Magnetic Domain Wall Motion under Microwave Excitation — •Lukas Fischer[1], Rouven Dreyer[2], Jae-Chun Jeon[1], Georg Woltersdorf[2], and Stuart Parkin[1] — [1]Max-Planck Institute of Microstructure Physics, Halle (Saale), Germany — [2]Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany

Chiral domain walls (DWs) and their synchronous motion via current pulses in magnetic conduits (so-called magnetic racetracks) are of enormous interest due to their fast speed, non-volatility, and capability of creating high bit-density for advanced memory and logic technologies. Most experimental and numerical studies have focused on the motion of the DWs by spin-orbit torque using nanosecond-long current pulses which are not efficient in coupling to magnetization precessions of the magnetic material, typically occurring in the GHz regime.

Here we present that the microwave excitation of chiral Néel DWs in a magnetic microwire with perpendicular magnetic anisotropy significantly impacts the DW motion. We use either magnetic fields or electrical currents at RF-frequencies to explore the pronounced impact on the DW motion. Firstly, we directly visualize the high-frequency response of the DW by using the Super-Nyquist sampling magneto-optical Kerr effect. We then determine the effect of this excitation on the DW motion. When the DW is excited in the presence of a static, transverse magnetic field, it exhibits unidirectional self-propulsion. Moreover, the resonant excitation in a static, longitudinal field leads to a current-triggered, sustained DW motion over micrometer distances, which dramatically increases the effective DW displacement.

Assembly of Magnetic Heterostructures with Chiral Nanographenes — •Chi Fang, Wenhui Niu, Jitul Deka, and Stuart Parkin — Max Planck Institute of Microstructure Physics, Halle(Saale) 06120, Germany

Chirality-induced spin selectivity (CISS) is an emergent phenomenon whereby chiral molecules act as efficient spin filters, selectively transmitting electrons of a particular spin orientation. A central challenge in advancing CISS-based spintronics lies in experimentally verifying spin filtering in structurally defined, laterally extended molecular systems, using standard solid-state device techniques that yield reproducible and robust spin-dependent transport signals. Here, we present direct experimental evidence of the CISS effect in helical nanographenes (NGs), using magnetoresistance (MR) measurements in magnetic heterostructures. The device architecture included a bottom electrode ferromagnetic con-

tact, orthogonally patterned and electrically isolated by an AlOx layer to confine current to the junctions. NG, a synthetically tailored chiral molecule, was spin-coated to form a thin, uniform layer serving as a spin-filter interface. Different from previous works, the ferromagnet layer grown directly on the substrate offers a better performance of the magnetic properties. Both enantiomeric devices showed MR values around 1 % at room temperature, with minimal variation over the 10*400 K temperature range, indicating robust and reproducible spin selectivity. [1] B. Bloom et al. Chem. Rev. 124(4), 2014;[2] S. Ham et al. Micromachines 15(4), 528, 2024;[3] S. Yang et al., Nat. Rev. Phys. 3, 328, 2021.

Alloying-Driven Modifications of the Magnetic Properties in Transition-Metal Iodides — •Paulina Jureczko[1,2] and Martin Gmitra[1,3] — [1]Institute of Experimental Physics, Slovak Academy of Sciences, 04001 Košice, Slovakia — [2]Institute of Physics, University of Silesia in Katowice, 41-500 Chorzów, Poland — [3]Institute of Physics, Pavol Jozef Šafárik University in Košice, 04001 Košice, Slovakia

Single-layer transition-metal dihalides have recently emerged as a platform for exploring two-dimensional magnetism and topology. Using density-functional theory, we investigate the electronic and magnetic properties of MI_2 monolayers and alloyed $M_{1-x}N_xI_2$ systems, where M and N represent Mn, Fe, Co, Ni. We analyze how chemical substitution modifies exchange interactions and spin-orbit-driven topological features by computing the Berry curvature and Chern numbers. The results reveal that alloying provides an efficient route for tuning magnetic anisotropy and topological phases in transition-metal iodides, underscoring their potential relevance for 2D spintronics.

This work has been funded by the EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I05-03-V02-00071.

