per nanoparticle. Our results are consistent with recent experimental work on polyethylenimine polyplexes.

CPP 50.4 Thu 12:15 ZEU/0260

Polymer-assisted condensation as key to chromatin localization — •Arghya Majee[1] and Jens-Uwe Sommer[1,2,3] — [1]Leibniz Institute of Polymer Research Dresden, Germany — [2]Institute for Theoretical Physics, TU Dresden, Germany — [3]Cluster of Excellence Physics of Life, TU Dresden, Germany

We put forward a novel mechanism [1] to account for the experimentally observed [2] positional shifts of chromosomes within the cell nucleus, which appear to be driven by compositional alterations in the nuclear lamina. By considering chromatin as a biomolecular condensate we demonstrate that the adsorption of the chromatin-binding proteins at the lamina leads to a wetting of the condensate while spreading of the chromatin on the lamina is avoided. This leads to the non-monotonous density profile of the polymer with respect to the surface which can be explained by the competition between the tendency of the protein component to wet the surface and the conformational restrictions of the polymer near the impenetrable surface. A change in the composition of the the lamina can lead to repositioning of chromatin towards the center of the nucleus. Our theory not only offers an explanation for specific chromatin conformation experiments, but also contributes to the broader understanding of wetting onto responsive surfaces in multi-component systems.

CPP 50.5 Thu 12:30 ZEU/0260

Bridging Scales to Understand the Role of Ubiquitylation and Sumoylation in Protein Phase Separation — •Supriyo Naskar, Kurt Kremer, and Oleksandra Kukharenko — Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany

The post-translational modifiers, such as mono- and poly-ubiquitins and SUMOs, are known for their ability to modulate protein-protein interactions by becoming covalently attached to other target proteins. Despite the high similarity in the tertiary structure and sequence, they differentially influence the target protein properties. In this work, we employed a multiscale simulation approach that encompasses atomistic to different levels of coarse-grained modeling techniques, combined with data-driven methods, to explore the structural differences and multidimensional energy landscapes of ubiquitin, SUMO, and their conjugates. We finally investigate the influence of distinct features of the targets and modifiers on protein phase separation and aggregation, providing molecular-level insight into the corresponding in vitro measurements and informing further experiments through the adjustment of relevant parameters.

CPP 51: Focus Session: 75 Years Polymer Physics Division: From Curiosity to Smart Materials (joint session CPP/BP)

Polymer materials are ubiquitous in modern society. In recent years, the focus has been on the development of functional, tunable or responsive materials, oftentimes inspired by biological materials. At this, a number of fundamental problems arise, e.g. regarding the interaction of polymers with water, biomolecules or inorganic nanoparticles and the resulting self-assembled morphologies as well as the underlying dynamics and the kinetics of morphological changes upon a stimulus. These problems are nowadays addressed in an interdisciplinary way by experimental methods, computer simulations and theory, often in close collaboration with polymer chemists. In five talks by renowned speakers, the focus session aims at highlighting few of these aspects that are currently under investigation worldwide. The fact that the Polymer Physics Division of the German Physical Society was founded in 1951 and hence, 2026 is the 75th anniversary, seems to be a good occasion to bring modern polymer physics into the focus.

Organized by Christine M. Papadakis, Christian Holm, Tayebeh Ameri and Kristian Franze.

Time: Thursday 15:15–17:45 Location: ZEU/LICH

Topical Talk CPP 51.1 Thu 15:15 ZEU/LICH

The Loops of Life — Brian Chan and •Michael Rubinstein — Duke University, Durham, NC, USA

In mammalian cells, the cohesin protein complex is believed to regulate chromatin during interphase through active loop extrusion, in which dynamic loops are formed by cohesin translocating along chromatin. We developed a theoretical model that quantifies how key parameters, including cohesin residence time on chromatin, extrusion velocity, and the number density of chromatin-bound cohesins, regulate genomic contacts. The model describes chromatin contact probabilities and predicts that loop formation probability is a nonmonotonic function of loop length. Our theory demonstrates that active loop extrusion causes the apparent fractal dimension of chromatin to cross over between two and four at contour lengths on the order of 30 kilobase pairs. This work provides a theoretical basis for the compact organization of interphase chromatin, explaining the physical reason for the segregation of topologically associated domains and suppression of chromatin entanglements by up to a factor of 50, which contributes to efficient gene regulation by distal elements such as enhancers or silencers.

Topical Talk CPP 51.2 Thu 15:45 ZEU/LICH

Polyelectrolytes and Biological Systems: A Charged Relationship — •Matthias Ballauff — Chemie und Biochemie, Freie Universitaet Berlin

If charges are appended to linear or crosslinked polymers, a polyelectrolyte results. Polyelectrolytes are ubiquitous and play a major role in biophysics. Important natural polyelectrolytes as e.g. DNA or Heparin are central in biology, and a thorough understanding of these systems and of charge-charge interaction is one of the main tasks of biophysics. In my lecture, I will discuss our recent research done on -Interaction of linear polyelectrolytes with proteins. This problem is also relevant for the formation of biocondensates by the interaction of cationic and anionic proteins; -Charged polymer networks and their interaction with proteins; -Role of polyelectrolytes in virus infections. In all cases, a quantitative understanding of the systems in terms of analytical models can be achieved, which may pave the way for future pharmaceutical applications.

Topical Talk CPP 51.3 Thu 16:15 ZEU/LICH

From block copolymer morphologies to functional polymer membranes — •Volker Abetz — Helmholtz-Zentrum Hereon, Institute of Membrane Research, Max-Planck-Str. 1, 21502 Geesthacht, Germany — University of Hamburg, Institute of Physical Chemistry, Martin-Luther-King-Platz 6, 20146 Hamburg, Germany

Depending on solvent selectivity and the time of evaporation different structures can be obtained in cast block copolymers, showing that there is an interplay between kinetics and thermodynamic driving forces during the self-assembly before the sample is dry. When preparing membranes from block copolymer solutions, besides molecular weight, composition of the block copolymer and its concentration, also the choice of solvent, and the casting conditions play an important influence on the obtained morphology of the finally obtained membrane. This is especially important when membranes are prepared via the so-called non-solvent induced phase separation process after initial self-assembly by partial evaporation of solvent. The obtained membranes, when prepared successfully, display a rather isoporous top layer and can be subsequently post functionalized, in order to tune pore size and pore surface property. Different examples of the separation properties will be shown and also the potential use as a membrane reactor will be discussed.

Topical Talk CPP 51.4 Thu 16:45 ZEU/LICH

Molecular electronic materials and devices for solar energy conversion — •Jenny Nelson — Imperial College London

To maximize the potential of solar power, new materials will be needed to harvest and convert solar energy alongside existing photovoltaic technologies. Molecular electronic materials, such as conjugated polymers and molecules, can achieve photovoltaic conversion through a process of photon absorption, charge separation at a heterojunction, and charge collection. Through a remarkable series of advances in materials design, the efficiency of photovoltaic energy conversion in molecular materials has risen from 1% to over 20% within two decades. We will discuss the factors that control the function of molecular solar cells including the nature of the charge separating heterojunction, and the impact of chemical and physical structure on phase behaviour, energy and charge transport, light harvesting, and loss pathways, comparing experimental measurements with a computational model of the generation and evolution of excited states and charges in such systems. We identify key molecular parameters that are likely to assist charge generation and consider the extent to which these parameters are optimised in the best performing materials. Finally, we will address the limits to conversion efficiency in such systems.

Topical Talk CPP 51.5 Thu 17:15 ZEU/LICH

Control of cell and tissue stiffness by biopolymer networks and particle inclusions — •Paul Janmey — University of Pennsylvania, Philadelphia, PA, USA

Filamentous networks of semiflexible polymers are ubiquitous in biology. Collagen fibers form much of the extracellular matrix, the cytoskeleton controls cell mechanics, and chromatin fibers span the volume of the nucleus. The mechanical properties of the biopolymer fibers, the way in which the fibers link into networks, and the types of cells within the network all affect the way in which tissues respond to mechanical stress.

Invited Talk CPP 53.1 Fri 9:30 ZEU/LICH

Limits and Prospects of Organic Solar Cells — •Dieter Neher — Institute of Physics and Astronomy, University of Potsdam, Karl-Liebknecht-Str 24-25, 14476 Potsdam

Since the advent of low bandgap non-fullerene acceptors (NFAs), the performance of organic solar cells (OSCs) has improved significantly, with record efficiencies that now safely exceed 20 %. A critical parameter is the offset between the relevant frontier orbitals at the DA heterojunction, which in most NFA-based blends is the difference in HOMO energies. Here we combine a wide range of methods, from femtosecond transient absorption to steady state photoluminescence and electroluminescence, spectroscopy to study the mechanisms and efficiency of free charge generation and recombination. For a wide series of NFA-based OSCs, we find that the singlet exciton decay is the main competing pathway for free charge generation while reformation of singlet excitons from reformed CT states dominates the radiative recombination in EL. To explain our data as function of the HOMO offset, we set up a 5-state model which includes singlet and triplet excitons. Our results show that state-of-the-art OSCs already exhibit an optimum HOMO-HOMO-offset. Future work should, therefore, focus on optimizing photon harvesting and reducing bimolecular recombination in order to push the device efficiency well beyond 20 %.

CPP 53.2 Fri 10:00 ZEU/LICH

Temperature Degradation of Slot-Die Printed Organic Solar Cells — •Christoph G. Lindenmeir[1], Simon A. Wegener[1], Christopher R. Everett[1], Julian E. Heger[1], Sigrid Bernstroff[2], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Elettra-Sincrotrone Trieste S.C.p.A., Basovizza, Trieste, Italy

Organic solar cells (OSCs) have emerged as promising candidates for next-generation photovoltaics due to their rapid efficiency improvements, low toxicity, and compatibility with low-cost, solution-based fabrication methods such as slot-die printing. Their high optical absorption, combined with their lightweight and flexible design, makes them particularly attractive for space applications. Offering a superior power-to-weight ratio compared to conventionally used III-V multijunction cells, OSCs can significantly reduce manufacturing and launch costs. While short-term demonstrations have confirmed their functionality in space, their long-term stability under extreme temperatures, high vacuum, and ionizing radiation still needs to be investigated. Therefore, this study compares the influence of constant-temperature conditions on active-layer morphology and electrical performance with that of temperature cycling. To investigate the degradation process, we employed operando grazing-incidence small-angle X-ray scattering (GISAXS), a nondestructive technique for probing thin-film morphology. Simultaneously, we monitored the electrical performance of the devices under vacuum to simulate space conditions.

CPP 53.3 Fri 10:15 ZEU/LICH

Electronic coarse-graining for accurate and scalable modeling of organic semiconductors — •Andriy Zhugayevych[1], Denis Andrienko[1], and Sergei Tretiak[2] — [1]Max Planck Institute for Polymer Research — [2]Los Alamos National Laboratory, USA

Modeling the electronic properties of organic semiconductors remains challenging due to their complex multiscale structure, which limits the applicability of methods developed for small-molecule solids and inorganic crystals. Fragmentation techniques designed for biomolecular systems are unsuitable for π-conjugated materials because of wavefunction delocalization. We present an electronic coarse-graining methodology that enables accurate and scalable electronic-structure calculations for organic semiconductors composed of monomers with closed-shell π-systems, allowing complete fragmentation along σ-bonds. The approach is demonstrated for crystalline polymers, highlighting how side-group modifications influence the electronic properties of thiophene-based systems such as polythiophene, P3HT, and PEDOT [1]. We further analyze errors introduced by oversimplified electronic models using examples of large flexible molecules, including non-fullerene acceptors for solar cells [2] and OLED materials. The approach can be applied - albeit in less automated way - to broader class of semiconductors, including metal-organic polymers [3], frameworks, and some inorganic semiconductors [4].

[1] Preprint at https://cmsos.github.io/escp; [2] J. Chem. Phys. 159, 024107 (2023); [3] Chem. Sci. 13, 8161 (2022); [4] J. Phys. Chem. Lett. 12, 4674 (2021).

CPP 53.4 Fri 10:30 ZEU/LICH

Facile Correction Method for DFT Band Structures Towards Hybrid Density Functional Level for 2D-Covalent Organic Frameworks — •Laura Fuchs, Maximilian F. X. Dorfner, Matthias Knechtges, Johann Olbrich, and Frank Ortmann — Department of Chemistry, TUM School of Natural Sciences, and Atomistic Modeling Center, Munich Data Science Institute, Technical University of Munich, Germany

Density functional theory (DFT) is the method of choice for predicting the majority of structural, and electronic properties of organic and inorganic materials. Generalized gradient approximations, such as the semi-local PBE functional, are widely used in the community but have one major drawback: the band gap problem. The fundamental band gap is typically underestimated by up to a factor of two by these approaches, which is critical since this electronic property is of utmost importance for assessing the applicability of the investigated material for (opto-)electronic purposes.

Here, we establish a robust linear correlation between the semi-local PBE band gaps and the more accurate, but more expensive, hybrid HSE06 band gaps by analyzing organic molecules as well as extended crystals such as covalent organic frameworks (COFs). By eliminating the need for costly hybrid functional calculations, our approach achieves up to a 54-fold speedup compared to conventional HSE06 computations. We compare various implementation strategies and evaluate each method's advantages and limitations, with particular focus on their implications for predicting electronic transport properties.

CPP 53.5 Fri 10:45 ZEU/LICH

The influence of vibrations on charge and energy transfer dynamics in a singlet fission donor-acceptor complex — •Karin S. Thalmann[1], Johan E. Runeson[1], Pedro B. Coto[2], and Michael Thoss[1] — [1]Institute of Physics, University of Freiburg, Germany — [2]Spanish National Research Council (CSIC), Madrid, Spain

Singlet fission is a photophysical process in molecular materials transforming a singlet excited electronic state to two triplet states [1], effectively doubling the number of charge carriers. This makes molecules exhibiting singlet fission possible candidates to increase the efficiency of solar cells beyond the Shockley-Queisser limit. To investigate this possibility, we analyse the charge and energy transfer dynamics in a donor-acceptor complex consisting of a bis(diazadiborine)-based chromophore [2] and tetracyanoquinodimethane. Using a combined approach of *ab initio* multireference perturbation theory calculations and quantum dynamical simulations based on a harmonic vibronic coupling Hamiltonian [3], we reveal competing charge and energy transfer mechanisms, such as singlet fission-based transfer and energy decay channels. Further, we expand our model Hamiltonian to include all vibrational degrees of freedom and the anharmonicity in the vibrational modes of the chromophore. The use of mixed quantum-classical approaches allows us to analyse the influence of these vibrational modes on the dynamics as well as the charge and energy transfer mechanisms.

CPP 53.6 Fri 11:00 ZEU/LICH

Tracking the degradation of non-fullerene organic solar cells in fluctuating environments — •Lixing Li, Thomas Baier, Xiaojing Ci, Zhaonan Jin, and Peter Müller-Buschbaum — TUM School of Natural Sciences, Chair for Functional Materials, 85748 Garching, Germany

The long-term operational stability of non-fullerene organic solar cells (OSCs) remains a critical challenge that limits practical applications. While substantial efforts have been devoted to understanding the degradation mechanisms of OSCs under extreme conditions such as high or low temperatures, far less attention has been paid to their potential recovery behaviour. In real-world environments, organic solar cells are not exposed to constant stress; instead, environmental factors such as temperature, humidity, and illumination fluctuate continuously over time. These dynamic variations may induce partial or even reversible changes in device performance and morphology. It is essential to explore not only how OSCs degrade under stress but also how they recover once the stress is relieved or altered. In this study, we investigate the recovery processes of BTP-4F non-fullerene organic solar cells subjected to multiple environmental parameters. Advanced characterisation techniques, including grazing-incidence X-ray scattering (GIXS) and atomic force microscopy (AFM), are employed to track both in-situ and ex-situ structural evolution within the active layer. These analyses provide new insights into the mechanisms governing the recovery and structural reorganisation of OSCs under dynamic environmental conditions.

CPP 54: Gels, Polymer Networks and Elastomers II

Time: Friday 9:30–11:15 Location: ZEU/0255

Invited Talk CPP 54.1 Fri 9:30 ZEU/0255

NMR-based molecular rheology and structural characterization of model gels — •Kay Saalwächter and Bidit Lamsal — Institut für Physik - NMR, Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany

Low-resolution proton NMR holds great potential for the routine assessment of the relation between the NMR-detected monomer-level mobility and the relevant physical properties of polymer-based materials. In elastomers and gels, multiple-quantum (MQ) NMR allows for the precise measurement of residual dipolar couplings (RDCs) among the monomer protons, which reflects the conformational space of the highly mobile network chains. In this way, not only the average network chain length but also structural inhomogeneities become accessible. In model networks made by end-linking of star polymers, we can go as far as quantifying connectivity motifs in gels made by heterocomplementary [1,2] and homocomplementary coupling reactions [3], either in one-component [1,3] or amphiphilic co-networks [2].

While the measured RDC is consistently found to be proportional to the gels' elasticity modulus [3], the absolute-level interpretation of the measured average RDC to predict the modulus remains a challenge. We here report on recent experiments performed on a variety of PEO-based model gels to elucidate the effects of solvent on local conformational fluctuations, thermodynamic aspects (solvent quality) and the inhomogeneity of the gels.

[1] Macromolecules 44, 9666 (2011); [2] Macromolecules 55, 6573 (2022); [3] Macromolecules 57, 3058 (2024)

CPP 54.2 Fri 10:00 ZEU/0255

Characterization of the deformation and fracture of tough double-network hydrogels — •Eric Euchler[1], Sitao Wang[2], Konrad Schneider[1], and Sven Wiessner[1,3] — [1]Leibniz-Insititut für Polymerforschung Dresden, Dresden, Germany — [2]Leibniz-Insititut für Polymerforschung Dresden, Dresden, Germany — [3]TUD Dresden University of Technology, Dresden, Germany

Double-network hydrogels (DNHs) feature two interpenetrating networks: a stiff, densely crosslinked first network that carries the load at low strain, and a flexible, loosely crosslinked second network that remains deformable under high strain, offering mechanical properties comparable to elastomers and soft load-bearing biological tissues. Additionally, a yielding phenomenon accompanied by necking of the sample can be observed. This necking zone forms under uniaxial tension and grows with continued loading, which is associated with the fracture of the first network. In this contribution, new insights into the mechanical deformation and damage behavior are given by advanced characterization approaches.

CPP 54.3 Fri 10:15 ZEU/0255

The Role of Connectivity Defects in Governing the Rheology and Microstructure of tPEG Networks — •Sayam Bandyopadhyay[1,2], Sebastian Seiffert[3], and Arash Nikoubashman[1,2] — [1]Leibniz-Institut für Polymerforschung Dresden e.V., Germany — [2]Institut für Theoretische Physik, Technische Universität Dresden, Germany — [3]Institut für Physikalische Chemie, Johannes Gutenberg-Universität, Germany

We utilized coarse-grained molecular simulations to examine how connectivity defects influence tetra-PEG (tPEG) polymer networks. Both homoleptic and heteroleptic systems were studied, with noncovalent end-group bonds modeled by an inverted Gaussian potential to control valency. Defects were introduced either by deactivating functional end groups or by deviating from ideal stoichiometry in heteroleptic mixtures. Post-gelation structure was quantified using structure factors, radial distribution functions of attractive beads, and internal loop statistics. Network dynamics and molecular mobility were assessed through mean-square displacements of individual tPEG molecules and through bond lifetimes. Our results show that defects enhance loop formation and substantially increase star-polymer mobility. As a consequence, networks with higher defect concentrations exhibit lower viscosity and faster stress relaxation. We also discuss the system's shear response simulated using a mesoscale solvent with hydrodynamic interactions to probe loop and link interconversion kinetics. These findings provide a molecular level understanding of how defects control the structure, dynamics, and mechanical properties of tPEG networks.

CPP 54.4 Fri 10:30 ZEU/0255

Assembling a true Olympic gel from >16,000 combinatorial DNA rings — Sarah K. Speed[1,2], Yu-Hsuan Peng[1,2], Azra Atabay[1,2], Krishna Gupta[1,2], Toni Müller[3,4], Carolin Fischer[5], Ilka Hermes[6], Jens-Uwe Sommer[3,4,7], Michael Lang[3], and •Elisha Krieg[1,2] — [1]Division of Polymer Biomaterials Science, Leibniz Institute of Polymer Research Dresden, Germany — [2]Faculty of Chemistry and Food Chemistry, Technische Universität Dresden, Germany — [3]Division of the Theory of Polymers, Leibniz Institute of Polymer Research Dresden, Germany — [4]Institute for Theoretical Physics, Technische Universität Dresden, Germany — [5]B CUBE - Center for Molecular Bioengineering, Technische Universität Dresden, Germany — [6]Division of Physical Chemistry and Physics of Polymers, Leibniz Institute of Polymer Research Dresden, Germany — [7]Cluster of Excellence Physics of Life, Technische Universität Dresden, Germany

Olympic gels consist of a three-dimensional network of mechanically interlocked cyclic molecules providing unique mechanical properties. We report the successful assembly of a true Olympic gel from a library of DNA rings comprising more than 16,000 distinct molecules. Each of these rings contains a unique sequence domain that can be enzymatically activated to produce reactive termini that favor intramolecular cyclization. Results are shown on the genetic, mechanical, and structural characteristics of the material by next-generation sequencing, oscillatory rheology, large-scale computational simulations, atomic force microscopy, and cryogenic electron microscopy.

CPP 54.5 Fri 10:45 ZEU/0255

On the symmetry breaking between gelation and network degradation — •Michael Lang — Division of the Theory of Polymers, Leibniz Institute of Polymer Research Dresden, Germany

Recent experiments indicate that there is a possible symmetry breaking between gelation and network degradation processes in contrast to the predictions of percolation models and classical mean field models. We analyze this problem by large scale computer simulations and mean field modeling in order to avoid possible problems of the experimental setup. The modeling is generalized to capture the main effects of cyclization and composition fluctuations on the gelation process. Both our modeling and the simulation data confirm the existence of the symmetry breaking already for systems above the overlap threshold. This indicates some general problems of the percolation approach for modeling polymer networks.

CPP 54.6 Fri 11:00 ZEU/0255

Crosslinking Mechanisms of Alginate-based Graft Copolymers with Thermoresponsive Side Chains — •Wenqi Xu[1], Sofia-Falia Saravanou[2], Yefan Song[1], Yandong Wang[1], Joachim Kohlbrecher[3], Constantinos Tsitsilianis[2], and Christine M. Papadakis[1] — [1]TUM School of Natural Sciences, Soft Matter Physics Group, Garching, Germany — [2]University of Patras, Greece — [3]PSI, Villigen, Switzerland

Alginates are naturally occurring, non-toxic polysaccharides which have seen extensive use in biomedicine. Here, we investigate an alginate-based graft copolymer, namely alginate-*g*-P(NIPAM$_{94}$-*co*-N*t*BAM$_6$), where a random copolymer of *N*-isopropylacrylamide (NIPAM) and *N*-*tert*-butyl acrylamide (N*t*BAM) is grafted onto a sodium alginate backbone [1]. While introducing thermoresponsive PNIPAM enables temperature-induced gelation, the hydrophobic comonomer N*t*BAM regulates the transition temperature and the mechanical properties of the hydrogel. The structure and the gelation mechanisms of the copolymers are studied in aqueous solutions using small-angle neutron scattering (SANS). At this, contrast matching of the backbone and the side chains was used to obtain selective information. The SANS data show strong forward scattering above the transition temperature of PNIPAM, which is attributed to the collapse of the side chains, resulting in hydrophobic globules which act as nodes of the hydrogel network.

CPP 55: Focus Session: Theoretical Modeling and Simulation of Biomolecular Condensates III (joint session CPP/BP)

Time: Friday 9:30–11:15 Location: ZEU/0260

Topical Talk CPP 55.1 Fri 9:30 ZEU/0260

Data-driven modelling of phase-separating intrinsically disordered regions — •Giulio Tesei[1,2], Fatima Kamal Zaidi[3], Shanlong Li[4], Julian O. Streit[1], Jianhan Chen[4], Tanja Mittag[3], and Kresten Lindorff-Larsen[1] — [1]Department of Biology, University of Copenhagen, Copenhagen, Denmark — [2]Department of Biomedical Science, Malmö University, Malmö, Sweden — [3]Department of Structural Biology, St. Jude Children's Research Hospital, Memphis, U.S.A. — [4]Department of Chemistry, University of Massachusetts, Amherst, U.S.A.

Intrinsically disordered regions (IDRs) constitute about one third of the human proteome and play important roles in biological processes. While lacking well-defined 3D structures, IDRs adopt heterogeneous ensembles influenced by multivalent interactions; these same interactions can promote phase separation and contribute to the formation of biomolecular condensates. I will first present CALVADOS, an efficient one-bead-per-residue model optimized on experimental data reporting on IDR conformational properties and extensively validated on both single-chain and phase behavior across diverse sequences. I will then describe how we used large sets of CALVADOS simulations to train machine-learning models that accurately predict single-chain compaction and homotypic phase-separation propensity directly from sequence. Finally, I will introduce a hybrid-resolution model with an atomistic backbone representation that matches the accuracy of CALVADOS for global dimensions and phase separation while also capturing local structure and backbone hydrogen bonding.

CPP 55.2 Fri 10:00 ZEU/0260

Born to Condense: Polysomes Drive Co-Translational Condensation of Biomolecular Condensate Proteins — •Zhouyi He, Jens-Uwe Sommer, and Tyler Harmon — Leibniz Institute of Polymer Research, 01069, Dresden, Germany

Biomolecular condensates formed by protein LLPS are ubiquitous and crucial in cells. While the physics and functions of LLPS are well studied, its interplay with protein synthesis, translation, remains largely unexplored. Here we propose Co-Translational Condensation (CTC), a mechanism in which nascent protein chains of polysomes, multiple ribosomes on one mRNA, interact with condensates, localizing translation to condensate surfaces. Using coarse-grained simulations, we show that protein domain architecture dictates the extend of CTC, consistent with a Langmuir adsorption model. Bioinformatic analysis reveals that most condensate-associated proteins have architectures favoring CTC, with strong interaction regions of nascent chains exposed on polysomes. Dynamically, simulation and reaction-diffusion modeling reveal that CTC is kinetically feasible within typical polysome lifetimes, either through large polysomes nucleating new condensates or via diffusion to pre-existing condensates. As a case study, we demonstrate that CTC enhances post-translational modifications by minimizing unmodified intermediates. More broadly, we anticipate CTC may also influence protein folding, misfolding, and signal-integration latency. Together, our results establish CTC as a general mechanism coupling translation with phase separation, with broad implications for protein evolution, cellular organization, and synthetic biology.

CPP 55.3 Fri 10:15 ZEU/0260

Local RNA/protein stoichiometry tunes the electrostatic microenvironment inside reconstituted multicomponent condensates — •Patrick M. McCall — Leibniz Institute for Polymer Research Dresden, Dresden, DE

Biomolecular condensates are demixed phases of biopolymers and, in living cells, commonly form through the associative phase separation of strongly-charged nucleic acids together with protein polyampholytes carrying a weak net charge. While condensates are proposed to offer distinct aqueous environments for the organization of cellular biochemistry, it remains unclear which physical aspects of the microenvironment are relevant and how widely they can vary between condensates. Motivated by the large asymmetry in structural charge between typical condensate components such as RNAs and RNA-binding proteins, we explore here the implications of electroneutrality on the electrostatic environment within model multicomponent condensates. Combining classical Donnan theory with recent measurements of the macromolecular composition of condensates reconstituted from full-length FUS protein and a homopolymeric RNA [McCall et al Nat Chem 2025], we compute the partitioning of salt ions as well as the Donnan potential across the phase boundary. We find that RNA/FUS stoichiometry tunes both co-ion exclusions over a wide range and is coupled to a pH jump across droplet interface. We also find that co-ion exclusion is suppressed by counter-ion condensation and enhanced by non-ideality of un-bound ions. These results provide insight into the range of ionic conditions accessible to a prominent class of biomolecular condensate.

CPP 55.4 Fri 10:30 ZEU/0260

Coarse-grained model to study the effects of electric fields on protein interactions — •Agaya Johnson[1], Debes Ray[2,4], Mahnoush Madani[3], Jan Dhont[2,3], Florian Platten[2,3], Kyongok Kang[2], and Sofia Kantorovich[1] — [1]University of Vienna, Kolingasse 14-16, 1090, Vienna, Austria. — [2]nstitute of Biological Information Processing IBI-4, Forschungszentrum Jülich, 52428 Jülich, Germany. — [3]Faculty of Mathematics and Natural Sciences, Heinrich Heine University Düsseldorf, 40225 Düsseldorf, Germany. — [4]Solid State Physics Division, Bhabha Atomic Research Centre, Trombay, Mumbai 400085, India.

Proteins can undergo transition between a wide range of organisational states, from soluble monomers to disordered phases and ordered structures. Experiments have shown that lysozyme in sodium thiocyanate solution can form homogeneous, crystalline, or liquid phases depending on the salt and protein concentrations, and that these phase boundaries can be shifted by applying an electric field. We present a coarse-grained model of lysozyme in sodium thiocyanate solution, representing the protein as an ellipsoid decorated with charged and adhesive surface patches. Counterions and monovalent salt are treated explicitly via excluded-volume repulsion and Coulombic interactions. We investigate (i) how patch size and salt*patch interactions influence ion distributions around a single protein, with and without an external electric field, and (ii) the resulting effective interactions between two proteins as functions of patch properties, salt concentration, and applied electric field.

CPP 55.5 Fri 10:45 ZEU/0260

Entropic Clustering of Stickers Induces Aging in Biocondensates — •Hugo Le Roy[1] and Paolo De Los Rios[2] — [1]Department of Civil, Chemical and Environmental Engineering, University of Genoa, Genoa, Italy — [2]Institute of Physics, Ecole Polytechnique Fédérale de Lausanne

Neurodegenerative conditions, such as Parkinson's disease, results from the aggregation of synaptic proteins such as alpha-synuclein. In a healthy presynaptic neuron, effective neurotransmission relies on the spatial organization of synaptic vesicles within phase-separated droplets. These vesicles release neurotransmitters into the synaptic cleft to activate ion-gated channels on the postsynaptic neuron.

In this work, we investigate how this transmission process is impaired during neurodegeneration. Specifically, we focus on the solidification of these phase-separated droplets, a phenomenon described as aging, leading to protein aggregation and associated with the emergence of pathology. We explore the connection between the mechanical properties of the condensates and their microscopic structure using a minimal physical model that treats complex molecules as stickers and spacers. We show that entropy maximization of spacers leads to an effective attractive force between stickers. As a result, our system displays a surprisingly slow relaxation toward equilibrium, reminiscent of glassy systems and consistent with the liquid-to-solid transition observed in aging droplets. By analyzing the clustering dynamics of stickers, we successfully explain the microscopic origin of this glassy relaxation.

CPP 55.6 Fri 11:00 ZEU/0260

Biomolecular condensates with a Twist: From Assembly to Arrest — •Mahesh Yadav[1,2] and Lukas Stelzl[2] — [1]Institute of Physics, Johannes Gutenberg University, Mainz — [2]Institute of Molecular Physiology, Johannes Gutenberg University, Mainz

In this work, we investigate the phase behavior of RNA-binding protein Fused in Sarcoma (FUS), whose multivalent and intrinsically disordered regions drive the formation of biomolecular condensates through liquid-liquid phase separation. FUS is a multi-domain protein with arginine-glycine-rich segments (RG-rich domains) that participate in essential cellular proceses. We examine how characteristic sequence motifs such as RGG.. mediate homotypic and nucleic acid binding, and how targeted point mutations (e.g., RtoK, RtoA) disrupt these motifs and impair condensate formation. Using the thermodynamics phase diagram as a benchmark we highlighted the shift in phase separation propensity of the FUS and its variants. Furthermore, we identify the role of key interactions such as electrostatics, π-π and cation-π in nucleic acid binding at atomistic scale. We further characterized the emergent viscoelastic behavior of FUS condensates at multiple scales. We observe that upon mutations the overall dynamics slows down which reflects the gel-like state. Within the condensate interior, protein chains exhibit sub-diffusive dynamics arising from intermittent binding and viscoelastic resistance, mobility at the interface is further suppressed due to anisotropic interactions and interfacial confinement. To quantify these behaviors across relevant scales, we employ multi-resolution simulation models.

CPP 56: Molecular and Polymer Dynamics, Friction and Rheology I

Time: Friday 10:45–12:00 Location: HÜL/S386

Invited Talk CPP 56.1 Fri 10:45 HÜL/S386

Liquid Dynamics at Interfaces — •Michael Vogel — Institut für Physik kondensierter Materie, TU Darmstadt, Hochschulstraße 6, 64289 Darmstadt

Liquids at interfaces are of great importance in nature and technology, for instance, in biological cells, clay minerals, and energy materials. Typically, the dynamics of liquids at interfaces significantly differ from those in the bulk. We combine nuclear magnetic resonance and broadband dielectric spectroscopy with molecular dynamics simulutations to determine the magnitude and range of these interface effects in broad frequency and temperature ranges. It is shown that the free energy landscape imposed by an interface on an adjoining liquid enables a basic understanding of the altered dynamical behavior [1]. It will be discussed that a knowledge of interface effects allows one not only to obtain valuable insights into the properties of confined water and, when avoiding crystallization, the anomalies and vitrification of bulk water [2-4], but also to steer ion transport in electrolyte-host systems for improved lithium-ion battery and proton-exchange membrane materials [5-7].

CPP 56.2 Fri 11:15 HÜL/S386

The analytical and numerical investigation of star-shaped copolymers with three arms in confined geometries — •Zoriana Danel[1], Joanna Halun[2], and Paweł Karbowniczek[1] — [1]Cracow University of Technology, Poland — [2]Institute of Nuclear Physics, Poland

The influence of star copolymer topology on the depletion interaction potentials, the depletion forces, the radius of gyration and the monomer density profiles is investigated analytically and numerically. The method of analytical calculation of the dimensionless depletion interaction potentials and the dimensionless depletion forces for a dilute solution of ideal star-shaped copolymers with three legs in combination f=2-1 in a Θ-solvent confined in a slit geometry of two parallel walls with repulsive surfaces and for the case of one repulsive and the other inert surface is proposed. Besides, molecular dynamic simulations of a dilute solution of star-shaped copolymers in a good solvent with three number of legs with N=801 monomers (300+300+200+1) for combination f=2-1 and N=701 monomers (300+200+200+1) for combination f=1-2 confined in a slit with different boundary conditions are performed and the results of the monomer density profiles for the above mentioned cases are obtained for the narrow and wide slit region. Furthermore, the numerical calculations of the radius of gyration for star-shaper copolymers in combination f=2-1 and f=1-2 are performed. The obtained results are interesting from scientific and practical point of view, because of their potential application in materials engineering, nano-technology, biotechnology and medicine.

CPP 56.3 Fri 11:30 HÜL/S386

Polymer melt dynamics in the light of viscoelastic hydrodynamic interaction — •Hendrik Meyer — Institut Charles Sadron, Université de Strasbourg, CNRS UPR22, 67034 Strasbourg, France

Our group has shown that anomalous center-of-mass (CM) diffusion occurring on intermediate time scales in polymer melts can be explained by the interplay of viscoelastic and hydrodynamic interactions (VHI). The theory has been solved for unentangled melts in 3D [1] and 2D [2] and excellent agreement between theory and molecular dynamics simulation is found. The theory was developed for momentum conserving dynamics as well as Langevin dynamics. The physical mechanism considers that hydrodynamic interactions are time dependent because of increasing viscosity before the terminal relaxation time. We show that this mechanism is generally active and relevant in melts including entangled systems, rings or stars.

CPP 56.4 Fri 11:45 HÜL/S386

Knots in Polymers under Shear Flow — •Maurice P. Schmitt[1], Andrey Milchev[2], and Peter Virnau[1] — [1]Institut für Physik, Johannes Gutenberg-Universität, Mainz, Germany — [2]Institute of Physical Chemistry, Bulgarian Academy of Sciences, Sofia, Bulgaria

Knots in polymers and biological macromolecules, such as DNA and proteins, are crucial to their structure and function. However, the effect of external forces on knots in polymers is still insufficiently understood. Here, we investigate the impact of shear and Poiseuille flow on knotted flexible polymers using Molecular Dynamics (MD) and Multi-Particle Collision Dynamics (MPCD) simulations. We find that under simple shear (Couette flow), initially loose knots in polymer coils tighten beyond a critical shear rate. Further increase of the shear rate leads to tumbling motions of the chains in flow and fluctuating knot sizes. In contrast, knotted polymer globules subjected to shear unfold into pearl-necklace-like conformations, whereby knots spread across multiple sub-globules and undergo dynamic topological transitions. In Poiseuille flow, knots also tighten under increasing flow strength, with fluctuations in knot size emerging at high shear rates. Unexpectedly, the slit thickness significantly influences the tightening process even at constant mean shear rate. These findings reveal that both Couette and Poiseuille flow induce major structural and topological transformations in knotted polymers, offering insight into the behavior of knots under hydrodynamic forces in confined and driven environments.

CPP 57: Hybrid, Organic and Perovskite Optoelectronics and Photovoltaics VIII

Time: Friday 11:30–13:00 Location: ZEU/LICH

CPP 57.1 Fri 11:30 ZEU/LICH

Novel n-Dopants for Improving Organic Solar Cells — •Yahya Asl Soleimani[1], Nora Engelmann[1], Stephanie Buchholtz[1], Jörn Vahland[2], Adrian Kishonti[2], Steffen Woltering[2], Karl Leo[1], and Johannes Benduhn[1] — [1]Institute of Applied Physics, Technische Universität Dresden, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]CREDOXYS GmbH, Liebigstraße 26, 01187, Dresden, Germany

Doping is a crucial concept in semiconductor technology, and it is no different for organic semiconductors. It increases conductivity and facilitates carrier injection and extraction. While substantial success has been achieved for organic molecular p-dopants, the same cannot be said for n-dopants. They suffer from an inherent disadvantage: the highest occupied molecular orbital (HOMO) of the n-dopant must be lower than the lowest unoccupied molecular orbital (LUMO) of the host, rendering them typically unstable under ambient conditions. Here, we report a new and efficient molecular n-dopant that can dope C_{60} to a conductivity of 20 S/cm. We investigate the origin of its efficacy and explore the doping mechanism using ultraviolet electron spectroscopy (UPS). Moreover, we incorporate the new n-dopant into organic solar cells, demonstrating its effectiveness by improving the power conversion efficiency of the reference devices.

CPP 57.2 Fri 11:45 ZEU/LICH

Computational Study of Electronic Trapping in TADF Host-Guest Systems — •Naomi Kinaret[1], Andrei Stankevych[2,3], Andriy Zugayevych[1], Rishabh Saxena[1], Alexander Vakhnin[3], Kun-Han Lin[1,4], Denis Andrienko[1], Heinz Bässler[2], Anna Köhler[2], and Andrey Kadashchuk[2,3] — [1]Max Planck Institute for Polymer Research, Mainz, Germany — [2]University of Bayreuth, Bayreuth, Germany — [3]National Academy of Sciences of Ukraine, Kyiv, Ukraine — [4]National Tsing Hua University, Hsinchu, Taiwan

Extrinsic traps created by dopants or impurities are ubiquitous in organic semiconductors and can critically influence charge transport [1]. Here we report a computational study of the trapping of charge carriers in amorphous host-guest systems of the thermally activated delayed fluorescence (TADF) emitter DMAC-TRZ in two different hosts, validated by low-temperature thermally- stimulated luminescence (TSL). In both hosts we find that DMAC-TRZ forms an additional Gaussian density of states (DOS), offset from the host DOS by a trap depth ϵ_t. In both systems trap depths and DOS widths, σ_{DOS}, agree with experimentally observed values over a range of compositions, showing that the nominal trap depth is concentration independent. In the case of deep traps, $\epsilon_t > 3\sigma_{DOS}$, we observe concurrent charge detrapping via guest-to-host and guest-to-guest pathways, with the latter dominating for $c_t > 5\%$. Guest-guest transfers are observed already at the low guest concentration of $c_t = 1\%$, attributed to local guest clustering and superexchange- mediated inter-cluster transfers.

[1] Kotadiya, N.B., et al., Nat. Mater. (2019).

CPP 57.3 Fri 12:00 ZEU/LICH

Interface Engineering toward High-Performance Subphthalocyanine-based Single-Component Organic Photodetectors — •Anncharlott Kusber[1], Ying Sun[2], Jakob Wolanksy[1,3], Fred Kretschmer[1], Conrad Winkler[1,3], Anna-Lena Hofmann[1], Ji-Seon Kim[2], Karl Leo[1], and Johannes Benduhn[1,3] — [1]Institute of Applied Physics, Technische Universität, Dresden, Germany — [2]Imperial College London, United Kingdom — [3]German Centre of Astrophysics, Görlitz, Germany

Organic photodetectors (OPDs) have attracted considerable attention due to their capability to convert light into electrical signals and enable high-quality imaging, while simultaneously offering the intrinsic benefits of organic materials. Single-component (SC) OPDs, using a single photoactive organic semiconductor material, have several advantages over the commonly used bulk heterojunction OPDs such as its simplified structure. The influence of several organic electron transport layers (ETLs) on energetic landscape at the immediate interface with organic layers has not yet been systematically reported. This is necessary to gain a deeper understanding of physics of organic interfaces, thereby enabling the further optimization of OPD performance. Sensitive measurement techniques were used to analyse the influence of different organic interfaces on the OPD performance.

These investigations lead to SubNc SC OPD devices, which achieves an EQE of 56 % at 0 V, an ultra-low J_D of $2.5 \cdot 10^{-11}$ A $\cdot$ cm^{-2} at -0.5 V and D* of $3.8 \cdot 10^{14}$ Jones at 0 V (based on calculated shot noise).

CPP 57.4 Fri 12:15 ZEU/LICH

Impact of additive on the morphology and electronic states of PPDT2FBT:PCBM organic solar cells — Md Moidul Islam[1,2], Hassan Ismail[1,2], Saib Qazi[1,2], Ulrich S. Schubert[1,2], and •Harald Hoppe[1,2] — [1]Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldtstrasse 10, 07743 Jena, Germany — [2]Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany

Among organic solar cells using PCBM as an acceptor, the donor PPDT2FBT yields one of the highest power conversion efficiencies (PCE) of nearly 10%. It has been demonstrated that the processing additive diphenyl ether (DPE) contributes to that success essentially. However, the exact mechanism responsible for the performance improvement has so far not been revealed. Therefore, we undertook a systematic study for comparing PPDT2FBT:PCBM solar cells, under variation of annealing temperatures and use of DPE. A combination of optical, electrochemical, microscopic, and further characterization methods enabled the decoding of the impact of DPE on the blend morphology. In addition, the limitation in device stability by extended morphological degradation has been revealed and strategies to overcome those are being discussed.

CPP 57.5 Fri 12:30 ZEU/LICH

Photo-physics of symmetric and asymmetric ITIC-2F non-fullerene acceptors in organic solar cells — •Shahidul Alam[1,2], Nisreen Alshehri[2], Michael Bulgakov[3], Zerui Li[4], Khawla Alkhezaim[2], Maryam Alqurashi[2], Oleksandr Matiash[2], Vojtech Nadazdy[5], Martin Hager[6], Ulrich S Schubert[6], Vladimir Dyakonov[3], Harald Hoppe[6], Peter Müller-Buschbaum[4], Andreas Sperlich[3], and Frédéric Laquai[1,2] — [1]LMU Munich — [2]KAUST, Saudi Arabia — [3]University of Wurzburg — [4]TU Munich — [5]Slovak Academy of Sciences, Slovak Republic — [6]FSU Jena

Fluorination is an effective strategy to tune the electronic and structural properties of organic semiconductors by lowering frontier orbital energies, enhancing intermolecular interactions, and improving stability. We investigated ITIC and its fluorinated derivatives, sITIC-2F and aITIC-2F, in blends with PBDB-T and its halogenated analogue PM6 to elucidate the effects of fluorination on molecular packing and energetics. Optically detected magnetic resonance reveals triplet excitons in all pristine materials and blends, with their donor-acceptor distribution governed by fluorination. These results demonstrate that fluorination effectively modulates molecular organization and excited-state dynamics, leading to improved structure-property-performance relationships in organic solar cells.

CPP 57.6 Fri 12:45 ZEU/LICH

Single-Component Vacuum-Deposited Organic Photodetectors Achieving NIR Detection — •Jakob Wolansky[1,4], Jacob Hille[1], Cedric Hoffmann[2], Michel Panhans[3], Frank Ortmann[3], Natalie Banerji[2], Karl Leo[1], and Johannes Benduhn[1,4] — [1]IAPP, TU Dresden, Germany — [2]DCBP, University Bern, Switzerland — [3]NAT-School, TU Munich, Germany — [4]DZA, Görlitz, Germany

Efficient charge separation in organic semiconductor devices typically relies on an energetic offset at the donor-acceptor interface to dissociate photogenerated electron-hole pairs. While such an offset facilitates charge generation, it can limit the maximum open-circuit voltage. Additionally, interfacial traps generate charge carriers in the dark. To address these limitations, significant research is exploring single-component (SC) architectures that minimize interfacial losses.

In this work, we investigate SC organic photodetectors in which a newly developed small molecule serves as the active layer. By chemically tuning the molecular structure, extended near-infrared absorption up to 900nm is achieved, while maintaining devices with a large linear dynamic range of 160dB, a -3dB cut-off frequency of 50kHz, and an external quantum efficiency of 20% at zero bias. Comparison with the widely studied small molecule DCV2-5T allows the extraction of structure-property relationships that serve as a basis for future molecular design. Furthermore, an in-depth analysis of the charge generation process in DCV2-5T provides new insights into the pathways governing efficient photogeneration in SC organic systems.

CPP 58: Gels, Polymer Networks and Elastomers III

Time: Friday 11:30–13:00 Location: ZEU/0255

CPP 58.1 Fri 11:30 ZEU/0255

X-ray induced structural changes in supramolecular polymer networks — •Niels C. Giesselmann[1,2], Yasothaa Thavayogarajah[3], Mostafa Ahmadi[3], Sebastian Seiffert[3], and Katrin Amann-Winkel[1,2] — [1]Institute of Physics, Johannes Gutenberg University, Mainz, Germany — [2]Max Planck Institute for Polymer Research, Mainz, Germany — [3]Institute of Chemistry, Johannes Gutenberg University, Mainz, Germany

Supramolecular polymer networks consist of non-covalently cross-linked macromolecules. Such transient links can be established through functionalized polymer building blocks. An interesting property of this group of materials is their ability to self-heal mechanical damage. We observed polymer networks made of star-shaped four-arm PEG building blocks with metal-complexing end groups. Due to their transient binding, the building blocks diffuse through the polymer network in a process that is not yet understood in detail. In this study, we employed both X-ray scattering in order to probe the structure of the network on the molecular as well as the macromolecular level. This way, we hope to better understand the mechanical and self-healing properties of these polymer networks. We report the emergence of structural changes in dependence of the X-ray flux that futhermore persist when measuring far away from the initially illuminated area. This effect can be explained by the affected molecules spreading throughout the sample by means of the transient binding dynamics mentioned above.

CPP 58.2 Fri 11:45 ZEU/0255

Deciphering the photopolymerization-induced nanostructure and interface formation for submicron additive manufacturing — •Shouzheng Chen[1,2,3], Yufeng Zhia[2], Lixing Li[1], Sarathlal Koyiloth Vayalil[2], Rolf A.T.M. van Benthem[4], Johan F.G.A Janssen[5], Mats K. G. Johansson[6], Peter Müller-Buschbaum[1], and Stephan V. Roth[2,6] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]DESY, Hamburg — [3]MLZ, TUM, Garching, Germany — [4]TU/e, Eindhoven, the Netherlands — [5]Covestro (Netherlands) B.V., Geleen, the Netherlands — [6]Department of Fibre and Polymer Technology, KTH, Stockholm, Sweden

UV-curing is widely used in additive manufacturing due to its controllable spatiotemporal characteristics. In submicron additive manufacturing, the involvement of solvents and limitations on film thickness complicate the precise regulation of nanostructures and interlayer interface. By using grazing incidence small angle X-ray scattering (GISAXS) and employing the oligomer (urethane dimethacrylate, UDMA)/monomer (2-ethylhexyl acrylate, 2-EHA) based resin system, we quantify the heterogeneous distribution of UDMA- and 2-EHA-rich nanodomains (around 23 nm and 13 nm in radii, respectively) in the cured system. Combining Bornagain, we reveal the buried "frozen" nano-wrinkles at interlayer interfaces(cones with radius of 70 nm, slope angle of 18°) induced by solvent and constraint stress synergistically. Our findings offer deeper insights for high precision submicron additive manufacturing.