Spintronic THz Frequency Conversion Mediated by Ferromagnetic/Oxide Interfaces — •Kang Jin[1], Ruslan Salikhov[1], Stefan Kober[2], Igor Ilyakov[1], Jan-Christoph Deinert[1], Aleksandra Lindner[1], Jürgen Fassbender[1,3], Sebastian F. Maehrlein[1,3], Zhe Wang[2], and Jürgen Lindner[1] — [1]HZDR — [2]TU Dortmund — [3]TU Dresden

Frequency conversion is a key nonlinear phenomenon for communication and data processing technologies. Exploring this phenomenon at terahertz (THz) frequencies is of particular interest, as the high carrier frequency enables faster data transfer and higher operational speeds. Previous experiments have revealed that THz frequency conversion could serve as a distinctive probe for THz-light-induced ultrafast spin-transfer currents (STCs) at Ferromagnetic (FM)/Non-Magnetic (NM) interfaces. Building on these findings, we report THz frequency conversion using cost-effective NM materials (such as SiO2 and Al2O3 films) and demonstrate their origin from the interfacial inverse Rashba-Edelstein effect. We compare conversion efficiencies and characteristics of different samples, revealing that FM interfaces, featuring off-stoichiometric SixOy and AlxOy, achieve conversion efficiencies comparable to heavy metal capping layers (i.e. Ta). The deposition sequence and the oxidation level of the samples were found to critically influence the sign of the spin-charge conversion. The observed THz second harmonic generation represents a spintronic foundation for developing THz frequency mixers and rectifying components.

Magnetic hyperfine fields in solids without inversion symmetry induced by an external electric field — •Alberto Marmodoro[1,2,3,4], Hubert Ebert[1], Sergiy Mankovsky[1], and Jan Minar[3] — [1]LMU Munich, Munich, DE — [2]Inst. of Physics of the Czech Acad. of Sci., Prague, CZ — [3]University of West Bohemia, Pilsen, CZ — [4]Czech Technical University., Prague, CZ

An electric field induces in a solid without inversion symmetry spin and orbital magnetization - a phenomenon called Edelstein effect. This induced magnetization has to have its counterpart in an induced magnetic hyperfine field seen by nuclear magnetic moments. Corresponding NMR experiments have been performed recently on Te with success [1]. Using Kubo's linear response formalism implemented on the basis of the relativistic Korringa-Kohn-Rostoker Green function technique a description for the field induced hyperfine field (EFI-HFF) has been developed in analogy to that for the spin and orbital Edelstein effect [2]. The EFI-HFF drastically differs from that induced by an external magnetic field as the later one does not need missing inversion symmetry. Making use of a Gordon decomposition of the electronic current a splitting of the EFI-HFF into its spin and orbital parts is achieved [3]. This allows to discuss them in relation to their counterparts concerning the magnetization as well as the role of the spin-orbit coupling for them. Corresponding numerical results are presented for Te.

Theoretical description of the optical activity and directional dichroism of chiral solids — •Hubert Ebert and Sergiy Mankovsky — Ludwig Maximilian University of Munich, Munich, DE

A scheme to deal with the optical activity and directional dichroism of solids on the basis of Kubo's linear response formalism is presented. Accounting for the $\vec{q}$-dependence of the radiation field implies that the corresponding optical transitions described in $\vec{k}$-space are no more vertical. More important, one is led to corrections to the electric dipole matrix element due to the electric quadrupole and magnetic dipole interaction. The scheme is implemented making use of the relativistic Korringa-Kohn-Rostoker Green function (KKR-GF) formalism. Corresponding applications to chiral Te that has time reversal ($\mathscr{T}$) but no inversion ($\mathscr{I}$) symmetry led to a $\vec{q}$-dependent optical conductivity tensor with off-diagonal elements caused by the interference of the electric dipole and its correction terms giving rise to optical activity. In the case of anti-ferromagnetic Cr_2O_3 without $\mathscr{T}$-symmetry the correction terms lead to directional dichroism that strongly depends on whether a magnetic configuration with or without $\mathscr{I}$-but with combined $\mathscr{I}\mathscr{T}$-symmtetry is considered.

MA 35.9 Wed 17:30 POT/0112

Intrinsic and Proximity-Enhanced Spin-Orbit Torques in Fe_3(Ge,Ga)Te_2 and WTe_2 Heterostructures — •Gusthavo Brizolla[1], Stepan Tsirkin[2], Yaroslav Zhumagulov[2], and Jaroslav Fabian[1] — [1]Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — [2]EPFL, Lausanne, Switzerland

Spin-orbit torques (SOTs) in 2D magnets and their heterostructures offer a route to ultra-thin, energy-efficient memories where currents can switch magnetization without external magnetic fields. Materials such as Fe_3GeTe_2 (FGT) and Fe_3GaTe_2 (FGaT), and their interfaces with low-symmetry WTe_2, are especially promising, but the angular dependence and microscopic origin of their SOTs are still not fully understood. Here we compute SOTs in FGT, FGaT and WTe_2-proximitized heterostructures using first-principles (DFT) calculations and compare two protocols for mapping the angular dependence: self-consistent magnetization rotation and rigid rotation of a fixed exchange field. They agree when spin-orbit mixing is weak, but differ strongly near in-plane alignment, where interband hot spots and evolving spin-orbit hybridization amplify the torkances. In WTe_2 heterostructures, broken symmetry and Te-Te interfacial hybridization further boost torques with out-of-plane spin polarization. These results provide design rules for field-free current control in 2D magnets and show that the angle dependence of spin-orbit coupling must be treated explicitly to obtain reliable SOT angular maps.

MA 35.10 Wed 17:45 POT/0112

Spin vacuum switching — •Eddie Harris-Lee[1,2], John Kay Dewhurst[2], Samuel Shallcross[1], and Sangeeta Sharma[1,3] — [1]Max-Born-Institut für Nichtlineare Optik und Kurzzeitspektroskopie, Berlin, Germany. — [2]Max-Planck-Institut für Mikrostrukturphysik, Halle, Germany. — [3]Institut für Theoretische Physik, Freie Universität Berlin, Berlin, Germany.

While physical mechanisms underpinning spin switching are established for nano- to pico-second time scales, here we present a physical route to magnetization toggle control at < 100 femtoseconds. A minority spin current injected into a ferromagnet is shown to create a minority "spin vacuum" that then drives rapid charge redistribution from the majority channel and spin switching. We demonstrate this mechanism reproduces many of the features of recent sub-picosecond switching of ferromagnetic Co/Pt multilayers, and provide simple practical rules for the design of materials to optimize "spin vacuum" control over magnetic order.

A Combined Theoretical and Experimental Study of Oxygen Vacancies in Co_3O_4 for Liquid-Phase Oxidation Catalysis — Amir Omranpour[1], •Lea Kämmerer[2], Catalina Leiva–Leroy[1], Anna Rabe[2], Takuma Sato[3], Soma Salamon[2], Joachim Landers[2], Benedikt Eggert[2], Eugen Weschke[4], Jean Pascal Fandré[5], Ashwani Kumar[5], Harun Tüysüz[5,6], Martin Muhler[1], Heiko Wende[2], and Jörg Behler[1] — [1]University of Duisburg-Essen and CENIDE — [2]Ruhr-University Bochum — [3]Max Planck Institute for Chemical Energy Conversion — [4]Helmholtz-Zentrum Berlin für Materialien und Energie — [5]Max-Planck-Institut für Kohlenforschung — [6]IMDEA Materials Institute, Spain

We combined Density Functional Theory (DFT) and experimental techniques to investigate oxygen vacancies (V_O) in bulk Co_3O_4 and during liquid-phase ethylene glycol oxidation. DFT calculations show that a V_O reduces two adjacent Co^{3+} ions to stable, high-spin Co^{2+} in distorted octahedral sites, simultaneously narrowing the band gap. Comparison of experimental O K-edge X-ray absorption spectra with DFT calculated spectra reveal that the fresh catalyst resembles the vacancy-containing calculation, but the post-reaction catalyst shifts toward the ideal Co^{3+} state, strongly suggesting that Co_3O_4 becomes more oxidized under liquid-phase ethylene glycol oxidation by refilling preexisting oxygen vacancies, a finding supported by increased conversion at higher O_2 pressures and the catalyst's stability and activity over multiple cycles. We gratefully acknowledge the DFG funding by CRC/TRR 247 (Project ID: 388390466) projects A01, A10, and B02.