CPP 58.3 Fri 12:00 ZEU/0255

From real polymers to random graphs: percolation thresholds in associative polymer solutions — •Xinxiang Chen, Lennart Hebestreit, and Friederike Schmid — Johannes Gutenberg-University Mainz, Mainz, Germany

Multivalent reversible crosslinking is ubiquitous in soft matter and biomolecular condensates, yet their sol-gel transitions often deviate from the classical Flory-Stockmayer picture due to chain conformations, intrachain binding, and loop formation. Here, we develop a unified framework combining molecular dynamics simulations with random-graph and random-geometric-graph approaches to quantitatively link real polymer architectures to abstract network models. For single- and two-component reversible polymers with one-to-one specific bind-

ing, we determine gel points from topological connectivity and find percolation thresholds substantially higher than Flory-Stockmayer predictions. By comparing spatially unconstrained random graphs with spatially correlated random geometric graphs, we show that intrachain binding and loops markedly reduce the effective interchain bonding needed to form an infinite cluster. Meanwhile, the theoretical results of the generating function and the Lagrange inversion further yield cluster size distributions and giant cluster fractions. Our work demonstrates how spatial correlations and polymer conformations fundamentally reshape reversible network formation, offering a unified topological and physical perspective on reversible gels and biomolecular condensates.

CPP 58.4 Fri 12:15 ZEU/0255

From Champagne Fizzling to Confined Polymer: Natural and Artificial Bubble Nucleation — •Carlos Arauz-Moreno[1,2], Keyvan Piroird[2], and Elise Lorenceau[1] — [1]Université Grenoble Alpes, CNRS, LIPhy, F-38000 Grenoble, France — [2]Saint-Gobain Research Paris, F-93360 Aubervilliers, France

Bubbles dazzle the senses when pouring a Champagne glass. However, there is a hidden trick to this elegant experience: natural nucleation sites, such as tartrate crystals from washing or cellulose fibers from drying, or artificial sites, like crenels in the flute, are used to trigger bubble nucleation by lowering the energy barrier required to grow a bubble; otherwise, Champagne wouldn't bubble at all. By using a model system of viscoelastic polyvinyl butyral (PVB), we show that the concepts of natural and artificial nucleation from Champagne equally apply to confined viscoelastic polymers. Our experimental results show that water vapor, which tends to aggregate inside the PVB matrix in the form of clusters, escapes in copious amounts from the polymer bulk when the latter is heated and decompressed (e.g., at 140°C, dP=1bar). However, bubbles may only form at naturally trapped fibers, dust speckles, or in artificial crenels on the glass surface. The number of natural nuclei is apparently and counterintuitively inversely proportional to the applied temperature. Moreover, bubbles can take on different shapes and sizes because coalescence does not occur. Finally, we investigated how the growth rate of bubbles is impacted by whether nucleation is natural or artificial, revealing a clear distinction between the two: the growth rate in the former is global while in the latter is local.

CPP 58.5 Fri 12:30 ZEU/0255

Steric Origins of Microgel Thermoresponsiveness Revealed by All-Atom Polymer Simulations — •Jannis Krüger[1], Letizia Tavagnacco[2], Emanuela Zaccarelli[2], and Thomas Hellweg[1] — [1]Physical and Biophysical Chemistry, Bielefeld University, Germany — [2]Department of Physics, Sapienza University of Rome, Italy

Microgels based on N-isopropylacrylamide (NIPAM) are well established in soft matter science due to their thermoresponsive swelling behavior. Dynamic light scattering (DLS) reveals a sharp decrease in the hydrodynamic radius at a characteristic volume phase transition temperature (VPTT), which occurs around 34°C. In our previous work[1] we observed that by adding a non-thermoresponsive comonomer such as N-tert-butylacrylamide (NtBAM), this transition broadens in temperature until it disappears at high molar contents. The VPT is typically interpreted in terms of hydrophilicity or hydrophobicity; however, the steric demand of chemical substituents is often overlooked. In this work, we compare DLS measurements with all-atom molecular dynamics simulations of NIPAM and NtBAM polymer chains in water, to show how subtle differences, like replacing an isopropyl with a tert-butyl group, substantially affects the coil-globule transition of polymers in water, thereby providing deeper insights into the molecular origin of the broadening and lowering of the VPTT in real microgels.

CPP 58.6 Fri 12:45 ZEU/0255

Photo-responsive microgels as model systems with tunable crosslinking density — •Dominik Wöll and Christian Metzen — Institute of Physical Chemistry, RWTH Aachen University

Functional microgels have powerful applications due to their specific structure, which can quickly respond to external stimuli such as temperature, pH, ionic strength, solvent composition, and light. We synthesized double-responsive poly(N-isopropylacrylamide) (PNIPAM) microgels that react to both light and temperature. The light responsiveness is achieved by the addition of photoswitchable trans-azobenzene (Azo) units that crosslink with the corresponding β-cyclodextrin (β-CD) units copolymerized into the microgel. Irradiation with light causes switching from trans-Azo to cis-Azo and thus opening of the crosslink. With the wavelength of light, and the corresponding photostationary state, the crosslinking density in these microgels can be precisely controlled with light. This model system allows us to investigate the influence of crosslinking density on the structure and properties of microgels.

CPP 59: Crystallization

Structure formation in Polyamide 6 under process-relevant conditions: In situ SAXS/WAXS study using a modular FlowCell setup — •Anna Katharina Sambale[1], Eric Euchler[1], Moritz Kurkowski[1], Enno Henn[1], Regine Boldt[1], Matthias Schwartzkopf[2], Sarathlal Koyiloth Vayalil[2,3], and Markus Stommel[1,4] — [1]Leibniz-Institut fuer Polymerforschung Dresden e.V., Dresden, Germany — [2]Deutsches Elektronen Synchrotron DESY, Hamburg, Germany — [3]Applied Science Cluster, UPES, Dehradun, India — [4]TUD Dresden University of Technology, Dresden, Germany

The microstructural evolution of semi-crystalline thermoplastics during melt processing is governed by local thermo-rheological conditions, which strongly influence crystallization kinetics and consequently, the final material properties. To analyze these interdependencies under process-relevant conditions, a modular FlowCell setup was developed for time-resolved in situ SAXS/WAXS experiments at the synchrotron beamline P03 at DESY, Hamburg. The setup combines a commercial single-screw extruder with customized temperature-controlled slit capillary that enables measurements during controlled cooling from the melt to solid state, with synchronized acquisition of IR-thermography data and, in extended configurations, Raman spectroscopy. Recent experiments on polyamide 6 demonstrate the impact of different cooling strategies and nucleation conditions on the resulting structure. The results highlight the relevance of spatially and temporally resolved analysis techniques for understanding structure formation towards industrial polymer processing.

CPP 59.2 Fri 11:45 ZEU/0260

Influence of Composition on Sanidic Liquid Crystalline Mesophases in Statistical Copolythiophenes — •Alexander Much[1], Jakob Danziger[1], Qian Wang[2], Michael Sommer[2], and Oleksandr Dolynchuk[1] — [1]Martin-Luther-Universität Halle-Wittenberg — [2]Technische Universität Chemnitz

Liquid-crystalline (LC) materials exhibit a variety of structural forms depending on the degree of order, allowing for the novel combination of their anisotropic properties. Board-like conjugated polymers with stiff backbones and short side chains, such as poly-(3-hexylthiophene) (P3HT), are of particular interest because they exhibit weakly explored sanidic LC mesophases.

Here, we study the influence of chemical side-chain modification on the LC phase transitions in statistical copolymers poly-(3-hexylthiophene)-stat-poly-[3-(6-cyanohexyl)thiophene] using differential scanning calorimetry (DSC) and temperature-resolved wide angle X-ray scattering. We find that the copolythiophenes go trough a cascade of sanidic LC mesophases during heating, similar to those in P3HT. Remarkably, the temperature range where sanidic mesophases exists follows the melting range from DSC as a function of comonomer composition and increases towards the intermediate composition with an apparent minimum in values of melting temperature and enthalpy. This suggest that energetic contributions reduce the thermal stability of sanidic LC phases in copolythiophenes, and that LC transition temperatures can be tuned through statistical copolymerization without negating their existence.

CPP 59.3 Fri 12:00 ZEU/0260

In-situ structure and morphology investigations of slot-die coated perovskite nanocrystal films — •Thomas Baier[1], Altantulga Buyan-Arivjikh[1], Lixing Li[1], Xiaojing Ci[1], Markus Döblinger[2], Matthias Schwartzkopf[3], Thomas Bein[2], Sarathlal Koyiloth Vayalil[3,4], and Peter Müller-Buschbaum[1] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]Department of Chemistry, LMU, Munich — [3]DESY, Hamburg — [4]UPES, Dehradun

Colloidal perovskite nanocrystals (PNCs) are promising in contributing to next-generation optoelectronic and energy conversion technologies. In this work, mixed-cation cesium-formamidinium lead-iodide (Cs(1-x)FAxPbI3) PNCs were synthesized via a colloidal hot-injection route and subsequently processed into thin-film active layers using slot-die coating for scalable manufacturing. The evolution of structural order during deposition was probed in-situ using grazing-incidence small- and wide-angle X-ray scattering (GISAXS and GIWAXS), providing direct insights into nanocrystal packing, ordering, and defect formation. Simultaneous optical characterization via photoluminescence (PL) provided complementary information on the evolution of optical properties during deposition, while transmission electron microscopy (TEM) en-

abled correlation with nanoscale information. By combining colloidal synthesis, in-situ structural probes, and optical characterization, this work directly links nanoscale assembly, defect states, and the optoelectronic performance of perovskite nanocrystal thin films.

CPP 59.4 Fri 12:15 ZEU/0260

Interplay of heterogeneous nucleation and prefreezing in PBS droplets on graphene — •Marthinus van Niekerk, Moritz Hartelt, and Oleksandr Dolynchuk — Experimental Polymer Physics, Martin-Luther-University Halle-Wittenberg, Germany

The dominant crystallization mechanism depends on the kinetics of formation and crystal growth. Heterogeneous nucleation, leading to spherulitic morphology, and prefreezing, leading to epitaxial morphology, are two mechanisms of interface-induced crystallization in polymers. However, research on prefreezing is in a seminal phase, and its possible competition with nucleation during cooling remains unexplored. Here, we study the crystallization behavior of dewetted poly(butylene succinate) (PBS) droplets on graphene, a known prefreezing substrate for PE and PCL, during cooling from the melt at different rates using optical- and atomic force microscopy and wide-angle X-ray scattering. Across a large range of cooling rates, nucleation was found to be dominant, resulting in spherulitic morphology in large droplets. However, indications of prefreezing were observed in very small droplets exhibiting epitaxial morphology. Subsequent annealing close to T_m resulted in significant reordering and enhancement of out-of-plane orientation, causing a change in morphology from spherulitic to epitaxial for all droplets up to several hundred nanometers. Theoretical analysis revealed a significant lattice mismatch between graphene and PBS, suggesting it is a plausible reason for the absence of rapid prefrozen layer growth during initial cooling from the melt.

CPP 59.5 Fri 12:30 ZEU/0260

Crystallization of polymer networks in the constant-strain and constant-stress ensembles — Atmika Bhardwaj[1], Huzaifa Shabbir[1], Jens-Uwe Sommer[1,2], and •Marco Werner[1] — [1]Bereich Theorie der Polymere, Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany — [2]Institut für Theoretische Physik, Technische Universität Dresden, Germany

We investigate how deformation and cross-links affect the crystallization of polymer networks using molecular dynamics simulations. A cooling- and heating cycle are simulated both under constant-strain and constant-stress conditions, monitoring specific volume, crystallinity, and orientational order as functions of temperature. In both ensembles, deformation induces chain pre-alignment along the loading direction, driving crystallization at higher transition temperatures. Under constant stress, the pre-alignment promotes crystal growth along the mechanically induced director resulting in a substantial increase of deformation in favor of that direction. These results show how mechanical ensemble, deformation, and cross-linking can be combined to tailor the shape response of polymer networks upon phase transition.

CPP 59.6 Fri 12:45 ZEU/0260

Surface-induced ordering and continuous breaking of translational symmetry in conjugated polymers — Anton Sinner, Alexander Much, and •Oleksandr Dolynchuk — Martin Luther University Halle-Wittenberg, Germany

Surface-induced liquid crystalline (LC) phase transitions elicit fundamental interest and hold potential for leveraging the accompanying anisotropic order at the surface. Board-like conjugated polymers are of particular interest due to the novel sanidic LC phases they exhibit, which have remained largely unexplored. Specifically, although preferential molecular orientation near the free surface has been observed in films of conjugated polymers, the mechanism of its formation is not yet fully understood. In this study, grazing-incidence X-ray scattering is employed to monitor the formation and breaking of positional order in situ in thin films of two conjugated polymers representative of two classes: polythiophenes and polydiketopyrrolopyrroles. Our findings demonstrate that the surface induces positional order in films of both conjugated polymers via the formation of a highly oriented, sanidic disordered LC phase. The ordering process continues upon cooling and undergoes multiple LC transitions into more ordered phases, both at the surface and in the bulk, which can compete with each other. The positional smectic-like order parameter displays continuous temperature dependence in the vicinity of the transition, signifying a continuous breaking of translational symmetry by the surface. Theoretical analysis enables accurate description of the order parameter when critical behavior is considered.

CPP 60: Molecular and Polymer Dynamics, Friction and Rheology II

Time: Friday 12:15–13:00 Location: HÜL/S386

CPP 60.1 Fri 12:15 HÜL/S386

Fouling in Emulsion Polymerization of Different Copolymers investigated in-situ with the Quartz Crystal Microbalance (QCM) — •Kevin Marvin Hoffmann and Diethelm Johannsmann — Clausthal University of Technology, Institute of Physical Chemistry, Arnold-Sommerfeld-Straße 4, 38678 Clausthal-Zellerfeld, Germany

In emulsion polymerization, reaction and particulate fouling leads to clogging, product contamination, and reduced heat transfer efficiency. Common techniques for in-line monitoring of fouling are based on the heat transfer efficiency across the surface and the pressure drop in pipes or tubes. These techniques show fouling layers at thicknesses of a few tens of micrometers, at least. They are not sensitive enough to study the initial stages of a fouling.

A quartz crystal microbalance with dissipation monitoring (QCM-D) was used to study fouling in-situ. The QCM infers changes in mass on its surface to changes of its resonance frequency. It is sensitive down to the nanometer range. In addition to an estimate of the layer thickness, the QCM-D provides for additional information, derived from the comparison between the shifts in frequency and half-bandwidth as well as the comparison between different overtones.

It was found that polyacrylates behaved characteristically differently from polyvinyl acetates. The polyacrylates formed compact and stiff fouling layers. The polyvinyl acetates formed softer and more porous, extended layers. We assume that the stabilizing agent has a major impact on the fouling layer's nature.

CPP 60.2 Fri 12:30 HÜL/S386

Cluster growth dynamics of nickel particles in viscoelastic matrices — •Konstantin Gerstenberger und Günter K. Auernhammer — Leibniz Institute of Polymer Research Dresden, Hohe Str. 6, 01069 Dresden, Germany

Magnetic elastomers can dynamically modify their mechanical properties in response to a magnetic field giving them the potential for new applications as soft actuators. A common method of producing these materials involves embedding magnetic particles in an elastomer matrix. In the presence of an applied magnetic field, the particles tend to arrange themselves into chain-like clusters which react to external stimuli, even if the matrix is crosslinked.

As part of the research unit FOR 5599 on structured magnetic elastomers we investigate the formation process of these materials, paying particular attention to the interaction between particle cluster formation and simultaneous crosslinking of the surrounding matrix. We use particle tracking velocimetry techniques to observe the cluster development over time and investigate how this process depends on various parameters. Therefore, it can be concluded that the development of chains is influenced by not only the particle concentration and matrix viscosity, but also the rotation of the applied magnetic field. This rotation can be used to adjust the mean length of the chains to a specific value.

Further investigation of larger sample sizes will be possible due to a new kind of Hallbach array that is currently under construction. This presentation will also cover the general idea of this machine.

CPP 60.3 Fri 12:45 HÜL/S386

Maps of High Viscoelastic Properties Generated with an Instrument Combining a Quartz Crystal Microbalance (QCM) with an AFM — •Cedric Jünemann, Diethelm Johannsmann, and Arne Langhoff — Clausthal University of Technology, Instutite of Physical Chemistry, Arnold-Sommerfeld-Straße 4, 38678 Clausthal-Zellerfeld

We present an instrument, which images the high-frequency viscoelastic properties of various samples. The instrument combines an atomic force microscope (AFM) with a quartz crystal microbalance with dissipation monitoring (QCM-D). Imaging becomes possible by a fast measurement of a resonator's frequency and bandwidth, achieved with a multi-frequency lockin amplifier (MLA). The MLA tracks multiple overtones simultaneously. To improve contrast and to facilitate quantitative interpretation, the colloidal force probe configuration was used. The cantilever was modified by gluing a glass sphere with a diameter of 50 μm to the tip, thereby increasing the contact radius to a few hundred nanometers. The sphere is heavy enough to clamped in place by inertia, which simplifies the analysis. A quantitative interpretation can rely on ratios between the different QCM signals, which eliminates the unknown contact area from the analysis. Printed drops and a biofilm composed of yeast were chosen for demonstration. This approach provides for a flexible method to investigate viscoelastic properties on the nanoscale at high frequencies.

CPP 61: Closing Talk (joint session CPP/BP/DY)

Time: Friday 13:15–14:00 Location: HSZ/0002

Invited Talk CPP 61.1 Fri 13:15 HSZ/0002

Biomolecular Condensates: Challenges for Polymer Physics — •Jens-Uwe Sommer — Leibniz-Insitut für Polymerforschung Dresden, Bereich Theorie der Polymere,Hohe Straße 6, 01069 Dresden, Germany — TU Dresden, Insitut für Theoretische Physik, Zellescher Weg 17, D-01069 Dresden, Germany

Biomolecular condensates (BMCs) constitute an emerging paradigm in the understanding of biological functions. They shift the focus from individual biochemical processes toward the collective behavior of biopolymers, in which phase-separation mechanisms and intrinsically disordered proteins lacking canonical enzymatic roles play central and often decisive functions. Consequently, universal principles of complex (bio)polymer solutions gain relevance, and several classical questions in the physics of living matter can now be revisited from this polymer-physics perspective. In this talk, I will discuss theoretical approaches and concepts that are based on universal principles, with a particular emphasis on current challenges in the field.

Thin film growth on weak surfaces: influence of substrate inhomogeneities — •Eric Karajic[1], Martin Oettel[1], Edwin Mozo[2], and Fabio Reis[2] — [1]University of Tübingen, Institute of Applied Physics — [2]Universidade Federal Fluminense, Instituto de Fisica

The initial island density in the growth of thin films on perfectly smooth surfaces is set by an interplay between flux, diffusion and the stability of small clusters [1]. However, real surfaces have inhomogeneities which may trap freely diffusion adsorbates and act as initial nucleation sites. Using kinetic Monte-Carlo (KMC) simulations, we investigate the influence of trapping strength and density of inhomgeneities on the initial growth behavior. We discuss the consequences for basic growth modes on weakly interacting surfaces [2]. For layer-by-layer growth, island densities may vary grossly between first and second layer, but for island growth the possible return to smooth growth at intermediate layer thicknesses is not affected. DS 1.2 Mon 9:45 REC/C213

Organic self-assembled monolayers as barrier material in Josephson junctions — •Moritz Singer[1], Harsh Gupta[1], Rui Pereira[2], Benedikt Schoof[1], and Marc Tornow[1,2] — [1]TU Munich, Garching, Germany — [2]Fraunhofer EMFT, Munich, Germany

Superconducting qubits employ Josephson junctions (JJs) to provide the nonlinearity needed to address a unique two-state system. The JJs consist of two superconducting electrodes which are separated by a nanometer-thin layer acting as tunnel barrier and is mostly fabricated from oxides. The thickness of the oxide is highly sensitive to process variations, and it hosts many two-level systems (TLS) which give rise to dielectric losses, thereby limiting the qubit coherence times. In this study, we report on JJs comprising an organic self-assembled monolayer (SAM) as the insulating barrier material. Our JJs consist of Ta electrodes on a Nb seed layer, separated by a SAM of octadecene (C18H36) molecules that are grown on the thin native TaOx layer of the bottom electrode. We fabricated JJs with three different electrode sizes in the μm - range and measured critical currents Ic between 3.7 μA and 30.6 μA at 100 mK, in good quantitative agreement with the expected values according to the Ambegaokar-Baratoff relation. We further analyzed the data using the Simmons tunneling model, adapted to account for the two-layer TaOx/SAM barrier. We obtain barrier heights ranging from 0.43-0.57 eV for the SAM-JJs, which is significantly higher than for JJs fabricated with a Ta-oxide barrier only (barrier height 0.25 eV). This shows that the properties of JJs can be modified and tuned by introducing a SAM as barrier material.

DS 1.3 Mon 10:00 REC/C213

Prediction of room-temperature two-dimensional pi-electron half-metallic ferrimagnet — •Jan Phillips[1], João C. G. Henriques[1,2], Antonio T. Costa[1,3], and Joaquín Fernández-Rossier[1,4] — [1]International Iberian Nanotechnology Laboratory (INL), Av. Mestre José Veiga, 4715-330 Braga, Portugal — [2]Universidade de Santiago de Compostela, 15782 Santiago de Compostela, Spain — [3]Universidade do Minho, R. da Universidade, 4710-057 Braga, Portugal — [4]On permanent leave from Departamento de Física Aplicada, Universidad de Alicante, 03690 San Vicente del Raspeig, Spain

We propose a strategy to obtain conducting organic materials with fully spin-polarized Fermi surface, lying at a singular flat band, with antiferromagnetically coupled magnetic moments that reside in pi-orbitals of nanographenes. We consider a honeycomb crystal whose unit cell combines two molecules with S=1/2: an Aza-3-Triangulene, a molecule with orbital degeneracy, and a a 2-Triangulene. The analyzed system is half-metallic with a ferrimagnetic order, presenting a zero net total magnetic moment per unit cell. We combine density functional theory calculations with a Hubbard model Hamiltonian to compute the magnetic interactions, the bands, and the collective spin excitations. We obtain very large intermolecular exchange couplings, in the range of 50 meV, which ensures room temperature stability. This crystal being a half-metal with fully compensated magnetic moments combines two characteristics that would make it ideal for spintronics applications.

DS 2: Focus Session: Tunable Correlations in van der Waals Quantum Materials I (joint session TT/DS/HL)

The library of strongly correlated layered materials has intensively grown, giving now access to the full breadth of symmetry broken emergent phases, ranging from excitonic, to magnetic, superconducting, or Mott insulating ground states. At the same time, also the ways of tuning these correlated phases in 2D are steadily developing, e.g, via twisting or stacking, engineered defects, or applied external fields. Taken together, this nowadays allows for sheer endless possibilities to tailor layered correlated quantum materials on demand opening unprecedented avenues towards both deep insights into emergent phenomena and novel functionalization routes based on many-body properties.

This focus session will highlight recent advancements and breakthroughs achieved in this field, which we expect to be of great interest to the broadest audience and to stimulate discussions crossing field boundaries.

Coordinators: Lennart Klebl (Uni Würzburg, Jonas Profe (Uni Frankfurt), Malte Rösner (Uni Bielefeld), Ursula Wurstbauer (Uni Münster)

Time: Monday 15:00–18:15 Location: HSZ/0003

See TT 12 for details of this session.

DS 3: Thin Film Properties I: Methods

DS 3.1 Mon 15:00 REC/C213

Update on the IBA activities in Bonn — •Henry Schumacher, Dennis Sauerland, and Sebastian Neubert — Helmholtz-Institut für Strahlen und Kernphysik, Universität Bonn

The *Bonn Isochronous Cyclotron* can accelerate protons, deuterons and light ions with nominal energies of 7 to 14 MeV/nucleon. At one of the five beam lines, a new experimental site for material analysis is in development.

This new experiment will house a small number of surface barrier detector for RBS (backwards direction) and beam characterization (off-axis, foward direction) as well as a silicon drift detector for PIXE measurements and utilize a low energy alpha particle beam.

In this talk, a general overview over the setup and progress, preliminary detector tests, count rate estimations and preparatory measurements will be presented.

DS 3.2 Mon 15:15 REC/C213

The TXPES Beamline at SESAME: A New Facility for Advanced Soft X-ray Photoelectron Spectroscopy — •Zeynep Reyhan Ozturk — TARLA, Ankara, Turkey — SESAME, Balqa, Jordan

The TXPES (Turkish X-ray Photoelectron Spectroscopy) beamline at SESAME is a newly installed soft X-ray facility dedicated to high-resolution XPS, UPS, and ARPES for advanced surface and interface analysis. With a broad tunable photon-energy range, TXPES enables detailed investigation of electronic structure, chemical composition, band dispersion, and oxidation states in a wide variety of materials.

The end station features a multi-chamber UHV system including a preparation chamber, an analysis chamber, and a high-pressure cell for in situ and near-ambient pressure studies. The analysis chamber houses a hemispherical electron energy analyzer capable of XPS/UPS/ARPES, along with an ion gun, LEED, and LEIS, enabling comprehensive structural and chemical characterization at different depth sensitivities. TXPES combines tunable soft X-rays, high-resolution electron spectroscopy, and controlled environments to study surface oxidation, adsorption, catalysis, thin-film interfaces, and electronic band alignment with exceptional sensitivity. The integration of a high-pressure cell expands these investigations to realistic gas conditions, bridging the gap between model systems and real-world applications. The beamline represents a major collaborative effort between Turkish institutions and SESAME and is progressing toward full operation and user access in the near future.

DS 3.3 Mon 15:30 REC/C213

Bringing Synchrotron-Level HAXPES to the Lab: DeepCore-X for Buried Interface Characterization — •Martin Schmid[1], Elin Cartwright[2], Eleni Anargirou[1], Marcus Lundwall[2], and Susanna Eriksson[2] — [1]Scienta Omicron GmbH, Limburger Str. 75, 65232 Taunusstein — [2]Scienta Omicron AB, Danmarksgatan 22, 75323 Uppsala

Buried interfaces in multilayer semiconductor devices, such as MOSFETs, solar cells, and memory architectures, critically impact performance and reliability. Hard X-ray Photoelectron Spectroscopy (HAXPES), with greater information depth than conventional XPS, enables nondestructive analysis of buried layers. We introduce DeepCore-X, a next-generation lab instrument combining soft and hard XPS in one system, delivering synchrotron-like performance. Powered by a Ga Kα MetalJet source (9.25 keV), it offers 1000 W continuous operation and a hundred-fold intensity advantage over other lab HAXPES sources. The system supports high-throughput measurements across complex stacks. Automated sample handling, multi-point acquisition, and operando bias capabilities make it ideal for evaluating band bending, trap states, and chemical shifts. We will present recent results and application examples, including non-destructive depth profiling, to demonstrate how DeepCore-X bridges the gap between surface analysis and full device stack characterization without requiring synchrotron access.

DS 3.4 Mon 15:45 REC/C213

Simulation-Guided GIXPS: How to Maximize Signal and Depth Sensitivity in Photoelectron Emission Experiments — •O. Rehm[1], E. Kusari[1], D. Capalbo[1], A. Gloskovskii[2], C. Schlueter[2], L. Baumgarten[3], and M. Müller[1] — [1]Fachbereich Physik, Universität Konstanz, 78457 Konstanz — [2]DESY, 22607 Hamburg — [3]FZ Jülich GmbH, PGI-6, 52425 Jülich

(Hard) X-ray Photoelectron Spectroscopy ((HA)XPS) is a powerful technique for probing the chemical and electronic structure of thin films, interfaces, and multilayers, but access to synchrotron radiation is typically highly limited. To address this constraint, we present a simulation-guided approach that optimizes (HA)XPS experiments through grazing-incidence (GI) geometries. At GI angles (0.3°-2°) refraction and total reflection of X-rays generate pronounced angle-dependent interference effects that shift the weighted contribution maximum of photoelectrons to well-defined depths within the sample. Our approach - GIXPS - predicts these conditions in advance, enabling targeted enhancement of surface, interface, or bulk sensitivity. It boosts photoemission intensity by up to two orders of magnitude at characteristic GI angles, enabling faster data acquisition and better depth resolution while preserving the element-specificity of (HA)XPS. This methodology provides a practical route to more efficient, depth-selective experiments and is a powerful tool for designing and carrying out optimized interface- and bulk-sensitive (HA)XPS measurements - thus enabling the more efficient use of limited synchrotron beamtime. O. Rehm *et al.*

DS 4: Thin Film Properties II

Time: Monday 16:30–18:15 Location: REC/C213

DS 4.1 Mon 16:30 REC/C213

Epitaxial Growth and Structural Characterization of Non-centrosymmetric B20-PtAl Thin Films — •Ayusa Aparupa Biswal[1], Darius Pohl[2], Bernd Rellinghaus[2], Edouard Lesne[1], and Claudia Felser[1] — [1]Max-Planck-Institute für Chemische Physik fester Stoffe, Dresden, Germany — [2]Dresden Center for Nanoanalysis (DCN), cfaed, TU Dresden, Dresden, Germany

Topological chiral semimetals with the non-centrosymmetric cubic B20 structure (space group P213) are distinguished by chirality in their crystal, magnetic, and electronic structures [1]. B20 compounds do not possess inversion or mirror symmetry but preserve rotational symmetries. Non-magnetic B20 compounds, such as CoSi, RhSi, PdGa, and PtAl, host multifold fermions originating from topological band crossings. These lead to large Chern numbers and produce Fermi arcs, alike those found in Weyl semimetals [2,3]. We report on the heteroepitaxial growth of crystalline PtAl thin-films with a non-centrosymmetric cubic B20 structure. We employ magnetron sputtering and explore the phase space of sample composition, growth temperature, post-annealing process, as well as resorting to suitable substrates and crystalline buffer layers. The samples are structurally characterized by a combination of X-ray diffraction and atomic-scale high-resolution transmission electron microscopy, which reveals a thickness-dependent microstructure of the B20 films, attributable to a combination of strain relaxation and the formation of extended defects, which are under detailed investigation. [1] B. Bradlyn et al., Science 353 (2016).[2] D. S. Sanchez, et al., Nature 567 (2019).[3] Z. Rao et al., Nature 567 (2019).

DS 4.2 Mon 16:45 REC/C213

high-quality Bi_2Te_3 TI thin films on [0001]-oriented sapphire substrate grown by MBE — •Ismet Gelen, Ahmet Yagmur, Luke Benson, and Satoshi Sasaki — School of Physics and Astronomy, University of Leeds, Leeds LS2 9JT, UK

Over the past decades, topological insulators (TIs) have attracted great attention for their exotic property of being insulating in the bulk while conductive on the surfaces through topological surface states [1], offering promising prospects for future spintronic technologies [2]. Molecular beam epitaxy (MBE) growth method is very important to produce high-quality epitaxial thin film TIs samples. However, producing a high-quality thin film requires careful consideration of substrate preference, growth temperature, and growth rate. This study focuses on the systematic growth of high-quality Bi_2Te_3 TI thin films on a sapphire [0001] substrate with minimal lattice mismatch. We found that growth temperature has a big influence on the surface morphology, which can lead to small or large triangular terraces. When temperature is too low it can create pillars when it is too high it creates defects/holes in films. We will report our optimization of the Bi_2Te_3 growth in terms of X-ray reflectivity/diffraction, atomic force microscopy, Raman spectroscopy, and magnetotransport properties by measuring standard Hall-bar type devices at low temperatures. Finally, we obtain films with large grain size without defects/pillars, and with high mobility and low carrier density.

DS 4.3 Mon 17:00 REC/C213

exploring ehalgogenide ABX3 perovskites: challenges and insights from physical vapor deposition — •Sebastian Zimmermann[1], Roland Scheer[2], and Torsten Hölscher[1] — [1]B5 Photovoltaics, Just Transition Center, Martin Luther Universität Halle-Wittenberg — [2]Photovoltaics Groups, Martin-Luther-Universität Halle-Wittenberg

The discovery of new solar cell materials is crucial for the next generation of multijunction systems in photovoltaics. This work focuses on synthesizing thin-film materials that are theoretically well suited for photovoltaic applications. To form these materials, we use physical vapor deposition (PVD). At the beginning, we aim to synthesize chalcogenide perovskites. Chalcogenide perovskites are crystals with a perovskite structure (typically ABX3), where X stands for selenium or sulfur, A for group II metal like Ca or Ba and B for a transition metal like Ti or Zr. Compared to other perovskites, their advantages include lower toxicity and the predicted long-term stability of the layers. This talk presents results of microstructural analysis of PVD synthesized chalcogenide perovskite films and discuss challenges encountered during synthesis. Our results provide new insights in the field of photovoltaic materials and are intended to open up new perspectives for multijunction thin-film solar cells.

DS 4.4 Mon 17:30 REC/C213

Molecule Adsorption at Me-polar and N-polar Sc(x)Ga(1- x)N Surfaces Investigated by Photo Electron Spectroscopy — •Fabian Ullmann[1,2] and Stefan Krischok[1,2] — [1]TU Ilmenau, Ehrenbergstraße 29, 98693 Ilmenau — [2]Zentrum für Mikro- und Nanotechnologien, Gustav-Kirchoff-Straße 7, 98693 Ilmenau

ScGaN can occur in various crystal structures. The most important ones are wurtzite and rock salt formation. Depending on the scandium concentration, a phase transition between these orientations can be found. ScGaN surfaces with different scandium concentrations and orientations were grown by molecular beam epitaxy (MBE) to investigate the near-surface electronic structure. Two different substrates were used to achieve either Me-polar (SiC) and N-polar (sapphire) wz-ScGaN surfaces. The interaction of gas molecules (oxygen and water) in vacuum were analyzed by X-ray (XPS) and ultraviolet photoelectron spectroscopy (UPS).

DS 4.5 Mon 17:45 REC/C213

Molecular Beam Epitaxy of ferrimagnetic Mn_4N — •Adriano Notarangelo, Michael Hanke, Lutz Geelhaar, Oliver Brandt, and Philipp M. John — Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, 10117 Berlin, Germany.

Mn_4N is a ferrimagnetic transition-metal nitride that crystallizes in the antiperovskite structure. With its strong perpendicular magnetic anisotropy and high Curie temperature of ≈ 743 K, Mn_4N emerges as a promising material for rare-earth-free spintronics and other magnetic device applications. Since the magnetic properties of Mn_4N are sensitive to stoichiometry, strain, and lattice defects, achieving high-quality epitaxial growth is essential.

In this work, we grow 60 nm–thick Mn_4N layers by plasma-assisted molecular beam epitaxy on sub-1% lattice-mismatched $SrTiO_3$(001) substrates. After carefully calibrating the Mn/N flux ratio to achieve a 4:1 stoichiometric balance, we obtain phase-pure Mn_4N(001) films with no detectable secondary Mn_xN_y phases. X-ray diffraction reveals that optimal crystalline quality is achieved for growth temperatures between 300 and 400°C, while substantial Mn desorption hinders growth above 600°C. The out-of-plane lattice constant decreases from 3.854 to 3.828 Å as the growth temperature increases from 300 to 500°C, indicating an increased in-plane tensile strain imposed by the epitaxial constraint to $SrTiO_3$ with its larger lattice constant.

The optimization of Mn_4N film growth on $SrTiO_3$ is a solid basis for its growth on industry-relevant substrates such as Si, SiC, and GaN.

DS 4.6 Mon 18:00 REC/C213

Investigations of cubic boron nitride nucleation using in situ RHEED during pulsed laser deposition — •Falko Jahn, Laura Dienelt und Steffen Weissmantel — Laserinstitut Hochschule Mittweida, Technikumplatz 17, 09648 Mittweida

Due to its outstanding properties such as second-highest hardness, the cubic allotrope of boron nitride (c-BN) has attracted significant interest from both academia and industry for decades. So far, challenges in the thin film deposition of this material have prevented a successful industrial application, for example as a wear-resistant coating for cutting tools. Although pulsed laser deposition (PLD) has enabled progress in this particular field, several aspects of the film formation process remain insufficiently understood. In particular, the process of nucleation from the hexagonal to the cubic phase still contains unanswered questions. In this work, the microstructure of the growing film is characterized in situ using reflection high-energy electron diffraction (RHEED). This enabled further insight into the nucleation process. The results provide support for the nucleation model of subplantation. These findings contribute to a deeper understanding of c-BN nucleation during PLD or similar PVD techniques.

Soft X-ray Microscopy of Ferroic Thin Films — •Tim A. Butcher[1], Simone Finizio[2], Michael Schneider[1], Jörg Raabe[2], Stefan Eisebitt[1], and Bastian Pfau[1] — [1]Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy, 12489 Berlin, Germany — [2]Paul Scherrer Institut, 5232 Villigen PSI, Switzerland

Any technological advance involving ferroic thin films requires a clear picture of their domain structures at the nanoscale. These can be studied by soft X-ray microscopy at synchrotron lights sources, which combines high spatial resolution with sensitivity to ferroic order. This presentation will provide an overview of several ferroic thin films and the application of coherent diffractive imaging methods such as Fourier Transform Holography and soft X-ray ptychography to their study [1]. One example is the room-temperature multiferroic BiFeO3 for which ptychography can probe the magnetoelectric coupling by resolving both the antiferromagnetic spin cycloid and the ferroelectric domains in a single measurement [2,3]. Furthermore, an example of imaging dynamics will be provided with the ptychographic investigation of magnetic domain walls [4].

DS 6.2 Tue 10:00 REC/C213

Atomic Scale Insights into the Polymorphism of Ruddlesden-Popper Nickelates and Titanates — Shihao Wei[1], Stefania Baronio[2], Bruce Davidson[2], Ke Zou[2], and •Nicolas Bonmassar[1] — [1]Materials Physics, Institute for Materials Science, University of Stuttgart, Heisenberstr. 3, 70569, Germany — [2]Quantum Matter Institute, University of British Columbia, Vancouver, Canada

Ruddlesden-Popper (RP) oxides provide an ideal platform for investigating coupled structural and electronic phenomena, as subtle variations in layering and cation coordination can significantly alter their functional properties. Using oxide molecular beam epitaxy, we can grow distinct nickelate and titanate RP phases with atomic-layer precision, demonstrating the controlled stabilization of distinct polymorphs by tuning the rock-salt and perovskite layers. Advanced scanning transmission electron microscopy provides insights into the resulting structures at an atomic scale, enabling the direct identification of the respective polymorph and the characterization of extended defects, such as stacking faults. By correlating local structure with electronic properties, we can establish clear structure-property relationships across all samples. Electron energy-loss and energy-dispersive X-ray spectroscopy reveal the differences in transition-metal oxidation states, defect density and oxygen orbital occupation between the different RP phases and polymorphs. Our results highlight how precise control of the individual layers leads to the control over the polymorphs in RP nickelates and titanates.

DS 6.3 Tue 10:15 REC/C213

Memristive behaviour in Nickelate Perovskite thin films — •Foelke Janssen[1,2] and Beatriz Noheda[1,2] — [1]Zernike Institute for Advanced Materials, University of Groningen, The Netherlands — [2]Groningen Cognitive Systems and Materials Center (CogniGron), University of Groningen, The Netherlands

Memristive devices can adopt multiple resistance states depending on the history of the electric signal applied, emulating the basic behavior of synapses and neurons. They hold great promise as low energy consumption devices for in-memory and brain-inspired computing. Materials that undergo a metal-to-insulator phase transition (MIT) are interesting as volatile memristors and can also be used as neuristors by being the active component in self-oscillating circuits. Rare-earth (RE) nickelates ($RENiO_3$) display a MIT at temperatures that can be tuned by changing the RE cations, the strain state, the film thickness or the oxygen vacancy content. Compared to other transition-metal oxides, nickelates are especially interesting as memristive devices due to the robustness of the perovskite structure under intense local heating. In this work, we demonstrate that nickelates can also be used to mimic short term memory in synapses via multilevel resistance states that can be achieved in $SmNiO_3$ thin film structures upon voltage pulsing, harnessing the metal-insulator phase transition, without involving ionic transport. Furthermore, we also demonstrate $SmNiO_3$ as a neuron and discuss the mechanisms behind both devices.

Structure and optical properties of Ga2O3 thin films deposited by reactive and non-reactive sputtering — •Marcell Gajdics, Ildikó Cora, Dániel Zámbó, Zsolt Endre Horváth, Miklós Serényi, and Béla Pécz — Institute for Technical Physics and Materials Science, HUN-REN Centre for Energy Research, H-1121 Budapest, Hungary

Ga2O3, as an ultrawide bandgap semiconductor has numerous potential applications in the field of optoelectronics and high-power electronics. Gallium oxide thin films can be grown by a variety of methods, among which radio frequency sputtering is a commonly used technique. In most cases, a ceramic Ga2O3 target is used for the sputter deposition of Ga2O3. In our work, we present an alternative method, i.e. reactive sputtering of a liquid Ga target. We have shown that by using this technique, layers close to the ideal stoichiometry can be deposited with higher deposition rates than by using a Ga2O3 target. The optical properties (e.g. refractive index) were studied as a function of the oxygen concentration in the films. Post-deposition annealing experiments were also performed on the amorphous as-deposited layers to study the annealing-induced structural and optical changes. It was found that as a first step of crystallization γ-Ga2O3 phase was formed and the thermodynamically stable β-Ga2O3 appeared only at higher temperatures. The photoluminescence emission and the optical bandgap were also measured at different annealing temperatures and the results were correlated with the structural properties.

DS 6.5 Tue 11:00 REC/C213

Depth Profiling of Oxygen Migration in Ta/HfO_2 Stacks During Ionic Liquid Gating — •Martin Wortmann[1,2], Beatrice Bednarz[3], Olga Kuschel[3,4], Fabian Kammerbauer[3], Mathias Kläui[3], Andreas Hütten[1], Joachim Wollschläger[4], Gerhard Jakob[3], and Timo Kuschel[1,3] — [1]Bielefeld University, Bielefeld, Germany — [2]Bielefeld University of Applied Sciences and Arts, Bielefeld, Germany — [3]Johannes Gutenberg University Mainz, Mainz, Germany — [4]Osnabrück University, Osnabrück, Germany

Ionic-liquid gating enables electric-field-driven ion transport at thin-film interfaces to manipulate structural, electronic, optical, and magnetic properties [1]. Oxygen is driven from a donor oxide layer into an underlying acceptor metal layer, but the resulting spatial distribution and voltage dependence of oxygen migration remain poorly understood. Here, we investigate the formation of Ta_2O_5 at the interface between the HfO_2 donor and Ta acceptor layers as a function of gate voltage, time, and HfO_2 thickness using oxidation-state depth profiling by combining X-ray reflectivity measurments with multi-line angular-resolved X-ray photoelectron spectroscopy [2,3]. The results elucidate both the quantitative oxygen distribution as well as the underlying mechanism [4].

Invited Talk DS 6.6 Tue 11:15 REC/C213

Charge transfer at interfaces of free-standing oxide membranes and heterostructures — Kapil Nayak[1], Lee-Kang Huang[1], Anton Kaus[1], Marcus Wohlgemuth[1], Alexandros Sarantopoulos[1], Christoph Baeumer[2], Regina Dittmann[1], and •Felix Gunkel[1,2] — [1]PGI-7, FZ Jülich — [2]MESA+, UTwente

Free-standing oxides, based on the delamination of atomically defined epitaxial thin films, provide new opportunities to combine functional complex oxides with semiconductor electronics and other typically incompatible technology environments. The nanoscale confinement of these transferable membranes enables unique structures and functionalities, applicable in hybrid electronics as well as energy applications. Here, we discuss the synthesis of transferable perovskite oxide membranes and heterostructures via the all-perovskite sacrificial-layer route. We present control strategies to achieve singly-terminated membranes, using chemical treatments as well as direct growth mode control. These yield atomically smooth membrane-based substrates, serving as ideal template for heterostructure growth on Si. We use typical charge-transfer oxide heterostructures, such as LaAlO3/SrTiO3, to probe the interfacial charge-transfer across the heterostructure interface. To disentangle growth-induced redox response and thermodynamic ion-exchange, we employ in-situ x-ray spectroscopy and correlate the interplay of confinement-phenomena, redox-chemistry & growth kinetics. Finally, we will provide an outlook on membrane-based oxide heterostructures used in electrochemical water splitting, offering new opportunities for analysis and integration.

Voltage-Controlled Magnetism via Electrically Triggered Metal-Insulator Transitions — •Lorenzo Fratino — Laboratoire de Physique Théorique et Modélisation, CY Cergy Paris Université

Phase separation is key to understanding magnetism in correlated systems like manganites. This talk will show how the resistive switching in metal-insulator transition (MIT) materials can be used to create and control artificial phase separation with voltage. In (La,Sr)MnO*, a threshold voltage triggers an electrothermal MIT, creating a paramagnetic insulating barrier inside a ferromagnetic metallic matrix [1]. We can use this to directly tune magnetic properties, achieving effects like voltage-triggered magnetic anisotropy switching [2]. We also developed a CdS/LSMO heterostructure where light injection modulates resistance drop*comparable to a 9 T magnetic field, while surprisingly decoupling the optical and magnetic responses [3]. This work establishes a versatile pathway for voltage-controlled magnetism using MIT materials [4].

DS 7.2 Tue 10:15 REC/B214

Thermoelectric power factors of defective scandium nitride nanostructures from first principles — •Luigi Cigarini[1], Urszula D. Wdowik[1], and Dominik Legut[1,2] — [1]IT4Innovations, VŠB Technical University of Ostrava, Czech Republic — [2]Department of Condensed Matter Physics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic

In scandium nitride (ScN), structural defects and chemical impurities strongly affect thermoelectricity (TE), although transport mechanisms remain unclear [1-3]. Reported electronic transport in ScN thin films shows large variability, and strategies to enhance TE efficiency often yield conflicting results [4,5]. Here, using the Landauer approach, we analyze how different types of imperfections affect electronic transport in ScN lattice. Defects are classified according to their symmetry (isolated, multiple contiguous, involving stacking mismatches) and chemical nature (oxygen impurities, nitrogen-site vacancies). Our theoretical results identify two dominant defect classes with opposing effects on TE performance: (i) contiguous nitrogen vacancies, which enhance el. conductivity but reduce the magnitude of the Seebeck coeff. (S), and (ii) oxygen substitutions coupled with nearby stacking mismatches, which increase the magnitude of S while hindering el. conductivity. In this way, we propose a rationale that relates part of the experimental variability to its microscopic origin [6]. [1] Phys. Rev. Mater. 3, 020301 (2019), [2] J. Mater. Chem. C 4, 3905 (2016), [3] Phys. Rev. B 86, 195140 (2012), [4] J. Appl. Phys. 113, 153704 (2013), [5] Appl. Surf. Sci. Adv. 25, 100674 (2025), [6] Preprint: arXiv:2509.14762.

Understanding Charge Transport in ZnO Quantum Dots Through Combined Thermoelectric and High-Field Measurements — •Henrik Holzhauser, Morteza Shokrani, and Martijn Kemerink — IMSEAM, Heidelberg University, Germany

ZnO Quantum Dot (QD) solids are an attractive material for a wide range of applications. ZnO QDs also make an excellent model system for QD solid in general owing to the ability to tune the effective diameter of ZnO QD via UV illumination, and the effective electronic localization length via ligands. The charge transport in QD solids is typically explained as thermally activated tunnelling or hopping between the localized states of individual QDs. As such, the electric conductivity is both electric field and temperature dependent. In comparison, the Seebeck effect in QD solids, especially in connection with the electrical conductivity, is not as precisely understood. Here, we combine measurements of the Seebeck coefficient for various ZnO QDs with electric field- and temperature-dependent conductivity measurements, all performed at lattice temperatures ranging from 100 to 300K. We used bare ZnO QDs and ZnO QDs with ligands of various lengths and measured all QD solids at multiple UV-induced effective diameters. The wide range of experiments allows us to obtain a comprehensive understanding of the dominant mechanisms and the characteristic energy and length scales in the system. We find that transport is dominated by energetic disorder resulting from a diameter-dependent charging energy, in combination with an effective localization energy that reflects both wavefunction decay and morphology.

DS 7.4 Tue 11:00 REC/B214

Classification of Metal - Insulator Transitions: Insights from characteristic Property Changes and related Quantum Mechanical Bonding Descriptors — •Tim Bartsch[1], Raagya Arora[4], Carl-Friedrich Schön[1], Umesh Waghmare[3], and Matthias Wuttig[1,2] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany — [3]Theoretical Sciences Unit, School of Advanced Materials JNCASR Jakkur, Bangalore 560064, India — [4]John A. Paulson School of Engineering and appled science, Havard University, Cambridge Massachusetts

The nature of the transition between metals and insulators is one of the most fascinating topics in condensed matter physics. The end points of this transition are well-defined, i.e. a solid which has a non-vanishing electrical conductivity σ in the limit T * 0 K is a metal, while an insulator is characterized by σ = 0 S/m (T * 0 K). In 1980, Rosenbaum and co-workers investigated the metal-insulator transition in phosphorus-doped silicon, by measuring the low-temperature resistivity of samples with different doping concentrations. Here, we are pursuing a rather different goal. We are looking at a range of different crystalline insulators and check whether they can be classified as pressure-controlled MITs based on characteristic changes in their properties. Such pressure-driven MITs occur in all insulating solids at sufficiently high pressures when the orbital overlap of neighboring atoms increases sufficiently to favor a metallic state.