KNB mechanism in convex polygon molecular magnets: bipartite entanglement transfer with the aid of electric field. — •Zhirayr Adamyan[1,2], Vadim Ohanyan[1,2], Ani Chobanyan[1], Hamid Arian Zad[3], Jozef Strecka[3], Azadeh Ghannadan[4], and Saeed Haddadi[4,5] — [1]Laboratory of Theoretical Physics, Yerevan State University, 1 Alex Manoogian, 0025 Yerevan, Armenia — [2]CANDLE, Synchrotron Research Institute, 31 Acharyan Str., 0040 Yerevan, Armenia — [3]Department of Theoretical Physics and Astro- physics, Faculty of Science, P. J. Safarik University, Park Angelinum 9, 041 54 Kosice, Slovak Republic — [4]Saeeds Quantum Information Group, P.O. Box 19395-0560, Tehran, Iran — [5]Faculty of Physics, Semnan University, P.O. Box 35195-363, Semnan, Iran

The unique properties exhibited by single molecular magnets (SMMs) have led to their integration into hybrid devices, emphasizing their quantum nature. We examine models of 1/2-spin molecular magnets arranged in a convex polygon configuration, utilizing a Katsura-Nagaosa-Balatsky (KNB) mechanism to couple the spin degrees of freedom to an external electric field. This KNB mechanism enables extensive control over quantum entanglement through both the magnitude and direction of the electric field. By employing a rotating configuration of the KNB-coupled electric field, where the field's magnitude remains constant while its direction changes, we demonstrate the controllable transfer of bipartite entanglement between different pairs of spins in the model.

Making molecular changes visible using near-surface transport of micron-sized magnetic particles — •Yahya Shubbak, Nikolai Weidt, Arne Vereijken, Rico Huhnstock, and Arno Ehresmann — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Strasse 40, 34132 Kassel, Germany

Transport of magnetic particles (MPs) in liquid close to the surface of a flat substrate containing a periodic magnetic domain pattern is a promising lab-on-a-chip (LOC) technology for detecting MP-bound analytes, even when their size is negligible compared to the MP size. As proof of principle, we show that simple observation of MP motion via optical microscopy is sufficient to distinguish MPs of the same nominal size, but surface-functionalized with two different functional groups. The different surface chemistry changes the liquid-mediated MP-to-substrate forces acting during close-to-surface transport, resulting in significant variations in the experimentally observable MP velocity. More specifically, superparamagnetic MPs measuring 2 micrometre in diameter with a polymer coating of solely carboxyl (COOH) end groups, or a mixture of carboxyl and amino (NH2) groups, respectively, have been studied. Transport of these MPs above a magnetic stripe domain pattern in double-distilled water showed a remarkable difference in their average velocities, rendering the COOH-functionalized MPs almost twice as fast as the NH2 counterparts for otherwise identical experimental parameters. This result enables the magnetophoretic separation of MPs based on their surface properties.

MA 36.5 Wed 16:00 POT/0151

Magnetic cuboidal particles as field sensors for microscaled magnetic stray field landscapes — •Jonas Bugase, Christian Janzen, Arne Vereijken, Yahya Shubbak, Nikolai Weidt, Rico Huhnstock, and Arno Ehresmann — Institute of Physics , University of Kassel, 34132 Kassel

Recently, magnetic domain patterns engineered in thin-film systems have been widely used in data storage, spintronics, and magnetic imaging. Characterizing the micron-scale magnetic stray fields emerging from these patterns remains a topical but challenging task [1]. We present a non-mechanical, optically trackable method to visualize effective magnetic field directions using anisotropically shaped magnetic particles. These particles are fabricated via 2-photon polymerization lithography and magnetic exchange-biased layer deposition to achieve custom shapes and anisotropies. When positioned in the field landscape of a periodically patterned substrate [2] within a quiescent liquid, the particles spontaneously orient and reorient in response to local micron-scale stray fields. This enables efficient characterization of complex magnetic domain patterns. We further explore probing local field variations with superimposed external fields facilitating diagnostic and biomedical microfluidic applications [3].