DS 7.5 Tue 11:15 REC/B214

Effect of Ge doping and thickness on anomalous Nernst effect in Fe4N thin films — •Robin K. Paul[1], Jakub Vít[2], Karel Knížek[2], Petr Levinský[2], Ondřej Kaman[2], Mariia Pashchenko[2], Lenka Kubíčková[2], Kyo-Hoon Ahn[2], Markéta Jarošová[2], Joris More-Chevalier[2], Stanislav Cichoň[2], Tomáš Kmječ[3], Jaroslav Kohout[3], Marcus Hans[4], Stanislav Mráz[4], Jochen M. Schneider[4], Giovanni d'Andrea[1], Lambert Alff[1], Esmaeil Adabifiroozjaei[1], Leopoldo Molina-Luna[1], Oliver Gutfleisch[1], and Imants Dirba[1] — [1]TU Darmstadt, Darmstadt, Germany — [2]Institute of Physics of the CAS, Praha, Czech Republic — [3]Charles University, Praha , Czech Republic — [4]RWTH, Aachen, Germany

Anomalous Nernst Effect(ANE)-based devices have recently emerged as a promising alternative to Seebeck based ones, offering simpler geometries. However, their adoption is constrained by lower efficiencies compared to Seebeck-based counterparts. This study focuses on exploring materials with high ANE coefficients. Among the candidates, Fe_4N has attracted attention due to its cost-effectiveness, and tunability through elemental doping. DFT calculations indicate that doping Fe_4N with Ge can enhance its ANE coefficient. In this work, thin films of doped $Fe_{4-x}Ge_xN$ were fabricated onto MgO substrates. The evolution of crystal structure and microstructure are systematically characterized correlating with Nernst effect. ANE is also reported to increase with decrease in film thickness which was investigated by preparing Fe_4N films of thickness from 5nm to 50nm.

DS 8: Transport Properties

Time: Tuesday 14:00–15:30 Location: REC/B214

DS 8.1 Tue 14:00 REC/B214

Polaron Transport in $BiVO_4$ — •Nils Sekinger[1,2], Tsedenia Zwedie[1,2], and Ian Sharp[1,2] — [1]Walter Schottky Institute, Technical University Munich — [2]Physics Department, TUM School of Natural Sciences, Technical University of Munich

Bismuth vanadate ($BiVO_4$) has received considerable attention as a potential photoanode for photocatalytic applications, thanks to its moderate bandgap of ~2.5 eV and favourable band edge energetics. However, it is believed that photogenerated electrons localise at vanadium sites to form small polarons, while holes localise around BiO_8 units to form large polarons, thereby inhibiting their transport [1]. This study investigates charge transport in monoclinic $BiVO_4$ using temperature-dependent photoconductivity measurements. Under illumination, we observe two distinct thermally-activated transport regimes. With decreasing temperature, the large-barrier electron hopping transport characteristic transitions to a lower barrier regime that may arise from the freeze-out of electron transport, resulting in a dominant influence from minority holes. The transport barriers, hopping distances, and effective masses of both small and large polarons in the dark and with illumination at different intensities are investigated. Analysing the dependence of the resistivity on temperature and light intensity provides critical insights into the polaronic conduction mechanism and offers experimental validation for theoretical models describing polaron transport. These findings improve our understanding of charge transport in $BiVO_4$ and its use in photocatalytic and electrochemical applications.

DS 8.2 Tue 14:15 REC/B214

Correlation of impedance and structural properties in oxides on the microscale — •Jan L. Dornseifer[1,2], Christopher P. Körbächer[1,2], Martin Becker[1,2], Janis K. Eckhardt[2], Matthias T. Elm[1,2], and Peter J. Klar[1,2] — [1]Institute of Experimental Physics I, Justus-Liebig-University Giessen, Germany — [2]Center for Materials Research (ZfM), Jusuts-Liebig-University Giessen, Germany

The charge transport properties of ionically and/or electronically conducting thin films are governed by their elemental composition and microstructure, including their morphology and grain architecture. Electrochemical impedance spectroscopy (EIS) is widely used to probe the electrical properties, yielding macroscopic parameters. However, linking these to the underlying microscopic transport processes requires theoretical models that have so far failed for samples with expansions comparable to their grain sizes.

Here, we present an experimental approach to directly relate impedance, microstructure and microscopic transport properties. Using cerium oxide and vanadium oxide networks with well-defined microscale transport paths, the impedance of individual networks was measured via microelectrodes. Complementary SEM, EDX, and micro-Raman spectroscopy provided detailed structural information. Correlating these data with the impedance offered new insights into the microstructural influences on the charge transport. This represents a promising way to reliably determine microscopic transport properties of polycrystalline thin films on the microscale.

DS 8.3 Tue 14:30 REC/B214

Magnetotransport and Electron Optics in Bilayer Graphene — •Florian Schöppl[1], Ming-Hao Liu[2], Alina Mrenca- Kolasinska[3], Klaus Richter[1], Korbinian Rohrmüller[1], Korbinian Schwarzmaier[1], and Angelika Knothe[1] — [1]Institut für Theoretische Physik, Regensburg, Germany — [2]Department of Physics, National Cheng Kung University, Tainan City, Taiwan — [3]AGH University of Krakow, Kraków, Poland

The remarkable sample quality of bilayer graphene (BLG), combined with the strong electrostatic tunability of its band structure, makes BLG an excellent platform for electron optics. While the system's purity enables ballistic transport on micrometer scales [1,2], trigonal warping near each K point induces a valley-dependent momentum selection, resulting in characteristic anisotropic transport and scattering phenomena [3,4]. To study the interplay between such warping effects and symmetry breaking from gate-defined potentials, we employed quantum-mechanical tight-binding models as well as semiclassical simulations and find pronounced directional conductance in BLG cavities. Motivated by these anisotropic properties, we further analyze unguided -ringless- Aharonov-Bohm configurations and used wave-matching algorithms to tailor electrostatically defined lenses [5] and mirror geometries.

Multiscale Simulation of Charge Transport Across Grain Boundaries in Organic Polycrystalline Thin-Film Semiconductors — •Junior-Wilfried Tadjeugue-Nangmo[1,2] and Harald Oberhofer[1,2] — [1]University of Bayreuth — [2]Bavarian Center for Battery Technology, Bayreuth, Germany

Grain boundaries (GBs) are known to critically limit charge carrier mobility in organic polycrystalline semiconductors as already used in e.g. organic field effect transistors. In our contribution, we address Technologies with a multiscale computational framework that correlates a GB's morphology with its influence on the charge transport properties. Our approach is, at its core, based on phase-field simulations of grain growth to generate realistic GB networks. Electronic structure calculations then reveal deep trap states and significant energetic disorder at the GB, leading to substantial injection barriers. Charge transfer rates across GBs are then calculated from a hopping model which are finally fed into kinetic Monte Carlo (KMC) simulations to demonstrate the device level influence of GBs. They elucidate the fundamental role of grain boundaries in limiting charge transport and provide critical guidelines for the development of future high-performance organic electronics devices.

DS 8.5 Tue 15:15 REC/B214

Modeling of Indium Tin Oxide Back Contacts in CIGSe Solar Cells — •Oliver Wolf[1], Merve Demir[2], Matthias Maiberg[2], Torsten Hölscher[1], and Roland Scheer[2] — [1]B5 Photovoltaics, Just Transition Center, Martin Luther University Halle-Wittenberg — [2]Photovoltaics Group, Martin Luther University Halle-Wittenberg

Copper Indium Gallium Diselenide (CIGSe) thin-film solar cells achieve high efficiencies >23% on opaque molybdenum (Mo) back contacts (BC). Substituting the molybdenum by a transparent conductive oxide, such as Indium Tin Oxide

(ITO), facilitates applications in tandem solar cells or bi-facial configurations, but leads to deteriorated Fill Factors and Open-Circuit Voltages. The origin of the inferior solar cell performance remains unclear, but impeded electronic transport at the rear CIGSe/ITO interface appears most likely, especially in view of thin Gallium Oxide interlayers. To elucidate possible transport mechanisms, temperature-dependent current-voltage (JVT) and capacitance-frequency (CfT) characteristics were performed and analysed by means of numerical simulations with Sentaurus from Synopsys. In the measurements, we observe the occurrence of temperature-dependent kinks in the JVT and steps in CfT, which clearly distinguish the measurements of the solar cells with ITO BC from those with Mo. Based on simulation, tunneling processes turn out to be the dominant transport mechanism at the rear interface. Our results are able to describe the observed performance deficits in CIGSe solar cells with ITO BC.

DS 9.1 Tue 14:00 REC/C213

Analysis of the MgF_2 || VO_2 Interface in Applications as Smart Windows by Secondary Ion Mass Spectrometry (SIMS) — •Yan Ravil Wollenweber-Bienerth, Peter J. Klar, Anja Henss, and Martin Becker — Institute of Experimental Physics I and Center for Materials Research, Heinrich-Buff-Ring 16, Justus-Liebig-Universität Giessen, D-35392 Giessen, Germany

Smart Windows are special fenestration devices whose transmittance switches as a function of the ambient temperature. Vanadium dioxide (VO_2) is by far the most studied material for such applications. Usually, high substrate temperatures are needed to obtain VO_2 thin films. This results in detrimental diffusion of alkaline ions from the substrate into the thermochromic layer. Buffer layers between the substrate and the VO_2 may prove a suitable option for reducing this effect. Additionally, these help to increase visible transmittance and, in case of rutile materials, yield a reduction of the VO_2 growth temperature. Magnesium fluoride (MgF_2) is one viable candidate thanks to its excellent optical properties and chemical resistance. Simulations, however, show a significant influence of the interfaces between the layers on various properties. By controlling interface morphology, an improvement of the layer properties can be anticipated.

Here, we utilize SIMS depth-profiling to analyze multi-layer stacks of VO_2 and MgF_2 grown by ion-beam sputter deposition (IBSD). The stacks werde deposited on quartz glass substrates with MgF_2 serving as buffer layer. We show that this type of buffer layer improves the layer properties.

DS 9.2 Tue 14:15 REC/C213

Modification of crystal structure of TiO_2 thin films for artificial photosynthesis — •Lauri Palmolahti — University of Würzburg, Würzburg, Germany — Tampere University, Tampere, Finland

Progressing climate change has created a need for carbon-neutral energy production methods, such as artificial photosynthesis. The corrosive nature of artificial photosynthesis requires the use of coatings to protect otherwise unstable photocatalytic materials. The crystallite structure and size significantly affect the protective properties and chemical stability of the thin film. In this work, the effect of defect composition in amorphous TiO_2 thin films on vacuum annealing induced crystallization was studied. The chemical stability and protective properties of these crystallized films were then examined under conditions similar to those in artificial photosynthesis. The defect composition of the amorphous phase, such as Ti^{3+}, O^{1-}, and precursor traces, was tuned by changing the deposition parameters. The results showed that amorphous TiO_2 thin films without Ti^{3+} defects crystallized into microcrystalline anatase, whereas a moderate number of these defects led to the formation of nanocrystalline rutile. An excessive number of defects resulted in a mixed amorphous–nanocrystalline rutile phase. Impedance spectroscopy and stability tests revealed that microcrystalline anatase was prone to grain boundary corrosion, whereas nanocrystalline rutile was chemically stable and retained its protective properties for extended periods of time, making it a suitable choice for protective coatings in artificial photosynthesis.

DS 9.3 Tue 14:30 REC/C213

Investigation of epitaxial ITO layers on YSZ as a transparent conductive back contact for photoelectrochemical applications — •Margaretha Huber[1], Sergej Levashov[1], Tsedenia Zewdie[1,2], Ian D. Sharp[1,2], and Johanna Eichhorn[1] — [1]TUM School of Natural Sciences — [2]Walter Schottky Institut

Photoelectrochemical (PEC) water splitting is a promising route toward sustainable, high-energy-density solar fuels for carbon-neutral energy storage. Transparent conducting oxides such as indium tin oxide (ITO) often serve as back contacts due to their high electrical conductivity, electrochemical stability in the oxygen evolution reaction, and favorable band alignment. ITO grown on cubic oxide substrates such as yttria-stabilized zirconia (YSZ) can act as an epitaxial template with low lattice mismatch, enabling fully epitaxial oxide heterostructures with well-defined interfaces and reduced defect densities. Here, we investigate epitaxial ITO (100) thin films on YSZ grown by e-beam evaporation through a systematic variation of deposition rate, substrate temperature, and post-deposition annealing atmosphere, thereby tuning crystallinity, lattice parameters, carrier transport, and surface morphology. The correlation between structural quality and stoichiometry, and their impact on electrical properties, is investigated using X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS), and atomic force microscopy (AFM). These ITO/YSZ templates are evaluated using $BiVO_4$ as a model photoanode to enable efficient charge extraction and provide design guidelines for epitaxial oxide heterostructures for PEC water splitting.

DS 9.4 Tue 14:45 REC/C213

Room-temperature H_2 gas sensing in ultra-thin SnO_2 films grown via atomic layer deposition — •Rudi Tschammer[1], Dominic Guttmann[1], Carlo Tiebe[2], Karsten Henkel[1], Carlos Morales[1], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Cottbus, Germany — [2]Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany

Transitioning to an energy system based entirely on renewable energy sources requires long-term energy storage utilizing energy vectors such as hydrogen (H_2). Given its high diffusivity, broad explosive range, and low ignition energy, the adoption of H_2 requires safety systems along the hydrogen value chain. Therefore, there is a need for sensitive, specific and selective conductometric H_2 sensors operating at room temperature (RT) and compatible with complementary metal-oxide semiconductor (CMOS) technology. Earlier work by our group investigated ultra-thin cerium oxide films grown by atomic layer deposition (ALD) and demonstrated H_2 sensing at RT. This performance was due to the abundant defects present in the films. Building on these results, we present a comprehensive investigation of ALD-grown tin oxide (SnO_2), a widely researched metal oxide for H_2 gas sensing. Using *in-situ* X-ray photoelectron spectroscopy (XPS), we observe a distinct dependence of defect concentration on film thickness and oxidant. *Ex-situ* H_2/air gas sensing measurements and near-ambient pressure XPS further link film properties and sensing behavior. These findings pave the way for novel RT H_2 gas sensors based on ALD technology.

DS 9.5 Tue 15:00 REC/C213

Composition and band gap of aluminum alloyed beta-gallium oxide determined by XPS — •Lukas Schewe[1], Jana Rehm[2], Ming-Chao Kao[3], Vedran Vonk[3], Zbigniew Galazka[2], Saud Bin Anooz[2], Andreas Popp[2], and Jan Ingo Flege[1] — [1]Fachgebiet Angewandte Physik und Halbleiterspektroskopie, BTU Cottbus-Senftenberg — [2]Leibnitz-Institut für Kristallzüchtung, Berlin — [3]CXNS-Center for X-ray and Nano Science, DESY, Hamburg

Beta-phase gallium oxide has a band gap of 4.85 eV, suggesting strong potential for high-power electronics applications. Its properties can be enhanced by increasing the band gap via aluminum alloying. Here, we discuss the structural, electronic, and surface properties of β-$(Al_xGa_{1-x})_2O_3$ bulk crystals and thin films grown by metal-organic vapor-phase epitaxy (MOVPE) with Al contents of up to 40 %. Their Al content was determined by X-ray photoelectron spectroscopy (XPS) and compared with values obtained from X-ray diffraction (XRD) and inductively coupled plasma optical emission spectroscopy (ICP-OES). Additionally, potential doping gradients towards the bulk have been investigated by acquiring spectra at different take-off angles and by XPS depth profiling, revealing different aluminum concentrations in the bulk and at the surface. Furthermore, we establish a correlation between Al content and electronic band gap, i. e., with changes in the optoelectronic properties, which were determined by a combination of XPS electron-loss spectra and optical absorbance measurements. Finally, Auger spectroscopy and XRD analysis confirm the excellent chemical and structural quality of β-$(Al_xGa_{1-x})_2O_3$ thin films.

DS 10: Focus Session: Nickelate Superconductivity: Insights into Unconventional Pairing and Correlation Effects I (joint session TT/DS/MA)

Nickel, a direct neighbor of copper in the periodic table, has been considered a promising candidate for high-temperature superconductivity since the early 1990s. After more than three decades of research, this prediction was confirmed with the discovery of superconductivity in nickelates, marking the beginning of the "nickel age" of superconductivity. Recent advances include Sm-based infinite-layer nickelates with transition temperatures approaching 40 K, as well as bilayer nickelates exhibiting superconductivity above 90 K under pressure and up to 60 K under compressive epitaxial strain. These results highlight the crucial roles of structural engineering, epitaxial strain, and precise synthesis control, and they open new frontiers for both fundamental understanding and materials design. This focus session aims to define key scientific challenges ahead, strengthen collaboration within Germany and Europe, and accelerate progress toward higher superconducting transition temperatures.

Coordinators: Marta Gibert (TU Wien), Mattias Hepting (MPI FKF Stuttgart), Ilya M. Eremin (Ruhr-University Bochum)

DS 11: Layer Deposition

Time: Wednesday 9:30–11:45 Location: REC/B214

DS 11.1 Wed 9:30 REC/B214

Photo-Assisted Atomic Layer Deposition — •Paul Butler[1,2], Simon Wörle[1,2], Pengyu Hu[1,3], Manfred Stemplinger[1,2], and Ian D. Sharp[1,2] — [1]Walter Schottky Institut, Technische Universität München, 85748, Garching, Germany — [2]Physics Department, TUM School of Natural Science, Technische Universität München, 85748, Garching, Germany — [3]Department of Electrical Engineering, TUM School of Computation, Information and Technology, Technische Universität München, 85748, Garching bei München, Germany

Atomic layer deposition (ALD) is a powerful technique for uniformly coating complex surfaces with thin films, though achieving lateral control remains one of its main challenges. This work demonstrates the implementation of visible-wavelength excitation to assist in the ALD process, thereby providing an opportunity for selective-area deposition using beam-shaping. We demonstrate that optical laser excitation can be used to assist in several ALD processes. An optical laser was used to selectively photo-assist the deposition of TiO_2 on gold as well as monolayer MoS_2 at low temperatures. The molecular precursors, titanium isopropoxide (TTIP) and ozone were used for the low-temperature deposition of TiO_2 on gold, while tetrakis(dimethylamido)titanium (TDMAT) and water were used for the deposition of TiO_2 on MoS_2. Photoexcitation is also shown to reduce the nucleation delay when $MeCpPtMe_3$ and ozone are used to deposit platinum films on Si and SiO_2 surfaces, using. Samples are characterized with spectroscopic ellipsometry and AFM before and after depositions, with in-situ ellipsometry during ALD procedures.

DS 11.2 Wed 9:45 REC/B214

Epitaxial growth of wurtzite $Al_{1-x}Hf_xN$ thin films by reactive magnetron sputtering — •Valentin Walbrunn[1,2], Laura I. Wagner[1,2], Verena Streibel[1,2], Mingyun Yuan[3], and Ian D. Sharp[1,2] — [1]Walter Schottky Institute, Technical University of Munich, Germany — [2]Physics Department, TUM School of Natural Sciences, Germany — [3]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Germany

Ternary nitrides such as transition metal (TM) wurtzite $Al_{1-x}TM_xN$ compounds offer great potential for future electromechanical and ferroelectric devices. While this class of materials is exemplified by $Al_{1-x}Sc_xN$, alternative TM elements such as Hf, Zr, and Ti remain largely underexplored, despite predictions of increased piezoelectric responses and the benefit of reduced reliance on rare earth elements. In this work, we explore reactive magnetron co-sputtering of wurtzite aluminum hafnium nitride ($Al_{1-x}Hf_xN$) to achieve epitaxial thin films suitable for high-frequency surface acoustic wave (SAW) applications. We tune the Hf content by scaling the power applied to the metallic Hf and Al targets in an Ar/N_2 atmosphere and determine optimized conditions with Hf cation fractions up to 40 %. X-ray diffraction confirms the formation of a wurtzite phase with strong c-axis orientation, and rocking curve measurements indicate improved crystalline quality, comparable to sputtered $Al_{1-x}Sc_xN$. These films demonstrate epitaxial wurtzite $Al_{1-x}Hf_xN$ as a promising material platform for high-frequency SAW applications.

DS 11.3 Wed 10:00 REC/B214

Epitaxial growth of hexagonal boron nitride (h-BN) by thermal laser epitaxy (TLE) — •Markus A. Blonski[1], Gideok Kim[2], João Marcelo Lopes[1], Audrey Gilbert[1], Lutz Geelhaar[1], Jochen Mannhart[2], Darrell G. Schlom[3], and Patrick Vogt[1,2] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — [2]Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany — [3]Cornell University, Ithaca, USA

Thermal laser epitaxy (TLE) is a novel thin film synthesis technique in which the substrate and sources are heated by high-power infrared lasers. Without heating elements, TLE achieves unprecedentedly high growth temperatures and pressures, exceeding those of traditional methods like standard chemical vapor deposition (CVD) or molecular beam epitaxy (MBE). TLE enables thermal in situ substrate termination, accelerating surface treatment and avoiding pre-growth contamination. Using TLE, we map an unrivaled growth pressure and temperature (P-T) parameter space for h-BN growth on $Al_2O_3(0001)$ substrates. To optimize substrate termination, the Al_2O_3 surface is nitridized to form an AlN adlayer at $T \sim 1800\,^{\circ}C$ under an NH_3 atmosphere with a pressure of $P = 10^{-3}$ mbar. This termination process is followed by h-BN growth at 1600 °C to 2000 °C with NH_3 pressures ranging from 10^{-6} mbar to 10^{-1} mbar. We demonstrate epitaxial h-BN growth under unprecedented P-T conditions, characterized by Reflection high-energy electron diffraction, Fourier transform infrared spectroscopy, Raman spectroscopy and atomic force microscopy.

DS 11.4 Wed 10:15 REC/B214

Local growth of GaAs on Si(001) and Si(001)4.5° by Laser-assisted MOVPE — •Christian Bruckmann, Jürgen Bläsing, Armin Dadgar, and André Strittmatter — Institute of Physics, Otto-von-Guericke-University Magdeburg, Germany

The demand for increasingly performant, energy-efficient semiconductor devices is driving the research on how to combine III/V- with Si-based components in the most efficient way possible. While the monolithic integration on the Si substrate offers advantages compared to hybrid integration schemes, the heteroepitaxy of III/V-compound semiconductors is challenging due to different material properties. The Laser-assisted MOVPE enables an additive fabrication of semiconductor devices allowing cost-efficient low-volume production of special device structures. Key part is a high-power laser diode used for local heating of the substrate surface leading to local growth. GaAs islands were grown on Si(100) as well as Si(100) 4.5 ° substrates using a two-step growth approach which consists of a low-temperature nucleation layer followed by a high-temperature buffer layer. Optimization of the growth parameters and characterization with AFM and XRD shows qualitative trends similar to conventional MOVPE. For an island with a diameter of 260 nm and a height of 230 nm a XRD FWHM of 0.47 ° (ω-Scan, GaAs(004)) was obtained. Increasing the layer thickness to 3 μm yields a FWHM of 0.26 ° at optimum. Roughness measurements in the island center lead to RMS values of 4.0 nm (5 x 5 μm^2).

DS 11.5 Wed 10:45 REC/B214

Interface formation in ALD-based SnO_2/CeO_x heterostructures — •Dominic Guttmann[1], Rudi Tschammer[1], Carlos Morales[1], Malgorzata Kot[2], Michal Mazur[2], Damian Wojcieszak[2], Paulina Kapuscik[2], Wiktoria Kolodzinska[2], Jarosław Domaradzki[2], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Cottbus 03046, Germany — [2]Faculty of Electronics, Photonics and Microsystems, WUST, 50-372 Wroclaw, Poland

The electrical resistance of SnO_2 ultrathin films (< 20 nm) made by atomic layer deposition (ALD) strongly depends on thickness, due to intrinsic film defects at interfaces arising from changes in the ALD reaction mechanism during the first cycles and from the film/substrate interaction. Modifying interface properties in SnO_2/CeO_x heterostructures can enhance H_2 sensing performance. We studied the initial growth of SnO_2 by ALD on CeO_x substrates prepared by either electron beam evaporation (EBE) or ALD. Employing the commercial precursor tetrakis(dimethylamino)tin (TDMASn) and ozone (O_3) as well as in vacuo and near-ambient-pressure X-ray photoelectron spectroscopy, we examined how substrate preparation affects the SnO_2 nucleation behavior in the first cycles. SnO_2 growth on EBE-CeO_x indeed starts with the first precursor cycle, whereas ALD-CeO_x requires an additional conditioning step. Connecting these findings to surface chemistry, distinct C1s and N1s signatures attributed to TDMASn adsorption indicate a slow C/N buildup, consistent with previous reports on ALD-grown SnO_2 on Si, SiO_2, and Al_2O_3.

DS 11.6 Wed 11:00 REC/B214

Enhancing the antiferroelectric response of $AgNbO_3$ thin films — •Sreelakshmi Prasanna, Juliette Cardoletti, Philipp Komissinskiy, Thorsten Schneider, and Lambert Alff — Institute of Materials Science, TU Darmstadt, Darmstadt, Germany

Dielectric capacitors are widely utilized in numerous advanced high power electronic systems due to their distinctive features of high-power density, ultrafast charge/discharge capability, long storage lifetime, etc. Among them, antiferroelectrics have attracted extensive attention for energy storage applications because of their double hysteresis loop and zero remnant polarization. Within this class of materials $AgNbO_3$-based lead-free perovskites are promising candidates due to their environmentally friendly nature and strong intrinsic antiferroelectric response. In this work, we have grown $AgNbO_3$ thin films using pulsed laser deposition and examined their structural properties using X-ray diffraction and SEM. The presence of metallic Ag particles on the $AgNbO_3$ surface with a size ranging from nanometres to micrometres indicates excessive Ag creating conductive pathways and severely compromise the electrical performance, suppressing the antiferroelectric behaviour. We demonstrate a post-annealing and post-deposition treatment to remove excessive Ag in grain boundaries and as well as on the surface, while preserving the $AgNbO_3$ phase.This procedure reduces the leakage current significantly and enables the access to the antiferroelectric properties of $AgNbO_3$. This simple and effective way to enhance the performance of $AgNbO_3$ thin films opens the way to their application in eco-friendly energy storage devices.

DS 11.7 Wed 11:15 REC/B214

Low-Temperature Atomic Layer Deposition of Rutile Titanium Dioxide Buffer Layers for Thermochromic Windows — •Jan Leithäuser, Waafa Al Nachwati, Philip Klement, Sangam Chatterjee, and Martin Becker — I. Physikalisches Institut, Justus-Liebig-Universität Gießen, Heinrich-Buff-Ring 16, 35392 Gießen, Germany

Vanadium dioxide (VO_2) exhibits a reversible semiconductor-metal transition (SMT) at approx. 68°C and enables thermochromic smart windows that modulate solar heat gain. To achieve high solar modulation (T_{sol}) at industrially compatible temperatures, a smooth, chemically stable rutile TiO_2 buffer layer is required. Here, we demonstrate that atomic layer deposition (ALD) of TiO_2 at 200 °C, followed by low-temperature annealing, results in dominant rutile at 220 °C, provided the TiO_2 thickness is at leat 30 nm; thinner layers (10 nm) crystallize as anatase. Integrating such ALD-grown rutile buffers into VO_2 || TiO_2 || Glass structures allow for optimal VO_2 growth windows at 400 - 450 °C and yields a T_{sol} comparable to that of high-temperature sputtered rutile buffers. The ALD approach maintains nanometer-scale roughness. This low-temperature route to rutile TiO_2 represents an advancement for scalable, energy-efficient thermochromic coatings compatible with temperature-sensitive substrates.

DS 11.8 Wed 11:30 REC/B214

Interface induced ferromagnetism and Superconductivity in epitaxially engineered thin films — •Mostafa Marzouk[1,2], Anupam Singh[2], Igor Mazinchenko[2], Malli Tangi[2], Sergey Ostanin[2], Younghyuk Kim[2], Ilya Kostanovski[2], Arthur Ernst[2], Mathew Gilbert[2], and Stuart Parkin[2] — [1]Current Address: Institute for Topological Insulators, University of Wuerzburg, 97074 Würzburg, Germany — [2]Max-Planck institute of Microstructure Physics, 06120 Halle (Saale), Germany

Two-dimensional electron gases (2DEGs) at oxide interfaces offer several advantages that are not typically found in semiconductor-based 2DEGs. One key advantage is their high sheet carrier density, which is essential for achieving the high current densities required in power and memory applications.

In this talk, I will present the emergent phenomena at oxide interfaces we grew using state-of-the-art molecular beam epitaxy (MBE), with a primary focus on the two-dimensional electron gases formed at KTaO-based interfaces. We observe the development of ferromagnetism in the KTaO3(110)/LaTiO3 and KTaO3(111)/LaTiO3 2DEGs. Remarkably, these ferromagnetic 2DEGs retain high electron mobilities, reaching approximately 250 cm2/V.s at 2 K and 20 cm2/V.s at 300 K. The presence of ferromagnetism is confirmed through anomalous Hall effect hysteresis loops, butterfly-shaped magnetoresistance hysteresis loops (down to 1.7 K), out-of-plane magnetization hysteresis loops, and x-ray magnetic circular dichroism (XMCD) measurements at 2 K.

Purcell enhancement of photocurrent in a van der Waals self-cavity — •Xinyu Li — Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

We report the observation of Purcell-enhanced terahertz (THz) photocurrent emission in exfoliated flakes of the van der Waals (vdW) semimetal WTe_2, which act as intrinsic plasmonic self-cavities. Unlike conventional cavities that require external mirrors, micron-scale vdW flakes confine electromagnetic fields via edge reflections, supporting standing-wave plasmonic modes in the THz range. Using ultrafast optoelectronic circuitry, we measured coherent near-field THz emission resulting from nonlinear directional photocurrents excited at crystal edges. Emission spectra reveal resonant enhancement at discrete frequencies, tunable by excitation fluence and device geometry. We attribute this effect to cavity-modified photonic density of states - i.e., the Purcell effect - acting on driven, nonlinear transport currents. An analytical model capturing the self-cavity resonance conditions accurately reproduces experimental trends across multiple devices. Our findings establish WTe_2 as a bias-free, geometry-tunable THz emitter and demonstrate the potential of self-cavity engineering for controlling nonlinear, nonequilibrium dynamics in quantum materials.

Further details are available at arXiv:2507.07987.

DS 12.2 Wed 9:45 REC/C213

Radial Rashba spin-orbit fields in commensurate twisted transition-metal dichalcogenide bilayers — •Thomas Naimer[1], Paulo E. Faria Junior[2], Klaus Zollner[1], and Jaroslav Fabian[1] — [1]Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — [2]Department of Physics, University of Central Florida, Orlando, Florida 32816, USA

In commensurate twisted homobilayers, purely radial Rashba spin-orbit fields can emerge. We employ first-principles calculations to investigate the band structures and the spin-orbit fields close to the high-symmetry points K and Γ of several commensurate twisted transition-metal dichalcogenide homobilayers: WSe_2, $NbSe_2$, and WTe_2. The observed in-plane spin textures can for the most part be reproduced successfully using a model Hamiltonian, enabling us to extract relevant parameters. Exploring different lateral displacements between the layers, we confirm that the relevant symmetry protecting the radial Rashba is an in-plane 180° rotation axis. Our calculations on WTe_2 bilayers show that their lack of C_3 symmetry results in spin textures that are neither radial nor tangential. All authors acknowledge support by the FLAG ERA JTC 2021 project 2DSOTECH, the European Union Graphene Flagship project 2DSPIN-TECH (grant agreement No. 101135853) and SFB 1277 (Project-ID 314695032).

DS 12.3 Wed 10:00 REC/C213

Spatially Controlled Photoelectrochemical Thinning of 2D Transition Metal Dichalcogenides — •Simon Wörle[1], Lukas Wolz[1], Sergej Levashov[1], Franz Gröbmeyer[2], Johanna Eichhorn[1], Emiliano Cortes[2], Jeremy Robinson[3], and Ian Sharp[1] — [1]Technical University of Munich — [2]Ludwig Maximilian University of Munich — [3]U.S. Naval Research Laboratory

The integration of two-dimensional transition metal dichalcogenides (TMDs) into functional devices and catalytic systems requires detailed understanding and control of their behavior in reactive environments. Here, we systematically investigate the photoelectrochemical (PEC) stabilities of MoS_2, WS_2, $MoSe_2$, and WSe_2 mono- and multilayer flakes under dark and illuminated conditions, revealing two distinct oxidation mechanisms. In the dark, anodic potentials promote oxidation at defect-rich TMD edge sites, with subsequent dissolution of the oxidized species causing progressive lateral shrinkage, while the basal planes remain stable. Under white light illumination from a solar simulator, photoexcited holes drive electrochemical thinning of TMD multilayer flakes, which proceeds at anodic potentials lower than those required for lateral edge oxidation in the dark. This PEC-driven thinning enables controllable top-down fabrication of large-area TMD films with well-defined thicknesses. Importantly, the use of a focused laser beam rather than white light illumination enables precise spatial control over the PEC oxidation process, allowing localized patterning and thinning in predefined regions for the processing and integration of 2D materials into functional devices.

DS 12.4 Wed 10:15 REC/C213

Pairing symmetry of Ising superconductors via the upper critical field — •Lena Engström[1], Ludovica Zullo[2], Tristan Cren[3], Andrej Mesaros[1], and Pascal Simon[1] — [1]Université Paris-Saclay, CNRS, Laboratoire de Physique des Solides, 91405 Orsay, France — [2]Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany — [3]Sorbonne Université, CNRS, Institut des Nanosciences de Paris, UMR7588, F-75252 Paris, France

Several conflicting predictions have been made for the symmetry of the pairing in transition metal dichalcogenide (TMD) superconductors. An indication of if singlet or triplet pairing is present can be given by the upper critical field (Hc2), the magnetic field required to fully suppress superconductivity. Monolayer 1H-NbSe2 and 1H-TaS2 have extremely large critical fields, due to a large Ising spin-orbit coupling (SOC), yet they do not scale with SOC and temperature as expected for other TMDs. In our work on few-layer 2H-stacked TMDs, we highlight that the Ising SOC has nodal lines in the Brillouin zone imposed by symmetry. By deriving the susceptibility, we have found that the scaling of the critical field can be traced back to whether the Fermi surface intersects with these lines or not. Reinterpreting existing experimental data, we find that a predominantly singlet order is consistent with the measured Hc2. We propose two experiments where a signature of spin-singlet pairing would be visible, while discussing the possibility of mixed-parity pairing.

DS 12.5 Wed 10:30 REC/C213

Single-Metal-Atom Chains in Transition-Metal Dichalcogenides: Electronic, Magnetic, and Catalytic Properties — •Prosun Santra, Mahdi Ghorbani-Asl, and Arkady V. Krasheninnikov — Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

One-dimensional metallic nanostructures exhibit Peierls instabilities, Tomonaga-Luttinger liquid behavior, Majorana fermions, and half-metallicity, which is interesting in the context of spintronics. Stable single-metal-atom chains (SMACs) were experimentally manufactured by embedding transition metal (TM) atoms at mirror twin boundaries (MTBs) in MoS_2. Using DFT calculations, we study the energetics and properties of SMACs formed by 21 TM elements embedded in MTBs in 2D $MoSe_2$, $MoTe_2$, WS_2, and WSe_2. Spin-polarized calculations reveal localized magnetism and half-metallicity in multiple systems, ideal for nanoscale spintronics. We further study the catalytic properties of these systems. Our results indicate that selected SMACs can surpass Pt(111) in hydrogen evolution reaction activity, so that these defect-engineered structures not only are versatile 1D quantum-spintronic platforms, but may also be utilized as low-cost, high-performance electrocatalysts for green H_2 production.

Magnetoelectric flat band induced by a $\sqrt{3} \times \sqrt{3}$ charge density wave in monolayer $CrSe_2$ — •Victor Pardo[1], Pablo Savino Real[1], Carmen Fuente Santiago[1], Jan Phillips[2], Javier Corral Sertal[1], Adolfo Otero Fumega[3], and Santiago Blanco Canosa[4] — [1]Instituto de Materiais iMATUS, Universidade de Santiago de Compostela, E-15782 Campus Sur s/n, Santiago de Compostela, Spain — [2]Iberian International Nanotechnology Laboratory, INL Braga, Portugal — [3]Department of Applied Physics, Aalto University, 02150 Espoo, Finland — [4]Donostia International Physics Center (DIPC), San Sebastián, Spain

We investigate the electronic and magnetic properties of the $\sqrt{3} \times \sqrt{3}$ charge-density-wave (CDW) phase of $CrSe_2$ using first-principles calculations within density functional theory. We find that the most stable configuration corresponds to a ferromagnetic ground state, which hosts a remarkably flat electronic band exactly at the Fermi level. We show that the flat band derives from an a_{1g}-like component of the Cr t_{2g} manifold in a trigonal environment, combined with bonding–antibonding splittings induced by the formation of Cr trimers in the CDW structure. Strong hybridization between Cr d and Se p orbitals is crucial for stabilizing this band exactly at the Fermi level. Spin–orbit coupling affects only the remaining d bands, leaving the flat band intact. We establish how to tune the existence of this flat-band by relating it to the electric polarization caused by the CDW, hence describing a mechanism to turn on/off strong correlations with an external tuning parameter such as an electric field.

DS 12.7 Wed 11:15 REC/C213

Topological Superconductivity in $NbSe_2$-based Ising-Type Superconductors — •Jozef Haniš[1], Marko Milivojević[2], Zoltan Tajkov[3], and Martin Gmitra[1] — [1]Institute of Experimental Physics SAS Watsonova 47 040 01 Košice, Slovak Republic — [2]Institute of Informatics, Slovak Academy of Sciences, Dúbravská cesta 9 845 07 Bratislava 45, Slovakia — [3]Eötvös Loránd University, Pázmány Péter sétány 1/A, Budapest, Hungary

Topological superconductivity offers the promise of Majorana-bound states for fault-tolerant computation. We develop a symmetry-guided framework for superconducting pairing in Ising-type transition metal dichalcogenides, focusing on $NbSe_2$-based systems. We identify multiple topological phases–classified by Chern numbers and $\mathbb{Z}_2$ invariants–enabled by spin-orbit-induced triplet pairing. We present topological phase diagrams for different doping regimes and discuss zigzag-ribbon band-structure calculations. This work was supported by the EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I05-03-V02-00071, and the Slovak Academy of Sciences project IMPULZ IM-2021-42.

DS 12.8 Wed 11:30 REC/C213

Modeling Pressure-Induced Exciton Screening in hBN/WSe2/hBN Heterostructures — •Adlen Smiri[1], Shalini Badola[2], Amit Pawbake[2], Clément Faugéras[2], and Iann C. Gerber[1] — [1]Université Fédérale de Toulouse Midi Pyrénées, INSA-CNRS-UPS, LPCNO, 135 Av. de Rangueil, 31077 Toulouse, France — [2]Laboratoire National des Champs Magnétiques Intenses, LNCMI-EMFL, CNRS UPR3228, Univ. Grenoble Alpes, Univ. Toulouse, Univ. Toulouse 3, INSA-T, Grenoble and Toulouse, France.

Hydrostatic pressure is an effective tool to tune excitonic properties in two-dimensional semiconductors. We investigate the pressure dependence of excitonic Rydberg states in a WSe2 monolayer encapsulated in hBN and observe a reduction of the 1s-2s and 1s-3s energy separations with increasing pressure. First-principles calculations indicate negligible changes in the band structure and effective masses, pointing to pressure-modified dielectric screening as the main mechanism. A microscopic dielectric model for the WSe2 monolayer with an effective vacuum gap reproduces the observed excitonic shifts, demonstrating that enhanced screening governs exciton renormalization. These results provide a quantitative framework for tuning excitonic interactions in van der Waals heterostructures.

DS 12.9 Wed 11:45 REC/C213

Above room temperature ferromagnetism in wafer-scale Fe_3GaTe_2/SiC and the origin of double-step hysteresis in MBE-grown Fe_3GaTe_2 films — •Tauqir Shinwari[1], Victor Ukleev[2], Chen Luo[2], Kacho Imtiyaz Ali Khan[1], Florin Radu[2], and Joao Marcelo Jordao Lopes[1] — [1]Paul-Drude-Institut für Festkörperelektronik, Berlin, Germany — [2]Helmholtz Zentrum Berlin for Materialien und Energie, Albert-Einstein Straße 15, 12489 Berlin, Germany

Two-dimensional (2D) magnetic materials provide a versatile platform for next-generation spintronic devices, where scalable growth and robust ferromagnetism are the key factors. Fe_3GaTe_2 is a 2D ferromagnet with a high Curie temperature (~ 360K) and strong perpendicular magnetic anisotropy, making it a particularly promising candidate for energy-efficient spin-based technologies. Until now, most studies on Fe_3GaTe_2 have relied on millimeter-sized bulk crystals and exfoliated flakes, which are unsuitable for wafer-scale integration and reproducible device processing. In this work, we demonstrate high-quality, large-area epitaxial growth of Fe_3GaTe_2 thin films directly on SiC(0001) substrates by MBE. The films exhibit robust above-room-temperature ferromagnetism together with strong out-of-plane magnetic anisotropy, as confirmed by magnetometry and element-specific x-ray techniques. A double-step hysteresis loop is observed in MBE-grown Fe_3GaTe_2 films, pointing to the coexistence or coupling of distinct magnetic subsystems, which will be discussed in the context of Fe site selectivity, thickness dependence, and interfacial effects.

DS 13: Layer Properties

Time: Wednesday 15:00–16:15 Location: REC/B214

Invited Talk DS 13.1 Wed 15:00 REC/B214

Tailored thermal treatments for multi-layer, multi-material polymer devices — •Katherina Haase, Shaoling Bai, Mike Hambsch, Vojtech Millek, and Stefan C. B. Mannsfeld — Faculty of Electrical and Computer Engineering & Center for Advancing Electronics Dresden (cfaed), TUD Dresden University of Technology, 01069 Dresden, Germany

Thermal annealing constitutes an important processing step during the fabrication of organic semiconductor-based devices as it removes residue solvent and often leads to improved structural order. Recently, we have explored an additional aspect of thermal annealing - its impact on the dissolution of conjugated polymer (CP) thin films. We could show that thermal annealing induces physical cross-linking in a wide range of CPs,[1] which distinctly increased their stability in the original solvent. Hence, we suggested that tailored thermal treatments could enable polymer heterojunction devices though simple sequential coating.

In this presentation, we discuss the important finding that the thermal physical cross-linking (TPC) effect produces solvent-resistant thin films for a wide variety of CPs that could be combined into a multitude of novel devices, and explore the fabrication of solution-coated, polymer heterojunction-based synaptic transistors - devices that could not have been realized without the application of cross-linking.

DS 13.2 Wed 15:30 REC/B214

Mechanical Stress Evolution in Polycrystalline Ge Thin Films under MeV Ion Irradiation — •Karla J. Paz Corrales[1], Aaron Reupert[2], Kevin Lubig[2], Frank A. Müller[2], Berit Marx-Glowna[3], Ralf Röhlsberger[3], Till Weickhardt[1], Giancarlo Soavi[1], Martin Hafermann[1], Elke Wendler[1], and Carsten Ronning[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, 07743 Jena, Germany — [2]Otto Schott Institute of Materials Research, Friedrich Schiller University Jena, 07743 Jena, Germany — [3]Helmholtz-Institut Jena, Fraunhoferstr. 8, 07743 Jena, Germany

Polycrystalline Ge thin films were deposited by magnetron sputtering, annealed at 600 °C for 1 h, and irradiated with 1.8 MeV Au ions over a broad fluence range. Structural, optical, and in-situ mechanical stress analyses were performed to investigate irradiation-induced property modifications. At low fluences, the films show a reduction of the initial tensile residual stress from the preparation process. This stress compensation is linked to the formation of point defects, which also decrease the optical band gap. These defects can migrate to grain boundaries, where recombination enhances the resistance to amorphization compared with single-crystalline Ge. At higher fluences, defect accumulation increases tensile stress and leads to the formation of mixed polycrystalline-amorphous phases. With further irradiation, the films fully transform into an amorphous phase, as evidenced by changes in both structural and optical properties. In this amorphous state, additional stress relaxation occurs, attributed to plastic flow or to interface effects between the film and substrate.

DS 13.3 Wed 15:45 REC/B214

Optical tuning of Sr(Mo,Ti)O_3 thin films through solid solution — •Anjima Kallam Valli, Juliette Cardoletti, and Lambert Alff — Institute of Materials Science, TU Darmstadt, Darmstadt, Germany

Transparent conductive oxides are key materials in display technology and renewable energy applications, being used as transparent electrodes in solar cells and optoelectronic devices. Perovskite oxides such as $SrMoO_3$, $SrVO_3$, and $SrNbO_3$ exhibit exceptional metallic conductivity combined with optical transparency. Among them, bulk $SrMoO_3$ shows a conductivity of $2 * 10^7$ S m^{-1} exceeding that of platinum at room temperature; however, its optical transparency is limited to the UV visible range (300 to 500 nm). This work investigates the broadening of the transparency window of $SrMoO_3$ through partial B-site substitution of molybdenum by titanium. Titanium incorporation modifies the carrier density and thereby tunes the plasma frequency, shifting the optical reflection edge toward longer wavelengths. Epitaxial Ti-substituted $SrMoO_3$ thin films have been grown by pulsed laser deposition. Structural analysis was performed by XRD, and their electrical transport properties, including resistivity and carrier density, were characterised using van der Pauw and Hall-effect measurements. Optical transparency has been evaluated by spectroscopic analysis. Through tailoring of the transparency with varying Ti concentration, this work opens the door to various optoelectronic device applications.

Automating calculations for advancing the simulations of solid interfaces — •Elisa Damiani, Margherita Marsili, and Maria Clelia Righi — Dipartimento di Fisica e Astronomia, University of Bologna, Italy

Solid-solid interfaces are ubiquitous and simulations help understanding their properties, and may represent powerful screening and designing tools. Often first-principles electronic structure methods must be used: for example to characterize their transport, electronic, optical and magnetic properties, and also their adhesion and friction. Nevertheless, these approaches comes along with computational complexity and costs. In this talk I will present how we address these computational challenges by developing TribChem, a software that automates the creation of interface models, the identification of the optimal computational parameters, job submission, and data retrieval and storage. I will also show how this code has been successfully applied to the systematic study of different classes of interfaces such as metal-metal, metal-semiconductor, and metal-2D-materials ones, and illustrate the current developments that carried out to increase the complexity of the systems that can be addressed (amorphous and molecular solids) employing a Bayesian Optimization approaches.

These results are part of the SLIDE project that has received funding from the European Research Council (ERC) under the European Union*s Horizon 2020 research and innovation program (Grant agreement No. 865633).

Engineering at the Thinnest Scale: Insights into the Stability of 2D GaN on Liquid Metal Catalysts — •Tomoko Yokaichiya, Karsten Reuter, and Hendrik H. Heenen — Fritz-Haber-Institut der MPG, Berlin

Hexagonal GaN (h-GaN), theorized to be metastable when confined to only a few nanometers, stands out as a promising wide-bandgap semiconductor for next-generation nanoelectronics. Although early studies report that h-GaN can be synthesized using e.g. liquid metal catalysts, its definitive experimental identification is challenging. This difficulty arises from a structural ambiguity due to possible defects, multilayer-stacking variations, and competing polymorphs of h-GaN's characteristic honeycomb structure, as predicted by pioneering, yet simplified electronic-structure studies. In this work, we use density functional theory alongside large-scale atomistic simulations based on machine-learned interatomic potentials to re-assess the stability of h-GaN at finite temperatures and in the presence of a liquid metal substrate. We systematically investigate the structural and electronic properties of h-GaN, examining how they evolve with layer thickness and possible structural variations. Furthermore, we analyze its thermodynamic competition with bulk wurtzite GaN and alternative thin-film polymorphs, including a previously suggested haeckelite phase. Our results reveal that h-GaN exists within a delicate stability window. Based on these insights, we propose key signatures to guide experimental detection and outline whether h-GaN may become synthesizable as a feasible 2D semiconductor.

DS 14.2 Wed 15:15 REC/C213

Superconducting and dielectric properties of monolayer α-$TaSi_2N_4$ — •Timon Mosko[1] and Martin Gmitra[1,2] — [1]Institute of Physics, Pavol Jozef Safarik University in Kosice, Park Angelinum 9, 04001 Kosice, Slovakia — [2]Institute of Experimental Physics, Slovak Academy of Sciences, Watsonova 47, 04001 Kosice, Slovakia

The monolayer α-$TaSi_2N_4$ belongs to the recently discovered MA_2Z_4 family of two-dimensional intercalated materials, exhibiting wide range of physical properties, including semiconducting, metallic, topological, and superconducting behavior. Members of this group, such as $MoSi_2N_4$, WSi_2N_4 have already been successfully synthesized, highlighting the structural and electronic tunability of the inspected group of materials. We investigated the superconducting and dielectric properties of monolayer α-$TaSi_2N_4$ using a combination of ab initio and effective model approaches. The phonon-mediated superconductivity is examined through first-principles calculations, an effective tight-binding Hamiltonian in Wannier basis and further analyzed within the Migda-Eliashberg theory of superconductivity. Our results reveal that α-$TaSi_2N_4$ is an anisotropic two-band superconductor. Additionally, we study the dielectric response via electric susceptibility using linear response theory within the RPA, combining Green's function formalism with tight-binding modeling.