Metal-free magnetism and organic 2D crystals — •Hongde Yu and Thomas Heine — TU Dresden, Dresden, Germany

Organic 2D crystals with metal-free magnetism have attracted considerable research interest owing to their promising applications in organic spintronics and quantum information technologies. However, achieving stable spin-polarization and controlling magnetic interactions in these systems remains challenging due to strong electronic coupling and the closed-shell nature of most organic monomers. In this talk, I will present a strategy to induce spin-polarization and tailor magnetic interactions in organic 2D crystals. By assembling triangulene monomers into dimers and extended 2D polymers, we theoretically explore strategies to control magnetic interactions and electronic structures. We showed substantial magnetic coupling (J) up to -198 meV through rational chemical design of triangulene dimers. Furthermore, triangulene-based 2D crystals exhibit unique electronic features, including a Dirac point flanked by twin flat bands. By tuning the Fermi level, we predict metal-free ferromagnetism with Curie temperatures of ~260 K and half-metallic behavior. Furthermore, we proposed a mixed-topology design strategy enabling purely organic 2D FM semiconductors with J values up to 127 meV and Curie temperatures exceeding 500 K. Beyond conventional FM and AFM, I will also present a simple approach to achieve metal-free altermagnetism.

Modelling the Spin States of Frustrated Nanographenes and Their Dimers: Challenges & Insights — •Helen Preiss, Hongde Yu, and Thomas Heine — Dresden University of Technology, Germany

Metal-free magnetism is an emerging field with promising applications especially in quantum computing. Fundamentally, metal atoms are replaced by organic radicals as spin-carriers, which can be extended to 1D or 2D networks via suitable coupling reactions while possibly maintaining a long-range magnetic order. One class of such radical building blocks are the topologically frustrated nanographenes. For these, it is impossible to pair all π-electrons into alternating single and double bonds, resulting in an open-shell system. A prominent example is the recently synthesised Clar's goblet, a biradical with a singlet ground-state according to Lieb's theorem. We will show that BS-DFT fails to quantitatively predict the magnetic coupling in this molecule, and to describe its dimer even qualitatively, owing to the delocalised nature of the spin centres and their inherent multi-reference character, while higher level ab initio methods struggle with the sheer size of the systems. Alternatively, Clar's goblet may be thought of as two olympicenyl radicals fused together by a six-membered ring. Sublattice-balanced and C-C-linked olympicenyl dimers thus offer themselves as a comparable yet simpler system to study. By comparing both types of nanographene, we gain insights into the limitations of modelling the magnetic states and both inter- and intramolecular coupling of organic molecules with BS-DFT.

Tuning chiral-induced unidirectional spin-charge conversion via molecular organization — •Ashish Moharana[1], Zhitian Ling[2], Hao Wu[2], Tomasz Marszalek[2], and Angela Wittmann[1] — [1]Institut für Physik, Johannes-Gutenberg-Universität Mainz, 55099 Mainz, Germany — [2]Max Planck Institute for Polymer Research, Ackermannweg 10, 55128, Mainz, Germany

The observation of spin-dependent transmission of electrons through chiral molecules has led to the discovery of chiral-induced spin selectivity (CISS). The high efficiency of the spin filtering effect in chiral molecules has recently gained significant interest due to the high potential for novel hybrid molecule magnetic spintronics applications. However, the fundamental mechanisms underlying the CISS effect at the molecule-metal interface remain an open challenge. In our work, we explore spin-to-charge conversion at hybrid chiral helical nanographene and heavy metal interfaces. We demonstrate that spin-to-charge conversion in hybrid chiral heterostructures can be tuned by controlling the ordering, and crystallinity of helical nanographene molecules at the interface. We show a more than two-fold increase in interfacial CISS efficiency with increasing molecular crystallinity. Quantifying the impact of spin to charge as a function of the molecular structure reveals the role of the molecular design and organization in the spin filtering effect, paving the path toward the three-dimensional engineering of hybrid interfaces.