This work was supported by the Slovak Academy of Sciences project IMPULZ IM-2021-42, and by the Ministry of Education, Research, Develop-

ment and Youth of the Slovak Republic, provided under Grant No. VEGA 1/0104/25.

DS 14.3 Wed 15:30 REC/C213

Probing the Quantum Spin Hall State in Atomic Monolayers via NanoARPES — •Cedric Schmitt[1,2], Lukas Gehrig[1,2], Kilian Strauss[1,2], Jonas Erhardt[1,2], Matthew Watson[3], Jörg Schäfer[1,2], Simon Moser[1,2,4], and Ralph Claessen[1,2] — [1]Physikalisches Institut, Universität Würzburg — [2]Würzburg-Dresden Cluster of Excellence ct.qmat — [3]Diamond Light Source, UK — [4]AG Oberflächen, Ruhr-Universität Bochum

Our recently discovered quantum spin Hall insulator indenene [1], a triangular monolayer of indium on SiC(0001), exhibits a 120 meV gap and monodomain growth on the μm scale. To verify its topological nature, we use circular dichroism in ARPES as a bulk-sensitive probe of orbital angular momentum (OAM) linked to its Berry curvature [2]. Due to SiC's stepped morphology, stacking-dependent OAM cancellation complicates microARPES. We overcome this challenge using nanoARPES with sub-600 nm resolution, resolving OAM asymmetry at individual terraces of SiC. Our study establishes dichroism as a robust spectroscopic tool for topological classification within a single SiC terrace.

Physical Properties of $Ti_3C_2Cl_2$ MXenes — •Moritz Vanselow[1], Maksim Riabov[2], Thierry Ouisse[2], Hanna Pazniak[2], and Ulf Wiedwald[1] — [1]University of Duisburg-Essen and Center for Nanointegration Duisburg-Essen — [2]Université Grenoble Alpes, CNRS, Grenoble INP, LMGP, France

Hydrophobic $Ti_3C_2Cl_2$ MXenes are synthesized by Lewis acid molten-salt etching of $Ti_3C_2Cl_2$ followed by delamination process[1] and subsequently deposited from acetonitrile suspension ($\sim$ 0.1 mg/mL) on Si(100)/SiO_2 substrates. Using in-situ mass spectrometry and Auger electron spectroscopy in ultrahigh vacuum, we show that $Ti_3C_2Cl_2$ exhibits enhanced thermal robustness up to 900°C as compared to conventional mixed-terminated $Ti_3C_2T_x$ MXenes with T_x = −F, = O, and −OH. Complementary ex situ XRD and XPS confirm the absence of intercalated water and uniform −Cl terminations, resulting in sharp and intense (00l) peaks with c = 2.223 ± 0.015 nm and reflecting its high degree of structural order. Low-temperature specific heat measurements reveal distinct phonon signatures expected for the two-dimensional $Ti_3C_2Cl_2$. We determined the Debye temperature to 548 K in a temperature interval 20–50 K consistent with DFT model calculations[2] and a Sommerfeld constant of γ = 19.2 mJ mol^{-1} K^{-2}. This work is supported by ANR-23-CE09-0031-01 and DFG ID 530103526.

Phase field crystal model of out-of-plane deformations in thin crystalline sheets induced by thermal expansion — •Emma Radice[1], Marco Salvalaglio[1,2], and Axel Voigt[1] — [1]Institut für Wissenschaftliches Rechnen, Technische Universität Dresden, Dresden, Germany — [2]Dresden Center for Computational Materials Science (DCMS), TU Dresden, Dresden, Germany

Thin, flexible crystalline sheets exhibit unique elastic properties due to their ability to undergo out-of-plane deformations.Understanding this behavior requires a description that couples in-plane elasticity, out-of-plane bending and the presence of defects. We develop a mesoscale description for these systems by extending the Phase-Field Crystal (PFC) model. PFC model describes crystal structures at diffusive timescales through a periodic, microscopic density field and it allows one to incorporate both elasticity and topological defects into a continuum description. Our extension permits a spatially varying equilibrium lattice spacing, enabling the representation of localized lattice eigenstrain to mimick thermal effects or lattice mismatch in heterostructures. We validate the extended model against analytical predictions from the Föppl von Kármán equations for uniaxial compression and from Eshelby's inclusion problem. Using this validated framework, we then study how locally induced compressive stresses drive out-of-plane deformation (buckling) in the sheets. Our approach, implemented via a Fourier pseudo-spectral method, exploits the PFC model's natural ability to capture the complex, coupled interactions among elasticity, out-of-plane bending and defect dynamics.

Magnetotransport in Z-Folded ABC-Stacked Trilayer Graphene Structures — •Maximilian Mischke, Lina Bockhorn, Sofiya Lazareva, and Rolf Haug — Institut für Festkörperphysik, Leibniz Universität Hannover

Folded graphene (multi)layers promise to contain rich and interesting physics [1-3], so we produced a sample to investigate the influence of such a fold on magnetotransport properties of graphene. The measurements were carried out in a 4He cryostate at 1.4 K while the samples' carrier concentration was controlled via a global backgate. The sample itself consists of a z-folded ABC-trilayer graphene partially encapsulated in hBN with electrical contacts that allow for measurements in the unfolded region as well as through the fold. We observed filling factors that are unexpected for ABC-trilayer graphene. The untypical transport behaviour can be explained by angle dependend interlayer coupling and screening effects in the z-fold.

Quantum dots in proximitized BLG/TMD heterostructures — •Ching-Hung Chiu and Angelika Knothe — Institut für Theoretische Physik, Universität Regensburg, 93053 Regensburg, Germany

Bilayer graphene (BLG) has attracted attention recently due to the possibility of inducing layer-selective Spin-orbit coupling (SOC) by proximitizing with transition metal dichalcogenides (TMDs) [1,2]. Simultaneously, the gate-tunable band gap in BLG enables electrostatic confinement of charge carriers into gate-defined quantum point contacts and quantum dots [3,4]. Here, we theoretically investigate the interplay of proximity effects and confinement by studying confined quantum states in proximitized BLG/TMD quantum dots. We calculate the states' properties, such as their splittings and spin polarisation, as a function of SOC coupling parameters and the dot's size and shape. Our studies go alongside experimental realisations of confinement in BLG/TMD heterostructures [5,6] and pave the way for using and controlling the dot's spin and valley states as qubits.

Influence of Polymethyl Methacrylate molecular weight on Graphene transfer and its intrinsic properties — •Monika Choudhary[1], Rasuole Lukose[1], Moriom Akter[1], Christian Wenger[1,2], and Mindaugas Lukosius[1] — [1]Leibniz-Institut für Innovative Mikroelektronik (IHP), Frankfurt Oder, Germany — [2]Semiconductor Materials, BTU Cottbus-Senftenberg, Cottbus, Germany

Polymethyl methacrylate (PMMA)-assisted wet transfer is widely used for integrating large-scale graphene grown on Ge(100)/Si substrates via chemical vapor deposition onto insulating SiO2/Si substrates[1,2]. However, the influence of PMMA molecular weight (MW) on properties of transferred graphene is insufficiently quantified. To address this, we investigate graphene transferred using low (50K), medium (600K), and high (950K) MW PMMA to isolate how polymer chain length governs film integrity and contamination. Characterization by atomic force microscopy (AFM), and spatially resolved X-ray photoelectron spectroscopy (XPS) reveals reduced contamination and smoother topography for graphene with 600K transfers. Additionally, micro-Raman spectroscopy demonstrates strain-free graphene with reduced doping and a 2D peak full width at half maximum (FWHM) of 35.53 cm-1 consistent with as-grown values. 1. DS 14.9 Wed 17:15 REC/C213

High-performance graphene field-effect transistors on cyclic olefin copolymer substrates for advanced sensor applications — •Hamid Reza Rasouli[1], Begimai Adilbekova[1], Ghazaleh Eshaghi[1], Axel Printschler[1], David Kaiser[1], Marco Reinhard[2], Alexander Rolapp[2], Tom Reinhold[2], Uwe Hübner[3], Michael Meister[2], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, 07743 Jena, Germany — [2]IMMS Institut für Mikroelektronik- und Mechatronik-Systeme gemeinnützige GmbH (IMMS GmbH), 99099 Erfurt, Germany — [3]Leibniz Institute of Photonic Technology, Albert-Einstein-Straße 9, 07745 Jena, Germany

While graphene field-effect transistors (GFETs) are highly attractive for liquid-phase sensing, their performance on SiO2/Si substrates is compromised by oxide-induced charge trapping, leading to pronounced hysteresis and reduced stability. We present arrays of GFETs microfabricated on cyclic olefin copolymer (COC) substrates, which passivate SiO2 providing a low-trap and chemically inert platform in combination with flatness. GFET devices on COC demonstrate remarkably improved Dirac point stability, negligible hysteresis even in low-ionic strength buffers, and reproducibility across the arrays. For their functionalization, we employ an ultrathin carbon nanomembrane (CNM) that enables robust immobilization of various capture molecules while preserving graphene's transport properties. The CNM/GFET/COC architecture provides stable liquid-phase operation highlighting its strong potential for scalable and advanced sensor applications.

An on-chip heating platform for localized thin-film repair, non-equilibrium microstructures, and phase control — •Nensi Toncich, Nerea Abando Beldarrain, Jacopo Simone Crippa, Henning Galinski, and Ralph Spolenak — Laboratory for Nanometallurgy, Department of Materials, ETH Zürich, Switzerland

Localized on-chip heat generation and rapid thermal quenching is critical for systematic probing of phase transitions of nanofabricated systems, tailoring non-equilibrium microstructures and localized thin-film repair. Here we introduce a reactive multilayer [1] based on-chip heating platform that enables temperatures above 1000 °C, millisecond-scale heating and self-quenching rates on the order of 10^5 °C s^{-1} while preventing chemical interdiffusion. Using a diffusion-resistant, thermally conductive barrier, this platform enables three distinct, reproducible outcomes across different material systems: (i) localized melting and reflow of Au to repair electrical discontinuities, (ii) controlled microstructural evolution of Au, transforming equiaxed grains into elongated, high-aspect-ratio structures that are difficult to achieve with conventional processing, and (iii) a monoclinic-to-tetragonal phase transformation in the ZrO_2, demonstrating precise, site-specific phase engineering.

By combining ultrafast, high-temperature thermal pulses with diffusion-stable barriers, this platform offers a unique strategy for precise, on-demand modification of thin films, with broad applications in electronics, functional coatings, and nanofabrication.

DS 16.2 Thu 9:45 REC/C213

Enhanced resistive switching in hybrid perovskite-MoS2 memristors — •Georgios Chatzigiannakis[1,2], Anastasia Soultati[1], Spiros Gardelis[2], and Maria Vasilopoulou[1] — [1]INN, NCSR Demokritos, 15341 Athens, Greece — [2]Physics Department, National and Kapodistrian University of Athens, Panepistimiopolis Zografos, 15784 Athens, Greece

Memristors are emerging two-terminal devices with tunable resistance states and strong potential for next-generation non-volatile memory and neuromorphic computing. Their reversible switching between high- and low-resistance states (HRS/LRS), combined with non-volatile information retention, makes them attractive for energy-efficient data storage. Metal halide perovskites have recently gained interest in thin-film memristive technologies due to their low fabrication cost, solution processability, and rich ionic dynamics, while 2D TMDs such as MoS2 provide excellent interfacial properties that modulate charge transport and defect chemistry.

We demonstrate a hybrid perovskite memristor incorporating MoS2 nanosheets, exhibiting significantly enhanced electrical performance compared to pristine devices. The MoS*-integrated device achieves endurance up to 200 switching cycles, stable retention beyond 12 000 s, and a large memory window (HRS:LRS ~100). In contrast, the pristine device shows only ~25 cycles and a window below 50. These results highlight the crucial role of TMD:perovskite interfaces in stabilizing ion-migration pathways and improving resistive-switching reliability in hybrid thin-film memristors.

DS 16.3 Thu 10:00 REC/C213

Resistive Sensor for in situ electrical monitoring during atomic layer deposition — •Lucas Rave, Colin Schormann, Stefanie Haugg, Kristian Deneke, Jun Peng, Robert Blick, and Robert Zierold — Center for Hybrid Nanostructures, University of Hamburg, Germany

Atomic layer deposition (ALD) provides exceptional coating conformality with sub-nanometer resolution, driving the new semiconductor technology node processes. Conventional in situ diagnostics, such as spectroscopic ellipsometry and quartz crystal microbalances, focus on mass and optical morphology information during deposition. However, rich electrical information remains limited. To address this, we developed an electrical in situ monitoring detector capable of resolving resistance changes for individual precursor and purge pulses. This detector contains custom-patterned titanium electrodes on Si/SiO_2 substrates, whose resistance evolution directly reflects cycle-resolved ALD surface reactions. Using this approach, we probed the deposition process for oxides, including ZnO, Al-doped ZnO (AZO), and TiO_2, capturing characteristic signatures of nucleation delays, self-limiting ligand exchange, and dopant-induced conductivity changes. Our method reveals how different precursor chemistries manifest in distinct electrical transients and provides a quantitative link between surface reaction kinetics and film evolution. The resistance-based in situ sensing offers a practical, compact, and integrable diagnostic tool for understanding and optimizing ALD processes, enabling improved control over thin-film quality in micro- and nanofabrication.

DS 16.4 Thu 10:15 REC/C213

Molecular insights into the mechanical and dynamical properties of mechanically interlocked polymer thin films — •Yang Wang[1], Andrea Giuntoli[1], and Xuzhou Yan[2] — [1]Zernike Institute for Advanced Materials, University of Groningen, 9747 AG Groningen, Netherlands; — [2]State Key Laboratory of Synergistic Chem-Bio Synthesis, Frontiers Science Center for Transformative Molecules, School of Chemistry and Chemical Engineering, Shanghai Jiao Tong University, Shanghai 200240, P. R. China;

Mechanically interlocked networks (MINs) comprise molecular components connected by mechanical bonds, introducing topological constraints that alter deformation pathways. Coarse-grained molecular dynamics simulations are used to investigate substrate-supported and free-standing MIN thin films based on [c2]daisy chain architectures, with systematic variation of extension distance, cross-linking degree, interfacial cohesive strength, and strain rate. Strongly attractive substrates induce pronounced dynamic confinement, whereas weak adhesion leads to enhanced, free-surface-like mobility. Rings exhibit slower dynamics than axle chains, whose mobility is governed by proximity to binding sites. Pull-out and biaxial deformation simulations reveal a three-stage ring-sliding mechanism that suppresses excessive bond scission, maintains network connectivity at large strains, and delays macroscopic failure, thereby enhancing toughness and energy dissipation. These results provide molecular-level insight into MIN thin film mechanics and inform the design of adaptive, energy-dissipating polymer materials.

A Pathway Towards All-Optical Light-Propagation Switching — •Jakob Lindenthal, Frithjof Pietsch, Markas Sudzius, Johannes Benduhn, and Karl Leo — TU Dresden, Institut für Angewandte Physik, Nöthnitzer Str. 61, 01187 Dresden

Dynamic switching of the light propagation is a key enabler for integrated nanophotonic circuits. Optical gratings are a widely used, versatile component for coupling light into and out of waveguides. However, their diffraction efficiency is generally set and limited well below unity by static design and process parameters such as etch depths or geometric profile quality. We experimentally demonstrate the use of a dielectric-mirror cavity for enhancing the diffraction efficiency of grating couplers beyond these intrinsic limits. Using a second counterpropagating input beam achieves near-perfect dynamic control of the coupling amplitude. The experiments are backed by analytical and numerical modeling of the cavity-enhanced diffraction efficiency and the interaction of light waves in optical-gratings multiport devices. These findings extend the concept of coherent perfect absorption (CPA) from thin absorbing layers to diffractive structures, providing an all-optical propagation switching mechanism for efficient signal input and control in compact photonic circuits and nano-optic systems.

DS 16.6 Thu 11:00 REC/C213

Investigation of Temperature-Dependent Loss Mechanisms in Tantalum and Niobium Thin-Film Coplanar-Waveguide Resonators — •Philip Schneider[1], Moritz Singer[1], Harsh Gupta[1], Benedikt Schoof[1], and Marc Tornow[1,2] — [1]TU Munich, Garching, Germany — [2]Fraunhofer EMFT, Munich, Germany

Superconducting qubits can enable scalable quantum computing. Niobium (Nb) is widely used as the base superconductor, but tantalum (Ta) can improve performance by hosting fewer two-level system (TLS) losses, especially in its native oxide. We sputter-deposited Ta and Nb thin films on silicon and studied three stacks: pure Nb, Nb with a thin Ta cap, and Ta on a thin Nb seed layer, realizing distinct interface scenarios. The thin films were characterized by resistivity,

critical temperature, RRR and X-ray diffraction. Coplanar waveguide resonators were fabricated from the ~ 200 nm films to determine their internal quality factor (Q_i) in the few GHz regime. Temperature- and power-dependent measurements (100-1700 mK, -80 to -160 dBm) were fitted with a combined TLS-quasiparticle loss model to analyze loss-channels. To probe the effect of native oxide at the metal-air interfaces, the resonators were re-measured post four weeks of air exposure. In the single-photon regime at 100 mK, the average Q_i changes from 1.38×10^6 (BOE) to 1.19×10^6 (native oxide) for Nb, from 1.58×10^6 to 1.11×10^6 for Ta-capped Nb, and from 1.07×10^6 to 1.20×10^6 for Ta on an Nb seed layer. Thus, while all stacks provide Q_i in the 10^6 range, Nb-based devices degrade post oxidation, whereas the Ta dominated film remains robust and even slightly improves.

DS 16.7 Thu 11:15 REC/C213

Gallium phosphide on insulator for integrated quantum photonics — •Tobias Bucher[1], Otto Arnold[1,2,3], Katsuya Tanaka[1,2,3,4], Muyi Yang[1,2,3,4], Carsten Ronning[1], and Isabelle Staude[1,2,3,4] — [1]Institute of Solid-State Physics, Friedrich Schiller University Jena, 07743 Jena, Germany — [2]Abbe Center of Photonics, Friedrich Schiller University Jena, 07745 Jena, Germany — [3]Institute of Applied Physics, Friedrich Schiller University Jena, 07745 Jena, Germany — [4]Max Planck School of Photonics, Germany

Gallium phosphide (GaP) emerges as a promising material for quantum nanophotonics due to its high refractive index with low absorption in the visible, combined with a strong second-order nonlinear response and the absence of linear birefringence. Growing high-quality, single-crystalline GaP thin films on low-index substrates, however, faces challenges due to lattice and thermal mismatch, and process complexity in common epitaxial methods. Here, we demonstrate ion slicing of GaP thin films and anodic bonding onto low-index glass substrates. We fabricate GaP thin films from (100) and (110) bulk crystals with thicknesses of 760 ± 40nm. Structural and optical characterisation is used to optimise the implantation and bonding conditions with the goal of achieving high-optical quality and low absorption suitable for nanophotonic applications.

DS 16.8 Thu 11:30 REC/C213

Enhancement of photoluminescence of Er3+ ions by Mie-resonant silicon nitride metasurfaces — •Fengkai Wei[1,2], Carsten Ronning[1], Duk-Yong Choi[2], Xinru Ji[3], and Tobias Kippenberg[3] — [1]Institut für Festkörperphysik, Friedrich Schiller University Jena, Germany — [2]Research School of Physics, Australian National University, Australia — [3]Institute of Physics, Swiss Fed- eral Institute of Technology Lausanne (EPFL), CH-1015 Lausanne, Switzerland

Mie-resonant high-index dielectric nanoparticles and metasurfaces have been suggested as a viable platform for enhancing both electric and magnetic dipole transitions of fluorescent emitters. While previous work has demonstrated the enhancement of magnetic dipolar transitions from Eu3+ ions using silicon nanocylinders, this approach was limited by silicon's strong absorption at the Eu3+ emission wavelength in visible range. Erbium features a characteristic infrared emission wavelength of 1550nm, which is widely used in telecommunication. It makes Er a good candidate of emitters in metasurface for infrared applications. This study explores the enhancement of Er3+ ions using dielectric metasurfaces composed of Mie-resonant silicon nitride metasurface. Er3+ ions were introduced into the metasurface via ion implantation. Strong room-temperature photoluminescence (PL) was only observed after annealing, which activates the ions.Maximum PL enhancement occurred at a nanocylinder radius of ~410 nm, aligning with simulations. This study demonstrated a significant ~40-fold PL enhancement on metasurface over a planar reference.

Use of hybrid electrochromic devices for dynamic solar control in buildings — •Eleftheria Merkoulidi and George Syrrokostas — Solar Energy Laboratory, Department of Physics, University of Patras, Rion, Greece

Nowadays, the three main sectors that consume a lot of primary energy are: transport, industry, and buildings. Especially in the EU during 2023, buildings were responsible for 40% of total energy consumption, for approximately 50% of all-natural gas use, and a large portion of this energy (80%) is dedicated specifically to heating, cooling, and hot water supply for occupants. Therefore, improving the energy efficiency of buildings is critical. One effective way to improve energy efficiency is by controlling the significant energy losses (up to 60%) that occur through windows. These losses are caused by heat transfer mechanisms (conduction, convection, and radiation), as well as air leakage. A promising technological solution involves the use of adaptive chromogenic windows, such as electrochromic smart windows (ECWs). They can improve the energy efficiency of a building by modulating the sunlight and solar heat entering a building in real time, by changing their appearance (from transparent to opaque), under an applied electric field. In the present study, a way to improve their optical performance is investigated, by using a cobalt based redox electrolyte as a novel alternative to other redox couples used so far, with promising results.

DS 16.10 Thu 12:15 REC/C213

Influence of Crystal Orientation on the Oxygen Evolution Reaction in La_2NiMnO_6 Films — •Felix Tegtmeyer[1], Pia Henning[2], Shagun Thakur[2], Tobias Meyer[2], Ulrich Ross[3], Vasily Moshnyaga[4], and Jasnamol Palakkal[2] — [1]Department of Ultrafast Dynamics, Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]Institute of Materials Physics, University of Göttingen, Germany — [3]4th Physical Institute, University of Göttingen, Germany — [4]1st Institute of Physics, University of Göttingen, Germany

Double perovskites such as La_2NiMnO_6 (LNMO) promise applications for catalysis in energy storage and conversion. However, investigations of the oxygen evolution reaction (OER) in LNMO remain limited to nanoparticles and powders while the effects of crystal orientation remain elusive. In this work, we study monocrystalline LNMO thin film catalysts grown by metalorganic aerosol deposition at ambient air. By controlling the facet which is in contact with the electrolyte, the influence of crystal orientation is identified. We found that the activity of LNMO films with (100) crystal orientation is enhanced by one order of magnitude compared to (111) oriented films. We attribute this to the availability of both Ni and Mn active sites for the (100) surface. Moreover, an overall enhancement of the activity is identified for higher thicknesses. In long-term chronoamperometry measurements, the LNMO film retains a high activity and excellent bulk stability while the degradation is limited to a surface-near region.

DS 17: Focus Session: High-Temperature Superconductivity in Hydride Materials at High Pressures (joint session TT/DS)

Superconductors with record transition temperatures up to 250 K have been discovered and confirmed in hydride materials at high pressures over the last decade, enabled by major advances in both computational and experimental approaches. Density functional theory, combined with structure search algorithms and machine learning methods, enables high-throughput predictions of novel high-pressure phases. Ab initio microscopic theories, including Eliashberg theory and superconducting density functional theory, successfully predict transition temperatures of identified phases, with several predictions now confirmed experimentally. The synthesis of novel hydrides has revealed the importance of including hydrogen quantum fluctuations in theoretical predictions. Experimentally, advances in high-pressure synthesis techniques have enabled the preparation of novel hydride phases, while electrical transport measurements, tunneling spectroscopy, and magnetic studies have established a strong body of evidence for superconductivity by probing zero resistance, the superconducting gap, and magnetic response. This focus session will emphasize these breakthroughs, highlight ongoing challenges in both experiment and computation, and provide an outlook for finding high-temperature superconductors at lower and ambient pressures.

The forgotten sister of the CISS effect: spin polarization induced via proximity of adsorbed chiral molecules — •Franziska Schölzel[1], Aybüke Gülkaya[2], Dominik Hornig[1], Rico Ehrler[1], Lokesh Rasabathina[1], Aleksandr Kazimir[3], Christina Lamers[3], Olav Hellwig[1], Michael Mehring[1], Shuxia Tao[2], and Georgeta Salvan[1] — [1]Chemnitz University of Technology, Chemnitz, Germany — [2]Eindhoven University of Technology, Eindhoven, the Netherlands — [3]Leipzig University, Leipzig, Germany

Within the past years a new research field around chirality induced spin selectivity (CISS) has emerged and gains increasing attention. The central part is often played by complex chiral or helical molecules; ferromagnetic, gold capped, sometimes structured substrates and electrical transport measurements [1]. An aspect most often forgotten within this framework is the effects static equivalent [2]. We observed the Spin Polarization Induced via the Proximity of Adsorbed Chiral Molecules (SPIPAC) effect in nickel thin films for various chiral molecules. This study probes the resulting magneto-optical signal of the Ni substrate using Circular Dichroism spectroscopy. Furthermore, the impact of film thickness of the substrate, molecule density on the surface and the chirality of the molecules is explored.

DS 18.2 Thu 15:15 REC/C213

Understanding interface-controlled CISS-MR (magnetoresistance) via electric dipole inversion using ambient STM — •T. N. Ha Nguyen[1], Lech Tomasz Baczewski[2], Aleksandr Kazimir[3], Christina Lamers[3], and Christoph Tegenkamp[1] — [1]Analysis of Solid Surfaces, Nanostructures and Quantum Materials, Technische Universität Chemnitz, Germany — [2]Reichenhainerstr., 70 — [3]Institute for Drug Discovery, Medical Faculty University of Leipzig, Leipzig, Germany

Recent studies have highlighted the significant influence of electric dipole moment orientation in chiral molecules on spin polarization. When chiral molecules with strong dipole moments adsorb onto a surface, their orientation breaks the interfacial symmetry, leading to enhanced spin-polarized currents. Using scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS), we measured spin-polarized electron transport through polyalanine molecules, which possess substantial dipole moments. Notably, inverting the dipole moment while maintaining the molecule*s chirality results in a reversal of the chiral-induced spin selectivity magnetoresistance (CISS-MR). Our findings not only highlight the crucial role of electric dipole moments in chiral molecules but also provide insights into the CISS mechanism, particularly regarding the interface effect.

DS 18.3 Thu 15:30 REC/C213

Effect of adsorbed chiral molecules on the magnetic properties of skyrmion-hosting multilayers — •Mariam Hassan[1,2], Ivan Saldatov[3], Lokesh Rasabathina[4], Franziska Schölzel[1,2], D.R.T Zahn[1,2], Olav Hallwig[1,4], and Georgeta Salvan[1,2] — [1]Research Center for Materials, MAIN, Chemnitz University of Technology, Germany — [2]Semiconductor Physics, Institute of Physics, Chemnitz University of Technology, Germany — [3]Institute for Metallic Materials, IFW, Dresden — [4]Functional Magnetic Materials, Institute of Physics, Chemnitz University of Technology, Germany

Chirality-induced spin selectivity (CISS) and Magnetism Induced by Proximity of Adsorbed Chiral molecules (MIPAC) effects are phenomena that caught significant interests over the last few decades because of the large spin polarizations generated by organic molecules and the alteration of the surface's magnetism upon the adsorption of chiral molecules respectively [1,2]. On the other hand, magnetic skyrmions have emerged as a promising path for next-generation information storage and processing technologies. Thus, tuning skyrmion properties is of increasing interest for application in future spintronic devices. In light of the CISS and MIPAC effects, the use of chiral molecules might represent an attractive approach to address the challenge of tuning skyrmion properties [3]. In this work, we aim to investigate how adsorbed chiral molecules interact with magnetic skyrmions that are stabilized in [Co/Ni]N ferromagnetic multilayers with PMA. We observe that the adsorbed chiral molecules locally change the magnetic properties of the film, affecting the density of skyrmion nucleation sites.

DS 18.4 Thu 15:45 REC/C213

Self-Assembly of Helical Molecular Monolayers Using a Coarse-Grained Chiral Patchy Model — •Hadis Ghodrati Saeini[1], Faezeh Shabani[1], Sibylle Gemming[1], Christoph Tegenkamp[1], Florian Günther[2], and Jeffrey Kelling[1,3] — [1]Technische Universität Chemnitz, Chemnitz, Germany — [2]São Paulo State University, Rio Claro, Brazil — [3]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

The Chiral-Induced Spin Selectivity (CISS) effect makes helical molecules promising for spintronic applications, yet their surface self-assembly remains poorly understood due to experimental and computational constraints. Although Density-Functional Tight-Binding (DFTB) potentials accurately describe polyalanine (PA) α-helix SAMs, their high computational cost limits large-scale and kinetic investigations.

We introduce a coarse-grained chiral patchy model parameterized to fit the PA-specific DFTB potential, capturing its essential chiral symmetry and interaction features while remaining computationally efficient. Validation is achieved by comparing low-energy configurations obtained from annealing Monte Carlo simulations using the DFTB-based potential with dynamic pathways from coarse-grained molecular dynamics. Dynamic simulations made feasible by this model successfully reproduce the final assembled morphologies and allow explorations of potential metastable states, demonstrating its reliability and versatility for studying the kinetics of helical molecular self-assembly.

DS 18.5 Thu 16:00 REC/C213

Exploring the Origins of Helical Bundle Stability and Their Role in the CISS Effect — •Faezeh Shabani[1], Sibylle Gemming[1], Georg Kuenze[2], Paul Kluge[2], and Florian Guenther[3] — [1]Technische Universität Chemnitz, Chemnitz, Germany — [2]Universität Leipzig, Leipzig, Germany — [3]Instituto de Geociências e Ciências Exatas, Universidade Estadual Paulista, Rio Claro, Brazil

Helical bundles provide a highly regular and tunable chiral environment, making them ideal model systems for investigating the principles of the CISS effect and exploring possibilities for generating electronic hyperpolarization through (super)helical geometries. Beyond their relevance to chiral-induced spin selectivity, helix bundles also play important roles in nature: they consist of two or more α-helices supercoiled around a central axis and function as essential structural motifs in many biological systems. In this talk, we explore these characteristics using DFTB+ calculations. This computational approach allows us to analyze the energetic origins of specific bundling motifs, assess the role of dispersion interactions, and ultimately understand why certain helix bundle architectures are favored in nature.

DS 18.6 Thu 16:30 REC/C213

Unwinding the Helicity-Driven Electronic Properties in Polyproline I and II Chains — •Saba Arshad, Faezeh Shabani, and Sibylle Gemming — TU Chemnitz, Chemnitz, Germany

Polyproline is a polypeptide that adopts two distinct helical conformations, polyproline I (PPI) and polyproline II (PPII), with identical primary sequence but markedly different helicities and structural behavior, providing a valuable platform for examining electronic properties and their potential impact on CISS (Chirality-Induced Spin Selectivity) effects. Here, we employed density-functional approaches for chains with different numbers of monomers to investigate how helical geometry influences the electronic properties of both conformers. Our results reveal significant differences in the HOMO-LUMO gap and density of states between PPI and PPII, with the gap consistently narrowing as additional monomers are incorporated. Dipole moments calculated for chains of increasing length display distinct scaling trends for PPI and PPII helices, highlighting how both chain length and topology govern emerging molecular electronic applications.

DS 18.7 Thu 16:45 REC/C213

Modelling spin particles in an infinite helical box — Alex Mureşan[1,2], Fabian Prasse[1], and •Sibylle Gemming[1] — [1]Institute of Physics, TU Chemnitz, Germany — [2]Faculty of Physics, Babes-Bolyai University, Cluj-Napoca, Romania

Calculating the electronic states of a quantum mechanical particle in a potential well with infinitely high walls is probably the most readily accessible, still analytically solvable textbook example of quantisation via spatial confinement. As such, it is an ideal starting point for including additional terms to the Hamiltonian in order to adapt the model to a specific experimental setting, e.g. by introducing multiple particles or external fields. Here we present an extension that assumes an externally given spatial modulation of the potential well with helical characteristics as boundary condition. We derive analytical solutions for the motion of classical, Newtonian particles on a helical path, for charged Schrödinger-type quantum particles in a one-dimensional helical confinement, and quantum-mechanical spin 1/2-particles in a helical spin-orbit-split environment, which is encountered in investigations of the chirality-induced spin selectivity effect. We show that the model extension steps successively refine the eigenspectra of the simplest case, and that the spin-orbit interaction term leads to an extra splitting within the helical confinement.

Invited Talk DS 18.8 Thu 17:00 REC/C213

Insights from Quantum Dynamics Simulations: From Molecules to Organic-Material Interfaces — •Frank Ortmann — Technical University of Munich, Munich, Germany

Understanding charge, exciton and spin dynamics in molecular systems is critical for advancing organic semiconductor-based technologies. We present insights from our work addressing distinct yet complementary aspects of these phenomena for organic-electronics materials. First, we explore charge-transfer dynamics in electron-phonon coupled model systems, identifying regimes such as polaron transport and transient localization, emphasizing their seamless transitions across vibrational modes and temperatures. Second, a comparative analysis of the Matrix Product State (MPS) and Multilayer Multiconfiguration Time-Dependent Hartree (MCTDH) methods demonstrates their efficacy in modeling non-adiabatic exciton dissociation, revealing specific sensitivities to electronic-vibrational entanglement in complex systems. Lastly, we introduce current work toward a general quantum mechanical treatment of spin transport in donor-acceptor systems. These works underline the theoretical advances in capturing the interplay of various degrees of freedom in molecular optoelectronics and spintronics.

Techno-Enviro-Economic Evaluation for Thin-film Solar Cells Integrated with Hybrid Renewable Energy System — •Tawfik Hussein — Mechanical Engineering Dep., National Research Centre (NRC), El Buhouth st.,Dokki, Cairo, Egypt

Thin-film solar cells (TFSC) have recently emerged as a transformative technology in renewable energy, offering advantages such as lightweight design, flexibility, and cost-effectiveness compared to conventional crystalline silicon photovoltaics. This study focuses on designing an optimal hybrid renewable energy system (HRES) that integrates TFSC to maximize the efficient use of renewable energy sources (RES). A proposed HRES, combining multiple RES with TFSC, was developed to supply reliable electricity to a scientific farm in Egypt, with full technical, environmental, and economic evaluation.

The research examines TFSC performance under diverse environmental conditions, highlighting their higher efficiency in low-light and high-temperature scenarios. System indicators including performance, net present cost, CO* emissions, and renewable fraction were analyzed. Results demonstrate that TFSC-based HRES delivers reliable, low-cost energy with notable environmental benefits. Compared to conventional systems, the proposed design achieves substantial reductions in both costs and carbon emissions, enhancing sustainability. These findings confirm TFSC as a promising solution for future renewable energy systems, addressing the increasing demand for affordable and eco-friendly power generation.

DS 20.2 Thu 18:30 P2

Structural and electronic characterization of sputtered MoSe2 and WSe2 thin films on ITO substrates using synchrotron-based XAFS/XRF techniques — •Sabit Horoz[1,2], Emre Timuçin Tabaru[1], Latif Ullah Khan[3], Messaoud Harfouche[3], and Ali Karatutlu[1,4] — [1]Sivas University of Science and Technology, Sivas, Türkiye — [2]Sivas Cumhuriyet University Nanophotonics Application and Research Center-CÜNAM, 58140 Sivas, Turkey — [3]SESAME, Allan, Jordan — [4]Bilkent University Ankara, Türkiye

Two-dimensional transition metal dichalcogenides (TMDs) such as molybdenum diselenide (MoSe2) and tungsten diselenide (WSe2) exhibit remarkable optoelectronic and catalytic properties. In this work, thin films of MoSe2 and WSe2 were fabricated on indium-tin oxide (ITO) substrates using a sputtering technique and analyzed at the SESAME Synchrotron facility through X-ray Absorption Fine Structure (XAFS) and X-ray Fluorescence (XRF) spectroscopy. XAFS results at the W L3- and Mo K-edges confirmed well-ordered W-Se and Mo-Se bonds, demonstrating crystalline TMD structures. Upon annealing up to 170 °C in air, partial oxidation led to the formation of WO3 and MoO3 phases, accompanied by a visible color change from silver to transparent. Complementary Raman, UV-VIS-NIR, and ellipsometric analyses supported these findings.

DS 20.3 Thu 18:30 P2

Investigation of a hygrosensitive polymer coating for colorimetric humidity sensing — •Ketrin Pavlova[1], Katerina Lazarova[1], Darinka Christova[2], Martina Docheva[1], and Tsvetanka Babeva[1] — [1]Institute of Optical Materials and Technologies "Acad. J. Malinowski" Bulgarian Academy of Sciences, Sofia, Bulgaria — [2]Institute of Polymers, Bulgarian Academy of Sciences, Sofia, Bulgaria

A thin coatings of newly synthesized branched copolymers of poly(vinyl alcohol) comprising graft poly(N,N-dimethylacrylamide) with different side chains were studied as sensitive media for environmental changes of the relative humidity (RH). Spin-coating method was applied to deposit the thin films of both copolymers on Si-substrates, followed by temperature heating. Reflectance spectra of the samples were measured and then used to determine coating's thickness and optical constants. Sensing abilities of the coatings when exposed to different humidity level in range 5-95 RH% were examined and parameters such as hysteresis H and thickness change Δd were calculated. Possible application of the coatings for colorimetric detection is demonstrated.

DS 20.4 Thu 18:30 P2

Sputtered germanium absorbers for building-integrated semi-transparent photovoltaics — •Nico Ruskaup[1], Kai Gehrke[1], Stephan Heise[2], and Martin Vehse[1] — [1]Institut für Vernetzte Energiesysteme, Deutsches Zentrum für Luft- und Raumfahrt e. V., Carl-von-Ossietzky-Straße 15, 26129 Oldenburg — [2]Institut für Solarforschung, Deutsches Zentrum für Luft- und Raumfahrt e. V., Carl-von-Ossietzky-Straße 15, 26129 Oldenburg

Architectural glass facades worldwide typically utilize solar-control coatings deposited in inline magnetron sputter coaters to prevent buildings from excess solar heating. To use the electricity-generating potential of these facades, we aim to enable the glass industry to integrate photovoltaic functionality into their glazing using existing production lines. This requires a semi-transparent, fully sputtered thin-film solar cell. As a first step, here we demonstrate sputtered ultrathin germanium absorber layers for semi-transparent solar cells. We compare their optoelectronic properties and their microstructure with established reference layers deposited by plasma-enhanced chemical vapor deposition (PECVD) and identify sputter-process conditions that yield germanium absorbers with PECVD-comparable properties suitable for device integration. We present a sputtered germanium layer built into a solar cell, which delivers a power conversion efficiency of 2.8%. These results demonstrate that sputtered germanium is a viable absorber for thin-film photovoltaics and represent an important step towards an industrially sputtered semi-transparent solar cell for window applications.

DS 20.5 Thu 18:30 P2

Enhanced Ferroelectric Behavior in NH4Cl-Doped SnO2/Perovskite Multilayer Memristors — •Katerina Maskanaki[1], Evangelos Evangelou[1], and Anastasia Soultati[2,3] — [1]Department of Physics, University of Ioannina, 45110 Ioannina, Greece — [2]Institute of Nanoscience and Nanotechnology (INN), National Center for Scientific Research Demokritos, 15341 Agia Paraskevi, Athens, Greece — [3]Department of Electrical & Computer Engineering, Hellenic Mediterranean University (HMU), Heraklion 71410, Crete, Greece

Perovskite-based materials have emerged as promising candidates for neuromorphic computing due to their diverse conduction mechanisms and tunable electronic properties. This study is focused on the development and characterization of multi-layered memristors with the structure ITO/SnO2:NH4Cl/RbCsMAFAPbI3/P3HT/Al. A reference device employing a pristine SnO2 layer was also fabricated to compare the memristive behavior to the modified devices incorporating an NH4Cl-doped SnO2 nanocomposite layer in various concentrations. All configurations exhibited stable memristive switching; however, the NH4Cl-modified devices demonstrated significantly enhanced ferroelectric behavior, achieving endurance over 200 switching cycles and robust data retention exceeding 10^3 s. The high reproducibility and scalability of these perovskite memristors highlight their strong potential for next-generation neuromorphic and memory applications.

DS 20.6 Thu 18:30 P2

How Matrix-Mediated Osmotic Forces Govern Spatio-Temporal Dynamics and Spreading in Two-Species Biofilms — •Anthony Pietz[1], Uwe Thiele[1], and Karin John[2] — [1]University Münster, Münster, Germany — [2]University Grenoble Alps, Grenoble, France

Biofilms are thin films of bacterial communities encased in a self-produced polymeric matrix that thrive on immersed or moist surfaces [1]. The matrix confers the biofilm mechanical resistance and drives an osmotic influx of nutrients rich water into the biofilm.

While the osmotic spreading of biofilms with only one species has been extensively studied, much less is known about how matrix-mediated osmotic forces influence the spatio-temporal organization and spreading dynamics in multispecies communities. Experiments on two-species mixtures of matrix producers / non-producers show that the latter becomes confined to the advancing biofilm edge [2].

We numerically investigate the dynamics of such a two-species biofilm where the matrix-producing species attractively interacts with the matrix. Our description supplements a thermodynamically consistent thin-film approach for a passive suspension by bioactive growth terms. We analyse the resulting spatio-temporal dynamics and identify conditions under which multispecies and monospecies biofilms develop.

[1] Wilking et al. Biofilms as complex fluids. MRS Bulletin 36: 385, 2013. [2] Yan et al. Extracellular-matrix-mediated osmotic pressure drives Vibrio cholerae biofilm expansion and cheater exclusion. Nature Communications 8: 327, 2017.

DS 20.7 Thu 18:30 P2

Coherent control in size selected semiconductor quantum dot thin films — •Victor Kärcher[1,2], Tobias Reiker[1], Pedro F. G. M. da Costa[3], Andrea S. S. de Camargo[4,5], and Helmut Zacharias[1] — [1]Center for Soft Nanoscience, University of Münster, 48149 Münster, Germany. — [2]Insititute of Physics, University of Münster, 48149 Münster, Germany. — [3]São Carlos Institute of Physics, University of São Paulo, São Carlos, SP 13566-590, Brazil. — [4]Federal Institute for Materials Research and Testing (BAM), 12489 Berlin, Germany. — [5]Friedrich-Schiller University Jena (FSU), 07743 Jena, Germany.

We introduce a novel technique for coherent control that employs resonant internally generated fields in CdTe quantum dot (QD) thin films at the L-point. The bulk band gap of CdTe at the L-point amounts to 3.6 eV, with the transition marked by strong Coulomb coupling. Third harmonic generation (λ = 343 nm, hν = 3.61 eV) for a fundamental wavelength of $\lambda = 1,030$ nm is used to control quantum interference of three-photon resonant paths between the valence and conduction bands. Different thicknesses of the CdTe QDs are used to manipulate the phase relationship between the external fundamental and the internally generated third harmonic, resulting in either suppression or strong enhancement of the resonant third harmonic, while the nonresonant components remain nearly constant. This development could pave the way for new quantum interference-based applications in ultrafast switching of nanophotonic devices.

DS 20.8 Thu 18:30 P2

Ion slicing of gallium phosphide — •Otto Arnold[1,2,3], Tobias Bucher[1], Katsuya Tanaka[1,2,3,4], Muyi Yang[1,2,3,4], Carsten Ronning[1], and Isabelle Staude[1,2,3,4] — [1]Institute of Solid-State Physics, Friedrich Schiller University Jena, 07743 Jena, Germany — [2]Abbe Center of Photonics, Friedrich Schiller University Jena, 07745 Jena, Germany — [3]Institute of Applied Physics, Friedrich Schiller University Jena, 07745 Jena, Germany — [4]Max Planck School of Photonics, Germany

Gallium phosphide (GaP) has unique non-linear and quantum optical properties, such as second harmonic generation and spontaneous parametric down-conversion. For integrated optics, preparing the single crystalline GaP on a low reflective index material would be useful, as the reflective index scales with the mode confinement of the enhanced near-field. So far, GaP thin films are grown epitaxially or with MOCVD, which are both expensive and complicated. An alternative approach is ion slicing, where a helium-irradiated GaP is bound to a borosilicate glass. We fabricated high quality GaP thin-film in (100) and (110) crystal orientation on glass, with a thickness of 760 (40) nm. Energy-dispersive X-ray spectroscopy (EDX) and Rutherford backscattering spectrometry (RBS) characterization of the fabricated thin-films allow us to further optimize the irradiation profile and bonding parameters towards best optical performance for further nanofabrication of resonant meta-surfaces operating in the visible and near-infrared.

DS 20.9 Thu 18:30 P2

Piezoelectric coatings on Fiber Bragg Gratings for electric field measurement — •Florian Schmidbauer and Jens Ebbecke — Technology Campus Teisnach Sensor Technology, Deggendorf Institute of Technology, 94244 Teisnach

Monitoring high-voltage systems is gaining increasing importance. Conventional sensors often rely on electrical components that exhibit cross-sensitivities and require electrical wiring, which can pose a source of interference in certain applications. In addition, the physical dimensions of sensor heads can limit their usability.

An alternative approach employs Fiber Bragg Gratings (FBGs) coated with piezoelectric materials. Through the piezoelectric effect, mechanical deformation of the piezoelectric layer induces strain in the FBG, resulting in a measurable shift of its resonance wavelength. This type of sensor offers several advantages, including electrical passivity, a compact form factor, and the capability for remote and rapid signal interrogation via optical fibers.

This work presents the current progress in the development of such a sensor. Barium Titanate (BaTiO3) was selected as the piezoelectric material due to its high piezoelectric coefficient and more environmentally friendly profile compared to PZT. The coating was successfully applied using two different methods: sol-gel dip coating and pulsed laser deposition. Potential application areas and opportunities for further design optimization are also discussed.

DS 20.10 Thu 18:30 P2

Thermoelectric-based position-sensitive detector — Jun Peng, Lucas Rave, Pai Zhao, Rakshith Venugopal, Kristian Deneke, Stefanie Haugg, Robert H. Blick, and •Robert Zierold — Center for Hybrid Nanostructures, University of Hamburg, Germany

Precise positioning is a never-ending goal in both fundamental science and technology. Conventional position-sensitive detectors (PSDs), which rely on lateral photoelectric effects in semiconductor junctions, are inherently restricted in operating temperature and are often unsuitable for detection beyond the optical regime. Here, we present a new detector architecture, the thermoelectric-based position-sensitive detector (T-PSD), that extracts spatial information solely from heat conduction and thermoelectric conversion. Specifically, the device incorporates an ALD-deposited Al-doped ZnO (AZO) thermoelectric thin film on an isotropic substrate, where Seebeck voltages measured across multiple electrodes encode the position of an incident heat spot. It can detect single heat spots arising from various energy sources, including electromagnetic radiation, electrons, and macroscopic mechanical heat. The thin-film design enables submicrometer spatial resolution in 1D configurations, while a two-ratio voltage decoding scheme provides robust and intensity-independent localization in 2D devices. Furthermore, the T-PSD exhibits broad temperature compatibility and is particularly well suited for high-energy beams, which remain challenging to localize with existing PSD technologies.

DS 20.11 Thu 18:30 P2

Research Infrastructure Access in NAnoscience & nanotechnology (RIANA) — •Ryan Yang — Helmholtz-Zentrum Dresden-Rosendorf, Dresden, Germany

RIANA is a Horizon Europe-funded consortium of seven Analytical Research Infrastructures in Europe (ARIE) comprising of 69 research facilities that offer open, curiosity-driven research in nanoscience and nanotechnology. By integrating advanced capabilities within Europe in simulation, material synthesis, nanofabrication, characterization, and analysis, RIANA provides a single-point entry for users to perform targeted and impact-orientated investigations.

Users can simply submit a single application to access any of the nanoscience infrastructures within RIANA. A comprehensive service, anchored by 21 Junior Scientists and supported by a panel of senior facility experts will guide users through technique selection, experimental operation, data analysis and publication. Parallel Innovation Services tailor access for industry (especially SMEs) helping mature technologies, raise TRLs, and scale production processes. The Smart Science Cluster (SSC) network of on-site Junior Scientists ensures hands-on support at every research stage, from experiment design to result interpretation. Specifically, users requiring beam-time among other methods of research can take advantage of RIANA and the FIB aspects of their projects will be delegated to the RADIATE network such as the HZDR*s Ion Beam Center.

My poster will introduce this EU project and how potential users can tap into this resource.

DS 20.12 Thu 18:30 P2

Tailoring of MoO3 Thin Films by Irradiation with Energetic Heavy Ions — •Islam Al-Hamad[1], Ayman El-Said[1], Mohammad Al-Kuhaili[1], Shavkat Akhmadaliev[2], and Stefan Facsko[2] — [1]Physics Department and Interdisciplinary Research Center for Advanced Materials, King Fahd University of Petroleum and Minerals, Dhahran 31261, Saudi Arabia — [2]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

In recent years, energetic heavy ions have been used to modify the physical properties of various materials [1]. In this study, we investigate the influence of irradiation of molybdenum trioxide (MoO3) thin films with MeV ions of various parameters [2]. The films were deposited on fused silica using thermal evaporation technique. After irradiation, the films were characterized using optical spectroscopy and XRD techniques, showing the effectiveness of ion-irradiation in tuning the films optical and structural properties by varying ion beam parameters. This is highly important for the design of advanced metal oxide materials for sensing, switching, and energy applications.