MA 36.9 Wed 17:15 POT/0151

Revealing molecular alignment in thin films of DyCu5 single-molecule magnets via XMCD — •David Anthofer, Ashish Moharana, Alexander Hagenow, Dominik Laible, Tristan Fischer, Eva Rentschler, Hans-Joachim Elmers, and Angela Wittmann — Johannes-Gutenberg Universität Mainz, Deutschland

Single-molecule magnets (SMMs) have recently gained significant interest due to their ability to retain magnetic information at the molecular level, offering potential applications in ultra-compact and high-density data storage devices. A crucial challenge hindering their application in technology is the integration with thin-film devices. To tackle this, we probe the magnetic properties of DyCu5 SMMs deposited by dip-coating on a gold surface, where layer thickness is controlled by rinsing or not rinsing the sample. Using X-ray magnetic circular dichroism combined with sum-rule analysis for 4f elements, we extract the spin and orbital moments of the central Dy3+ ion. Rotating the sample relative to the incident beam reveals magnetic anisotropy in the thin layer, indicating preferential molecular alignment at the interface. In thicker films, this anisotropy vanishes, suggesting that the molecules are ordered on top of the gold surface, but have a random orientation with increasing coverage. While engineering ordered molecular assemblies on surfaces is generally challenging, our results demonstrate that a readily accessible dip-coating protocol can induce ordered alignment in the low-coverage regime, providing a practical route toward incorporating SMMs into thin-film devices.

MA 36.10 Wed 17:30 POT/0151

Probing the magnetic behavior of the metastable high-spin state achieved by light-induced excited spin-state trapping in Fe (II) spin-crossover complexes — •Sangeeta Thakur[1], Marcel Walter[1], Tarek Al Said[2], Eike F. Kuhlemann[3], Clara W. A. Trommer[3], Torben Adam[3], Karsten Holldack[2], Felix Tuczek[3], and Wolfgang Kuch[1] — [1]Institut für Experimentalphysik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, 14109 Berlin, Germany — [3]Institut für Anorganische Chemie, Christian-Albrechts Universität zu Kiel, 24098 Kiel, Germany

The magnetic behavior of the metastable high-spin (HS) state of the Fe (II) complexes mononuclear [Fe(bpz)$_2$(bipy)]; (bpz = dihydrobis(pyrazolyl)borate) and dinuclear [(Fe(bpz)$_2$)$_2\mu$-(ac(bipy)$_2$)] (ac(bipy)$_2$ = bridging ligand) was investigated at 5 K by frequency-domain Fourier transform electron paramagnetic resonance (EPR) spectroscopy in a magnetic field of 1-10 T. The magnetic field map of the EPR measurements indicates a large value (70-90 cm^{-1}) of zero-field splitting (ZFS) for the dinuclear and mononuclear complexes. Comparatively, the HS-locked complexes [Fe(H$_2$B(pz)$_2$)$_2$(4,7-Me$_2$-phen)] and [Fe(tris(3-Methylpyrazolyl)borate)$_2$] exhibit values of ZFS around around 10-17 cm^{-1}. The large ZFS obtained for the dinuclear and mononuclear complexes could be due to the contribution of spin-orbit coupling (SOC). To the best of our knowledge, this is the first time the spin Hamiltonian parameters for Fe (II) SCO complexes were investigated in the metastable HS state.

MA 36.11 Wed 17:45 POT/0151

Insights into magnetic and magnetocaloric features of 3d-4f nonanuclear Gd3Cu6 complex from a mixed spin-(7/2, 1/2) Heisenberg diamond cluster — •Jozef Strecka and Katarina Karlova — Pavol Jozef Safarik University, Kosice, Slovakia

Low-temperature magnetization curves and magnetocaloric features of 3d-4f molecular complex [Gd3Cu6L6(OH)6(CH3OH)6(H2O)6]Cl3.5H2O (LH2 = 1,1,1-trifluoro-7-hydroxy-4-methyl-5-aza-hept-3-en-2-one) to be further abbreviated as Gd3Cu6 are examined within the framework of exact diagonalization method as well as the cluster-based mean-field theory. The magnetic compound Gd3Cu6 reveals in low-temperature magnetization curves an intermediate magnetization plateau at 21.27 Bohr magnetons, which is far below the saturated magnetization value of 27 Bohr magnetons expected for three spin-7/2 Gd3+ and six spin-1/2 Cu2+ magnetic ions per magnetic molecule. The crystal structure of the Gd3Cu6 complex is built from three condensed cubane-like moeties Gd2Cu2, which are from the magnetic point of view equivalent with three corner-sharing diamond motifs. The nonanuclear coordination compound Gd3Cu6 thus affords an intriguing experimental realization of the mixed spin-(7/2, 1/2) Heisenberg diamond chain composed from three unit cell. The magnetic compound Gd3Cu6 displays at sufficiently low temperatures an enhanced magnetocaloric effect, which is due to a geometric spin frustration quite superior with respect to that one of paramagnetic salts built from Gd3+ magnetic ions.