Acknowledgements: Parts of this research were carried out at the Ion Beam Center at the Helmholtz-Zentrum Dresden-Rossendorf e. V., a member of the

Helmholtz Association. A.S. El-Said acknowledges the support by KFUPM, Saudi Arabia (Project: ISP24236).

DS 20.13 Thu 18:30 P2

Quantifying surface/H-plasma interactions via in-situ observation of metal - insulator transition (MIT) in rare earth perovskites ($MNiO_3$) — •Balázs Antalicz[1], Sophia Sahoo[2], Parikshit Phadke[1], Roland Bliem[1], and Gertjan Koster[2] — [1]ARCNL, Materials & Surface Science for EUVL, Science Park 106, 1098 XG Amsterdam, The Netherlands — [2]University of Twente, Inorganic Material Science Group Hallenweg 23, 7522 NH Enschede, The Netherlands

In 'green' plasma reactors and semiconductor manufacturing, reactive H species clean surfaces, but also induce degradation, e.g. via blistering or embrittlement. To retain device performance, low-cost & complexity exposure monitoring is required – which faces fundamental challenges.

To solve this, materials with strong response to hydrogenation are of interest. For example, Pt-dissociated H_2 was shown to induce MIT in $MNiO_3$ perovskites, which was accompanied by an up to 10^7-fold electrical resistance increase. Because H-plasma contains multiple pre-activated species, we anticipate simpler sensor designs are possible, without the Pt catalyst.

Using an accelerated plasma exposure tool, we then demonstrate MIT in epitaxially grown, Pt-free $NdNiO_3$. X-ray diffraction (XRD) and X-ray photoelectron spectroscopy (XPS) shows partial Ni^{3+} reduction, and loss/alteration of crystallinity. Further results explore re-settability by annealing in O_2, and correlate O 1s XPS spectra with crystal-field theory, structure changes, and the onset of the insulator state.

DS 20.14 Thu 18:30 P2

Distributed Bragg Reflector-Enhanced Grating Coupler on SiON-Doped Silicon Platform for 905 nm Using Particle Swarm Optimization — •Metehan Ari[1], Iremnur Duru[1], Ali Karatutlu[1,2], and Timuçin Emre Tabaru[1] — [1]Sivas University of Science and Technology — [2]] Institute of Materials Science Nanotechnology and National Nanotechnology Research Center (UNAM) Bilkent University

A vertical grating coupler operating at 905 nm was designed on a silicon oxynitride-doped silicon (SiON-Si) platform for on-chip LiDAR. For the first time, the SiON-Si layer served as the core of a grating structure. The material exhibited a refractive index of 2.27, CMOS compatibility, and negligible two-photon absorption, with its electronic structure confirmed via soft X-ray absorption spectroscopy at the HESEB beamline (SESAME).

To enhance performance, a Distributed Bragg Reflector (DBR) consisting of three alternating SiON-Si/SiO* layers was integrated beneath the grating to suppress substrate leakage. Design optimization using Particle Swarm Optimization (PSO) and FDTD analysis demonstrated that the DBR increased coupling efficiency from ~35% to 53%. Consequently, the optimized device achieved 53% (-2.76 dB) efficiency for TM-polarized vertical coupling at 905 nm. Fabricating both the grating and waveguide within the same SiON-Si layer eliminated heterogeneous interfaces, maintained single-mode behavior, and validated the platform's potential for integrated photonic circuits.

DS 20.15 Thu 18:30 P2

XRD Data Analysis and Curve Fitting Using Differential Evolution in Python — •Simon Lorch, Tobias Pollenske, and Joachim Wollschläger — Institute of Physics, University of Osnabrück, Barbarastr. 7, 49076 Osnabrück, Germany

Precise evaluation of X-ray diffraction (XRD) data is essential for understanding thin-film and interface structures at the atomic scale. In this contribution, we present a Python-based framework for automated fitting and quantitative analysis of experimental diffraction data using Differential Evolution (DE) as a global optimization strategy. The method minimizes the difference between measured and simulated intensity curves by evolving parameter sets such as layer thickness, density, and interfacial roughness toward the global minimum of an error function. Unlike conventional structure-factor-based approaches, the model deliberately omits detailed atomic scattering factors and instead focuses on the optimization of macroscopic parameters to reproduce the experimental curve shape. This allows a robust and efficient fitting of complex multilayer systems even in cases where structural details or phase information are incomplete. Compared to traditional gradientbased approaches, DE shows superior robustness against local minima and enables reliable fitting of complex multilayer systems with correlated parameters. The implementation allows user-defined boundary conditions, parallel evaluation of population members, and integration of physical models for scattering amplitude and Debye-Waller damping. This open and modular approach shows how evolutionary algorithms can make XRD data analysis more reproducible and accurate.

DS 20.16 Thu 18:30 P2

Stress Evolution in Gold Thin Films Under Ion Irradiation — •Jasmin Kahl[1], Karla Paz[1], Berit Marx-Glowna[2], and Carsten Ronning[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, 07743 Jena, Germany — [2]Helmholtz-Institut Jena, Fraunhoferstr. 8, 07743 Jena, Germany

Gold thin films are important for applications requiring mechanical stability and radiation tolerance in optoelectronic devices. This work investigates the stress evolution of polycrystalline Au films irradiated with He, Si, Ag, and Au ions at various energies and fluences. In-situ stress measurements during irradiation show that the as-deposited films are pre-stressed and the mechanical stress increases under irradiation producing a tensile stress. SEM and FIB cross-section images confirm that this stress increase is associated with grain growth, which depends strongly on the ion species. Grain growth increases local density and generates tensile stress because the films are constrained by the substrate. Large grains are advantageous in applications such as electrical interconnects and microstructures, as they reduce electromigration and optical losses. X-ray diffraction reveals structural damage, lattice distortion, and possible crystallite reorientation, while AFM shows increased surface roughness due to sputtering. These results highlight the strong influence of ion species and irradiation conditions on Au thin films, guiding the optimization of gold-based components in demanding environments.

DS 20.17 Thu 18:30 P2

Structural and magnetic properties of epitaxial Fe-Sn thin films. — •Benedikt Eberts[1], Franz Weidenhiller[2], Matthias Küss[1], Lin Chen[2], Christian Back[2], and Manfred Albrecht[1] — [1]Institute of Physics, University of Augsburg, 86135 Augsburg, Germany — [2]Institute of Physics, University of Augsburg, 86135 Augsburg, Germany

Magnetic Weyl semimetals exhibit strong spin-orbit coupling and nontrivial band structures, enabling efficient field-free manipulation of magnetic states through spin-orbit torque [1], which makes them highly attractive for spintronic applications. Among them, the ferromagnetic Weyl semimetal Fe3Sn2 and the antiferromagnetic Dirac semimetal FeSn provide a good platform for investigating spin-orbit-driven phenomena. Both compounds crystallize in a layered Kagome lattice, where the corner-sharing triangles lead to strong frustration. In this work, we have grown high-quality epitaxial thin films of FeSn and Fe3Sn2. The films were deposited at elevated temperatures using magnetron sputtering. A seed layer system of Pt and Ru on Al2O3(0001) substrates was used to promote epitaxial growth. Thin films of varying thickness were prepared and characterized using XRD, AFM, MFM, SEM, TEM, and SQUID magnetometry. FMR measurements on Fe3Sn2 revealed low damping and the expected sixfold symmetry associated with the Kagome lattice. These thin films will next be used to study charge-spin conversion processes [2]. [1] Lyalin, I. et al., Nano Lett. 21, 6975-6982 (2021) [2] Zhang, S.-L. et al., Phys. Rev. Lett. 123, 187201 (2019)

DS 20.18 Thu 18:30 P2

Single-crystalline Ni thin films as templates for epitaxial growth of 2D materials — •Paula Vierck, Audrey Gilbert, Domenik Spallek, Jonas Lähnemann, and J. Marcelo J. Lopes — Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany

Hexagonal boron nitride (h-BN) offers multiple interesting applications as a component in heterostructures with other 2D materials, for example as a passivation layer or a tunnel barrier in electronics. However, the synthesis of large-scale high quality h-BN required for such applications remains challenging, and the vast majority of the van der Waals heterostructures having h-BN as a building block are still prepared using mechanically exfoliated h-BN flakes.

To serve as a substrate for large-scale h-BN grown by molecular beam epitaxy (MBE), in this work, we investigate the synthesis of Ni films on Al_2O_3(0001) and MgO(111) using magnetron sputtering. The structure and morphology of the Ni films is characterized using X-ray diffraction (XRD), atomic force microscopy (AFM) and electron backscatter diffraction (EBSD). The structural quality of the Ni films is improved by systematically varying experimental parameters such as substrate temperature, sputtering power, film thickness and the post-growth annealing temperature, finally resulting in single crystalline Ni films with (111) orientation only.

DS 20.19 Thu 18:30 P2

Structural and optical properties of undoped β-Ga2O3 thin films deposited by ultrasonic spray pyrolysis — •Polina Shamrovska, Narmina Balayeva, and Dietrich Zahn — Technische Universität Chemnitz, Chemnitz, Germany

β-Ga2O3 thin films have gained significant research interest due to their wide bandgap, high thermal stability and breakdown voltage, making them suitable for e.g. UV photodetectors. Here, β-Ga2O3 thin films were deposited on c-plane sapphire substrates via ultrasonic spray pyrolysis, a cost-effective technique suitable for large-scale production. The deposition was performed with Ga(NO3)3 dissolved in a 1 : 1 water-ethanol mixture at a substrate temperature of 190 °C and post-deposition annealing was performed at 1000 °C. The films were characterized by Raman, AFM, XRD, optical transmittance, and conductivity measurement.

The stoichiometric β-phase Ga2O3 films revealed a preferred (-201) orientation in agreement with previous results [1]. The samples show transparency of up to 85% in the visible range and the conductivity increases with increasing film thickness. The results obtained reveal that ultrasonic spray pyrolysis allows the fabrication of highly crystalline and transparent β-Ga2O3 films suitable for further studies as solar-blind UV photodetectors.

[1] Akazawa, Housei, Vacuum, 2016, 123: 8-16.

DS 20.20 Thu 18:30 P2

Analyzing interface properties of energy materials using thin film model systems materials — •Julius K. Dinter, Anja Henss, and Matthias T. Elm — Institute of Experimental Physics I, Justus-Liebig University, Heinrich-Buff-Ring 16, D-35392, Giessen, Germany

Energy materials used in modern electrochemical devices must provide sufficiently high ionic and electronic conductivity, as both ions and electrons are stored and/or transported during device operation. However, most ionic conductors exhibit negligible electronic conductivity, and the opposite is true for typical electronic conductors. Consequently, artificial mixed-conducting composite materials are often prepared by combining ionic and electronic conducting compounds. These artificial mixed ionic-electronic conductors exhibit a large number of internal interfaces, which strongly influence charge storage and transport in the composite.

To clarify the role of such interfaces on overall electrochemical behavior, thin-film model systems with controllable and well-defined interfaces are essential. In this work, we present the fabrication of artificial mixed-conducting thin films based on lithium-ion- and oxygen-ion-conducting oxides prepared by pulsed laser deposition. Structural and compositional characterization using XRD, Raman spectroscopy, time-of-flight secondary ion mass spectrometry, and electrochemical impedance spectroscopy confirms the successful deposition and integrity of the designed model systems.

DS 20.21 Thu 18:30 P2

InAsP quantum emitters on InP with single-photon emission from O- to C-band up to 80 K — •Yiteng Zhang[1], Doaa Abdelbarey[1], Markus Etzkorn[2], Zenghui Jiang[1], Ankita Choudhary[1], Tom Fandrich[1], Arijit Chakraborty[1], Chenxi Ma[1], Pengji Li[1], Xin Cao[1], Eddy P. Rugeramigabo[1], Michael Zopf[1,3], and Fei Ding[1,3] — [1]Leibniz University Hannover, Institute of Solid State Physics, Appelstraße 2, 30167 Hannover, Germany — [2]Technische Universität Braunschweig, Laboratory for Emerging Nanometrology (LENA), Langer Kamp 6a, 38106 Braunschweig, Germany — [3]Leibniz University Hannover, Laboratory of Nano and Quantum Engineering, Schneiderberg 39, 30167 Hannover, Germany

We grow InAsP nanostructures on InP(001) by high-temperature annealing under arsenic flux followed by controlled cooling. In situ RHEED and ex situ AFM/TEM show that this sequence produces coherent, compositionally graded InAsP islands. Low-temperature micro-photoluminescence reveals spectrally isolated emission lines from individual emitters covering the telecom O- to C-bands; power dependence and second-order correlations under continuous-wave excitation show excitonic behaviour and clear antibunching with g2(0)<0.1, confirming single-photon emission. Temperature-dependent measurements indicate that single-photon emission persists up to temperatures above 80K.

DS 20.22 Thu 18:30 P2

Investigations of point defects in Nb3Sn thin films for SRF application — •Sebastian Klug[1], Maik Butterling[2], Eric Hirschmann[1], Andreas Wagner[1], and Maciej Oskar Liedke[1] — [1]Institute of Radiation Physics, HZDR, Germany — [2]Reactor Institute Delft, Delft University of Technology, The Netherlands

Bulk Niobium cavities are the state-of-the-art option to realizes high-performing linear particle accelerators. To achieve even better performance and lowering operational costs, a thin film approach with different superconducting materials is necessary. Nb3Sn coatings are promising candidates because of its high superconducting transition temperature (Tc up to 17 K). Magnetron sputtering is a very suited PVD method which provides high deposition rates and a large spectrum of deposition parameters optimization. Maximizing the transition temperature and the lower critical magnetic field Hc1 could be correlated to the structure and point defects in thin films like vacancies, their agglomerations and pores. To study this effect, positron annihilation spectroscopy (PAS) with a high sensitivity to small void-like defects is used. PAS provides non-destructive and depth-resolved information of defect type, size and density as well as their local atomic chemistry in many material types like metals, polymers, ceramics and semiconductors. In this contribution, investigations on magnetron sputtered Nb3Sn thin film samples will be presented. A special focus is set to positron annihilation spectroscopy to study the influence of different deposition parameters on defect formation and the resulting superconducting performance.

DS 20.23 Thu 18:30 P2

Surface Investigations of Ga-polar wz-GaN Grown by Plasma Assisted MBE — •Abdul Qadir Shabaz[1,2], Anees Ul Hassan[1,2], Fabian Ullmann[1,2], and Stefan Krischok[1,2] — [1]TU Ilmenau, Ehrenbergstraße 29, 98693 Ilmenau — [2]Zentrum für Mikro- und Nanotechnologien, Gustav-Kirchoff-Straße 7, 98693 Ilmenau

Since very high polarization gradients are predicted for wz-GaN/rs-ScN interfaces, well-oriented, clean Ga-polar wz-GaN surfaces are required in order to grow rs-ScN on top of this layer in a ultra high vacuum to achieve high quality interfaces. These thin layers were grown via plasma-assisted molecular beam epitaxy on 6H-SiC substrate. X-ray photoelectron spectroscopy (XPS), ultra violet photo electron spectroscopy (UPS), scanning electron microscopy (SEM) and atomic force microscopy (AFM) were performed to investigate electronic structure, composition and morphology of the surfaces.

DS 20.24 Thu 18:30 P2

Bonding and properties in NiTe-$NiTe_2$: Transition from normal metal to Dirac semimetal — •Christian Stenz[1], Kethusan Karunanathan[1], Paul Zhuromskyy[1], Kijoon Cheong[1], Tim Bartsch[1], and Matthias Wuttig[1,2] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany

We investigate the evolution of bonding and electronic properties across the NiTe-$NiTe_2$ system, focusing on the transition from conventional metallic behavior in NiTe to topological Dirac semimetallicity in $NiTe_2$. NiTe exhibits isotropic bonding between Ni d- and Te p-electrons, characteristic of a normal metal. In contrast, $NiTe_2$ forms a layered structure with a pseudo van-der-Waals gap and weak Te p-p interactions, hosting Dirac nodes near the Fermi level that give rise to non-trivial topological surface states and linear magnetoresistance. By tuning the Ni content in sputtered thin films, we control the interlayer coupling mediated by Ni d-electrons, enabling systematic exploration of the transition between these bonding regimes. Using density functional theory and tight-binding calculations, we analyze how additional d-electrons influence the band structure, Berry curvature, and Dirac cone formation in $NiTe_2$. Correlations between these electronic changes and material properties - such as optical and electrical conductivity, linear positive magnetoresistance, emergence of soft anharmonic bonds and bond rupture behavior - are examined.

DS 20.25 Thu 18:30 P2

Development of sacrificial layers grown on rare-earth scandate substrates for epitaxial KNN/KTN layer transfer — •Diana Avetisyan, Jeremy Maltitz, Jutta Schwarzkopf, and Jens Martin — Leibniz-Institut für Kristallzüchtung

Future technologies in sensing, communication, and computing require integrated devices with ultra-low-loss processing, precise control of photons, electrons, and spins, fast switching, broad frequency operation, and strong nonlinearities. Silicon photonics alone cannot meet these demands, making hybrid integration via layer transfer a promising approach. A promising material is sodium-doped potassium niobate, potassium tantalate, and their alloys to enable integration with photonic and acoustic devices. These materials exhibit exceptional electro-optic coefficients, nonlinear Kerr coefficients, piezoelectric coupling coefficients, and elasto-optic coefficients. The project focuses on transferring freestanding sodium-doped potassium niobate membranes onto SiO_2/Si substrates. This involves growing sodium-doped potassium niobate on a sacrificial layer/substrate stack, chemically etching the sacrificial layer, and transferring the membrane. Different substrates and sacrificial layers are explored to achieve crack- and wrinkle-free membranes. The membranes are characterized for surface topography, crystalline structure, ferroelectric, piezoelectric, and electromechanical properties for future device applications.

DS 20.26 Thu 18:30 P2

Formation and protection of two-dimensional electron gases at SrTiO3 interfaces via redox reactions — •Shi-Hui Liu, Georg Hoffmann, and Roman Engel-Herbert — Paul-Drude-Institut für Festkörperelektroni, Berlin, Germany

Strontium titanate (SrTiO3) has been the workhorse for development of new physical phenomena over decades. Recently, new momentum was generated when the formation of a two-dimensional electron gas (2DEG) via oxygen scavenging effect at the SrTiO3/AlOx interface was observed, i.e. oxidation of the deposited metal-layer upon reduction of the SrTiO3 [1]. However, depending on the Al layer thickness, these 2DEGs degrade over time due to diffusion of oxygen from the gas phase through the AlOx layer refilling the vacancies.

In this work, amorphous aluminum layers with thicknesses ranging from 0.5 to 2.5 nm were deposited on TiO2-terminated SrTiO3 (001) substrates using molecular beam epitaxy. The complementary methods of in-situ x-ray photoelectron spectroscopy, and capacitance-voltage measurements were performed to monitor the interfacial redox reaction and to identify the spatially confined conduction channel, respectively. Since the 2DEG remains stable only for a limited time within an optimum aluminum layer thickness, strategies for protecting and stabilizing the 2DEG will be pointed out.

DS 20.27 Thu 18:30 P2

E-Beam Evaporation of thin metal and oxide films on Al_2O_3 (0001) — •Laurenz Hüffmeier, Tobias Pollenske, and Joachim Wollschläger — Institute of Physics, University of Osnabrück, Barbarastr. 7, 49076 Osnabrück, Germany

Ultrathin metal and oxide films are used in numerous fields of application, particularly in optics, electronics, and energy applications. With the increasing importance of these technologies, the requirements for these films are also rising in order to improve their properties. Precisely manufactured films with well defined structural and physical properties are required, as even minimal deviations in thickness or structure can significantly impair device performance. A suitable method for the growth of such layers is physical vapor deposition (PVD), which enables the controlled deposition of a wide variety of materials under high vacuum conditions. Here, electron beam evaporation (EBPVD) is advantageous since extremely clean films can be deposited and high evaporation rates of up to a few micrometers per second are possible.

Hence, in this work, ultrathin magnesium oxide, praseodymium oxide, cobalt, and platinum films were deposited on insulating Al_2O_3 (0001) substrates using EBPVD. The structural properties of the resulting layers were analyzed by XRR. XPS measurements were performed on all films to examine their near-surface chemical composition. For the cobalt layers deposited with different emission currents, XPS was performed both in situ and ex situ to investigate the influence of atmosphere conditions on the oxidation states.

DS 20.28 Thu 18:30 P2

Towards Low-Temperature ALD of Topological Insulator Sb_2Te_3 — •Luise Merkwitz[1,2], Paul Pöhler[1,2], Steffen Ziller[1], Knut Ulbrich[1], Marek Ulbrich[1], Sebastian Lehmann[1], and Kornelius Nielsch[1,2] — [1]Institute for Metallic Materials, Leibniz Institute for Solid State and Materials Research, IFW Dresden, D-01069 Dresden, Germany — [2]Technical University Dresden, D-01069 Dresden, Germany

Low-Temperature ALD expands the range of applications for ALD enabling not only the deposition of thin films on temperature-sensitive substrates but also the possibility of a more ressoure-efficient setup and reaching advantages in material conformity and less sample defects.

We have designed, constructed and developed a state-of-the-art Low-Temperature ALD reactor for high-quality thin films. Our previous results demonstrate the technical functionality and reproducibility of known Low-Temperature ALD processes. In addition, our latest results reveal a never before published Sb_2Te_3 synthesis which we consider to be a highly promising Room-Temperature ALD process.

DS 20.29 Thu 18:30 P2

Using layered metamaterials in spin - ventil structures as a basis for artificial neural network — •Vladimir Boian[1], Cătălin Cimbir[1], and Vladimir M Fomin[2] — [1]Technical University of Moldova, Institute of Electronic Engineering and Nanotechnologies, Chisinau, Moldovau — [2]IET, Leibniz IFW Dresden, Dresden, Germany

Elaboration of a superconducting artificial neural network (ANN) the most promising solution in the design and development of non-von Neumann architectures. There are two main components of ANN: the nonlinear switch neuron constituting a spin valve, and the linear connection element the synapse. This study presents the results of computer modeling of superconducting spin valves on the base of Josephson Junction with weak link prepared from artificial magnetic metamaterials, and of superconducting synapses, based on hybrid layered structures superconductor/ferromagnet. The proximity effect in a superlattice formed by superconducting Nb nanolayers and ferromagnetic Co layers with different thicknesses and coercive fields is analyzed both theoretically and experimentally. In this sense, they can be applied as tunable kinetic inductors for the design of ANN synapses. Metamaterials based on Nb and Co nanolayers are a very promising class of artificial magnets for superconducting spintronics and quantum computing. The use of artificial neural networks with a radically reduced consumption of electricity are increasingly appreciated worldwide.

DS 20.30 Thu 18:30 P2

From Localised to Delocalised Charge Carriers: An Optical Investigation on Metal-Insulator Transitions — •Thomas Schmidt[1], Navjot Bamrah[2], Liron B. Michael[2], Ricardo P. M. S. Lobo[3], and Matthias Wuttig[1,2] — [1]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany — [2]I. Institute of Physics (IA), RWTH Aachen University, Germany — [3]LPEM, ESPCI Paris, CNRS, PSL University, 75231 Paris, France

Understanding metal-insulator transitions (MITs) has been a central topic in solid-state physics and materials science for decades. Various theoretical frameworks describe these transitions in terms of critical charge carrier densities (Mott MIT) or electron localisation induced by disorder (Anderson MIT). Typically, electrical conductivity measurements or their temperature-dependent derivative (TCR) are used to distinguish metallic from insulating behavior.

In this work, we propose an alternative approach based on optical spectroscopy. Reflectance spectra were recorded over a broad spectral range using a Fourier-transform infrared (FTIR) spectrometer. The optical functions were subsequently obtained through modeling of the measured data. Our analysis focuses on the evolution of the Drude response in the optical conductivity, which directly reflects the dynamics of free charge carriers. The Drude feature, defined by the ratio of the plasma edge to the scattering rate, provides valuable insight into the material-specific degree of electron (de)localisation and thus offers an alternative perspective on MITs and their relation to chemical bonding.

DS 20.31 Thu 18:30 P2

Investigating the Anisotropy of Optical Phonons in Ultrafast Optical Pump-Probe Experiments — •Felix Nöhl[1], Felix Hoff[1], Jonathan Frank[1], and Matthias Wuttig[1,2] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany

Phonons are quantized lattice vibrations closely linked to bond strength and atomic arrangement. A well-established tool to study incoherent optical phonons in frequency domain is Raman scattering. Ultrafast lattice dynamics and coherent phonons, capable of modulating macroscopic physical properties, are of interest to emerging research fields. In ultrafast optical pump-probe experiments, coherent optical phonons can be excited and directly measured in the time domain via transient changes in reflectivity. Due to their pronounced phononic response, bismuth and tin selenide were used to further explore the excitation and detection of coherent phonons. A pump polarization scheme for our optical pump-probe setup was implemented and polarization resolved pump-probe and Raman measurements compared. Clear symmetries were observed, highlighting the influence of the lattice structure. This improves our understanding of coherent phonon anisotropy in optical pump-probe measurements and enables modulation of the detected signal by changing the pump polarization.

DS 20.32 Thu 18:30 P2

Optimization of Reactive Ion Etching processes with Optical Emission Spectroscopy — •Daniel Breuer, Bich Nguyen, Teresa Wessels, and Markus Kaiser — Helmholtz Nano Facility, Forschungszentrum Jülich, Jülich, Germany

In modern technology, devices on the scale of micro- to nanometers play an important role. In the fabrication of those devices, the dry etching process is essential to structure them. Hereby the reactive ion etching technology has been established due to its very selective and anisotropic etching. To achieve reproducible results, process control is crucial. For this purpose, optical emission spectroscopy (OES) is employed to observe the spectra of the plasma during the process. Here, OES is used to ensure thorough cleaning of the RIE chamber after etching by defining the spectra of a clean chamber. Parameters, e.g. etching gas and time, are investigated with respect to their effect on chamber cleanliness. Finally, suggestions for a rigorous cleaning procedure are given. In addition, the endpoint detection is examined on a Si wafer with 200 nm SiN. Using OES, we aim to stop the plasma immediately when the SiN is etched through to prevent damage to the Si. We implement an endpoint detection by observing the characteristic line of the CN molecule, which is a typical product of the chemical etch reaction. The effects of various system parameters on the plasma, e.g. coupled power, chamber pressure and gas flow, are studied, as well as endpoint detection settings. In conclusion, a precise analysis of the plasma via OES allows us to specifically control the etching process.

DS 20.33 Thu 18:30 P2

Optimizing Erbium Luminescence in Silicon Nitride for Integrated Photonics via Oxygen Codoping and Thermal Annealing — •Felix Mania[1], Sören Lerner[1], Jiale Sun[2], Zheru Qiu[2], Xinru Ji[2], Tobias Kippenberg[2], and Carsten Ronning[1] — [1]Friedrich-Schiller Universität, Helmholtzweg 3, 07743 Jena, Germany — [2]École Polytechnique Fédérale de Lausanne, Switzerland

Erbium-doped fiber amplifiers revolutionized long-haul optical communications, thereby establishing erbium ions as promising candidates for amplification in integrated circuits. However, their practical application in integrated photonics is currently limited by low luminescence efficiency. In this study, we utilize ion implantation into ultralow-loss silicon nitride (Si_3N_4) and investigate the influence of oxygen codoping and thermal annealing on the formation of Er-O complexes, thereby modifying the local crystal field of the erbium ions within the host matrix. Specifically, we examine the effects of varying oxygen doping concentration and annealing temperature via photoluminescence and lifetime measurements. These findings provide a critical optimization strategy for CMOS-compatible erbium-based emitters essential for future photonic integration.

DS 20.34 Thu 18:30 P2

Domain Transfer from Simulation to Experimental Neutron and X-ray Reflectivity Data Using Probabilistic Generative Models — •Jeyhun Rustamov[1], Ritz Aguilar[1], Vedhas Pandit[1], Nico Hoffmann[2], and Jeffrey Kelling[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Helm & Walter IT-Solutions, Dresden, Germany

Machine learning (ML) models trained on simulations often fail to generalize to experimental data in neutron and X-ray reflectivity analysis. Furthermore, determining thin film parameters from reflectivity curves is an inherently ambiguous inverse problem. To address this, we employ conditional normalizing flows (cNFs) with a β-Variational Autoencoder (β-VAE) embedding network to learn the full distribution of physical parameters instead of single estimates.

To further improve performance on experimental data, we systematically explore three strategies for bridging the simulation-experiment domain gap: fine-tuning with labeled experimental data, utilizing generative models to create realistic synthetic data, and a novel physics-informed method. The proposed method incorporates a differentiable forward function based on the kinematic approximation to guide the generation of sample parameters via physics-informed loss during bidirectional training of cNFs.

Our approach distinctly leverages unlabeled experimental reflection data to address cNF performance challenges on real-world reflectivity measurements. Additionally, this methodology can be broadly applied to other inverse problems with similar domain-transfer challenges.

DS 20.35 Thu 18:30 P2

A Kramers-Kronig Consistent, Parameter Free, Probabilistic Dielectric Function Model — •Noah Stiehm[1,2], Stefan Krischok[1], Rüdiger Schmidt-Grund[1], and Jana de Wiljes[2] — [1]Technische Physik I, TU Ilmenau, Germany — [2]Mathematics of Data Science, TU Ilmenau, Germany

Utilizing a Bayesian probabilistic modeling approach to approximate the full posterior probability density $p(\theta \mid y)$ of a model's parameters θ given data y can provide greater insight into the model's performance and parameter uncertainties than point estimates provided by classic, deterministic optimization algorithms.

Here we present a parameter free dielectric function model, that might be used in a Bayesian modeling context as a substitute for the well known B-spline models. Our approach is based on Gaussian processes (GP), which are a flexible class of random functions, that enable numerical sampling in an efficient manner. We utilize a GP to model the time-domain response function $\chi(t - t')$ as a latent function, from which the dielectric function $\varepsilon(\omega)$ is constructed via a discrete Fourier transform. The resulting dielectric function is therefor Kramers-Kronig consistent by construction. We implement approximate and exact (depending on available compute resources) sampling strategies to include our model in different Bayesian modeling frameworks which utilize either Markov Chain Monte Carlo (MCMC) or particle filter methods. We demonstrate our model's performance in scenarios with significant uncertainties: a sample with a concentration gradient of a AgAl alloy, and pump-probe transient ellipsometry data.

DS 20.36 Thu 18:30 P2

Tunability of optoelectronic properties of the alpha-phase MoO3 thin films — •Zhihua Yong, Lars Steinkopf, Marin Rusu, and Thomas Unold — Helmholtz-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, 14109 Berlin, Germany

Alpha-phase MoO3 is widely used as a large bandgap hole transport layer (HTL) in solar cells due to its high work function, good hole conductivity and stability. For an appropriate energy level alignment with the active layer, the optoelectronic parameters of the MoO3 layers must be fine tuned. In this work, we fabricate uniform as well as combinatorially synthesised MoO3 films via Pulsed Laser Deposition on fused silica substrates in the temperature range of 350*480oC. The film thicknesses were targeted at approximately 15 nm, as usually applied for HTLs, and confirmed by X-Ray Reflectivity measurements. All films were found to be polycrystalline and contained only the α-phase with an orthorhombic crystal structure (Pbnm space group), as observed by X-Ray Diffraction and Raman Spectroscopy. Electronic properties of the MoO3 films were investigated by combining Kelvin probe (KP) measurements and photoelectron yield spectroscopy (PYS) under inert N2 atmosphere at ambient pressure. We show by means of KP-PYS studies that the ionisation energy and work function of the films can be fine tuned between 5.72 to 6.10 eV and 5.72 to 6.00 eV, respectively, by varying the deposition temperature. That results in a fine variation of the valence band maximum with respect to Fermi level. The degenerate state of the films is observed for deposition temperatures equal or higher than 425°C.

DS 20.37 Thu 18:30 P2

Heterodyne detection of the second harmonic signal in THz pump - optical probe experiments — •Sergei Ovcharenko, Alexey Melnikov, and Georg Woltersdorf — Institut für Physik, Martin-Luther-Universität Halle, 06120 Halle (Saale), Germany

Broadband Terahertz (THz) radiation is a widely used for resonant excitation of magnon modes or spin waves in magnetic materials. Furthermore, studying the THz emission from ferromagnetic (FM) materials allows us to investigate elementary processes in ultrafast spintronic. However, experimental investigation of such effects requires broadband THz detection: the commonly used sampling in electro-optical crystals is limited by phonon absorption, Zeeman-torque sampling requires accurate determination of the magneto-optical constants of a specific FM sample. An alternative approach is the detection of the THz field-induced second harmonic (TFISH) signal, based on third-order nonlinearity $\chi(3)$ in ambient air gases. Heterodyne detection, interference between the TFISH and SH light from a reference source, allows retrieval of the full THz pulse profile. The SH heterodyning technique is also applicable to extract weak SH signals, related to THz-induced magnetization dynamics in thin films. Our work reveals a phase modulation effect in the heterodyne TFISH signal: the air gap between TFISH and reference SH sources alters the detected THz pulse shape and spectrum through propagation effect in presence of the THz field. Using the developed instrument, we performed test experiments on heterodyne SH detection of THz-induced magnetization dynamics.

DS 20.38 Thu 18:30 P2

In_2Te_3 as a Covalent Spacer in GeSbTe-based Phase Change Superlattices — •Lucas Bothe[1], Maximilian Buchta[1], and Matthias Wuttig[1,2] — [1]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), FZJ, Jülich, Germany — [2]I. Institute of Physics (IA), RWTH Aachen University, Germany

Superlattices (SL) containing GeSbTe are promising material systems to overcome typical shortcomings of Phase Change Materials (PCM) by reducing the reset current by an order of magnitude. The reason for the increased energy-efficiency of SLs remains unclear. Typically, two metavalent materials, e.g. $GeSb_2Te_4$ and Sb_2Te_3, are used in superlattices to achieve superior switching performance. It is debated that Sb_2Te_3 plays a major role in achieving this performance increase. In this work however, Sb_2Te_3 is exchanged with In_2Te_3, replacing a metavalent with a covalent sesqui-chalcogenide to investigate its influence on the switching performance. In a first step, this work presents the growth of $GeSb_2Te_4/In_2Te_3$-SLs via MBE. XRD, RHEED, SEM and EDX were employed to characterize the samples. Pronounced Laue Fringes and clearly visible SL satellite peaks in the XRD-scans demonstrate the excellent sample quality and allow for exact characterization of the achieved SL-stacking. RHEED data allows the characterization of the coupling between $GeSb_2Te_4$ and In_2Te_3, which appears to be weak but not strictly of van-der-Waals character. As a next step the samples will be optically switched with a laser set up to compare the switching characteristics to those of $GeSb_2Te_4/Sb_2Te_3$-SLs.

DS 20.39 Thu 18:30 P2

Electrical switching dynamics of Ge-Sb-Te alloys for phase-change memories — •Alexander Kiehn[1] and Matthias Wuttig[1,2] — [1]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany — [2]I. Institute of Physics (IA), RWTH Aachen University, Germany

Off-stoichiometric Ge-Sb-Te alloys are promising candidates for next-generation phase-change memory (PCM) due to their nonvolatile nature, temperature stability, and fast switching speeds. These properties make them ideal for in-memory computing or applications in data storage, where fast, energy-efficient and reliable memory is crucial. However, in order to integrate PCM into standard semiconductor devices, it is necessary to reduce the switching voltage and current. This is greatly influenced by the composition of the sputtered Ge-Sb-Te layer, as well as the contact electrode material. Using CMOS-compatible fabrication processes, chips were manufactured based on a confined cell PCM design with new TaN contacts. Based on the electrical switching results, trends in thermal stability and the resulting voltage requirements are shown for different alloys. Further analysis also shows the SET and RESET speed as well as endurance of the devices.

DS 20.40 Thu 18:30 P2

Optimizing Crystallization Kinetics and Reducing Stochasticity of the Phase-Change Materials Sb2Se3 and Ge2SeTe through Controlled Crystalline Interface Growth — •Ramon Pfeiffer, Ramon Schmidmeier, Laura Gundermann, and Matthias Wuttig — I. Institute of Physics (IA), RWTH Aachen University, Germany

Chalcogenide phase-change material (PCM) alloys such as Antimony Triselenide (Sb2Se3) and Germanium Selenide Telluride (Ge2SeTe) can be switched repeatedly with low optical losses, making them interesting contestants for integrated photonic circuits. However, by switching from the predominately investigated as-deposited phase these materials are characterized by a relatively slow crystallization speed and high stochasticity. To address these shortcomings, we investigate methods such as the recrystallization from differently melt-quenched phases and a crystalline ring. The later approach, allows for controlled growth from a crystalline interface. An increase of crystallisation speed and decrease of stochasticity is verified by a pump probe setup and through Electron Backscatter Diffraction (EBSD) measurements respectively.

DS 20.41 Thu 18:30 P2

Hard X-Ray Momentum Microscope Measurements of $SrCoO_x$ Thin Films at Beamline P22 — •Volkmar Koller, Sourav Chowdhury, Sergii Chernov, Andrei Gloskovskii, and Christoph Schlueter — Photon Science | DESY Hamburg

Emerging memory devices are a possibility to reduce electricity expenditure in the future compared to established complementary metal-oxide-semiconductors

CMOS. For instance the Mottronic is based on a topotactic phase transition TPT associated with a metal-insulator transition MIT, instead of a manipulation of charges like in semiconductors. This might allow a further miniaturization of devices.

Here we show the Hard X-Ray Momentum Microscope HarMoMic at the beamline P22 of the PETRA III synchrotron at DESY as tool to monitor the electronic and crystalline structure of materials showing a TPT. Based on Hard X-ray Photoelectron Spectroscopy HAXPES the HarMoMic probes angle resolved the bulk electronic structure of single crystalline samples. Thus, the electronic band structure and X-ray photoelectron diffraction patterns XPD can be measured. From the XPD patterns the crystalline structure of a material can be determined by comparing it to simulations (Kikuchi Diffraction patterns).

As model system we show measurements of $SrCoO_x$(001) thin films grown via PLD on Nb-doped $SrTiO_3$(001). Upon the application of an electric bias it is electrochemically oxidized from $SrCoO_{2.5}$ (BrownMillerite, insulator, antiferromagnetic) to $SrCoO_{3-\delta}$ (Perovskite-like, metallic, ferromagnetic) undergoing a TPT.

DS 20.42 Thu 18:30 P2

Intercalation of thin Fe-films at the Graphene/SiC Interface — •Niels Rösch[1,2], Fabian Göhler[1,2], Rico Ehrler[1,2], Susanne Wolff[1,2], Olav Hellwig[1,2], and Thomas Seyller[1,2] — [1]Technische Universität Chemnitz, Institut für Physik, 09126 Chemnitz — [2]Forschungszentrum für Materialien, Architekturen und Integration von Nanomembranen, 09126 Chemnitz

The intercalation of graphene on silicon carbide (SiC) with different materials is an extensively studied field of research. The intercalation of metals into the graphene/SiC interface offers a route to tune the structural, electronic and magnetic properties of the system [1,2].

In the present study, we demonstrate the successful intercalation of iron (Fe) between graphene and SiC. 4H-SiC(0001) substrates were used to prepare the buffer layer (BL) precursor by polymer assisted sublimation growth (PASG) [3]. Intercalation was carried out under ultra-high vacuum (UHV) conditions by depositing 2 nm Fe atop the BL precursor at 300 ˚C, followed by an annealing at 750 ˚C for 30 min.

The successful intercalation of iron at the BL/SiC interface was confirmed by photoelectron spectroscopy and electron diffraction. Magnetic characterization via superconducting quantum interference device magnetometer (SQUID) revealed that the intercalated Fe layer exhibits ferromagnetic behavior.

DS 20.43 Thu 18:30 P2

High-Fermi velocity massless carriers in a triangular monolayer of Sb — Bing Liu[1,2], •Kilian Strauss[1,2], Philipp Eck[2,3], Jonas Erhardt[1,2], Tim Wagner[1,2], Philipp Kessler[1,2], Cedric Schmitt[1,2], Lukas Gehrig[1,2], Stefan Enzner[2,3], Martin Kamp[1,2], Jörg Schäfer[1,2], Giorgio Sangiovanni[2,3], Simon Moser[1,2], and Ralph Claessen[1,2] — [1]Physikalisches Institut, Universität Würzburg, D-97074 Würzburg, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, D-97074 Würzburg, Germany — [3]Institut für Theoretische Physik und Astrophysik, Universität Würzburg, D-97074 Würzburg, Germany

Two-dimensional (2D) quantum materials with high Fermi velocities are key candidates for ballistic transport and high-speed electronics. However, few 2D systems have the potential to demonstrate Fermi velocities exceeding that of graphene, remaining at the level of prediction. Here, we report the successful synthesis of a triangular monolayer of antimony (Sb) on the wide-gap semiconductor SiC. Using combined angle resolved photoemission spectroscopy (ARPES) and scanning tunneling microscopy (STM) in combination with density functional theory (DFT), we reveal orbital filtering that isolates broad-bandwidth, massless p_x and p_y states, yielding a compensated Fermi surface with an ultrahigh Fermi velocity surpassing that of pristine graphene. Linear dichroism in ARPES measurements confirm the orbital polarization of these high-velocity bands. This makes the triangular antimonene a compelling platform for next-generation quantum and high-speed electronic technologies.

DS 20.44 Thu 18:30 P2

Interfacial electronic structure of molecular adsorbates on WS2 and doped MoSe2 — •Carolin Sabrina Schüle, Michael Lämmerhofer, Joschua Bueble, Louisa Adlung, and Heiko Peisert — Institut für Physikalische und Theoretische Chemie Universität Tübingen, Germany

MoSe2 and WS2 are layered transition metal dichalcogenides (TMDCs) and promising alternative to conventional semiconductor materials. We studied interface properties of different molecules on MoSe2 and WS2. In the case of MoSe2 also p- and n-doped substrates were studied. Comparably weakly interacting phthalocyanines (CoPc, MnPc, CoPcF16) were compared to strong electron acceptors (HATCN, C60). It is known that opotoelectronic properties of TMDCs such as MoS2 can be tuned by transition metal phthalocyanines (TMPCs), depending strongly on the central metal atom of the phthalocyanine,[1], the mechanism, however, is not completely understood. Generally, for TMDCs two different interaction channels are possible: Interaction via the central metal atom and the macrocycle. It is shown that the different ionisation potential of the molecules affect the size of interface dipoles, as well as a band bending in the bulk substrates. However, the role of interface states is not negligible. Also, the doping level of MoSe2 have an influence on the strength of the interaction, although no integer charge transfer might be expected. [1] DOI: 10.1021/jacs.1c07795

DS 20.45 Thu 18:30 P2

Wannier-orbital Transient Polaron Localisation for electron and spin transport in organic semiconductors — •Nisarg Trivedi, Maximilian F.X. Dorfner, Michel Panhans, and Frank Ortmann — TUM School of Natural Sciences and Atomistic Modeling Center, Munich Data Science Institute, Technische Universität München

Transport in organic semiconductors is governed by a complex interplay between comparable energy scales of electronic coupling, thermal disorder, and electron-vibration interactions, making it difficult to describe within a unified framework. Building on the hybrid Transient Polaron Localization (TPL) model proposed by Hutsch *et al.* (npj Comput. Mater. 8, 228, 2022), we introduce an efficient extension using Wannier orbitals as a localized and orthonormal basis, enabling accurate treatment of charge transport in extended pi -conjugated systems which also allows us to generalise the framework for spin transport.

DS 20.46 Thu 18:30 P2

A Dual Time-Scale KMC-MD Approach for Simulating Self-Assembly Kinetics of Polyalanine α-Helix Monolayers — •Bo-Yue Zeng[1], Hadis Ghodrati Saeini[1], Sibylle Gemming[1], and Jeffrey Kelling[1,2] — [1]Technische Universität Chemnitz, Chemnitz, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Polyalanine α-helices show strong potential for spintronic applications because of their spin-filtering ability through the Chiral-Induced Spin Selectivity (CISS) effect. To build enhanced spin-filters and understand CISS, it is important to gain better control of molecular monolayer self-assembly. This requires large scale kinetic simulations which cover the long time scales of layer formation and annealing. The kinetics of polyalanine molecules anchored to metal substrates is governed by two separate time regimes: slow diffusion on the surface and fast relaxation of the organic ensemble.

To address these challenges, we present a dual time-scale simulation approach for 2D self-assembly that combines kinetic Monte Carlo (KMC) for slow diffusion with molecular dynamics (MD) for rapid relaxation. We demonstrate a parallel implementation based on the Alpaka abstraction layer to achieve performance portability across CPUs and GPUs. This proof of concept paves the way for large-scale simulations of mono-layer self-assembly in support of future spintronic applications.

DS 20.47 Thu 18:30 P2

Modeling intermolecular interactions and ordered packing in self-assembled monolayers of polyalanine α-helices — Hadis Ghodrati Saeini[1], Thi Ngoc Ha Nguyen[1], Christoph Tegenkamp[1], Sibylle Gemming[1], Jeffrey Kelling[2], and •Florian Günther[3] — [1]Technische Universität Chemnitz, Chemnitz, Germany — [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [3]São Paulo State University, Rio Claro, Brazil

Polypeptide molecules are attracting attention as promising candidates for electronic spin-filters due to the phenomenon of chiral-induced spin selectivity (CISS). This motivates substantial research to characterize the structural and electrical properties of self-assembled monolayers (SAMs) of peptide helices, for example, polyalanine (PA) α-helices. In this work, we aim to characterize the intermolecular interactions governing PA-SAM film formation. We developed an empirical potential that models the interaction between two isolated helices, derived using the density functional-based tight-binding (DFTB) method. This potential allowed us to simulate the most energetically favorable arrangements in SAM films via a Monte Carlo approach employing simulated annealing and the Metropolis algorithm. Statistical analysis of the relative positioning of adjacent molecules enabled us to classify the degree of frustration in the films. For enantiopure systems, a frustration-free arrangement was found, yielding a perfect hexagonal lattice. For mixtures of chiralities, the results showed parallel-aligned domains of differently handed helices. Both findings are in excellent agreement with experimental works.

DS 20.48 Thu 18:30 P2

Spin-Dependent Transport of CISS in Polyalanine on GMR-like Au/Co/Au Interfaces — •Andreas Cordier[1], Thi Ngoc Ha Nguyen[1], Huu Thoai Ngo[1], Julian Koch[1], Lech Thomas Baczewski[2], and Christoph Tegenkamp[1] — [1]Technische Universität Chemnitz — [2]Polish Academy of Sciences, Warszawa

Chiral molecules enable the investigation of spin-selective transport in a GMR-like Au/Co/Au geometry. We studied 16-mer L-polyalanine adsorbed on such multilayers by LT-UHV-STM and STS. Topography reveals interdigitated molecular arrangements with an intermolecular spacing of ~3 nm and reduced long-range order compared to ambient conditions. STS yields a HOMO-LUMO gap of ~1.8 eV and an asymmetry of the electronic states, consistent with shifts induced by the intrinsic molecular dipole under the junction electric field. The I-V characteristics show a clear dependence on the Co magnetization orienta-

tion, evidencing CISS-driven, spin-dependent transport through the PA layer and allowing an extraction of the molecular CISS-MR.

In magnetic-field-dependent feedback measurements, the tip stabilizes at distinct equilibrium positions depending on the prior Co magnetization direction, producing a robust Δz signal that vanishes on Au/Co/Au reference samples. Using a quantitative model accounting for all resistive elements of the GMR-like stack we relate the measured Δz to the spin-dependent transmission through the molecules. In combination with forthcoming electronic-structure input, this establishes the experimental foundation for a consistent determination of the CISS-induced magnetoresistance in chiral molecules.

DS 20.49 Thu 18:30 P2

Evolution of voids in molybdenum disilicide during electromigration experiments — •Julia Baldauf, Dennis Mitrenga, Tim Fink, and Philipp Kellner — CiS Forschungsinstitut für Mikrosensorik GmbH, Erfurt, Germany

Molybdenum disilicide (MoSi2) is used in macroscopic and microscopic heating devices.

The widespread use of MoSi2 is caused by its melting point of 2030˚C and its combability with CMOS processes. Because of the high melting point MoSi2 has been considered immune to electromigration phenomena. In reality electromigration is one of the main causes of chip failure for microheaters employing MoSi2 at temperatures of 600˚C up to 900˚C.

Artificially generated voids were made by using a gallium based focused ion beam, are approximately circular in shape and located near the center of a line under test made of MoSi2. We employed a laser scanning microscopy technique to observe changes of the shape of artificially generated voids. Slight changes in the shape of the voids and the formation of hillocks on the rim of the voids have been observed. Because of the low volume of the migrated material the chemical analysis remains challenging.

Machine learning is used to determine the effective ion charges used in Finite-Element-Methode-simulations of a digital twin. The digital twin will be used in conjunction with the experimental data to evaluate the effective ion charge determined by employing the machine learning algorithm.

DS 20.50 Thu 18:30 P2

Towards Study of Charge Transport Mechanisms Across Grain Boundaries in Organic Monolayer Films via Near-Field Photocurrent Spectroscopy — •Jian Xiao, Francesca Falorsi, Lukas Renn, and Thomas Weitz — Georg-August-University Göttingen, Göttingen, Germany

Organic semiconductors, particularly emerging organic thin films (OTFs) comprising one to several molecular layers, enable diverse nanoscale (opto-)electronic devices. Device performance critically depends on the crystalline order within OTFs, where grain boundaries (GBs) between dissimilarly oriented domains are widely recognized as limiting factors for charge transport. While previous studies have identified two GB types, barriers and valleys, distinguished by whether their lowest unoccupied molecular orbitals (LUMOs) lie above or below those of bulk grains, the detailed transport mechanisms across these interfaces remain poorly understood.

We will report our current efforts to develop scanning near-field optical microscopy (SNOM) to investigate excited photocurrents across GBs in organic monolayer films under illumination with photon energies comparable to the energy differences between GBs and bulk grains. Our approach aims to elucidate charge transport pathways across GBs and their contribution to macroscopic current formation. We further examine how GB type and the magnitude of interfacial energy differences influence transport mechanisms. These insights may inform charge transport studies across barriers in other optoelectronic material systems.

DS 20.51 Thu 18:30 P2

Superconducting diode effect in in epitaxial thin films of elemental superconductors — •Shanshan Guo[1], Nikolai Peshcherenko[1], Changjiang Yi[1], Ning Mao[1], Heda Zhang[1], Heiko Reith[2], Walter Schnelle[1], Edouard Lesne[1], Kornelius Nielsch[2], Yang Zhang[3], and Claudia Felser[1] — [1]Max-Planck-Institute für Chemische Physik fester Stoffe, Dresden, Germany — [2]Leibnitz IFW Dresden, Dresden, Germany — [3]Department of Physics and Astronomy, University of Tennessee, Knoxville, USA

The superconducting diode effect allows for nonreciprocal, dissipationless electronic transport. It has the potential to enhance transfer current efficiency compared to the traditional semiconducting equivalent and hence have a significant impact on the design of future electronic devices. While the field is fast evolving, there are still many unanswered questions about the underlying mechanisms and origin of the phenomenon. Here we investigate the superconducting diode effect in epitaxial thin films of elemental superconductors (V, Nb and Ta). We probe its supercurrent nonreciprocity as a function of magnetic field and temperature and discuss the role spin-orbital-coupling strength plays in the superconducting diode effect in a combined simple material/device structure. Our work should stimulate the refinement of theoretical models and enable a deeper understanding of the supercurrent rectification effect.

DS 20.52 Thu 18:30 P2

Cavity-modified electron mobility in monolayer black phosphorus from first principles — •Qinyan Yi[1], I-Te Lu[1], and Angel Rubio[1,2] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Center for Free-Electron Laser Science, Luruper Chaussee 149, 22761 Hamburg, Germany — [2]Initiative for Computational Catalysis, The Flatiron Institute, Simons Foundation, New York City, NY 10010, United States of America

Cavity materials engineering offers a new route to control material properties through quantum fluctuations, without requiring external driving fields such as laser pulses. However, theoretical studies of cavity-modified transport in realistic materials are still lacking. In this work, we perform an ab initio study of monolayer black phosphorus coupled to cavity photons using quantum electrodynamical density functional theory (QEDFT), which includes an additional electron-photon exchange potential in the Kohn-Sham Hamiltonian. Our results show that cavity photons can modify the electron-phonon interaction of black phosphorus and decrease the phonon-limited scattering rate, leading to an increase in electron mobility by about 10% for a realistic coupling ratio of mode strength to bare photon frequency of 0.1, which is the upper limit of a realistic device. These results demonstrate that cavity materials engineering can modify the materials transport, highlighting its promise as a practical, non-intrusive approach for tuning material properties.

DS 21: Optical Analysis of Thin Films

Time: Friday 9:30–12:30 Location: REC/C213

DS 21.1 Fri 9:30 REC/C213

From Semiconductors to Quantum Materials: Ultrafast Optical Signatures Across Chalcogenide Classes — •Timo Veslin[1], Felix Hoff[1], Jonathan Frank[1], and Matthias Wuttig[1,2] — [1]I. Institute of Physics (IA), RWTH Aachen University, Germany — [2]Peter Grünberg Institute - JARA-Institute Energy Efficient Information Technology (PGI-10), Jülich, Germany

Optical pump probe spectroscopy provides a powerful means to investigate and compare ultrafast dynamics in diverse material classes, ranging from covalently bonded semiconductors to quantum materials. In this study, we contrast the optical and structural responses of sesquichalcogenides like In2Te3 films with those of quantum materials such as Bi2Te3 or Sb2Te3. Femtosecond pump probe and complementary spectroscopic analyses reveal that In2Te3 exhibits remarkably stable optical and vibrational properties across a wide thickness range, attributed to its predominantly covalent bonding network. In contrast, quantum materials based on Bi or Sb display pronounced thickness-dependent responses and strong coupling between coherent phonons and electronic states. These materials demonstrate tunable coherent lattice motions through variations in pump fluence, polarization, and pulse sequencing, offering routes for ultrafast manipulation of quantum states. The comparison highlights a clear distinction between structurally robust semiconducting chalcogenides and highly responsive quantum materials. Together, these findings delineate how bonding character and electronic topology govern ultrafast optical behavior.

DS 21.2 Fri 9:45 REC/C213

Orientation-Dependent Near-Field Infrared Properties of a Chiral SURMOF — •Nadine von Coelln[1], Ana C. Fingolo[2], Benedikt Zerulla[3], Marjan Krstić[4], Christian Huck[1], Carsten Rockstuhl[3,4], Christof Wöll[2], and Petra Tegeder[1] — [1]Institute for Physical Chemistry, Heidelberg University, Germany — [2]Institute of Functional Interfaces — [3]Institute of Nanotechnology — [4]Institute of Theoretical Solid State Physics, Karlsruhe Institute of Technology, Germany

Chiral surface-anchored metal organic frameworks (SURMOFs) are promising candidates for enantioselective separation, molecular sensing and optoelectronic applications with circularly polarized light. Given the large possible design space, it is highly important to understand their spectral response and to be able to predictively model SURMOF structures to determine interesting candidates for experimental screening. In this work, we employ infrared scanning near-field optical microscopy (IR-SNOM) to probe anisotropic infrared properties. Crystallites with two distinct molecular orientations exhibited pronounced differences in their near-field infrared spectra. A controlled manipulation of crystal orientation confirmed that molecular orientation is the origin of these spectral differences. A multi-scale modeling approach, spanning single MOF unit cell simulations to thin-film Maxwell scattering calculations, was validated as it reproduced the spectral signatures and strong orientation sensitivity of the material [1].

Pressure-dependent photoluminescence and Raman spectra of GeSn alloys — •Stefan Zollner[1], Sonam Yadav[1], Meghan A. Worrell[1], Preston T. Webster[2], Rigo A. Carrasco[2], and Perry C. Grant[3] — [1]New Mexico State University, Las Cruces, NM, USA — [2]AFRL Space Vehicles Directorate, Albuquerque, NM, USA — [3]Arktonics LLC, Fayetteville, AR, USA

Optical spectra of $Ge_{1-x}Sn_x$ alloys (x<10%) grown on Si by chemical vapor deposition were acquired in a gas-membrane diamond anvil cell at pressures up to 10 GPa. The Si substrate contracts hydrostatically under pressure and imposes a biaxial stress on the thin epitaxial layer. The tetragonal distortion of the layer can be calculated from the bulk modulus of the substrate and the elastic constants of the layer. Room temperature Raman spectra of bulk Ge with 532 nm excitation show a parabolic blueshift from 300 cm^{-1} at atmospheric pressure to 335 cm^{-1} at 10 GPa. The blueshift due to pressure is linear and slightly larger for Ge on Si. We also acquired photoluminescence spectra of $Ge_{1-x}Sn_x$ alloys as a function of temperature and pressure. We observe a blueshift of the infrared $Ge_{1-x}Sn_x$ emission at 10 K of 46 meV/GPa which quenches at 0.6 GPa. For MWIR III/V multiple quantum wells, the blueshift is larger at 77 meV/GPa and the emission quenches at 1.3 GPa.

VIPR: A Modular Machine Learning Framework for Inverse Problems with Application to Reflectometry — •Sascha Creutzburg[1,6], Jeyhun Rustamov[2], Alexandros Koutsioumpas[4], Jens Bornschein[1,6], Marina Ganeva[4], Stefan Häusler[4], Bernd Helm[1,6], Alexander Hinderhofer[5], Mykhailo Levytskyi[4], Valentin Munteanu[5], Robert Juzak[1,6], Vedhas Pandit[2], Frank Schreiber[5], Jeffrey Kelling[2,3], and Nico Mothes[1,6] — [1]Helm & Walter IT-Solutions GmbH, Dresden — [2]Helmholtz-Zentrum Dresden-Rossendorf — [3]Chemnitz University of Technology — [4]Jülich Centre for Neutron Science, Heinz Maier-Leibnitz Zentrum — [5]University of Tübingen — [6]Saxony.AI

Ambiguous inverse problems are ubiquitous in experimental physics, where multiple parameter configurations can reproduce the same measurement and classical iterative approaches are often too slow for online analysis. We present the VIPR framework, a modular machine-learning approach for such problems in thin-film reflectometry. Its reflectometry plugin for X-ray and neutron reflectometry combines three approaches: (i) Reflectorch for fast parameter estimation, (ii) prior-amortized neural posterior estimation, and (iii) neural spline flows to capture multimodal posteriors and reveal alternative plausible structures. VIPR features streaming mode for near-real-time beamline feedback and is deployed at Heinz Maier-Leibnitz Zentrum for routine analysis. The framework integrates seamlessly into existing workflows and can be extended to other inverse problems via its plugin architecture. Code: https://codebase.helmholtz.cloud/vipr/vipr-framework

DS 21.5 Fri 10:45 REC/C213

Spectroscopic Imaging Ellipsometry at Cryogenic Temperatures: Uncovering a Structural Phase Change in 2D Polar Ga — •Jakob Henz[1], Arpit Jain[2], Joshua A. Robinson[2], Su Y. Quek[3], and Ursula Wurstbauer[3] — [1]University of Münster — [2]Center for 2DLM, PennState University — [3]Centre for Advanced 2D Materials, National University of Singapore

2D polar metals are a class of atomically thin 2D materials, realized by confinement heteroepitaxial growth (CHet). Hereby, metal atoms are intercalated between a graphene and 6H-SiC interface[1]. This results in a large area, stable 2D metal film with a bonding gradient ranging from covalent over metallic to a vdW-interaction within only two to three atomic layers[2].

Here, we use cryogenic spectroscopic imaging ellipsometry to investigate the temperature dependent light-matter interaction in bilayer 2D polar gallium down to 1 K.

Contrary to theoretical expectations[1], we find a change in the local dielectric response of the material from a homogenous behavior at room temperature to a heterogenous regime at low temperatures, characterized by two absorption peaks localized to distinct surface areas on the sample[3]. This change is interpreted to indicate a structural phase transition in the material.

Adsorption-Driven Vibrational and Electronic Changes on Cu(110) — •Sarang Bhasme, Mariella Denk, and Peter Zeppenfeld — Johannes Kepler University, Linz, Austria

Surface resonant Raman spectroscopy (SRRS) provides a sensitive approach for probing phonons and electron-phonon interactions on metal surfaces through resonant coupling to the surface electronic states.[1] In this work, SRRS combined with reflectance difference spectroscopy is employed to investigate adsorption induced modifications of the vibrational response of Cu(110) under ultra-high-vacuum conditions. Time-resolved SRRS measurements during controlled CO and Oxygen exposure reveal systematic evolution in phonon-related features, indicating changes in surface electronic structures and scattering pathways as adsorption progresses. These data enable comparative assessment of molecule-specific interactions and adsorption dynamics on the same surface.

Refining the Tanguy dispersion model for strong direct interband interactions — •Beáta Hroncová and Stefan Zollner — New Mexico State University, Las Cruces, NM, USA

In semiconductors, absorption near the band gap energy is dominated by electron valence-to-conduction band transitions. Exciton formation effectively reduces the band gap and enhances the absorption coefficient. A sharp excitonic peak corresponding to this bound state is observed in the spectral function, especially at low temperatures and low carrier concentrations [1]. At higher temperatures, the bound state is broadened and the peak disappears, but the Sommerfeld enhancement of the absorption persists.

A dispersion model of Wannier–Mott excitons with a screened Coulomb potential was derived by Tanguy [2]. However, if the band gap is small, the interactions between the conduction and valence bands are more prominent. This leads to deviations from the parabolic band curvature, and the effective mass approximation used for the calculation of the excitonic spectra is no longer accurate.

We study the dielectric response of InAs and InSb near the band edge measured by spectroscopic ellipsometry in a wide range of temperatures 50-800 K. With the use of $k \cdot p$ theory, we find the non-parabolicity of the electronic band structure, and describe how to include it in the Tanguy model. Herewith we achieve a better agreement between the theory and the experimental data.

DS 21.8 Fri 11:45 REC/C213

A Novel Characterization Tool for Optical Coatings and Thin Films — •Fabian Felixberger[1,2], Ayesha Khan[1,3], Jonathan Noé[1], Michael Förg[1], Manuel Nutz[1], Simone Strohmair[1], Ines Amersdorffer[1,3], David Hunger[3], Theodor Hänsch[2], and Thomas Hümmer[1] — [1]Qlibri GmbH, Munich — [2]Ludwig Maximilian University of Munich — [3]Karlsruhe Institute of Technology

Thin films and nanostructured surfaces play a crucial role in modern science and technology, with their applications ranging from optical components to biosensors. Their precise characterization is therefore essential for understanding and optimizing their function.

We show that inserting such materials in an optical resonator [1] offers a platform which allows the investigation of minimal amounts of scattering and absorption. In addition, it can be utilised for the detection of defects, deviations from surface flatness and local changes of the refractive index.

By raster-scanning the sample, we obtain spatially resolved maps that allow us to distinguish between point-like defects and extended surface features.

Our results prove that we have developed a versatile and open-access tool for non-destructive and quantitative analysis of optical coatings and thin films, suitable for a wide range of materials.

DS 21.9 Fri 12:00 REC/C213

Measuring sub-nanometer oscillations of a thin gold film by a combination of ultrafast imaging ellipsometry and interferometry — •Markus Olbrich[1,2], Theo Pflug[1,3], Andy Engel[1], Andrés Lasagni[2,4], and Alexander Horn[1] — [1]Laserinstitut Hochschule Mittweida, Hochschule Mittweida, Technikumplatz 17, 09648 Mittweida, Germany — [2]Institut für Fertigungstechnik, Technische Universität Dresden, George-Bähr-Str. 3c, 01069 Dresden, Germany — [3]Carl Zeiss SMT GmbH, Carl-Zeiss-Promenade 10, 07745 Jena, Germany — [4]Fraunhofer-Institut für Werkstoff- und Strahltechnik IWS, Winterbergstr. 28, 01277 Dresden, Germany

Measuring the transient dielectric function of laser-excited surfaces by ultrafast optical metrology is crucial for understanding fundamental processes such as the absorption of laser radiation, the dynamics of the electron-phonon non-equilibrium, or material ablation. Thereby, the measured transient dielectric function always represents the sum of changes in the optical properties and topography. To distinguish between these two contributions, a combination of ultrafast ellipsometry and ultrafast interferometry enables solving this problem. To demonstrate the advantage of the combination of both methods, the transient changes in the dielectric function and the surface topography in terms of periodic oscillations due to the induced shock and rarefaction waves are exemplarily demonstrated for an excited thin gold film upon single-pulsed irradiation with ultrafast laser radiation (λ = 800 nm, τ_H = 40 fs) at a fluence of 50 % of the ablation threshold.

DS 21.10 Fri 12:15 REC/C213

Long-term studies of the defect types in tritiated graphene using Raman microscopy — •Genrich Zeller[1], Magnus Schlösser[1], and Helmut H. Telle[2] — [1]KIT-IAP, Karlsruhe, Germany — [2]UAM, Madrid, Spain

Tritium loading of graphene and graphene-like materials is of interest, e.g., in astroparticle physics, where such materials are proposed as sources and targets for neutrino experiments like KATRIN or PTOLEMY, or in hydrogen-isotope separation membranes for nuclear fusion. Although hydrogenation of graphene is well established, the radioactive nature of tritium introduces additional experimental challenges and open questions.

Only in recent years has tritiation of graphene been demonstrated using self-radiolysis of tritium. In that initial proof-of-principle study, we found that tritium exposure not only led to the adsorption of atomic tritium but also to the creation of vacancy defects. A key component of the analysis of tritiated graphene is high-resolution Raman spectroscopy, which allows us to measure defect densities and to determine the nature of the defects. In this work, we follow up on our initial studies, and we observe the evolution of defect types during three years of storage under ambient conditions. We find that graphene adsorption sites become strongly depleted, evidenced by the recovery of the characteristic 2D band and an overall decrease in defect density as tracked by the D/G band ratio. The magnitude of this depletion substantially exceeds the annual reduction expected from tritium β-decay alone, indicating additional removal pathways besides radioactive decay.

Sessions

– Invited Talks, Topical Talks, Tutorials, Contributed Talks, and Posters –

DY 1: Tutorium: Physics of Behavior (joint session SOE/TUT/DY)

The emerging field of the physics of behavior seeks to quantitatively characterize complex behavior in biological agents under naturalistic conditions, using tools from dynamical systems theory and statistical physics. Even in simple organisms, behavioral richness demands new methods of measurement and analysis, as well as new theoretical frameworks. In the absence of a first-principles theory, data-driven approaches are essential, and the many interacting degrees of freedom call for descriptions capable of handling high-dimensional systems.

This tutorial introduces how concepts from dynamical systems theory and statistical physics can be applied to quantify behavior across biological scales and to develop simple yet predictive models. It is intended for physicists at all levels, beginning with graduate students, who are interested in computational approaches to modeling animal behavior. The tutorial is accompanied by an openly accessible code repository to support hands-on exploration of selected topics.

Time: Sunday 16:00–18:15 Location: HSZ/0004

See SOE 1 for details of this session.

DY 2: Focus Session: New Routes to Localization and Quantum Non-Ergodicity I (joint session TT/DY)

This session explores how quantum many-body systems can fail to thermalize through mechanisms that extend beyond conventional many-body localization. Recent work has discovered new mechanisms that lead to non-ergodic behavior, including Hilbert-space fragmentation, disorder-free localization, and confinement effects that arise from destructive interference in Fock space. At the same time, experiments with ultracold atoms, trapped ions, Rydberg platforms, and superconducting qubits directly reveal many-body scars, slow relaxation, and unusual transport. This session highlights these developments and identifies the central open questions that are now driving the field forward.

Coordinators: Roderich Moessner (MPI PKS Dresden), Frank Pollmann (TU München)

Time: Monday 9:30–12:15 Location: HSZ/0003

Topical Talk DY 2.1 Mon 9:30 HSZ/0003

Eigenstate thermalization in thermal first-order phase transitions — •Maksym Serbyn — IST Austria, Am Campus 1, 3400 Klosterneuburg

In my talk I will discuss the fate of eigenstates in quantum systems in vicinity of thermal first order phase transition. The eigenstate thermalization hypothesis (ETH) posits how isolated quantum many-body systems thermalize, assuming that individual eigenstates at the same energy density have identical expectation values of local observables in the limit of large systems. In my talk I will show that ETH requires generalization in the presence of thermal first-order phase transitions. I will argue that for energies in the vicinity of the thermal phase transition, eigenstate expectation values do not need to converge to the same thermal value. The system has a regime with coexistence of two classes of eigenstates corresponding to the two branches with distinct expectation values at the same energy density, and another regime with Schrodinger-cat-like eigenstates that are inter-branch superpositions; these two regimes are separated by an eigenstate phase transition. I will also discuss potential extensions of these results to more physical models, and outline how the special structure of eigenstates near first order phase transition can be probed via quench dynamics.

Topical Talk DY 2.2 Mon 10:00 HSZ/0003

Stabilizing Floquet orders to infinite time — •Anushya Chandran[1], Shreyas Raman[2], Robin Schäfer[3], and Alicia Kollàr[4] — [1]Boston University, Boston, USA — [2]Boston University, Boston, USA — [3]Helmholtz-Zentrum Berlin, Berlin, Germany — [4]University of Maryland, College Park, USA

Floquet engineering, in which the properties of a quantum system are modified through the application of strong periodic drives, is an indispensable tool in atomic and condensed matter systems. It enables quantum simulation, the dynamic stabilization of unstable states, and the realization of exotic topological order and time crystals. However, it is inevitably limited by intrinsic heating processes, so that the engineered states are, at best, pre-thermal. I will describe a general-purpose dissipative scheme that autonomously cools a strongly driven system to close to a desired Floquet engineered state. I will demonstrate this stabilization in a driven many-body spin chain, that either spontaneously breaks a symmetry or exhibits discrete time-crystalline order in the steady state.

Topical Talk DY 2.3 Mon 10:30 HSZ/0003

Dynamical landscape of out of equilibrium emergent lattice gauge theories in two dimensions — •Nilotpal Chakraborty — University of Cambridge

Many-body models with local constraints, such as dimer, ice or generally quantum link type models often are described as emergent gauge theories. I will describe a range of recent results, comprising classical and quantum dynamics of different kind, highlighting the rich dynamical phenomenology present in these models. In line with the session's topic, I will focus more on the two-dimensional U(1) quantum link model, and highlight its potential as a new route toward localisation and non-ergodicity in the absence of quenched disorder. In doing so, I will also present spectral signatures of such localization. Finally, I will end by discussing possibilities of realising the different constrained models and their dynamics in quantum simulators, for which there appears to be palpable current interest.

15 min. break

Topical Talk DY 2.4 Mon 11:15 HSZ/0003

Interference, topology, and new Hilbert-space routes to quantum non-ergodicity — •Yi-Ping Huang[1,2,3] and Tao-Lin Tan[1] — [1]Department of Physics, National Tsing Hua University, Hsinchu 30013, Taiwan — [2]Physics Division, National Center for Theoretical Sciences, Taipei 10617, Taiwan — [3]Institute of Physics, Academia Sinica, Taipei 115, Taiwan

A central challenge in nonequilibrium quantum physics is to understand why certain many-body systems fail to thermalize even in the absence of disorder or integrability. In this talk, I will outline a different perspective in which non-ergodicity is governed by hidden geometric structures in Hilbert space rather than by conventional real-space mechanisms. This viewpoint leads to the concept of interference-caged quantum many-body scars (ICQMBS), where exact many-body destructive interference confines eigenstates to small regions of the Fock-space graph. Remarkably, interference zeros and graph automorphisms emerge as universal organizing principles, revealing a class of topological ICQMBS whose robustness originates from local Fock-space topology rather than symmetries or constraints. This framework not only explains diverse non-ergodic phenomena from one-dimensional systems to two-dimensional gauge

models but also provides new tools for systematically identifying them. I will end with a brief look at stabilizing QMBS through the lens of Kramers-Wannier duality, illustrating the challenges and possibilities that arise when studying QMBS under duality.

Topical Talk DY 2.5 Mon 11:45 HSZ/0003

Fock-space cages and their spectral signatures — •Cheryne Jonay — University of Ljubljana

Generic quantum many-body systems thermalize. Yet several mechanisms can prevent this, notable examples include integrability, many-body localization, Hilbert-space fragmentation, and scars. We will discuss a new mechanism of ergodicity breaking that arises from destructive interference in Fock space. This leads to exact eigenstates localized on polynomially many configurations within an exponentially large, fully connected Hilbert space sector. We call these states Fock-space cages. They emerge naturally in kinetically constrained models with chiral symmetry. We will present graph-theoretic methods to explicitly construct cages with support ranging from O(1) to O(L) sites, and examine how their dynamical signatures, such as return probabilities and magnetization, resist thermalization. Finally, we will explore the spectral statistics through the lens of chiral random matrix theory. The exponentially degenerate zero-energy manifold produces distinctive signatures, yet the agreement with random matrix predictions varies across energy scales - a direct consequence of localized and thermal eigenstates coexisting within the same Hilbert space sector. We will also probe the stability of these phenomena: the gap between the zero-energy manifold and the spectral bulk may give rise to protected slow dynamics.

DY 3: Quantum-Critical Phenomena (joint session TT/DY)

Time: Monday 9:30–12:30 Location: HSZ/0101

See TT 2 for details of this session.

DY 4: Active Matter I (joint session BP/CPP/DY)

Time: Monday 9:30–12:45 Location: BAR/SCHÖ

DY 4.1 Mon 9:30 BAR/SCHÖ

Bayesian inference of magnetosensing in a magnetotactic bacterium — •Sascha Lambert[1], Emilie Gachon[2], Damien Faivre[2], and Stefan Klumpp[1] — [1]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany. — [2]Aix Marseille Université, CEA, CNRS, BIAM, 13115 Saint-Paul-Lez-Durance, France.

Magnetotactic bacteria are often assumed to align only passively with external magnetic fields, yet recent observations of the magnetotactic bacterium SS-5 reveal a pronounced increase in swimming speed under geomagnetic conditions. Because flagellated microorganisms typically follow helical paths, magnetic torques could, in principle, straighten their trajectories and create an apparent increase in speed, offering a purely mechanical explanation. We test this hypothesis using a physical swimming model based on Active Brownian Particles that incorporates magnetic torques, rotational propulsion, and helical motion, and we explore the relevant parameter space using Bayesian inference constrained by three-dimensional trajectory data. Posterior predictive simulations demonstrate that the mechanically induced increase in apparent speed is far too small to account for the experimental observations, even under extreme parameter choices. The results quantitatively rule out swaying as a sufficient explanation for the behaviour of SS-5 and instead support the presence of an active magnetic sensing mechanism.

DY 4.2 Mon 9:45 BAR/SCHÖ

Vorticity-induced surfing and trapping in porous media — •Pallabi Das[1], Mirko Residori[1], Axel Voigt[2,3,4], Suvendu Mandal[5], and Christina Kurzthaler[1,3,4] — [1]Max Planck Institute for the Physics of Complex Systems, Germany — [2]Institute of Scientific Computing, TU Dresden, Germany — [3]Center for Systems Biology Dresden, Germany — [4]Cluster of Excellence, Physics of Life, TU Dresden, Germany — [5]TU Darmstadt, Germany

Microorganisms often encounter strong confinement and complex hydrodynamic flows while navigating their habitats. Combining finite-element methods and stochastic simulations, we study the interplay of active transport and heterogeneous flows in dense porous channels. We find that swimming always slows down the traversal of agents across the channel, giving rise to robust power-law tails of their exit-time distributions. These exit-time distributions collapse onto a universal master curve with a scaling exponent of $\approx 3/2$ across a wide range of packing fractions and motility parameters, which can be rationalized by a scaling relation. We further identify a new motility pattern where agents alternate between *trapping* along fast streams and extended *surfing* phases, the latter determining the power-law exponent. Unexpectedly, trapping occurs in the flow backbone itself – not only at obstacle boundaries – due to vorticity-induced reorientation in the highly-heterogeneous flow environment. These findings provide a fundamentally new active transport mechanism with direct implications for biofilm clogging and the design of novel microrobots capable of operating in heterogeneous media.

DY 4.3 Mon 10:00 BAR/SCHÖ

Adhesion Patterns in Gliding Filamentous Cyanobacteria — •Elias Fischer[1], Paul Nieschwitz[2], Stefan Karpitschka[2], and Holger Stark[1] — [1]Institute of Physics and Astronomy, TU Berlin, Germany — [2]Department of Physics, Universität Konstanz, Germany

Filamentous cyanobacteria play an important role in many ecosystems and the carbon cycle of our planet. They exhibit gliding motility when in contact with solid surfaces or each other. Despite their ecological relevance and increased use in biotech applications, the exact nature of the force-generating process remains not fully understood.

Our recent measurements of filamentous cyanobacteria gliding across flat surfaces and visualized in kymographs show spatio-temporal adhesion regions along the filament, indicating an intrinsic helical shape. Based on our a novel approach for modeling the mechanical aspects of individual cyanobacteria filaments, we are able to interpret the complex kymograph patterns. Each filament is modeled as a helical chain of thin cylindrical segments in 3D with bending and twisting elasticity. The filaments interact with nearby surfaces and filaments via a hard-core repulsion and an exponentially decaying adhesion force. Importantly, the propulsion forces that push the filament forward are only applied locally at surface-contacting segments.

Our simulated kymographs reveal how both the helical shape and the adhesion strength strongly influence the filament's gliding speed and the dynamics of the surface-attachment regions. Thereby, we crucially contribute to the understanding of how real filamentous cyanobacteria generate their propulsion forces.

DY 4.4 Mon 10:15 BAR/SCHÖ

The 3D chirality of malaria parasites determines their motion patterns in 2D and originates at the apical pole — •Leon Lettermann[1], Mirko Singer[2], Smilla Steinbrück[2,3], Falko Ziebert[1], Sachie Kanatani[3], Photini Sinnis[3], Friedrich Frischknecht[2], and Ulrich Schwarz[1] — [1]Institute for Theoretical Physics & BioQuant, Heidelberg University — [2]Parasitology, Center for Infectious Diseases, Heidelberg University — [3]School of Public Health and Malaria Research Institute, Johns Hopkins University

Plasmodium sporozoites, the slender forms of the malaria parasite injected by mosquitoes into the skins of their vertebrate hosts, provide a medically highly relevant model system for active chiral particles. Using 3D tracking in synthetic hydrogels, we show that sporozoites consistently move on right-handed helical trajectories. When they encounter a two-dimensional substrate, they switch to clockwise circular motion, whereas circling on glass in medium occurs with the opposite sense of rotation, suggesting on glass they try to invade the medium above. Using a sandwich assay, we demonstrate that chirality also determines the reverse transition from two-dimensional to three-dimensional motion. Combining these measurements with a theory for gliding motility allows us to identify the likely origin of chirality, namely an asymmetric distribution of adhesins. After confirming this via two-sided traction force microscopy, we finally use STED super-resolution microscopy to reveal a corresponding tilt in the apical ring complex. In summary, our analysis thus uncovers both the biological relevance and the molecular basis of chirality in the movement of malaria parasites.

DY 4.5 Mon 10:30 BAR/SCHÖ

Squirmer dynamics in porous environments — •Mirko Residori[1], Christina Kurzthaler[1], and Sebastian Aland[2] — [1]Max Planck Institute for the Physics of Complex Systems — [2]TU Freiberg

We introduce a computational framework for simulating the dynamics of microswimmers in complex porous environments. Specifically, we adopt a diffusive domain approach to represent the surface of a micro-swimmer, modeled as a squirmer. This method ensures accurate and stable finite-element simulations, even in highly confined geometries. Validation against analytical and numerical benchmarks confirms the model*s accuracy and robustness. We then apply it to explore squirmer motion in heterogeneous porous media, revealing how

hydrodynamic interactions lead to behaviors such as dynamic trapping due to hydro-dynamically induced re-orientations. Moreover, we demonstrate that the squirmer parameter and the repulsive potential critically influence a squirmer's ability to navigate and escape confinement. The proposed framework offers a versatile and efficient tool for studying active motion in complex fluids and provides new insights into micro-swimmer transport and control in natural and engineered systems.

DY 4.6 Mon 10:45 BAR/SCHÖ

Dynamics of passive tracers in active dumbbell suspension — •Chandranshu Tiwari and Sunil P. Singh — Department of Physics, Indian Institute of Science Education and Research, Bhopal 462066, India.

The transport of passive tracers in active fluids exhibits rich dynamics arising from persistent interactions between active agents and the tracer. In our work, we employ Brownian dynamics simulations to investigate the dynamical behaviour of both isotropic(circular) and anisotropic(elliptical) tracers in active dumbbell suspension, considering only steric interactions. For circular tracers, we find that the speed shows a crossover from monotonically decreasing to increasing with tracer size as the dumbbells' speed is increased. The tracer's effective diffusion also displays a non-monotonic dependence on area fraction: the diffusivity first increases and then decreases at higher area fractions.

For anisotropic tracers, the characteristic non-monotonic trend persists. Moreover, their motion along the major and minor axes differs significantly. Anisotropic accumulation of active particles around the tracer generates direction-dependent forces and fluctuations, favouring motion along the major axis. Consequently, both the speed and diffusivity along the major axis exceed those along the minor axis.

15 min. break

Invited Talk DY 4.7 Mon 11:15 BAR/SCHÖ

Modeling and inference of magnetotactic motility in complex environments — •Stefan Klumpp — Institute for the Dynamics of Complex Systems, University of Göttingen, Göttingen, Germany

Magnetotactic bacteria orient themselves and swim along field lines of the geomagnetic field. Their magnetically directed self-propelled motion makes them an instance of dipolar active matter. Here we focus on the interaction of these bacteria with walls or obstacles. Experiments in microfluidic systems show that interactions with walls result in (possibly transient) alignment parallel to the wall, which may compete with the alignment with the magnetic field. The dynamic behavior arising from the competition of the two alignments includes U-turn trajectories in circular chambers and trapping and escape dynamics in channels with overlapping cylindrical obstacles. In a phenomenological picture, the resulting motion can be described in an Active Brownian Particle model by introducing a wall torque that competes with the magnetic torque, which results in good agreement with experimental observations. Systematic Bayesian inference of the wall torque from observations shows that only a part of the torque function (dependence on incident angle) can be learned reliably from the data.

DY 4.8 Mon 11:45 BAR/SCHÖ

Quantifying aggregation behaviour of filamentous cyanobacteria — •Elias Illing and Stefan Karpitschka — Fachbereich Physik, Universität Konstanz

Cyanobacteria are ubiquitous in nature, frequently causing ecological and economic harm by explosive growth, so called blooms.

We investigate the collective dynamics of entangled filamentous cyanobacteria in open liquid media, reminiscent of their aggregates found during later stages of blooms. We investigate the impact of illumination on the clustering and spreading of the bacteria and quantify the morphology of the bacterial aggregates by image analysis. We determine the critical density necessary for initial clustering and track the evolution of the subsequent stages, ranging from stable clusters to spreading mats. These states can be modulated by light intensity variations, potentially allowing for control of the morphological evolution of cyanobacterial aggregates.

DY 4.9 Mon 12:00 BAR/SCHÖ

Dynamically Induced Spatial Segregation in Multi-Species Bacterial Bioconvection — •Mingqi Yan[1,2], Chenxi Wang[3], Oscar Gallardo-Navarro[4], Rinat Arbel-Goren[4], Joel Stavans[4], and Erwin Frey[1,2] — [1]Department of Physics, Ludwig-Maximilians-Universität München, Theresienstraße 37, 80333 München, Germany — [2]Max Planck School Matter to Life, Hofgartenstraße 8, 80539, München, Germany — [3]School of Science, Harbin Institute of Technology, 518055, Shenzhen, China — [4]Department of Physics of Complex Systems, Weizmann Institute of Science, 7610001, Rehovot, Israel

Bacterial bioconvection is a classic example of collective behavior in active matter, where upward-swimming bacteria create density instabilities leading to large-scale fluid flows. While this phenomenon is well-studied in single-species suspensions, natural environments are typically inhabited by diverse microbial communities. Here, we investigate the collective dynamics of multi-species bacterial suspensions. Combining experiments with a continuum model, we show that different bacterial species can spontaneously segregate into stable, spatially interlocked domains. Our theoretical analysis reveals that this segregation is not driven by biochemical antagonism but rather by the interplay between species-specific motility characteristics and the self-generated hydrodynamic flows. This work provides new insights into how physical interactions alone can drive the spatial organization of complex microbial communities.

DY 4.10 Mon 12:15 BAR/SCHÖ

Light-switchable microbial rafts at air-liquid interfaces — •Gustav F. Nolte, Alexandros A. Fragkopoulos, Timo Völkl, Mechthild Rappold, and Oliver Bäumchen — University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany

In biological active matter, clustering occurs across a wide range of time and length scales, from molecular assemblies such as actomyosin networks to macroscopic systems like fire ant rafts. Here, we report on a fast, light-switchable, and fully reversible clustering phenotype on the microscale, observed at air-liquid interfaces: the raft formation of the biciliated microalga *Chlamydomonas noctigama*.

C. noctigama is a relative of the model organism *Chlamydomonas reinhardtii*, which exhibits light-switchable adhesion and subsequent clustering at solid-liquid interfaces [1,2]. We show how the cluster morphology depends on cell density and discuss potential growth mechanisms by analyzing dynamics of individual clusters. Furthermore, we characterize the dependence of raft formation on the light spectrum and interfacial free energy. Using micropipette force spectroscopy [3], we show that single cells exploit capillary forces for light-switchable ciliary adhesion to the air-liquid interface, enabling raft formation. In their natural habitats, reversible clustering may provide an advantage by allowing cells to accumulate in locations optimal for photosynthesis while increasing resilience to environmental stress.

DY 4.11 Mon 12:30 BAR/SCHÖ

Circadian gravitaxis: Photosynthetic microswimmers remodel local pH to actively tune vertical migration — Arkajyoti Ghoshal[1], Soumitree Mishra[1], Jayabrata Dhar[2], Hans-Peter Grossart[3,4], and •Anupam Sengupta[1,5] — [1]Physics of Living Matter, Department of Physics and Materials Science, University of Luxembourg, Luxembourg — [2]Department of Mechanical Engineering, National Institute of Technology Durgapur, India — [3]Department of Plankton and Microbial Ecology, Leibniz Institute of Freshwater Ecology and Inland Fisheries, Stechlin, Germany — [4]Institute of Biochemistry and Biology, Potsdam University, Germany — [5]Institute for Advanced Studies, University of Luxembourg, Luxembourg

Motile phytoplankton shuttle between bright surface waters and deeper nutrient rich layers, usually controlled by internal circadian clocks. Yet many species show irregular movements, defying the expected circadian rhythm. Studying a bloom forming photosynthetic species, we found that cells adjust their vertical migration by altering local pH, mediated by a shift in their gravitactic behavior. This self-modulation of pH generates sub-populations which are physiologically similar but swim differently, remaining vertically separated even under uniform conditions. Supported by a cell-level analysis and mathematical model, we confirm that the pH-mediated circadian shift is underpinned by morphological adjustments. Our results support a circadian gravitactic model in which diurnal pH control drives diversified migration, enhancing fitness particularly in acidifying oceans.

DY 5: Focus Session: Physics of Behavior (joint session SOE/DY)

Organizers: Greg Stephens (Vrije Univ. Amsterdam), Pawel Romanczuk (HU Berlin)

Physics has made important contributions to the remarkable progress in characterizing the molecules, cells, and circuits that generate natural behavior. Yet our understanding of behavior at the scale of the whole organism and in ecological and social contexts remains significantly less advanced. Even in simpler organisms, natural behavior is complex, requiring new tools for measurement (often through novel imaging), analysis, and theoretical insight. The emerging field of the physics of behavior addresses this gap by seeking to quantitatively characterize complex behavior in naturalistic settings. This focus session will highlight recent advances at the intersection of physics, neuroscience, biology, and social sciences with contributions from both theorists and experimentalists.

Time: Monday 9:30–12:45 Location: GÖR/0226

See SOE 2 for details of this session.

DY 6: Machine Learning in Dynamics and Statistical Physics I

Time: Monday 9:30–13:00 Location: HÜL/S186

DY 6.1 Mon 9:30 HÜL/S186

Reservoir Computing with Hydrodynamically Coupled Active Colloidal Oscillators — •Veit-Lorenz Heuthe[1], Lukas Seemann[1], Samuel Tovey[2], and Clemens Bechinger[1,3] — [1]Universität Konstanz, Konstanz, Germany — [2]Universität Stuttgart, Stuttgart, Germany — [3]Centre for the Advanced Study of Collective Behavior, Konstanz, Germany

Reservoir computing is a newly emerging framework that exploits the dynamical response of complex physical systems to external perturbations. The high-dimensional, non-linear dynamics of active matter systems with hydrodynamic interactions offsers great potential for highly tunable physical reservoirs. Here, we present a physical reservoir that exploits the hydrodynamic interactions between several hundred colloidal oscillators for chaotic timeseries forecasting. We demonstrate that the inherent memory in this system facilitates detection of hidden anomalies in non-Markovian time-signals. Our results highlight the potential of active matter for locating subtle, non-disruptive signatures in e.g. financial stock markets, physiological measurements or seismic and climate data. Achieving such computing functinalities in physical systems could enable the development of intelligent hardware for edge-computing.

DY 6.2 Mon 9:45 HÜL/S186

From Phase-Space Fluctuations to Predictive Power: Entropy Production as a Metric for Swarm Reservoir Computing — •Patrick Egenlauf[1,2] and Miriam Klopotek[1,3] — [1]University of Stuttgart, Stuttgart Center for Simulation Science, SimTech Cluster of Excellence EXC 2075, Stuttgart, Germany — [2]University of Stuttgart, Interchange Forum for Reflecting on Intelligent Systems, IRIS3D, Stuttgart, Germany — [3]Heidelberger Akademie der Wissenschaften, WIN-Kolleg, Heidelberg, Germany

In reservoir computing, a time-varying input is projected onto a high-dimensional state space, allowing a simple linear readout to retrieve task-relevant features. Physical substrates such as active-matter swarms promise efficient, low-energy computation, but a quantitative selection criterion, that reliably indicates a good reservoir, is missing. We simulated an interacting swarm subjected to an external driver and evaluated two entropy measures: system entropy, quantifying phase-space density fluctuations, and environment entropy, representing heat dissipation. For each parameter set of the swarm interactions, we computed the relative differences for the system and environment entropy between undriven and driven cases and measured the driver work performed on the system. Both relative differences display robust linear correlations with forecast accuracy, while the driver work matches the performance curve almost perfectly, indicating that driver-induced entropy production dominates the reservoir's information-processing capacity. Consequently, entropy production offers a quantitative metric for tuning swarm-based reservoirs toward optimal performance.

DY 6.3 Mon 10:00 HÜL/S186

Performing inference with physical response: Reservoir computing with active matter substrates — Mario U. Gaimann[1] and •Miriam Klopotek[1,2] — [1]University of Stuttgart, Stuttgart Center for Simulation Science, SimTech Cluster of Excellence EXC 2075, Stuttgart, Germany — [2]WIN-Kolleg of the Young Academy, Heidelberg Academy of Sciences and Humanities, Heidelberg, Germany

We explore questions of real-time inference and forecasting of chaotic signals, re-interpreting them in terms of nonequilibrium physical response, by studying a model of information processing with an active matter substrate used in the reservoir computing (RC) paradigm. The system becomes robustly optimal for computing in a particular dynamical regime due to its intrinsic ability to relax efficiently, which, under driving, unlocks maximal dynamical diversity and susceptibility to chaotic input signals; the mechanisms include self-healing, multi-step dynamical response, and adaptive morphological reorganization [1,2]. Shifting the system's response away from direct-agent toward collective variables is key, as evidenced by cross-correlative functions in dynamics [2]. These ideas shed light on self-optimizing inference in bio-inspired or material computing that flexibly exploits dynamics across diverse collective scales.

DY 6.4 Mon 10:15 HÜL/S186

Learning single and multiple chaotic systems with minimal reservoir computers — •Francesco Martinuzzi and Holger Kantz — Max Planck Institute for the Physics of Complex Systems

Chaotic dynamics are present in a multitude of natural and engineered systems. Recently, chaos has been modeled using machine learning (ML) methods thanks to their ability to infer underlying governing equations without directly accessing them. Among ML models, echo state networks (ESNs) have been widely investigated because of their simple construction and efficient training. However, ESNs typically rely on randomly initialized reservoirs whose stochastic connectivity makes them difficult to interpret and tune. To what extent are random and complex reservoir topologies actually necessary for learning chaotic dynamics with ESNs? We show that deterministic constructions of the reservoir matrix outperform random initializations for the reconstruction of chaotic attractors. By testing ten distinct deterministic topologies against random reservoirs on over 90 different attractors, our results demonstrate consistently better performance for deterministic reservoirs. Furthermore, we show how the same deterministic reservoir topologies can be leveraged to learn multiple chaotic systems with a single reservoir computer, thereby showcasing multifunctionality.

DY 6.5 Mon 10:30 HÜL/S186

Understanding task performance of time-multiplexed optical reservoir computing via polynomial expansion — •Elias Koch[1], Julien Javaloyes[2], Svetlana V. Gurevich[1,3], and Lina Jaurigue[4] — [1]Institute for Theoretical Physics, University of Münster, Wilhelm-Klemm-Str.9 48149 Münster, Germany — [2]Departament de Física and IAC3, Universitat de les Illes Balears, Campus UIB 07122 Mallorca, Spain — [3]Center for Data Science and Complexity (CDSC), University of Münster, Corrensstrasse 2, Münster, 48149, Germany — [4]Institute of Physics, Technische Universität Ilmenau , 98693 Ilmenau, Germany

We study the dynamics of a reservoir computer, realized as a linear optical microcavity with a time-multiplexed injection stream. In the first step, the output is processed with different nonlinearities, allowing to analyze the resulting polynomials and to what extend they can approximate different tasks. To that end, we compare two different discrete tasks, both derived from the Lorenz system through integration with a Runge-Kutta (4) scheme, but sampled to different stepsizes. There, we identify the respective underlying polynomial map and discuss the occuring terms. We compare these results with the impact of employing nonlinear nodes by introducing a Kerr nonlinearity in the optical microcavity.

DY 6.6 Mon 10:45 HÜL/S186

Physical Reservoir Computing with Ferroelectric Oxides for Time-series Classification Tasks — •Atreya Majumdar[1], Yan Meng Chong[2], Dennis Meier[1,2,3], and Karin Everschor-Sitte[1] — [1]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Duisburg, Germany — [2]Department of Materials Science and Engineering, Norwegian University of Science and Technology (NTNU), Trondheim, Norway —

[3]Research Center Future Energy Materials and Systems, Research Alliance Ruhr, Bochum, Germany.

Physical reservoir computing leverages the intrinsic complexity, non-linearity, and fading memory of material systems to process temporal data for solving time-series pattern recognition tasks. Magnetic and ferroelectric materials have recently emerged as promising reservoir computers, offering dynamics well suited for processing time-dependent signals [1]. Here, we demonstrate that the photocurrent dynamics of the ferroelectric semiconductor ErMnO3 can be harnessed as an effective physical reservoir for real-time time-series classification. Moreover, the relaxation time of the photocurrent can be controllably tuned, providing flexibility to capture different temporal features and thereby enhancing performance. Altogether, the results highlight the potential of ferroelectric oxides as scalable, energy-efficient platforms for real-time physical reservoir computing.

Checking the superiority of multi-model mean forecasts by reservoir computing — Daniel Estevez Moya[1,3], Erick A. Madrigal Solis[1,2], Ernesto Estevez Rams[3], and •Holger Kantz[1] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]University of Techology, Dresden, Germany — [3]Faculdad de Física, Universidad de La Habana, Cuba

In weather prediction and climate forecasts it has been observed that taking the arithmetic mean forecast of an ensemble of different models is often superior to most of the individual models. We use Reservoir Computing to generate easily a large ensemble of models and study their performance on deterministic toy models. While each individually trained reservoir comes with its own model error which is a systematic error, we verify that the arithmetic mean of these forecasts is closer to the truth than most of the individual forecasts. We present a detailed dynamical explanation for this observation.

Controlling dynamical systems into unseen target states using machine learning — Daniel Köglmayr[1,2], Alexander Haluszczynski[3], and •Christoph Räth[1,2] — [1]Deutsches Zentrum für Luft- und Raumfahrt (DLR) — [2]Ludwig-Maximilians-Universität (LMU) — [3]Allianz Global Investors (AGI)

Controlling nonlinear dynamical systems is a central task in many different areas of science and engineering. Combining previous work on controlling chaotic systems to arbitrary states [1] and extrapolating the system behavior into unseen parameter regions [2] using machine learning, we present here a novel, model-free, and data-driven methodology for controlling complex dynamical systems into previously unseen target states, including those with significantly different and complex dynamics. Leveraging a parameter-aware realization of next-generation reservoir computing (NGRC), our approach accurately predicts system behavior in unobserved parameter regimes, enabling control over transitions to arbitrary target states utilizing a new prediction evaluation and selection scheme [3]. By extending the applicability of machine learning-based control mechanisms to previously inaccessible target dynamics, this methodology opens the door to transformative new applications while maintaining exceptional efficiency. Our results highlight reservoir computing as a powerful alternative to traditional methods for dynamic system control.

Noise-Balanced Sparse Grid Surrogates for Multiscale Coupling of Monte Carlo and Continuum Models — •Tobias Hülser and Sebastian Matera — Fritz-Haber-Institut der MPG, Berlin

Incorporating a high-fidelity microscopic Monte Carlo model into multiscale simulations can easily become intractable, implying the necessity of surrogate models in many practical applications. Unfortunately, if the microscopic model depends on many macro-variables this can become quite challenging due to the 'curse of dimensionality'. Furthermore, the sampling noise in the underlying Monte Carlo data can lead to uncontrolled errors corrupting the surrogate even though it would be highly accurate in the case of noise-free data. To address these points, we have developed a novel sparse grids interpolation approach which balances interpolation and noise induced errors complemented by a multilevel on-the-fly construction during the multi-scale simulation. Besides its efficiency, an appealing feature is the ease of use of the approach with a single hyperparameter controlling the whole surrogate construction - from which data needs to be created (and how accurately) to the surrogate's accuracy with guaranteed convergence. We demonstrate the approach on examples from heterogenous catalysis, incorporating microscopic kinetic Monte Carlo models into convection-diffusion type reactor scale simulations.