This work was supported by the grant APVV-24-0091.

MA 36.12 Wed 18:00 POT/0151

Suppressing geometric frustration in triangular dysprosium cluster encapsulated in fullerenes — •Matheus Barbosa, Wei Yang, Noel Israel, Fupin Liu, Bernd Büchner, Stanislav Avdoshenko, and Alexey Popov — Leibniz Institute for Solid State and Materials Research, Dresden/Germany

Nitride clusterfullerenes are compounds in which a metallic cluster is encapsulated within a fullerene cage, exhibiting diverse magnetic properties that depend on the composition and geometry of the endohedral cluster. For the case of $Dy_3N@C_{80}$, the presence of the central nitrogen ion induces a strong uniaxial Ligand Field contribution, locking the magnetic moments of dysprosium centers in a triangular arrangement. Such geometry avoids simultaneous ferromagnetic alignment of the moments between the dysprosium ions, leading to ground state frustration and exhibiting rather efficient spin reorientation through the Quantum Tunneling channel. Their magnetic and geometric frustration is harmful for the Single Molecule Magnetism, resulting in closed hysteresis loops in zero-field and at 2 K. We here report the suppression of this frustration by functionalization of the fullerene cage. The photochemical reaction of $Dy_3N@C_{80}$ with adamantane aziridine produced the monoadduct $Dy_3N@C_{80}$-Ad. This additional space inside the fullerene has direct influence on the cluster, elongating the atomic distance in the Dy-N bond towards the modified fragment (breaking the spatial symmetry) and substantially increasing the Dy*Dy coupling constants. As a result, the monoadduct $Dy_3N@C_{80}$-Ad exhibits suppression of the geometric frustration and enhanced Single Molecule Magnetism.

MA 36.13 Wed 18:15 POT/0151

Orientation of Magnetic Anisotropy Axes in Single Molecule Magnets by Inelastic Neutron Scattering: A Case Study on Mn_2Y_2 — •Yifan Wang[1], Christoper E. Anson[2], Zayan A. Ali[1], Annie K. Powell[2], and Oliver Waldmann[1] — [1]Physikalisches Institut, Universität Freiburg, Germany — [2]Institut of Inorganic Chemistry, Karlsruhe Institute of Technology (KIT), Germany

Single molecule magnets (SMMs) are molecular systems that exhibit slow magnetic relaxation and well-defined spin states arising from strong magnetic anisotropy. These features give them potential for future information storage and have attracted much research interest. However, determining the magnetic parameters experimentally, especially the anisotropy orientations, remains challenging. In this work, we demonstrate, with regard to this point, the capability of inelastic neutron scattering (INS) on powder samples through a case study on the dimeric molecular spin cluster Mn_2Y_2. This complex belongs to a family of SMMs and consists of two magnetic spin-2 Mn^{III} ions coupled by antiferromagnetic exchange. The recorded INS spectrum on Mn_2Y_2 displays three cold transitions corresponding to singlet-triplet excitations. The transition energies enable a precise determination of the exchange coupling and the anisotropy magnitudes of the Mn^{III} centers. Most interestingly, a detailed analysis of the peak intensities is shown to yield, in addition, information on the orientation of the Mn^{III} magnetic anisotropy axes. The approach can be generally extended to related SMM families and provides a valuable addition to the range of experimental techniques.