DY 6.10 Mon 12:00 HÜL/S186

Learning Time Trajectories of a Stochastic Dynamical System with a Slowly Varying Parameter — •Changho Kim[1], Zihan Xu[1], Andrew Nonaka[2], and Yuanran Zhu[2] — [1]University of California, Merced, California, USA — [2]Lawrence Berkeley National Laboratory, Berkeley, California, USA

The statistics-informed neural network (SINN) is a reliable machine learning approach for learning and reproducing stochastic trajectories based on the statistical properties of sample trajectory data, particularly for stationary, Gaussian-like, multidimensional stochastic processes. However, to enable practical applications–such as surrogate modeling for the development of hybrid simulation methods–SINN must be extended to learn quasi-stationary dynamics driven by a slowly varying parameter. We enhance the SINN framework by incorporating this parameter as an additional input and by introducing loss functions to capture its influence, as well as proposing a new neural network structure that takes both white noise sequences and time trajectories of the slowly varying parameter as inputs. Additionally, we propose an alternative method for estimating a conditional probability density function to address computational constraints. We validate our approach through two benchmark problems: the dissociative adsorption problem and Langevin dynamics in an oscillating double-well potential.

DY 6.11 Mon 12:15 HÜL/S186

Learning spatiotemporal patterns from mean-field data — •Edmilson Roque dos Santos[1] and Tiago Pereira[2] — [1]MPI-PKS,Germany — [2]University of São Paulo, Brazil

Networks of coupled dynamical systems are fundamental models across the sciences, from physics to neuroscience. Despite their success, the governing equations of such systems are often unknown, limiting our ability to predict and control their dynamics. A major current effort is to learn these governing equations directly from data. However, existing approaches typically require access to the time series of all node states, which is rarely available outside controlled experiments. In most realistic scenarios, only aggregate or mean-field data, such as linear combinations of node states, can be measured. In this case, learning the governing equations from mean-field data inevitably becomes a secondary goal, since one must first learn the network trajectory that generated the observed measurements. This task is inherently challenging because distinct network states can yield identical macroscopic observations. Here, we address the problem of learning the network trajectory from random mean-field measurements. We show that accurate reconstruction becomes possible when the network exhibits structured spatiotemporal patterns, such as traveling waves. By representing these patterns sparsely in the Fourier domain, we leverage compressive sensing theory to formulate a convex optimization problem that robustly reconstructs the network trajectory. We illustrate our findings using a unidirectional ring of coupled Stuart-Landau oscillators.

DY 6.12 Mon 12:30 HÜL/S186

Discovering Mechanisms and Governing Laws with Sparse Regression — •Gianmarco Ducci, Maryke Kouyate, Juan Manuel Lombardi, Artem Samtsevych, Karsten Reuter, and Christoph Scheurer — FHI Berlin

Interpretable data-driven methods have proven viable for deriving complex vector fields directly from experimental data. Their inherent differential formulation, however, make them vulnerable to noise, which can compromise the sparsity of the inferred models. In order to promote sparsity, a weak formulation can be employed. Then, finding the optimal set of basis functions is a necessary prerequisite, yet a challenging task to determine in advance.

We present the release version of the Data-Driven Model Optimizer `ddmo`, a symbolic regression tool which provides fine-grained control over the admissible space of candidate terms. Its core contribution lies in the systematic optimization of the library of functions, implemented through two complementary engines: a standard SINDy-based differential formulation and a weak-form variant. Its modular structure further enables the optimization of test functions within the weak formulation. An overview of the software capabilities is provided, alongside with a case study illustrating the reconstruction of effective kinetics from experimental reactor data.

DY 6.13 Mon 12:45 HÜL/S186

POD-Subspace Reconstruction of Convective Reversal Dynamics from Limited Sensor Data — •Tim Kroll and Oliver Kamps — CDSC ,University of Münster

We introduce a data-driven modelling framework that leverages a hybrid LSTM-neural-network architecture to capture convection reversals from limited time-series measurements.. The method operates entirely in POD space, enabling efficient and accurate reconstruction of complex dynamical systems from limited observations by modelling non-orthogonal modes as a superposition of POD modes. The corresponding dynamics are modelled by an LSTM, incorporating knowledge about the history of the timeseries. We demonstrate its effectiveness on convection processes, showing that measurements from a single sensor - of either temperature T or velocity V - are sufficient to recover the full spatiotemporal dynamics, consisting of temperature, velocity or a combination of both, within the reduced representation. Furthermore this approach has potential to be applied in different scientific fields detached from convection or fluid dynamics.

DY 7: Focus Session: Large Deviations and Rare Events I

The modeling and understanding of large deviations and rare events is of crucial importance in a wide range of real-world applications, including climate science, actuarial statistics (insurance statistics), natural disaster management, or the description of financial markets. At the same time, such effects are fundamental for the understanding of many systems in condensed-matter physics. In first-order phase transitions, for instance, the coexisting phases are connected by transition states involving droplet excitations whose probability is suppressed by dozens or hundreds of orders of magnitude as compared to the pure-phase peaks. Likewise, for many disordered systems the behavior of typical cases is incompatible with that of the average sample as the problem is described by very broad, heavy-tailed distributions, where averages are dominated by rare events. For many models, like the Kadar-Parisi-Zhang equation or random-graph properties, there has been considerable analytical progress in the last decade. Likewise, new or improved numerical techniques have been proposed that now allow for the treatment of previously inaccessible problems or regimes. This focus session is devoted to an update on the state of the art in this rapidly evolving area.

Fast Rare Events in Exit Times Distributions of Jump Processes — •Raffaella Burioni — Department of Mathematics, Physics and Computer Sciences, University of Parma, Italy — INFN - Sezione di Milano Bicocca - Parma, Italy

Rare events in first-passage and exit-time statistics of jump processes can play a decisive role in triggering anomalous reactions and extreme responses in a wide range of systems. This is particularly relevant when jump lengths or waiting times follow broad, heavy-tailed distributions, for which rare events are not exponentially suppressed and can significantly affect macroscopic observables. Interestingly, in the presence of heavy-tailed distributions, large fluctuations follow the Big Jump Principle, a counterintuitive mechanism according to which rare events arise not from the accumulation of many small deviations, but from a single, dominant fluctuation.

We present a general framework for estimating the contribution of fast rare events to exit probabilities in jump processes with fat-tailed distributions. We apply this approach to discrete-time random walks, Lévy walks, and the Lévy-Lorentz gas, which are widely used to describe transport in biological systems and disordered media. We derive the scaling form of the probability distribution for fast exit events, in which the process leaves a finite interval over distances much larger than the typical scale and on timescales orders of magnitude shorter than the characteristic timescale of the dynamics. We discuss extensions to N independent walkers, where collective effects can further enhance the contribution of fast rare events to exit statistics.

DY 7.2 Mon 10:00 ZEU/0114

Rare Events, Many Searchers, and Fast Target Reaching in a Finite Domain — Elisabetta Ellettari[1], Giacomo Nasuti[1], •Alberto Bassanoni[1,2], Alessandro Vezzani[1,3], and Raffaella Burioni[1,2] — [1]University of Parma, Italy — [2]INFN, Parma associated group, Italy — [3]IMEM-CNR, Parma, Italy

Finding a target in a complex environment is a fundamental challenge in nature. An effective strategy to reduce the time needed to reach a target is to deploy many searchers, increasing the likelihood that at least one will succeed by using the statistics of rare events. When the underlying stochastic process involves broadly distributed step sizes, rare long jumps dominate the dynamics, making the use of multiple searchers particularly powerful. We investigate the statistics of extreme events for the mean first passage time in a system of N independent walkers moving with jumps distributed according to a power law, where target-reaching is governed by single, large fluctuations. We show that the mean first passage time of the fastest walker scales as $\langle \tau_N \rangle \sim 1/N$, representing a dramatic speed-up compared to classical Brownian search strategies. We derive a scaling law relating the number of walkers required to reach a target within a given time to the size X of the search region. As an application, we model biological fertilization, predicting how the optimal number of spermatozoa scales with uterus size across species. Our predictions match empirical data, and this theory applies broadly to any population of searchers operating within a region of size X, providing a universal framework for efficient search in disordered environments.

DY 7.3 Mon 10:15 ZEU/0114

Large deviations and uncertainty relations for self-interacting jump processes — •Francesco Coghi[1,2], Amarjit Budhiraja[3], and Juan P. Garrahan[1,2] — [1]School of Physics and Astronomy, University of Nottingham, Nottingham, NG7 2RD, UK — [2]Centre for the Mathematics and Theoretical Physics of Quantum Non-Equilibrium Systems, University of Nottingham, Nottingham, NG7 2RD, UK — [3]Department of Statistics and Operations Research, University of North Carolina, Chapel Hill, NC 27599, USA

Self-interacting jump processes are stochastic systems where transition rates depend on the process' own empirical occupation measure – that is, the time-averaged distribution of the states visited by the process – introducing a feedback that breaks Markovianity. In this talk, I will present a large deviation framework for such systems. Specifically, I will derive the level-2.5 rate functional describing the joint fluctuations of occupation and flux, obtained via an exponential tilting construction extended to the non-Markovian setting. From this, I will show how memory modifies fluctuation bounds, leading to kinetic and thermodynamic uncertainty relations that generalise those of standard Markov processes. I will conclude with two examples that illustrate how feedback reshapes fluctuation-dissipation trade-offs: a minimal two-state model and a collective exploration process inspired by ant dynamics.

DY 7.4 Mon 10:30 ZEU/0114

A pedestrian's approach to large deviations in semi-Markov processes with an application to entropy production — •Jonas H. Fritz, Alexander M. Maier, and Udo Seifert — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

Semi-Markov processes play an important role in the effective description of partially accessible systems. They occur, for instance, in coarse-graining procedures such as state lumping and when analyzing waiting times between few visible Markovian events. The finite-time measurement of any coarse-grained observable in a stochastic system depends on the specific realization of the underlying trajectory. Moreover, the fluctuations of such observables are encoded in their rate function that follows from the rate function of the empirical measure and the empirical flow in the respective process. Derivations of the rate function of empirical measure and empirical flow in semi-Markov processes with direction-time independence (DTI) exist in the mathematical literature, but have not received much attention in the stochastic thermodynamics community. We present an accessible derivation of the rate function of the tuple frequency in discrete-time Markov chains and extend this to the rate function of the empirical semi-Markov kernel in semi-Markov processes without DTI [1]. From this, we derive an upper bound on the rate function of the empirical entropy production rate, which leads to a lower bound on the variance of the mean entropy production rate measured along a finite-time trajectory. We illustrate these analytical bounds with simulated data. [1] Alexander M. Maier, Jonas H. Fritz and Udo Seifert, arXiv:2509.15077, 2025

DY 7.5 Mon 10:45 ZEU/0114

Concentration of observables in slow-fast dynamical systems with noise — •Xizhu Zhao[1,2] and Aljaž Godec[1,2] — [1]Mathematical Physics and Stochastic Dynamics, Institute of Physics, University of Freiburg, Freiburg, Germany — [2]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany

Stochastic differential equations involving separated timescales play an important role in modeling the dynamics of complex systems in physics, biology, and climate science. We explore the concentration of observables, i.e. functions or functionals of dynamical variables, in slow-fast dynamical systems with noise. Using stochastic analysis and singular perturbation theory, we determine the domains of concentration for observables in systems with a stable manifold or undergoing a bifurcation. We also derive bounds for the distribution of the first-exit time from these domains. The results show that the concentration of observables exhibits behavior distinct from that of microscopic sample paths.

Large deviations in resetting Brownian motions — •Satya Majumdar — CNRS, LPTMS, Universite Paris-Saclay, Orsay 91405, France

After a brief introduction to large deviations, I will focus on one dimensional resetting Brownian motions, first on a single particle and then on a gas of multiparticles. I will show that for a single partcle, while the position distribution of a resetting Brownian motion approaches a stationary form at long times, the

relaxation to this stationary state is unusual: it is described by a large deviation function that undergoes a second order dynamical phase transition. The same rate function also shows up in the distribution of the maximum up to time t of a set of independent resetting Brownian motions with a distributed initial positions. I will discuss the difference between the 'quenched' and 'annealed' initial positions and how they affect the statistics of the maximum.

DY 7.7 Mon 11:45 ZEU/0114

Large deviations and condensation in the cost of stochastic resetting — •John C. Sunil[1], Martin R. Evans[1], Richard A. Blythe[1], and Satya N. Majumdar[2] — [1]SUPA, School of Physics and Astronomy, University of Edinburgh, Peter Guthrie Tait Road, Edinburgh EH9 3FD, United Kingdom — [2]Université Paris-Saclay, CNRS, LPTMS, 91405 Orsay, France

Searching for misplaced objects is a task that we are all familiar with. In particular, the way we search for a misplaced object, such as keys, is by repeatedly resetting to the object*s last known location. It has been shown that such resetting expedites the mean time to complete the search process. However, in practice, resets must also incur costs, whether in time, energy, or money. This motivates examining the probabilities of rare cost fluctuations that deviate significantly from typical behaviour. In this talk, I will demonstrate the effect of costly resets and the large deviations exhibited by the tails of the total cost distribution using an exactly solvable model of diffusion with stochastic resetting. Further, I will discuss the eventual breakdown of the large deviation principle for certain classes of cost, resulting in a phase transition known as condensation.

Perturbative framework for finding the transition rates for active particles — •Vito Seinen[1], Peter Bolhuis[1], Daan Crommelin[2], Michel Mandjes[3], and Sara Jabbari-Farouji[1] — [1]University of Amsterdam — [2]Centrum Wiskunde & Informatica — [3]University Leiden

Activated escape or transition rates between metastable states have been a growing topic of research due to their relevance in many physical processes and their roles in certain non-equilibrium phase transitions. In the context of motility-induced phase separation (MIPS), such active transition rates are known to govern the nucleation processes that initiate phase separation. To gain insight into these phenomena, we develop a projection-operator formalism for a generic model of an active particle in a multi-well potential. We compute the transition rates perturbatively in two asymptotic regimes: one in which the dynamics of the activity (the driving process) is much faster than that of the particle (the driven process), and one in which the activity dynamics is much slower. From these asymptotic expansions, we construct an approximation that interpolates across the intermediate regime, thereby capturing all parameter ranges relevant in the rare-event limit. Our results provide deeper understanding of the complex dependence of active transition rates on the magnitude of the activity, the thermal noise strength, and the dynamical timescale of the active (driving) process*its persistence time

DY 7.9 Mon 12:15 ZEU/0114

Large deviation properties of Brownian particles in switching harmonic traps — •Chinmay Pradeep Chandratre and Alexander K. Hartmann — Institut of Physics, University of Oldenburg, Oldenburg (Germany)

For N independent particles in a harmonic trap with stiffness switching between μ_1 and μ_2, a complete characterization of the non-equilibrium steady state including the computation of joint distribution of particle positions has been performed under the stochastic-resetting protocol [1]. In the large-N limits, this allows for the computation of observables such as the distribution of the position M_k of the k-th rightmost particle (Extreme value statistics), spacing distributions $D_k = M_k - M_{k+1}$ and the particle count $N_L = \left|\{\, i : |x_i| \le L \,\}\right|$ for an interval $[-L, L]$. However, the finite-N regime with significant large-deviation corrections is analytically unknown. The numerical limitations in resolving the support of the distribution, especially in the tails, are circumvented through specialized large-deviation algorithms [2] by deploying modified Markov Chain Monte Carlo methods. The distributions $P(M_k)$, $P(D_k)$ and $P(N_L)$ and corresponding rate functions were obtained numerically from simulations performed for several system sizes. Conditional distribution rendered further insight into the correlations between M_k, D_k, and N_L.

Optimal escape processes of run-and-tumble particles — Karthik Cheruvary[2], •Rafael Diaz Hernandez Rojas[1], and Peter Sollich[1] — [1]University of Göttingen — [2]IISER Pune

Run-and-tumble (RT) motion is a fundamental mode of self-propulsion observed across diverse biological systems from bacterial chemotaxis to immune cell migration. Modelling this non-equilibrium system is challenging due to the non-Gaussian noise governing the self-propulsion direction, θ. To address this, we investigate the trajectories of a particle confined by a potential in $d = 2$ and subject to both thermal fluctuations and RT motion. We incorporate tumbling by modelling changes in θ as Poisson shot noise process with rate λ and generic distribution of angle changes, Δ. Employing a path-integral formalism in the weak noise limit, we derive exact equations of motion for all degrees of freedom, valid for arbitrary λ and distributions of Δ. This allows us to map the problem of finding the most likely escape trajectory to the minimisation of an appropriate action. Our analysis reveals that the effects of the non-Gaussian noise are more prominent in the limit of small λ, which corresponds to highly persistent RT motion. There, we show analytically that, regardless of the distribution of Δ, RT escape paths are exponentially more probable –exhibiting a lower action– than their active Brownian particle equivalent. The optimal RT trajectories are non-trivial and can exhibit discontinuities or very rapid changes in θ, implying that RT particles will exploit their tumbling ability to optimize escape from potential wells. We verify our theoretical predictions through extensive numerical simulations.

Phase locking and multistability in the topological Kuramoto model on cell complexes — •Iva Bačić[1,2], Michael T. Schaub[3], Jürgen Kurths[4], and Dirk Witthaut[1,5] — [1]Institute of Climate and Energy Systems: Energy Systems Engineering (ICE-1), Forschungszentrum Jülich, 52428 Jülich, Germany — [2]Institute of Physics Belgrade, University of Belgrade, Serbia — [3]RWTH Aachen University, Aachen, Germany — [4]Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany — [5]Institute for Theoretical Physics, University of Cologne, 50937 Köln, Germany

Higher-order group interactions fundamentally shape the dynamics and stability of oscillator networks. The topological Kuramoto model captures these effects by extending classical synchronization models to include interactions between cells of arbitrary dimension within simplicial and cell complexes. We present the topological nonlinear Kirchhoff conditions algorithm, a nonlinear generalization of Kirchhoff's circuit laws, that systematically identifies all phase-locked states in the topological Kuramoto model and reveals how higher-order topology governs multistability. Applying this framework to rings, Platonic solids, and simplexes, we uncover structural cascades of multistability inherited across dimensions, and demonstrate that cell complexes can exhibit richer multistability patterns than simplicial complexes of equal dimension. We find evidence hinting at universal multistability classes. Our results reveal how higher-order interactions affect synchronization and open new directions for understanding collective dynamics in systems with non-pairwise interactions.

Transition to turbulence in wind turbine wakes: synchronisation and nonlinear dynamics — •Thomas Messmer, Michael Hölling, and Joachim Peinke — Carl von Ossietzky Universität Oldenburg, School of Mathematics and Science, Institute of Physics, Oldenburg, Germany

The wake of a wind turbine is a typical shear flow that transitions from near- to far-wake, ultimately reaching fully developed turbulence. In this study, we investigate experimentally in a wind tunnel the wake dynamics of a periodically excited model wind turbine*a scenario motivated by applications such as floating wind turbines and periodic control strategies. Our findings reveal distinct excitation regimes with unique wake behaviours.

In one regime, the wake synchronises with the excitation period, forming an organised flow structure that accelerates the transition to turbulence. In another regime, nonlinear quasi-periodic dynamics emerge, characterised by the formation of multiple coherent structures that interact nonlinearly and also accelerate the transition to the far wake.

At the conference, we will discuss the mechanisms underlying synchronisation and quasi-periodic dynamics, as well as their implications for the fundamental problem of the transition to turbulence.

Invited Talk DY 8.5 Mon 10:30 ZEU/0118

Mean-field approach to finite-size fluctuations in coupled oscillator systems — •Oleh Omelchenko[1] and Georg Gottwald[2] — [1]University of Potsdam, Germany — [2]University of Sydney, Australia

Networks of coupled phase oscillators are one of the most studied dynamical systems with numerous applications in physics, chemistry, biology, and engineering. A variety of methods exists to explain their properties and dynamics in the thermodynamic limit, when the network size tends to infinity. However, the behavior of such systems in the more realistic case of a finite number of oscillators still remains poorly understood. In this talk, we revisit the paradigmatic Kuramoto-Sakaguchi model describing synchronization transitions in networks of all-to-all coupled heterogeneous phase oscillators, and propose an ab initio approach for characterizing analytically the statistical properties of finite-size fluctuations in this system. Our framework is applicable to any stationary partially synchronized state and does not require any prior knowledge about its structure. Moreover, it is sufficiently general such that it can be applied to a broader class of interacting particle systems.

Energy Transfer in a Coupled Duffing System — •Martyna Sedlmayr and Andrzej Rysak — Faculty of Mechanical Engineering, Lublin University of Technology, 36 Nadbystrzycka St., 20-618 Lublin, Poland

The Duffing system is a non-linear prototypical chaotic system, of interest in studies of damping and energy harvesting. In this work we analyse modifications to the energy transfer in the system when it is magnetically coupled to a harmonic oscillator. The form of the magnetic interaction is obtained from a fit to experimental data. Numerical analyses then determine the power either dissipated by, or supplied to, the Duffing system by its individual components. In all simulations, the Duffing potential itself is not changed. Our analysis focuses on assessing the impact of the coupled oscillator on the energy efficiency of the system. We demonstrate the effects of changing the value of the mass, the damping and the elasticity of the perturbing system. We focus on searching for configurations of the perturbation for which an increase in efficiency occurs, which can be caused by either modifying the dynamics or by providing additional energy.

DY 8.7 Mon 11:30 ZEU/0118

Transient Signatures of Flow-Topological Transitions in Nonlinear Quantum Oscillators — •Alejandro S. Gómez and Javier del Pino — Department of Theoretical Condensed Matter Physics, (IFIMAC), Universidad Autónoma de Madrid

Non-equilibrium phases in driven-dissipative systems are ubiquitous. Often, they appear as classical fixed point attractors and limit cycles, with standard phase transitions triggered by local instabilities. Yet the flow-topology framework [1] shows that transitions can also arise from nonlocal reorganizations, leaving attractors unchanged and emerging only in transients. Stationary quantum states still reflect these structures as probability hotspots, and local changes can induce Liouvillian spectral degeneracies. However, how the nonlocal, transient reorganizations manifest in the Liouvillian remains open.

In this talk, I will introduce a topological framework that extends the classification of fixed points [1] to capture the full phase-space connectivity considering also limit cycles. By linking open quantum dynamics to the classification of Morse-Smale flows [2], Crucially, we demonstrate that our graph invariant exposes transitions the Liouvillian spectrum misses altogether, related to global flow-topology transitions. I illustrate this framework by mapping the dissipative phases of a two-photon-driven Kerr resonator with added gain.

The disordered logistic map — Joseph W. Baron[1] and •Tobias Galla[2] — [1]Department of Mathematical Sciences, University of Bath, Bath, BA2 7AY, UK — [2]Instituto de Fisica Interdisciplinar y Sistemas Complejos IFISC (CSIC-UIB), 07122 Palma de Mallorca, Spain

The logistic map is a central model of low dimensional chaos. In disordered systems with many degrees of freedom on the other hand, one finds high-dimensional chaos, induced by heterogeneous interactions.

Here, we study a system of many logistic maps with quenched random interactions. Using dynamic mean-field theory, random matrix theory and simulations we show that minimal disorder removes the period-doubling cascade in the conventional logistic map. The cascade is replaced by a sudden onset of chaos. We find a separate and qualitatively different transition to chaos with more smoothly evolving trajectories. The power spectra of fluctuations exhibit different power-law behaviour near the two transitions. In a disordered Henon map we find very similar behaviour.

Our results show that even minimal disorder can severely disrupt the behaviour of well-known dynamical systems. The work also shows that discrete-time disordered systems can exhibit rather different behaviour from their continuous-time cousins [1]. Disordered maps highlight that different chaotic behaviours can be observed in one single system, and that each of these behaviours leaves a fingerprint before chaos sets in.

Transient nature of recurrence based local dimension estimates from finite time series — •Reik V. Donner — Magdeburg-Stendal University of Applied Sciences, Magdeburg, Germany — Potsdam Institute for Climate Impact Research, Potsdam, Germany

Local fractal dimensions are a widely used concept in dynamical system theory. However, comparing their empirical spatial patterns across published works reveals surprising inconsistency with theoretical expectations. This points to the fact that corresponding estimates obtained from finite time series are notoriously spurious. As an example, a very long trajectory of the Lorenz-63 system in its chaotic regime is subsampled in two different ways: generating ensembles of individual state vectors drawn independently at random from the complete record versus ensembles of contiguous time series segments. In the latter situation, which is commonly present in time series analysis, one obtains a broad distribution and non-random spatial pattern of local dimension estimates, while consideration of independent samples provides much more narrowly distributed and spatially unstructured estimates. While finite-time estimates may still be useful for identifying transient structures caused by the proximity to unstable periodic orbits or similar dynamically invariant objects, their practical interpretation for real-world time series should be carefully reconciled.

DY 8.10 Mon 12:15 ZEU/0118

Two-dimensional turbulent condensates without bottom drag — •Adrian van Kan[1], Alexandros Alexakis[2], and Edgar Knobloch[3] — [1]Department of Mathematics, Texas A&M University, College Station, USA — [2]Laboratoire de Physique de l'Ecole Normale Supérieure, ENS, Université PSL, CNRS, Paris, France — [3]Department of Physics, UC Berkeley, Berkeley, California, USA

The extent to which statistical equilibrium theory applies to driven dissipative dynamics remains an important open question in many systems. We use extensive direct numerical simulations of the incompressible two-dimensional (2D) Navier-Stokes equation to examine the steady state of large-scale condensates in 2D turbulence at finite Reynolds number Re in the absence of bottom drag. Large-scale condensates appear above a critical Reynolds number $Re_c \approx 4.19$. For $Re \gtrsim Re_c$, we find a power-law scaling of the energy with $Re - Re_c$, with the energy spectrum at large scales following the absolute equilibrium form pro-

posed by Kraichnan. At larger Re, the energy spectrum deviates from this form, displaying a steep power-law range at low wave numbers with exponent −5, with most of the energy dissipation occurring within the condensate at large scales. We show that this spectral exponent is consistent with the logarithmic radial vorticity profile of the viscously saturated condensate predicted by quasilinear theory. Our findings shed new light on the classical problem of large-scale turbulent condensation in forced dissipative 2D flows in finite domains, showing that the large scales are close to equilibrium dynamics in weakly turbulent flows but not for strong condensates ($Re \gg 1$).

DY 9.1 Mon 9:30 ZEU/0160

Dissipation enables robust extensive scaling of multipartite correlations — •Krzysztof Ptaszyński[1,2], Maciej Chudak[1], and Massimiliano Esposito[2] — [1]Institute of Molecular Physics, Polish Academy of Sciences, Mariana Smoluchowskiego 17, 60-179 Poznań, Poland — [2]Complex Systems and Statistical Mechanics, Department of Physics and Materials Science, University of Luxembourg, 30 Avenue des Hauts-Fourneaux, L-4362 Esch-sur-Alzette, Luxembourg

We investigate the multipartite mutual information between N discrete-state stochastic units interacting in a network that is invariant under unit permutations [1]. We show that when the system relaxes to fixed point attractors, multipartite correlations in the stationary state either do not scale extensively with N, or the extensive scaling is not robust to arbitrarily small perturbations of the system dynamics. In particular, robust extensive scaling cannot occur in thermodynamic equilibrium. In contrast, mutual information scales extensively when the system relaxes to time-dependent attractors (e.g., limit cycles), which can occur only far from equilibrium. This demonstrates the essential role of dissipation in the generation and maintenance of multipartite correlations. We illustrate our theory with the nonequilibrium Potts model. Finally, we present a generalization of our approach to permutation-invariant open quantum systems [2].

Nested Stochastic Resetting: Nonequilibrium Steady States and Exact Correlations — •Callum Britton[1], Henry Alston[2], and Thibault Bertrand[1] — [1]Imperial College London, London, United Kingdom — [2]Laboratoire de Physique de l'Ecole Normale Supérieure, Paris, France

Stochastic resetting has gained a lot of traction over the past few years. It has been shown to drive the formation of nonequilibrium steady states and the optimization of first-passage properties in an analytically tractable setting. Yet, most works have thus far focused on single-particle stochastic resetting. In this talk, we introduce nested stochastic resetting, an exactly solvable, many-body stochastic resetting model achieved by harnessing resets as unilateral interactions between particles. We look at a system of n particles, where the position of particle i is independently reset to the instantaneous position of particle $i-1$ according to a Poisson process. We derive analytically the steady-state statistics of these nested stochastic resetting processes including the stationary distribution for each process as well as its moments. In this system, we go one step further and calculate exactly the steady-state two-point correlations $\langle x_i x_j \rangle$ between processes by mapping the problem to one of the ordering statistics of random counting processes. We expect this framework will both help build a model-independent framework for random processes with unilateral interactions and find immediate applications, e.g., in the modelling of lossy information propagation.

DY 9.3 Mon 10:00 ZEU/0160

Mutual linearity: A generic property of steady-state Markov networks — •Robin Bebon and Thomas Speck — Institute for Theoretical Physics 4, University of Stuttgart, Heisenbergstraße 3, 70569 Stuttgart, Germany

Nonequilibrium response theory has long sought universal principles to characterize the behavior of observables under external perturbations. While powerful tools exist near thermal equilibrium, general results far from equilibrium remain sparse and often rely on specific assumptions that severely limit their applicability, e.g., a specific parametrization of transition rates. In this work, we prove a remarkably simple, yet broadly applicable result: In a Markov network, any two steady-state probabilities remain linearly related when perturbing transition rates along a single edge of the network. This mutual linearity holds for every irreducible Markov network, arbitrarily far from equilibrium, and is independent of the chosen rate parametrization. As key implications, we demonstrate that the relative response of all states in the network is identical and show that analogous linear relations follow for a broad class of observables, including generic state-dependent and counting observables. Crucially, the coefficients that enter these linear relationships are empirically accessible, which makes our results not only conceptually significant but also provide a novel practical tool for inference and model validation in biological and chemical systems.

Stochastic Path Integrals for Non-Markovian Dynamics: Fractional Operators, and Entropy Production — •Felipe Abril-Bermudez — Independent Researcher (formerly University of Aberdeen, UK)

Stochastic dynamics with long-range correlations, multiplicative noise, and memory effects give rise to rich non-equilibrium behaviors, including anomalous diffusion, metastability, and nontrivial entropy production. In this work, we develop a unified stochastic path integral (SPI) framework that extends the Parisi-Sourlas supersymmetric formalism to treat multidimensional Langevin systems with multiplicative noise, thresholds, and fractional operators driven by fractional Gaussian noise. The resulting generalized Fokker-Planck equation is solved for representative processes, enabling analytical estimation of Shannon entropy and entropy production rates, which exhibit the emergence of quasi-steady states with non-monotonic dissipation. In parallel, the formalism recovers the standard underdamped Langevin and Klein-Kramers results while providing a systematic treatment of non-Markovian dynamics responsible for anomalous transport, weak ergodicity breaking, and dynamical phases such as time glasses and time crystals. Thus, it is shown how the SPI can serve as a unified approach to study anomalous stochastic phenomena in complex systems.

DY 9.5 Mon 10:30 ZEU/0160

Thermophoresis of a tracer particle via coarse graining of an explicit nonequilibrium medium — •Wade Hodson and Aljaz Godec — Mathematical Physics and Stochastic Dynamics, Institute of Physics, University of Freiburg

We investigate the transport of a tracer particle embedded in an explicitly represented medium with a position-dependent temperature. The medium consists of a chain of harmonic oscillators, in which a temperature gradient is established by connecting each particle to its own heat reservoir. We then couple a tracer to this medium via a generic potential. Under these conditions, we find that the tracer preferentially diffuses in one direction due to the temperature gradient, a phenomenon known as thermophoresis. We study the model analytically in various regimes, including the weak coupling, low temperature, overdamped, Markovian, and hydrodynamic limits, and supplement these results with numerical computations. In the Markovian limit, we are able to coarse-grain over the medium's degrees of freedom to obtain a Langevin equation for the tracer, with a potential of mean force, a damping coefficient, and a diffusion coefficient which can be evaluated in the low-temperature regime. We focus on the analysis of this low-temperature Langevin equation, with a particular interest in the parameter regimes where the tracer can potentially exhibit negative thermophoresis, in which the tracer diffuses preferentially towards higher temperatures. Finally, we generalize our results to higher dimensions, by coupling the tracer to a two- or three-dimensional medium.

DY 9.6 Mon 10:45 ZEU/0160

Volterra Series leads to exact Dynamical Density Functional Theory — •Ion Santra — KU LEUVEN

We derive an exact Volterra series expansion for a mean mesoscopic field of an interacting particle system subject to a potential perturbation, expressing the Volterra expansion kernels in terms of the field's response functions, to any order. Applying this formalism to the mean particle density of a simple interacting fluid, we identify a form reminiscent of dynamical density functional theory, with, however, fundamental differences: A generally nonlocal mobility kernel appears, and the internal force derives from a functional of the *history* of mean density. In the limit of a slowly varying external force, the expansion kernels of this functional turn into the equilibrium direct correlation functions of the corresponding order, thereby, in this limit, recovering the equilibrium density functional. We identify a freedom in deriving this expansion, which, e.g., allows different forms of mobility kernels, and we explore two choices: A nonlocal mobility kernel results in a concise ans simple form to linear order. For interacting Brownian particles, a local mobility kernel results in a form reminiscent of previous forms for the density current.

Thermal Relaxation on Random Graphs via Metropolis and Glauber Dynamics — •Marija Vucelja — University of Virginia, Charlottesville, US — MPI-PKS, Dresden, Germany

Efficient sampling algorithms rely on dynamics that drive a physical system rapidly toward its target state. I will introduce the Mpemba effect – an anomalous thermal relaxation phenomenon in which a system initially at a higher temperature cools down more quickly than one starting at a lower temperature – and its heating analog, in which a cooler initial state can lead to faster heating than a hotter initial state. We investigate thermal relaxation in quenched disordered systems under Metropolis and Glauber dynamics, examining how varying transition rates affect relaxation behavior. We show that Metropolis dynamics on a complete graph cannot exhibit the Mpemba effect, whereas on an incomplete graph it can. Even rank-one perturbations of the transition rates are sufficient to generate anomalous relaxation. Finally, we discuss the probability of observing the Mpemba effect in the large-temperature limit.

DY 9.8 Mon 11:30 ZEU/0160

Fermionic quantum criticality far from equilibrium — •Rohan Mittal, Tom Zander, Johannes Lang, and Sebastian Diehl — Universität Zu Köln

Driving a quantum system out of equilibrium while preserving its subtle quantum mechanical correlations on large scales presents a major challenge, both fundamentally and for technological applications. At its core, this challenge is pinpointed by the question of how quantum effects can persist at asymptotic scales, analogous to quantum critical points in equilibrium. In this work, we construct such a scenario using fermions as building blocks. These fermions undergo an absorbing-to-absorbing state transition between two topologically distinct and quantum-correlated dark states. Starting from a microscopic, interacting Lindbladian, we derive an effective Lindblad-Keldysh field theory in which critical fermions couple to a bosonic bath with hydrodynamic fluctuations associated with particle number conservation. A key feature of this field theory is an emergent symmetry that protects the purity of the fermions' state even in the presence of the thermal bath. We quantitatively characterize the critical point using a leading-order expansion around the upper critical dimension, thereby establishing the first non-equilibrium universality class of fermions. The symmetry protection mechanism, which exhibits parallels to the problem of directed percolation, suggests a pathway toward a broader class of robust, universal quantum phenomena in fermionic systems.

ultrafast thermodynamics of the ferroelectric soft mode in laser-excited SrTiO3 — •Yulong Qiao and R. Matthias Geilhufe — Department of Physics, Chalmers University of Technology, Gothenburg, Sweden

Intense THz laser pulses allow to selectively pump and control optical phonon modes. This has led to the realization of metastable phases of matter, phonon-induced magnetism, and ultrafast magnetic switching. Following such a non-thermal path-way in the sub-picosecond timescale, has recently sparked questions on the temporal evolution of thermodynamic quantities, such as heat and entropy production, in the context of ultrafast thermodynamics [1].

In this work, we simulate the dynamics of the ferroelectric soft mode in SrTiO3 driven by a THz laser pulse using molecular dynamics [2]. We show that both the soft-mode dynamics and the associated energy transfer from the soft mode to other ionic degrees of freedom are accurately described by our stochastic thermodynamic theory. Moreover, the molecular dynamics simulations clearly reveal that the power spectral density of the noise is frequency-dependent. This indicates that the commonly adopted Markovian approximation breaks down. In this talk, I will also discuss the non-Markovian effects induced by the ultrafast laser pulse.

Ultrafast Thermodynamics - entropy, heat and criticality on picosecond timescales — •R. Matthias Geilhufe — Chalmers University of Technology, Gothenburg, Sweden

Materials are composed of a vast number of ions and electrons, arranging themselves in regular patterns. Due to immense progress in ultrafast spectroscopy, ranging from the low-frequency infrared to high-frequency X-ray regimes, collective excitations of charge, spin, lattice, and orbital degrees of freedom can now be triggered and probed on their characteristic time and length scales. Probing such excitations far from equilibrium motivates the field of ultrafast thermodynamics, which translates well-understood concepts, such as entropy and heat, to picosecond dynamics. I will introduce the concept of ultrafast thermodynamics using the example of entropy production due to laser-driven phonons [1] and magnons [2] using stochastic thermodynamics. Furthermore, I will show extensions of the formalism to non-Markovian behavior and quantum mechanics.

DY 12: Focus Session: Relaxation Timescales in Open Quantum Systems (joint session TT/DY)

In the quantum year 2025 many applications of quantum systems are revisited for their actual physical implementability. Realizing that no quantum system is truly isolated from its environment highlights the need for a thorough understanding of the coupling between an open system and its environment. While many standard treatments lead to Lindblad equations, the underlying approximations are not always applicable and require detailed case-by-case studies. This theoretical focus session provides a platform discussing modern developments in the field in the regime of strongly interacting or driven open systems and their impact on relaxation timescales. We aim to enhance attention and trigger also experimental activity in the field of system-environment interactions and the induced relaxation timescales.

Localized obstructed pairs with zero superfluid stiffness from doping an antiferromagnetic insulator — •Tamaghna Hazra[1], Nishchhal Verma[2], and Jörg Schmalian[1] — [1]Institüt für Theorie der Kondensierten Materie, Karlsruher Institut für Technologie, Karlsruhe, Germany — [2]Department of Physics, Columbia University

Doping a Mott antiferromagnet is widely expected to yield mobile Cooper pairs whose kinetic energy sets the superfluid stiffness. We show instead that, when doped charges propagate on the line graph of a lattice with strong antiferromagnetic exchange, they bind into *obstructed* Cooper pairs, which are compact localized bosons that possess *zero* superfluid stiffness at leading order in the strong-coupling expansion. The pair-hopping Hamiltonian generates an exactly flat bosonic band whose compact localized states dominate the low-energy Hilbert space, yielding a ground-state manifold with extensive degeneracy and a phase stiffness that vanishes anomalously as the *third* inverse power of the pairing strength in the strong-coupling limit. At quarter filling, the frustrated dynamics maps onto a quantum dimer model at the Rokhsar-Kivelson point, realizing a d-wave resonating-valence-bond spin liquid with topological ground-state degeneracy and deconfined holon excitations. Our results establish a mechanism for interaction-driven localization without disorder, in which strong magnetically-mediated pairing produces Cooper pairs whose kinetic energy collapses to zero, revealing a distinct failure mode of unconventional superconductivity in strongly-correlated materials.

DY 13.2 Mon 15:15 CHE/0091

Disorder-free localization from mass-imbalanced fractionalization — •Shi Feng, Johannes Knolle, and Michael Knap — Technical University of Munich, Garching, Germany

We report disorder-free localization of Majorana fermions over intermediate timescales in an emergent gapless non-integrable Z_2 quantum liquid. A large density of heavy visons induced by an external magnetic field provides coherent disorder that localizes the light fermions while preserving translation symmetry. Compelling evidence of the localization within intermediate time scale is provided by the time evolution of the local energy density, which shows negligible spreading after a local quench on its ground state; and a vanishing energy current response despite the gapless energy spectrum. These results demonstrate that the disorder-free localization can also occur near equilibrium at low energy, and offer an explanation to the thermal paradox in recent experiments where a linear specific heat coexists with vanishing thermal transport in frustrated Mott insulators with disorder-free gapless quantum magnets.

DY 13.3 Mon 15:30 CHE/0091

Fock space fragmentation in quenches of disordered interacting fermions — •Ishita Modak[1], Rajesh Narayanan[2], Ferdinand Evers[3], and Soumya Bera[1] — [1]Department of Physics, Indian Institute of Technology Bombay, Mumbai, India. — [2]Department of Physics, Indian Institute of Technology Madras, Chennai, India — [3]Institute of Theoretical Physics and Halle-Berlin-Regensburg Cluster of Excellence CCE, University of Regensburg, Regensburg, Germany

Hilbert space fragmentation primarily originates from specific kinematic constraints or emergent conservation laws in many-body systems with translation invariance. It leads to non-ergodic dynamics and breakdown of the eigenstate thermalization hypothesis. We demonstrate that also in disordered systems (e.g. random-field XXZ model), fragmentation appears as a natural concept offering fresh perspectives on many-body delocalization (MBdL). We split the Fock-space into potential-energy shells, which contain the accessible phase space for the relaxation of a quenched initial state. In this construction, dynamical observables reflect properties of the shell geometry, e.g., the drastic sample-to-sample fluctuations observed in the weak disorder regime, $W < W_c$, represent fluctuations of the shell-mass. Upon crossing over to strong disorder, $W > W_c$, the potential-energy shell decays into fragments; we argue that, unlike percolation, fragmentation is a strong-coupling scenario with turn-around flow: $W_c(L)$ diverges with increasing system size. We conjecture that the slowing down of the relaxation dynamics reported in traditional MBdL studies is a manifestation of Fock-space fragmentation introduced here.

DY 13.4 Mon 15:45 CHE/0091

Non-ergodic one-magnon magnetization dynamics of the Kagome lattice antiferromagnet — Henrik Schlüter, •Jannis Eckseler, and Jürgen Schnack — Bielefeld University

The present view of modern physics on non-equilibrium dynamics is that generic systems equilibrate or thermalize under rather general conditions, even closed systems under unitary time evolution. The investigation of exceptions thus not only appears attractive, in view of quantum computing where thermalization is a threat it also seems to be necessary. Here, we present aspects of the one-magnon dynamics on the Kagome lattice antiferromagnet as an example of a non-equilibrating dynamics due to flat bands. Similar to the one-dimensional delta chain localized eigenstates also called localized magnons lead to disorder-free localization and prevent the system from thermalization [1].

Cooling dynamics of a disorder-free localized Kitaev model — •Arkadeep Mitra, Francesco Piazza, and Markus Heyl — Theoretical Physics III, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, 86135 Augsburg, Germany

The Kitaev spin-1/2 model on a 2D honeycomb lattice has a Z_2 gauge symmetry that translates to an effective picture of free Majorana fermions on a background static charge field. This yields a ground state that realizes a quantum spin liquid (QSL) with fractional excitations. At high temperatures, however, it has recently been observed to enter a disorder-free localized phase, so that any experimental cooling of a Kitaev material has to cross this localized and associated phase transition. Motivated from this, we study theoretically the cooling dynamics upon coupling the Kitaev model to phonons with a symmetry breaking interaction. We envisage that signatures obtained from this dynamics could act as probes for QSL.

Scrambling signature of scars — •Thomas Michel[1], Mathias Steinhuber[2], Juan Diego Urbina[2], and Peter Schlagheck[1] — [1]Université de Liège, Liège, Belgique — [2]Universität Regensburg, Regensburg, Germany

We study signatures of scrambling, such as out-of-time-ordered correlators, that are associated with weakly unstable periodic orbits in a mixed or chaotic classical phase space, fulfilling Heller's criterion [1] for the existence of scars. As verified within generic dynamical systems like the kicked rotor and the driven pendulum, evaluating scrambling observables for coherent states centred in phase space about such periodic orbits gives rise to characteristic scar features both in the short and long time regimes, the latter amounting to a significant amendment of the characteristic growth exponent with respect to the generic semiclassical prediction [2,3]. Extensions to many-body scars in Bose-Hubbard rings [4] are discussed.

DY 13.7 Mon 16:45 CHE/0091

Many-Body Cages - Flat bands on the state graph — •Tom Ben-Ami[1,2], Markus Heyl[1], and Roderich Moessner[2] — [1]University of Augsburg, D-86135 Augsburg, Germany — [2]Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Straße 38, Dresden 01187, Germany

We identify the many-body counterpart of flat bands, which we term many-body caging, as a general mechanism for non-equilibrium phenomena such as a novel type of glassy eigenspectrum order and many-body Rabi oscillations in the time domain. We focus on constrained systems of great current interest in the context of Rydberg atoms and synthetic or emergent gauge theories. We find that their state graphs host motifs which produce flat bands in the many-body spectrum at a particular set of universal energies. Basis states in Fock space exhibit Edwards-Anderson type order in the absence of quenched disorder, with an intricate, possibly fractal, distribution over Fock space. This is reflected in a distinctive structure of a non-vanishing post-quench long-time Loschmidt echo, an experimentally accessible quantity. In general, phenomena familiar from single-particle flat bands manifest themselves in characteristic many-body incarnations, such as a reentrant 'Anderson' delocalisation, offering a rich ensemble of experimental signatures in the abovementioned quantum simulators. The variety of single-particle flat band types suggests an analogous typology–and concomitant phenomenological richness to be explored–of their many-body counterparts.

DY 13.8 Mon 17:00 CHE/0091

Dynamics in the presence of local symmetry-breaking impurities — •Yahui Li[1,2], Pablo Sala[3,4], Frank Pollmann[1,2], Sanjay Moudgalya[1,2], and Olexei Motrunich[3,4] — [1]Technical University of Munich, Germany — [2]Munich Center for Quantum Science and Technology, Germany — [3]California Institute of Technology, USA — [4]Walter Burke Institute for Theoretical Physics, USA

Continuous symmetries lead to universal slow relaxation of correlation functions in quantum many-body systems. In this talk, I will show how local symmetry-breaking impurities affect the dynamics of these correlation functions using Brownian quantum circuits. While explicitly breaking the symmetry is generally expected to lead to eventual restoration of full ergodicity, we find that approximately conserved quantities that survive under such circumstances can still induce slow relaxation. This can be understood using a super-Hamiltonian formulation, where low-lying excitations determine the late-time dynamics. We show that in one dimension, symmetry-breaking impurities modify diffusive and subdiffusive behaviors associated with U(1) and dipole conservation at late times, e.g., by increasing power-law decay exponents of the decay of autocorrelation functions. On the other hand, for an impurity that disrupts strong Hilbert space fragmentation, it leads to prethermal plateaus in autocorrelation functions. Overall, our approach systematically characterizes how symmetry-breaking impurities affect relaxation dynamics in symmetric systems.

Machine-learned classical density functional theory in higher dimensions with convolutional layers — Felix Glitsch, Jens Weimar, and •Martin Oettel — Institut für Angewandte Physik, Universität Tübingen

Through minimization of a grand free energy functional in classical density functional theory (cDFT), inhomogeneous systems in equilibrium can be efficiently computed. For that, the functional of the excess (over ideal gas) free energy is required which is known explicitly only in a few cases. Recent advancements use machine learning for constructing this functional from simulation data, mostly for systems with one-dimensional, planar inhomogeneities. We propose a machine learning model for application in two dimensions [1] akin to density functionals in weighted density forms, as, e.g., in fundamental measure theory. We implement the model with fast convolutional layers only and apply it to a system of hard disks in fully 2D inhomogeneous situations. The model is trained on a combination of smooth and steplike external potentials in the fluid phase. Pair correlation functions from test particle geometry show very satisfactory agreement with simulations although these types of external potentials have not been included in the training. The method should be fully applicable to 3D problems.

DY 14.2 Mon 15:15 HÜL/S186

Scalable Boltzmann Generators for equilibrium sampling of large-scale materials — •Maximilian Schebek[1], Frank Noé[1,2,3,4], and Jutta Rogal[1,5] — [1]Fachbereich Physik, Freie Universität Berlin, 14195 Berlin — [2]Fachbereich Mathematik und Informatik, Freie Universität Berlin, 14195 Berlin — [3]Microsoft Research AI for Science, 10178 Berlin — [4]Department of Chemistry, Rice University, Houston, Texas 77005, USA — [5]Initiative for Computational Catalysis, Flatiron Institute, New York, New York 10010, USA

Generating equilibrium ensembles is essential for modeling molecules and materials, yet traditional simulators like molecular dynamics suffer from limited sampling efficiency. Boltzmann Generators introduced the concept of one-shot deep learning for equilibrium sampling, but scalability to large systems has remained a major challenge. Here, we overcome this scaling limitation with a new Boltzmann Generator architecture that can model large materials systems. Our approach combines augmented coupling flows with graph neural networks to exploit local environments, enabling energy-based training and rapid inference. Compared to previous designs, it trains faster, uses fewer resources, and achieves superior sampling efficiency. Crucially, it transfers to much larger system sizes, allowing efficient sampling of materials with simulation cells exceeding a thousand atoms. We demonstrate its capabilities on Lennard-Jones crystals, mW water ice phases, and the silicon phase diagram, producing accurate equilibrium ensembles and free energies across scales where finite-size effects vanish.

DY 14.3 Mon 15:30 HÜL/S186

Autoencoder Learning Dynamics on MCMC Ising Dataset — •Max Weinmann[1,2,3] and Miriam Klopotek[1,3] — [1]University of Stuttgart, Stuttgart Center for Simulation Science, SimTech Cluster of Excellence EXC 2075, Stuttgart, Germany — [2]University of Stuttgart, Interchange Forum for Reflecting on Intelligent Systems, IRIS3D, Stuttgart, Germany — [3]Heidelberger Akademie der Wissenschaften, WIN-Kolleg, Heidelberg, Germany.

While consistent and abstract descriptions of learning dynamics in neural networks remain rare, they have become omnipresent and are used in many branches of science. As a result, predicting dynamics under diverse choices of ML model parameters can fail catastrophically and it remains difficult to mitigate these failures. Reliable control requires a deep understanding of the relevant mechanisms and conditions for learning particular kinds of datasets. Our study focuses on autoencoder architectures that perform well if they encode the dataset into a compressed representation that reflects core physical concepts of the data it is trained on, succeeding at a self-learned inverse model to decode this representation to reconstruct the original input (of physical origin). Some physical concepts are learned in a particular order, which depend on theoretical complexity of the representation and that of the ML architecture. We measure generalization ability against hard theoretical baselines and investigate the information geometry, stability, and physical interpretability of latent space over training time.

DY 14.4 Mon 15:45 HÜL/S186

Learning order: can neural networks discover phase transitions without symmetry functions? — •Carina Karner — Institute for Theoretical Physics, TU Wien, Vienna, Austria

Phase transitions in soft matter systems from crystallization to gelation arise from collective particle rearrangements that are challenging to capture in full microscopic detail. Conventional approaches rely on order parameters or symmetry functions to characterize emerging structures, but such descriptors may overlook crucial features in the often complex organisation of biolgical materials or synthetic super-structures. Here we investigate whether machine learning can uncover these hidden features directly from raw particle configurations. Using autoencoders trained on simulated trajectories of serveral soft matter systems, we show that the latent space encodes clear signatures of structural transitions without the need for handcrafted inputs. Our results suggest that neural networks can serve as unbiased tools to detect and interpret phase behavior in complex soft matter systems, revealing patterns that elude traditional symmetry-based analysis.

DY 14.5 Mon 16:00 HÜL/S186

Microscopy on Autopilot: Self-Supervised Transformers for Feature Detection and Control — •Damián Baláž, Gianmarco Ducci, Christoph Scheurer, Karsten Reuter, and Hendrik H. Heenen — Fritz-Haber-Institut der MPG, Berlin

The evaluation of microscopy experiments often relies on manual inspection or supervised machine learning. The former is inefficient, whereas the latter requires extensive labeling and may introduce human bias. Self-supervised learning, by contrast, learns from raw image data, capturing intrinsic visual patterns without the need for manual annotation. This improves generalization and objectivity, making it ideal for complex and dynamic microscopy data. Motivated by these advantages, we use a pre-trained self-supervised machine learning model (DINO), based on vision transformer architecture. This constitutes our central tool for feature detection and temporal analysis in microscopy experiments.

We demonstrate the versatility of our approach for two microscopy experiments: i) observing graphene flake growth on liquid copper ii) tracking crack formation in a cobalt oxide catalyst. In both cases, the model enables label-free, qualitative monitoring by identifying related structures based on similarity in the learned feature space. Beyond using it for analysis, we show how the same feature space representations can be used to predict experimental dynamics to autonomously steer processes toward desired targets via planning in feature space. Our findings highlight the potential of self-supervised vision models for real-time analysis and control in microscopy-based experiments.

DY 14.6 Mon 16:15 HÜL/S186

Learning microstructure in active matter — •Writu Dasgupta, Suvendu Mandal, Aritra Mukhopadhyay, and Benno Liebchen — Technische Universität Darmstadt, Darmstadt, Germany

Understanding the full parameter dependence of microscopic structure in active matter remains a central challenge, particularly for strong activity and high density, where simulations become increasingly expensive. Here, we present a data-driven approach that learns radial and angular correlations in terms of the pair-correlation function $g(r,\theta)$ of passive and active Brownian particles. Our predictions are in close quantitative agreement with Brownian dynamics simulations, even for parameter values that the neural networks had not previously encountered during training. Our predictions are subsequently distilled into compact, closed-form expressions using symbolic regression, providing an interpretable description of the underlying structure. Our approach offers a unified and computationally efficient route to understanding non-equilibrium correlations.

DY 14.7 Mon 16:30 HÜL/S186

Physical embodiment enabled learning for autonomous navigation of active particles in complex flow fields — •Diptabrata Paul[1], Nikola Milosevic[2], Nico Scherf[2], and Frank Cichos[1] — [1]Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, Leipzig University, 04103 Leipzig, Germany — [2]Max Planck Institute for Human Cognitive and Brain Sciences, 04103 Leipzig, Germany

Autonomous navigation at the microscale is a major challenge in active matter due to strong environmental noise and hydrodynamic disturbances. While living systems rely on sophisticated sensing and feedback to regulate functions from sub-cellular processes to chemotactic navigation strategies, artificial microswimmers lack such adaptive mechanisms and therefore struggle to respond effectively to stationary or dynamic perturbations. In this work, we introduce an actor-critic reinforcement learning (RL) framework and demonstrate that physical embodiment alone enables adaptive navigation without explicit environment sensing. Training of the active particle agent in strong and spatially varying flow fields leads to emergence of robust strategies that counteract hidden hydrodynamic perturbations excluded from the agent's observation space. This reveals that embodied dynamics encode sufficient information for effective decision-making, enabling RL to exploit morphology-environment coupling as an implicit sensing channel. Our approach bridges the gap between simple stimulus response schemes and higher-level adaptive behavior and establishes a foundation for online learning, and microscale robotics.

Machine Learning for Electric-Field Driven Nuclear Dynamics in Solids and Liquids — •Elia Stocco[1], Christian Carbogno[2], and Mariana Rossi[1] — [1]MPI for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Fritz Haber Institute of the MPS, Berlin, Germany

Simulating the interaction of electric fields with matter is fundamental to study dielectric properties and their interplay with structural and vibrational degrees of freedom. Therefore, it is desirable to obtain a general method that is able to deal with static and time-dependent fields, that is scalable to large complex systems, and that retains ab initio accuracy. We describe a machine-learning molecular dynamics method within the electric dipole approximation that describes the coupling of insulating materials to diverse electric fields, spanning liquids, solids, and confined systems [1]. In particular, we also take into account the influence of the electric field on the lattice degrees of freedom. We train equivariant MACE models [2], using density-functional theory data to learn the potential energy and dipole surfaces, including the multi-valued nature of the polarization in periodic systems. The external forces on various degrees of freedom are obtained through automatic differentiation. We present calculations of the dielectric permittivity of water, the temperature and light-driven ferroelectric-paraelectric phase transition of $LiNbO_3$, and simulations of piezoelectric systems. Machine-learned Potentials for Vibrational Properties of Acene-based Molecular Crystals — •Shubham Sharma, Burak Gurlek, Paolo Lazzaroni, and Mariana Rossi — MPI for the Structure and Dynamics of Matter, Hamburg, Germany

Machine-learning potentials (MLPs) have enabled efficient modelling of complex atomistic systems with ab-initio accuracy. A major challenge, however, is the construction of sufficiently large and diverse reference datasets using first-principles calculations. To mitigate this, several active-learning strategies have been proposed to improve training efficiency, especially when combined with molecular-dynamics sampling. In this work, we develop protocols for building training sets of MACE potentials [1], targeting an accurate description of the vibrational properties of weakly-bound condensed-phase systems [2]. We assess the performance of MACE against the VASP-ML framework [3], highlighting differences in predictive accuracy for energies, forces, and vibrational properties. We also propagate committee-based uncertainties to estimate errors in dynamical quantities coming from imperfect force predictions. Finally, we demonstrate the generalisation capability of the acene-based potential by applying it to host-guest systems, enabling the identification of distinct vibrational modes within the complex dynamical spectra. [1] I. Batatia et. al., Nat Mach Intell 7, 56-67 (2025); [2] B. Gurlek, S. Sharma et. al., npj Comput Mater 11, 318 (2025); [3] R. Jinnouchi et. al., PRB 100, 014105 (2019).

DY 14.10 Mon 17:30 HÜL/S186

Spin-phonon systems in the age of modern atomistic simulations — •Ilija Srpak[1,2], Michael J. Willatt[2], Stuart C. Althorpe[1], and Ali Alavi[1,2] — [1]Yusuf Hamied Department of Chemistry, University of Cambrige, Cambridge, United Kingdom — [2]Max Planck Institute for Solid State Research, Stuttgart, Germany

Spin-phonon systems are molecules or crystals containing open-shell atoms whose spin-spin interaction is significantly affected by lattice displacements, sometimes leading to spin-Peierls phase transition. They typically inherit some of the most challenging aspects of statistical physics where many configurations across the phase space may contribute to its properties, and of "strongly-correlated" physics where mean-field methods such as density functional theory and self-consistent field approaches break down.

Over the years a plethora of Monte Carlo based techniques was developed to tackle this problem with some success, but not without (sometimes significant) limitations. Approaching this problem from atomistic simulations background, we developed a path integral molecular dynamics framework which doesn't require any Monte Carlo during the simulation runtime to sample the phase space, it can take arbitrary system parametrizations or even ab-initio description and simulate the system at an arbitrary temperature as well as include nuclear quantum effect. Using neural networks we have developed this framework further. We achieved a speed up of 2-3 orders of magnitude and are able to treat higher dimensional systems.

DY 14.11 Mon 17:45 HÜL/S186

Self-Consistent Benchmarking of Machine Learning Force Fields via Energy-Landscape Exploration — •Anand Sharma[1,2], Igor Poltavskyi[1], and Alexandre Tkatchenko[1] — [1]Department of Physics and Materials Science, University of Luxembourg, Luxembourg — [2]Indian Institute of Science Education and Research Pune, India

The rapid growth of Machine Learning Force Field (MLFF) models has prompted the development of diverse benchmarks to assess their accuracy and transferability. Most existing approaches rely on predefined test datasets, introducing biases and limiting fair comparison between models.

We introduce a general, system- and model-agnostic benchmarking framework that evaluates MLFFs through self-generated datasets. For each model, molecular structures are obtained by sampling random initial configurations of atoms and relaxing them using the model's predicted forces. The resulting datasets are analyzed through (i) comparison with the model's original training data, (ii) validation against ab-initio reference calculations, and (iii) cross-model dataset comparison. Applied to the SO3LR [1] and MACE-MP-0 [2] models, our framework identifies gaps in their training set coverage and enables unbiased evaluation of models' predictive capabilities. Overall, our approach provides a consistent, extensible foundation for comparing and improving next-generation broadly applicable MLFFs.

DY 14.12 Mon 18:00 HÜL/S186

Solving Classical and Quantum spin glasses with Deep Boltzman Quantum States — Luca Leone[1], •Arka Dutta[1], Markus Heyl[1], Enrico Prati[2], and Pietro Torta[2] — [1]Theoretical Physics III, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, Augsburg, Germany. — [2]Department of Physics, University of Milan, Milan, Italy.

Variational neural network models achieved remarkable success in preparing the ground state of quantum many-body systems. However, addressing classical and quantum spin glasses remains challenging, as exponential growth of deep local energy minima due to disorder and energy frustration hinder conventional Monte Carlo methods. To bridge this gap, we introduce Deep Boltzmann Quantum States, a class of neural quantum states inspired by deep Boltzmann machines, trained by devising Neural Quantum Annealing, an algorithm incorporating the principles of quantum annealing. It solves large-scale classical and quantum spin glasses, matching the exact solution or the best available estimate for several instances of Ising spin-glass models with infinite-range interactions and hundreds of spins.

DY 14.13 Mon 18:15 HÜL/S186

Optimization and Representability of time-dependent Neural Quantum States: a study of the 1D critical quantum Ising model — •Wladislaw Krinitsin[1,2], Mohammad Abedi[1,2], Jonas Rigo[2], and Markus Schmitt[1,2] — [1]PGI-8, Forschungszentrum Jülich, Jülich, Germany — [2]Faculty for Informatics and Data Science, Regensburg University, Germany

In recent years, neural quantum states have emerged as a competitive and powerful numerical approach for many body systems. While they provide a flexible and scalable ansatz, able to represent any state as suggested by the function-approximation theorem, their practical limitations are still opaque, in particular regarding representability and optimization. In this work we investigate these questions within the framework of variational Monte Carlo on the example of the time evolution of the critical transverse-field Ising model in one dimension. Even for moderate system sizes, the departure from the exact solution occurs very early in the dynamics, allowing us to systematically analyze the representability of the state at each time step as well as the impact of different sampling strategies.

DY 15: Focus Session: Large Deviations and Rare Events II

The modeling and understanding of large deviations and rare events is of crucial importance in a wide range of real-world applications, including climate science, actuarial statistics (insurance statistics), natural disaster management, or the description of financial markets. At the same time, such effects are fundamental for the understanding of many systems in condensed-matter physics. In first-order phase transitions, for instance, the coexisting phases are connected by transition states involving droplet excitations whose probability is suppressed by dozens or hundreds of orders of magnitude as compared to the pure-phase peaks. Likewise, for many disordered systems the behavior of typical cases is incompatible with that of the average sample as the problem is described by very broad, heavy-tailed distributions, where averages are dominated by rare events. For many models, like the Kadar-Parisi-Zhang equation or random-graph properties, there has been considerable analytical progress in the last decade. Likewise, new or improved numerical techniques have been proposed that now allow for the treatment of previously inaccessible problems or regimes. This focus session is devoted to an update on the state of the art in this rapidly evolving area.

Time: Monday 15:00–18:30 Location: ZEU/0114

Invited Talk DY 15.1 Mon 15:00 ZEU/0114

Monte Carlo Simulation Methods for Rare-Event Sampling — •Wolfhard Janke — Institut für Theoretische Physik, Universität Leipzig, IPF 231101, 04081 Leipzig, Germany

Large fluctuations and rare events play an important role in many physical systems, with nucleation phenomena, first-order phase transitions and frustrated (disordered) systems being only the most prominent examples. To cope with such processes in Monte Carlo computer simulations, several generalized-ensemble approaches such as parallel and simulated tempering and "flat-histogram" methods have been devised and further improved over the years. After a brief overview of the basic ideas of multicanonical (MuCa), Wang-Landau (WL), and Stochastic Appxoximation Monte Carlo (SAMC) schemes, the talk will focus on more recently proposed "non-flat" variants that put even more emphasis on strongly suppressed rare events, and alternative formulations based on the (real) microcanonical ensemble. As illustrations, performance tests and results will be shown for spin glasses, first-order phase transitions in the q-state Potts and Blume-Capel model, Lennard-Jones particle and polymer clusters, and the density of states of O(n) spin models on triangular and hypercubic lattices spanning many hundreds orders of magnitude.

DY 15.2 Mon 15:30 ZEU/0114

Sampling rare events with neural networks — Moritz Riedel[1], Johannes Zierenberg[2], and •Martin Weigel[1] — [1]Institut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany — [2]Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany

Neural networks can be trained to generate samples from the Boltzmann distribution of many-particle systems. If suitable architectures such as normalizing flows or variational autoregressive networks are chosen, exact generation weights are known, and hence present biases can be corrected for. Still, such networks typically struggle to learn and reproduce configurations from the full range of configuration space, since effects such as mode collapse occur. For the simulation of rare events and suppressed states accessible in generalized frameworks such as the multicanonical ensemble such broad exploration is crucial. Here, we show how a combination of variational autoregressive network and autoencoder allows for a systematic exploration of configuration space in spin models, during which the network is able to learn the density of states. We demonstrate the efficacy of the approach in the Potts system in the strong first-order regime, and we also propose hybrid algorithms combining the neural network approach with traditional Monte Carlo techniques.

DY 15.3 Mon 15:45 ZEU/0114

Large deviation simulation of the coupling time of an Ising ferromagnet — •Mathis Groenhagen[1], Peter Werner[2], and Alexander K. Hartmann[1] — [1]Institut für Physik, Carl von Ossietzky Universität Oldenburg — [2]Laboratoire de Météorologie Dynamique - ENS, Paris

Coupling from the past, introduced by Propp and Wilson [1], is a Markov-chain Monte Carlo (MCMC) method capable of generating perfectly independent samples from a finite set of states, following exactly a given distribution. The performance of this algorithm for a given model can be characterized by it's *coupling time* τ_c, which measures the time to perfect statistical independence and depends on the used random numbers.

The algorithm is tested for one and two-dimensional Ising models without external field with the single-spin-update heat-bath algorithm. In order to access the distribution $p(\tau_c)$ over a wide range of the support down to densities as small as 10^{-200}, a large-deviation MCMC algorithm is used. With this, we have obtained $p(\tau_c)$ for different lattice dimensions D, edge lengths L and heat-bath temperatures T.

In particular, we observe a change of the shape of $p(\tau_c)$ at T_c for $D = 2$. For the paramagnetic case of $D = 2$ and $D = 1$, $p(\tau_c)$ follows a Gumbel distribution as predicted for the thermodynamic limit [2]. We have studied the dependency of the distribution parameters on T and L.

DY 15.4 Mon 16:00 ZEU/0114

Large deviations in response functions of the two-dimensional bond-diluted Ising model — •Lambert Münster[1], Alexander K. Hartmann[2], and Martin Weigel[1] — [1]Institut für Physik, TU Chemnitz, 09107 Chemnitz, Germany — [2]Institut für Physik, Carl von Ossietzky Universität Oldenburg, 26129 Oldenburg, Germany

Studies in statistical physics are most commonly focused on the typical, average behavior of a system. However, there exist cases in which rare events can have a significant impact on physical properties. The Griffiths phase in systems with quenched disorder is one such example. In this case rare regions in the disorder degrees of freedom cause large tails in response functions of physical observables such as the magnetic susceptibility and the specific heat. In this study rare-region effects are investigated by analyzing the distributions of physical observables in the bond-diluted Ising model. In order to obtain these distributions over a wide range of their support, a special type of Markov chain Monte Carlo algorithm is utilized for sampling rare events [1].

DY 15.5 Mon 16:15 ZEU/0114

Universality of the order-parameter large-deviation function for the critical 2D Ising and Blume-Capel models — Nikolaos G. Fytas[1], Víctor Martín-Mayor[2], Attilio L. Stella[3], Gianluca Teza[4], Alexandros Vasilopoulos[1], and •David Yllanes[5] — [1]University of Essex — [2]Universidad Complutense de Madrid — [3]Università di Padova — [4]MPIPKS, Dresden — [5]Universidad de Zaragoza

We revisit the longstanding question of universality in the probability density function (pdf) of the order parameter at criticality, traditionally assumed to hold only for the central region of the distribution. Focusing on the dimensionless magnetization $u = m/\sqrt{\langle m^2 \rangle}$, whose moments are universally defined in the thermodynamic limit, we hypothesize that universality extends to the full

pdf $p_L(u)$, including its exponentially suppressed large-deviation tails scaling as $u^{1+\delta}$. We test this conjecture with large-scale Tethered Monte Carlo simulations of the 2D Blume-Capel model at criticality for several values of the crystal field Δ, including the Ising limit ($\Delta = -\infty$) and approaching the tricritical point $\Delta_c \approx 1.97$. We simulate lattices up to $L = 4096$ with a tethered cluster algorithm, reaching the asymptotic regime for probability densities as small as 10^{-200}. Our results are strong numerical evidence for universality in the full $p_L(u)$ and settle the debated non-universality of the large-deviation function for m, where system-dependent amplitudes obscure scaling behavior. We consider the universality of the unusual combination of a finite-size amplitude with an amplitude for a scaling law related to the large-deviation function.

DY 15.6 Mon 16:30 ZEU/0114

Ising Model under Stochastic Resetting — •Shashank Kallappara[1], Parbati Saha[2], Varsha Banerjee[2], and Martin Weigel[1] — [1]Institut für Physik, TU Chemnitz, Germany — [2]Department of Physics, Indian Institute of Technology Delhi, India

Stochastic resetting refers to the interruption of a system's natural evolution by randomly returning it to a prescribed initial configuration. In this work, we investigate the effect of stochastic resetting on the Ising model and extend the results of Ref. [1] by examining how the resetting protocol modifies energetic properties of the system. In particular, we analyse the behaviour of the energy under different resetting rates and initial magnetisations. Furthermore, we study the impact of resetting in the case of conserved-order-parameter Ising model using Kawasaki dynamics, revealing qualitatively distinct behaviour compared to the nonconserved Glauber dynamics.

DY 15.7 Mon 17:00 ZEU/0114

Classical nucleation theory for active non-conserved scalar field theories — •Michalis Chatzittofi[1], Noah Ziethen[1], Cesare Nardini[2], and Michael Cates[1] — [1]DAMTP, Centre for Mathematical Sciences, University of Cambridge, Cambridge CB3 0WA, United Kingdom — [2]Service de Physique de l' Etat Condense, CNRS UMR 3680, CEA-Saclay, 91191 Gif-sur-Yvette, France

Classical nucleation theory (CNT) has been successfully used in equilibrium conserved theories to explain the behaviour of growing droplets. However, in non-equilibrium field theories such description is more challenging since the dynamics cannot be derived from a free-energy. In this work, we show that it is possible to generalize CNT for the case of out-of-equilibrium non-conserved field theories. By projecting onto the slow manifold of the dynamics, we propose a systematic recipe for deriving an exact analytical expression for the dynamics of the growing nucleus and the corresponding quasipotential. Our findings allow for analytical progress in the context of large deviations and can compliment numerical/machine learning approaches for finding instanton trajectories.

DY 15.8 Mon 17:15 ZEU/0114

Precise large deviations in statistical field theories with weak noise — •Timo Schorlepp[1], Tobias Grafke[2], Rainer Grauer[3], Georg Stadler[1], and Shanyin Tong[4] — [1]NYU Courant, USA — [2]Warwick, UK — [3]Bochum, Germany — [4]UPenn, USA

Large deviation theory (LDT) provides a common theoretical framework to compute probabilities of rare events in stochastic systems out of equilibrium. The theory consists of a saddlepoint evaluation of the path integral describing the stochastic process under study, and has successfully been used in various systems such as growing interfaces, active matter, lattice gases and macroscopic fluctuation theory, fluid dynamics and turbulence, etc. I will describe recent progress in going beyond leading-order LDT asymptotics, developing tractable methods to evaluate 1-loop (Gaussian) corrections around nontrivial LDT minimizers for weak noise Langevin equations and field theories. This allows for quantitative rare event probability estimates, beyond the usual log-asymptotics. To compute the corresponding LDT prefactors, I will present two complementary approaches based on either matrix Riccati differential equations, or (possibly renormalized) Fredholm determinants. I will illustrate these methods in multiple analytical/numerical examples: extreme growth events in the 1d KPZ equation at short times [1], extreme concentrations of a randomly advected passive scalar [2], and extreme strain events in the stochastically forced incompressible 3d Navier-Stokes equations [3]. References: [1] Schorlepp, Grafke, Grauer, J Stat Phys, 2023; [2] Schorlepp, Grafke, arXiv:2502.20114, 2025; [3] Schorlepp, Tong, Grafke, Stadler, Stat. Comput., 2023.

Probability graphons and large deviations for random weighted graphs — •Giulio Zucal — Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany — Max Planck Institute for Physics of Complex Systems, Dresden, Germany — Center for Systems Biology Dresden, Dresden, Germany

Graph limit theory studies the convergence of sequences of graphs as the number of vertices grows, providing an effective framework for representing large networks. In this talk, I will give a brief introduction to graph limits and report on recent extensions to weighted graphs and multiplex networks (probability graphons and P-variables). As an application of this theory I will present a large deviation principle (LDP) for random weighted graphs that generalizes the LDP for Erdős–Rényi random graphs by Chatterjee and Varadhan (2011), based on joint work with Pierfrancesco Dionigi.

DY 15.10 Mon 17:45 ZEU/0114

Extreme Value Analysis for Finite, Multivariate and Correlated Systems with Finance as an Example — •Benjamin Köhler, Anton J Heckens, and Thomas Guhr — Universität Duisburg-Essen, Germany

Extreme values and the tail behaviour of probability distributions are essential for quantifying and mitigating risk in complex environmental and socio-economic systems. In multivariate settings, accounting for correlations is crucial. Although extreme value analysis for truly infinite correlated systems remains an open challenge, we propose a practical framework for handling a large but finite number of time series.

We study the extremal behavior of high-frequency stock returns after rotating them into the eigenbasis of the correlation matrix. This separates information on the market as a whole and on sectoral behavior while allowing us to use univariate tools of extreme value analysis, even for high-frequency data where discretization effects normally complicate analysis.

Using a Peaks–over–threshold approach, we estimate the tail shape of the rotated returns while explicitly accounting for non-stationarity, a key feature in finance and many other complex systems. Our framework allows for tail risk estimation relative to larger trends and intraday seasonalities at both market and sectoral levels.

DY 15.11 Mon 18:00 ZEU/0114

On the Reconstruction and Predictability of Ocean Rogue Waves — Christian Behnken, Finn Köhne, Metthias Wächter, and •Joachim Peinke — Institute of Physics, University Oldenburg, Oldenburg

We present a data-driven algorithm which allows to reconstruct rogue wave events from surface elevation measurements of ocean gravity waves. In particular we extract from the data stochastic equations for joint multipoint statistics [1]. Our procedure is applied to measurements from the Sea of Japan and the German North Sea over several days. The estimated stochastic equations allow to generate large ensembles of realistic wave time series to investigate the predictability of rogue waves. Furthermore we use the large deviation algorithm "Trajectory-Adaptive Multilevel Sampling" [2] to predict up to now unkown extreme wave events. While the North Sea equations do not lead to Rogue Waves, we do find those for the Sea of Japan. Averaging over several similar rogue waves, we obtain well-known rogue wave patterns like the "three sisters", proposed by from nonlinear-wave equations. i.e. nonlinear Schrödinger equation [3].

Forecasting Extreme Events in Atmospheric Turbulence — •Finn Köhne and Joachim Peinke — Institute of Physics and ForWind, University of Oldenburg, Küpkersweg 70, D-26129 Oldenburg, Germany

Extreme wind speed fluctuations on time scales of seconds to minutes generate potentially significant mechanical loads for example on wind turbines and may lead to strong fluctuations in the power output [1,2]. Reliable short-term forecasts of such turbulent events are therefore of high relevance for many applications.

In this contribution, we use a stochastic framework based on the Fokker-Planck-equation (FPE) to forecast wind speed fluctuations in the atmospheric turbulence. We estimate drift and diffusion from measurement data to derive FPEs that describe the probabilistic evolution of wind speed increments without requiring data normalization [3].

The resulting model is used to perform probabilistic forecasts for extreme wind speed fluctuations. The quality of the forecast is quantified using receiver operating characteristic curves. The results demonstrate that the Fokker-Planck-based approach provides reliable short-term predictions of extreme events in the atmospheric turbulence.

Rayleigh instability in the presence of elastocapillarity — •Niphredil Klint and Andreas Isacsson — Chalmers University of Technology, Gothenburg, Sweden

A liquid jet, such as a stream of water, will disintegrate and form droplets if the length-to-radius ratio exceeds a critical value. This occurs due to propagating surface instabilities, a phenomenon known classically as the Rayleigh instability. At the nanoscale, thermal fluctuations affect the breakup dynamics, which may enter a stochastic regime [1]. Placing an elongated nanoscale liquid drop with a high aspect ratio on top of a highly compliant surface, the breakup process is affected by additional noise from thermally excited flexural phonons [2] as well as effects whereby the wetting causes the underlying surface to deform. We use large scale molecular dynamics (MD) simulations to examine the dynamics of the Rayleigh instability in the presence of elastocapillary effects at ambient temperatures. Specifically, we study the interactions between water and suspended graphene, where wetting induced deformations may occur for nanoscale droplets [3]. We focus on characterising the breakup and instability wavelength and isolate the effects of introducing graphene through a comparison of these results to simulations of only water. We also identify the correlation between out-of-plane fluctuations of the graphene and the concentration of water.

Air layers and wetting under drops impacting on pre-wetted surfaces — •Kirsten Harth and Shiva Moradimehr — Fachbereich Technik, Technische Hochschule Brandenburg, Germany

Drop impact at low Weber numbers causes the formation of a (temporary) air cushion between the drop liquid and the substrate. On hard, dry substrates, its qualitative thickness profile and the location of the thinnest point are strongly governed by the Weber number. For impact on bulk, soft surfaces, like PDMS gels, it was found that impacts on softer substrates entrap more air [1]. Are there similar effects of thin liquid films?

We address the air layer shapes, entrapped air volume and wetting underneath droplets impacting on a hard substrate pre-wetted by microscopic oil layers. We control the Weber number, the oil layer thickness (in the range of micrometers), the oil viscosity, and in that way the *softness* of the substrate. Despite the thinness of the film, we observe clear effects of the oil layer on the volume and drainage of the air entrapment, its profile shapes, and the wetting behavior.

Memory Effects in Contact Line Friction — •Niklas Wolf and Nico van der Vegt — TU Darmstadt, Darmstadt, Germany

When a drop of liquid comes into contact with a solid surface, it relaxes towards an equilibrium configuration, either wetting the surface or remaining in a droplet-like shape with a finite contact angle. The speed of this relaxation strongly depends on a friction force opposing the movement of the three-phase contact line. In analogy to the treatment of hydrodynamic friction we present an exact method, based on the Mori-Zwanzig formalism, to extract this friction from equilibrium data. Within the linear response regime, we obtain the frequency-dependent dissipative and elastic response of the contact line to an external perturbation, including a frequency-dependent friction coefficient. We find that the contact line exhibits long-lasting memory with a power-law decay due to coupling to the systems hydrodynamic modes. As a result the microscopic contact line dynamics are neither Markovian nor determined by the movement of a few molecules in the vicinity of the contact line.

DY 16.4 Mon 15:45 ZEU/0118

Reaction-Mediated Arrest and Gradient-Driven Droplet Transport — •Stefan Köstler[1,2], Yicheng Qiang[1], Malcolm Steen[1,2], Guido Kusters[1], and David Zwicker[1] — [1]Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany — [2]University of Göttingen, Institute for the Dynamics of Complex Systems, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Controlling droplet size and position is central to many biological and engineering processes. Chemical reactions can arrest coarsening and sustain spatial concentration gradients, while hydrodynamic flows generally accelerate coarsening and drive droplets along chemical gradients. Using continuum theory, we show that the competition between reactions, diffusion, and hydrodynamic advection yields rich behavior even in binary systems: Advection dominates the coalescence of small droplets, diffusion leads to Ostwald ripening for intermediate sizes, and reactions finally suppress coarsening. Interestingly, a range of droplet sizes is stable, depending on initial conditions and the strength of advection. Crucially, chemical gradients can actively steer droplets and couple to size-control. Our results demonstrate practical routes to control both the size distribution and spatial organization of droplets by tuning chemical activity and gradient-driven flows.

From bipedal to chaotic motion of chemically fueled partially wetting liquid drops — •Florian Voss[1] and Uwe Thiele[1,2] — [1]Institute of Theoretical Physics, University of Münster — [2]Center for Data Science and Complexity (CDSC), University of Münster

Chemomechanical coupling is essential to various phenomena in soft matter systems that are kept permanently out of thermodynamic equilibrium, e.g., in reactive complex liquids. Based on a thermodynamically consistent continuum model, we demonstrate that partially wetting liquid drops covered by chemically reacting surfactants display a variety of biomimetic motility modes like shuttling, bipedal, rotational and quasi-random motion when supplied with chemical fuel from an ambient bath. The dynamics originates from chemomechanical feedback between the reaction network on the drop and the Marangoni effect [1] and becomes increasingly complex as a result of competing length scales. Due to the generic underlying thermodynamic structure, we expect that our results are also relevant for other chemically active mixtures and soft matter systems.

Odd Droplets — •Thomas Appleford — University of Amsterdam, Amsterdam, Netherlands

In chiral systems such as active spinning colloidal matter, time-reversal symmetry-breaking interactions often give rise to a macroscopic continuum description in which the stress tensor contains off-diagonal terms. In fluids, these off-diagonal components lead to so-called "odd-viscous" deformations, in which energy is not dissipated. Odd viscous fluids have been shown to exhibit a rich variety of phenomena, including symmetry-broken flow around translating droplets and asymmetric droplet spreading on superhydrophobic surfaces. Our work investigates the behaviour of droplets in suspension. In particular, we present an analytical solution to the droplet-in-shear problem within the framework of two-dimensional odd Stokes flow, followed by the derivation of a formula for the apparent viscosity of a dilute emulsion. We then explore how chirality can be parametrically varied to tune the bulk rheological properties and control the system's overall energy dissipation.

DY 16.7 Mon 16:30 ZEU/0118

Stretching and Sliding Capillary Bridges — •Lennard Holschuh and Lars Pastewka — University of Freiburg, Department of Microsystems Engineering

Capillary forces play a critical role in the adhesion between two contacting bodies. However, existing theories of macroscopic adhesion on rough surfaces often assume dry conditions, attributing adhesive interactions solely to dispersion forces and overlooking the effects of capillary bridge formation. This study employs molecular dynamics simulations to directly examine the interactions of nanoscale probes with nominally flat surfaces in the presence of liquid bridges, which form due to condensation in humid environments. The objective is to link the thermodynamic understanding of capillary bridges with molecular simulations and atomic-force microscopy experiments. These calculations focus on investigating energy dissipation during adhesion (normal separation of the probe from the surface) and friction (lateral motion of the probe). By quantifying the interplay between relative humidity, adhesion, and friction, this work aims to improve the understanding of macroscopic adhesion in humid conditions and guide the development of materials with tailored properties for high-precision applications, such as microelectronic manufacturing.

Hyperuniformity in Ternary Fluid Mixtures: The Role of Wetting and Hydrodynamics — •Nadia Bihari Padhan and Axel Voigt — Institute of Scientific Computing, TU Dresden, 01069 Dresden, Germany

Phase separation in multicomponent fluids underlies the organization of complex materials and biological structures, including biomolecular condensates. The Cahn-Hilliard-Navier-Stokes (CHNS) framework provides a natural description of such systems by coupling diffusive and hydrodynamic processes. In this talk, I will present our study of hyperuniformity–suppressed large-scale density fluctuations–in ternary CHNS mixtures. We show that hydrodynamics systematically drives the system toward less hyperuniform states and generates a rich set of morphologies, such as interconnected droplets and double emulsions reminiscent of biological phase separation. In partial-wetting regimes, all three

components display comparable hyperuniformity, whereas in complete-wetting regimes the preferred wetting component exhibits a marked loss of hyperuniformity. These results identify wetting asymmetry as a key control parameter for spatial order in multiphase fluids and offer a pathway for tuning large-scale organization in soft-matter and biological systems.

Effect of Flow Coupling on Defect Binding and Unbinding in Nematic Fluids — •Jayeeta Chattopadhyay, Simon Guldager Andersen, Kristian Thijssen, and Amin Doostmohammadi — Niels Bohr Institute, University of Copenhagen, Blegdamsvej 17, Copenhagen, Denmark.

Topological defects play a central role in the ordering and dynamics of nematic fluids. We investigate how coupling to fluid flow modifies defect-mediated phase transitions in two-dimensional nematics using fluctuating nematohydrodynamic simulations. The system is driven by tuning the fluctuation strength, with increasing and decreasing fluctuations defining forward and backward protocols. Without flow coupling, the system undergoes a Berezinskii–Kosterlitz–Thouless (BKT)–like transition via the reversible binding and unbinding of $\pm 1/2$ defect pairs. When hydrodynamics is included, the transition depends on the flow–alignment parameter: non-aligning nematics ($\lambda = 0$) retain BKT-like behavior, whereas strain-rate–aligning nematics ($\lambda \neq 0$) form bend–splay walls, lowering the defect-creation threshold and preventing recombination, leaving defects unbound across all fluctuation strengths. In active nematics, defects remain unbound for all λ, showing that self-generated flows also inhibit bound-pair formation. These results demonstrate that coupling to fluid flow fundamentally alters topological phase behavior, suppressing the equilibrium BKT binding mechanism.

Electrophoresis in charged chiral active fluids with odd viscosity — •Reinier van Buel, Bogdan Cichocki, and Jeffrey Everts — Institute of Theoretical Physics, Faculty of Physics, University of Warsaw, Pasteura 5, 02-093 Warsaw, Poland

Understanding the motion of colloidal particles dissolved in fluids that exhibit odd viscosity – a specific component of the viscous stress tensor found in e.g. chiral active fluids – is of particular interest for realising nontrivial particle transport and characterising out-of-equilibrium thermodynamic properties. Although three-dimensional odd viscosity has not yet been experimentally observed, charge stabilisation is expected to be vital in enabling such measurements. Therefore, we introduce the notion of a charged chiral active fluid and we investigate some of its non-trivial electrokinetic properties. In particular, we focus on electrophoresis of a charged sphere suspended in such an odd viscous fluid. Here, the peculiar nature of odd viscosity breaks the spherical symmetry of the system, and through coupling with the electric double layer and its screening properties, alters the electrophoretic mobility. Using the Lorentz reciprocal theorem, we derive expressions for the electrophoretic mobility of a spherical particle based on the analytical solution for the uncharged flow. Furthermore, we highlight how the Hückel and Smoluchowski limits of the electrophoretic mobility are affected by odd viscosity. Our results demonstrate that odd viscosity leads to directional asymmetries in the electrophoretic mobility tensor, suggesting mechanisms for active control of charged colloidal motion in systems where odd viscosity is prevalent.

DY 16.11 Mon 17:45 ZEU/0118

Experimentally probing microscale torsional memory in a viscoelastic fluid — •Niloyendu Roy[1], Rupayan Saha[2], Debankur Das[2], Matthias Krüger[2], and Clemens Bechinger[1] — [1]Fachbereich Physik, Universität Konstanz, Konstanz, Germany — [2]Institut für Theoretische Physik, Universität Göttingen, Göttingen, Germany

Motion of a colloid inside viscoelastic fluids follows non-Markovian dynamics, meaning its trajectory is influenced by past motion. Such memory effects are typically attributed to intrinsic material timescales arising from relaxation of the fluid microstructure and are usually probed using translationally driven colloids. Here we show experimentally that rotational driving of a colloid by a controlled torque elicits a far richer form of memory: the relaxation of the resulting torsional stresses spans a broad distribution of timescales, even though the fluid itself possesses a single dominant relaxation time. This behaviour allows time-dependent torsional driving histories to be encoded and subsequently read out through characteristic non-monotonic recoil responses. By mapping the flow field and the spatial distribution of torsional stresses, we demonstrate that the geometry of rotation generates an orthogonality between the propagation of angular momentum and the storage of torsional stresses, producing a spatio-temporal memory field not accessible through translational forcing. These results establish torsional driving as a powerful route to generate, store, and retrieve memory in viscoelastic fluids, opening new possibilities for soft-matter information storage and torque-responsive microdevices.

3D Optofluidic Control Using Reconfigurable Thermal Barriers — •Falko Schmidt[1,2], Carlos David Gonzalez[3], Marc Sulliger[1], Emilio Ruiz-Rena[4], Raul A. Rica[3,5], Jaime Ortega-Arroyo[1], and Romain Quidant[1] — [1]Department of Mechanical and Process Engineering, ETH Zurich, Zurich 8092, Switzerland — [2]Peter Debye Insitute for Soft Matter Physics, Leipzig University, 04103 Leipzig, Germany — [3]Universidad de Granada, Department of Applied Physics, Granada 18071, Spain — [4]Department of Applied Physics II, University of Malaga, Malaga 29071, Spain — [5]Universidad de Granada, Research Unit Modeling Nature (MNAT), Granada 18071, Spain

Optothermal manipulation enables precise control of small particles via optical and thermal forces, leveraging thermo-osmotic and convective flows for short- and long-range motion. We present a reconfigurable optofluidic method enabling diverse manipulations such as guiding, sorting, trapping, and separating particles. Using light absorption on plasmonic surfaces of gold nanorods, localized hot spots are generated, creating temperature-driven flows. A near-infrared laser spatially modulates temperature landscapes, monitored by 3D holographic microscopy and optical diffraction tomography. Single and double heat sources produce three-dimensional flow control. This creates an optofluidic barrier that redirects particles within a microfluidic chamber. This approach offers a versatile foundation for advancing microfluidic technologies, enabling applications in sorting, trapping, and adaptive system design.

Dynamics and Ordering of Microdroplets in Marangoni Flow Field — •Akshay Kallikkunnath and Frank Cichos — Molecular Nanophotonics, Peter Debye Institute for Soft Matter Physics, Faculty of Physics and Earth System Sciences, Leipzig University, Linnéstraße 5, 04103 Leipzig, Germany

Collective organization and internal dynamics are intimately linked and emerge across biological scales, with ordered structures providing a framework within which individual constituents remain dynamically active. Here, we study a system of water-in-oil microdroplets containing heat-releasing particles that organize under thermally induced flows. A sub-kelvin temperature increase from the heated particle at the air-oil interface generates Marangoni circulation that advects the droplets. Interactions through the flow field lead to robust ordering, while internal particle dynamics reflect coupling between local thermal gradients and microscale hydrodynamics. This provides a controllable platform to probe self-organization and emergent order by generating flows driven by weak, localized thermal fields in a fully fluid-in-fluid environment.

Field-controlled self-organization in an active spin system — Mintu Karmakar[1,2,3], •Matthieu Mangeat[4], Swarnajit Chatterjee[5,4], Heiko Rieger[4], and Raja Paul[3] — [1]WIUCAS, Beijing, China — [2]Universitat de Barcelona, Barcelona, Spain — [3]IACS, Kolkata, India — [4]Saarland University, Saarbrücken, Germany — [5]CY Cergy Paris Université, Cergy-Pontoise, France

We investigate the collective response of active Potts particles to an external magnetic field and uncover three striking nonequilibrium phenomena. We first examine how the flocking transition is reshaped for a homogeneous and unidirectional field: the coexistence regime between an apolar gas and a polar liquid is replaced by a phase separation between two polar-ordered phases, a low-density, weakly polarized background and a high-density, strongly polarized band, both moving along the field. Second, when the particles self-organize into a high-density longitudinal lane whose long axis is perpendicular to the field, the lane slowly treadmills against the field direction, driven by the weakly polarized background. Finally, we identify a field-induced interface pinning regime that arises

when the domain is divided into two regions with opposite field directions, causing particles to accumulate and perform a back-and-forth motion at the interface. This pinning phenomenon also leads to the emergence of a disordered state in the presence of a random field orientation. A coarse-grained hydrodynamic theory supports and confirms the phenomena observed in our microscopic simulations.

DY 17.2 Mon 15:15 ZEU/0160

Nucleation kinetics in two-dimensional polar active fluids — •Yuta Kuroda and Thomas Speck — Institute for Theoretical Physics IV, University of Stuttgart, Germany

Polar active fluids constitute one of the most important classes of active matter. These systems possess alignment interactions that cause the local polarization to align with that of neighboring particles, leading to a flocking transition in which global polar order emerges. Extensive numerical and analytical studies have established that the flocking transition is discontinuous, and consequently, the phase diagram possesses a coexistence region in which propagating polar bands appear. Despite intensive studies on flocking transitions, the nucleation mechanism responsible for the formation of these bands remains poorly understood. In this work, we numerically investigate the nucleation kinetics of polar bands using a particle model, namely active Brownian particles with a Kuramoto-type alignment interaction, and we report the behavior of the nucleation rate over a wide range of parameters.

DY 17.3 Mon 15:30 ZEU/0160

Collision dynamics of active Brownian hard disks — •Jonas Buba — Soft Matter Theory Group, Theoretical Physics: Lab for Emergent Phenomena, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Active matter systems, composed of self-driven agents, display emergent behaviors such as collective motion, clustering, and motility-induced phase separation (MIPS). To better understand the microscopic origin of MIPS, we study collisions of active Brownian hard disks within the framework of dynamical density functional theory (DDFT). The particle interactions are modeled using fundamental measure theory (FMT). Each particle is represented by a Gaussian density peak, which allows us to quantify the mean delay from collisions for different configurations. The post-collision density resulting from the simulation can be described by a convolution of the pre-collision density, enabeling the analysis of different contributions to the delay.

DY 17.4 Mon 15:45 ZEU/0160

Active Ornstein-Uhlenbeck Particles: A Stochastic Path Integral Approach — •Carsten Littek, Mike Brandt, and Falko Ziebert — Institut für Theoretische Physik, Universität Heidelberg, Germany

In a recent publication (arXiv:2509.26296) we have developed a path integral formulation of the stochastic dynamics of a single active Brownian particle (ABP), with or without a constant torque, confined by a harmonic trap. This approach is based on the particle's microscopic degrees of freedom and we have derived exact analytic time-dependent expressions for key observable quantities such as the mean position and mean square displacement without the necessity of solving the Fokker-Planck equation. Here we present the application of this approach to the dynamics of active Ornstein-Uhlenbeck particles (AOUP). In particular, we generalize our formulation to systems of many AOUPs interacting via a suitable two-particle potential and derive the statistical quantities relevant in the context of collective phenomena, such as motility-induced phase separation (MIPS).

DY 17.5 Mon 16:00 ZEU/0160

Self-alignment and chirality in dense active matter: from flocking to circling crystals — •Marco Musacchio[1], Alexander Antonov[1], Hartmut Löwen[1], and Lorenzo Caprini[2] — [1]Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, Universitätsstraße 1, D-40225 Düsseldorf, Germany — [2]Physics Department, University of Rome La Sapienza, P.le Aldo Moro 5, IT-00185 Rome, Italy

Several experimental systems in active matter are characterized, at the single-particle level, by an effective torque that aligns particle orientation with their instantaneous velocity. This mechanism, known as self-alignment, appears in both biological and granular active systems. In dense active systems, a sufficiently strong self-alignment can suppress mips and drive the system from a clusterized flocking state to an homogeneous one, where all particles move collectively, with aligned velocities. This flocking transition is approached for a broad range of densities, even close to maximal packing, where the system is in a crystalline configuration. Specifically, in the crystal case, the flocking transition can be predicted analytically since the dynamics can be mapped onto a velocity-dependent Landau*Ginzburg free energy, revealing that this disorder*order transition is second order. The onset of chirality drives the system from collective flocking to a circling crystal phase, characterized by coherent circular motion of all the system. Further increasing chirality suppresses the global rotation, leading to a vortex-like structure in the velocity field. These findings are experimentally testable in systems governed by self-alignment and chirality.

DY 17.6 Mon 16:15 ZEU/0160

Number fluctuations distinguish different self-propelling dynamics — •Tristan Cerdin[1,2], Sophie Marbach[2], and Carine Douarche[1] — [1]Université Paris-Saclay, CNRS, FAST, 91405, Orsay, France — [2]CNRS, Sorbonne Université, Physicochimie des Electrolytes et Nanosystèmes Interfaciaux, F-75005 Paris, France

In nonequilibrium suspensions, static number fluctuations N in virtual observation boxes reveal remarkable structural properties, but the dynamic potential of $N(t)$ signals remains unexplored. Here, we develop a theory to learn the dynamical parameters of self-propelled particle models from $N(t)$ statistics.

Theoretical plots of the mean-squared number difference $\langle \Delta N^2(t) \rangle$ exhibit 3 scaling regimes in time corresponding to the 3 regimes of self-propelled particles: diffusive, advective and effectively diffusive again at long times. By expanding the theory in each of these regimes, we recover limiting laws for the number fluctuations, which can be used in practice to quantify self-propulsion properties.

Additionally, unlike traditional trajectory analysis, $N(t)$ statistics distinguish between models, by sensing subtle differences in reorientation dynamics that govern re-entrance events in boxes. This paves the way for quantifying advanced dynamic features in dense, out-of-equilibrium suspensions.

DY 17.7 Mon 16:30 ZEU/0160

Flocking transitions in dense mixtures of active self-aligning and passive particles — •Weizhen Tang[1], Amir Shee[2], Zhangang Han[1], Pawel Romanczuk[3,4], Yating Zheng[3,4], and Cristián Huepe[1,5,6] — [1]School of Systems Science, Beijing Normal University, Beijing, China — [2]Department of Physics, University of Vermont, USA — [3]Department of Biology, Humboldt Universität zu Berlin, Unter den Linden 6, Berlin, Germany — [4]Research Cluster of Excellence 'Science of Intelligence', Berlin, Germany — [5]Northwestern Institute on Complex Systems and ESAM, Northwestern University, Evanston, USA — [6]CHuepe Labs, 2713 West Augusta Blvd #1, Chicago, USA