MA 37: Non-Skyrmionic Magnetic Textures

MA 37.1 Wed 15:00 POT/0351

Regularized micromagnetic theory for Bloch points — •Vladyslav M. Kuchkin[1], Andreas Haller[1], Andreas Michels[1], Thomas L. Schmidt[1], and Nikolai S. Kiselev[2] — [1]Department of Physics and Materials Science, University of Luxembourg — [2]Peter Grünberg Institute, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

Magnetic singularities, known as Bloch points, pose a significant challenge for the micromagnetic theory due to the divergence of the effective field at these points. In this talk, we present a recently developed regularized micromagnetic model that does not assume a fixed magnetization length, but treats magnetization as an order parameter on the $\mathbb{S}^3$ sphere, thus allowing it to vary in length from zero up to a threshold value. Such an extension of micromagnetics respects the fundamental properties of local spin expectation values in quantum systems. Relying on the $\mathbb{S}^3$ order parameter, we derive Landau-Lifshitz-Gilbert and Thiele equations and apply them to the dynamics of several spin textures: domain walls in nanowires, chiral bobbers, and magnetic dipole strings. The results demonstrate how the extended formalism accounts for the dynamics of Bloch points observed experimentally and open up prospects for modeling complex spin structures, including the nucleation and annihilation of topological states such as skyrmions and hopfions.

MA 37.2 Wed 15:15 POT/0351

Magnetoelastic Fingerprints in Dysprosium Iron Garnet Thin Films: Inversion of Effective Local Anisotropy within Domain Walls — •Lukas D. Ćavar[1], Julian Skolaut[2], Olena Gomonay[1], Miela J. Gross[3], Khang Vi Becker[1], Simon J. Sochiera[1], Dirk Backes[4], Caroline A. Ross[3], and Angela Wittmann[1] — [1]Johannes Gutenberg Universität, Mainz, DE — [2]Christian-Albrechts-Universität zu Kiel, DE — [3]Massachusetts Institute of Technology, Cambridge, MA, USA — [4]Diamond Light Source, Oxfordshire, UK

A promising direction for future computing devices is to embed topological spin textures in compensated collinear magnetic systems. Yet in the absence of significant stray fields, these textures must be stabilized unconventionally. While we observe a wide variety of topological textures in magnetoelastic systems, including the altermagnet α-Fe2O3 ('hematite') and the ferrimagnet dysprosium iron garnet (DyIG), their specific origin is not clear. Here, we compare Néel vector mapping via x-ray magnetic linear dichroism photoemission electron microscopy and stray-field imaging by scanning nitrogen vacancy center magnetometry to show that the DyIG 360° domain wall profile exhibits significant deviations from the classical domain wall profile. These are consistent with an inversion of the effective local anisotropy, i.e. the easy and hard axes trading places within the domain wall body. Thereby we obtain quantitative insight into the mechanism, scale, and energetics of the magnetoelastic stabilization of topological textures in thin films with strong magneto-elastic coupling and uncover a new degree of straintronic freedom for next-generation spin devices.

MA 37.3 Wed 15:30 POT/0351

Hopfions in Symmetry-Transformed Magnetic Models — •Sandra Chullipparambil Shaju, Maria Azhar, and Karin Everschor-Sitte — Faculty of Physics and CENIDE, University of Duisburg-Essen

Three-dimensional (3D) topological spin structures continue to attract significant interest due to their rich physics and potential for future information technologies. We present a systematic framework of continuously transformed models that enables the stabilisation of topologically non-trivial 3D spin configurations. By applying this approach, we construct an effective model that hosts Hopfions embedded in a ferromagnetic background, with distinct energetic and dynamical characteristics. Our results provide new routes for investigating the formation, stability, and dynamics of three-dimensional topologically non-trivial textures.

MA 37.4 Wed 15:45 POT/0351

Fractional Hopfions in Composite Magnets — •Sanjay Ashok and Jan Masell — Karlsruhe Institute of Technology (KIT), Karlsruhe

Hopfions are three dimensional magnetization textures studied due to their unique physical-, topological properties and their functionalization prospects [1]. These textures are usually doughnut shaped and classified by their integer topological winding number called Hopf index. In our work, we demonstrate that hopfions with fractional Hopf index, called fractional hopfions [2, 3], can be stabilized in composite magnets. We identify a two-slab composite magnet with slab-dependent Dzyaloshinskii-Moriya interaction (DMI) as a suitable material platform for stabilizing fractional Hopfions. We further distinguish the role of Bloch-, Neel- and Antiskyrmion-type DMI in composite magnets and their effect on the winding of fractional hopfions [4]. By studying the phase diagram of fractional hopfions we predict the range of external magnetic field and uniaxial anisotropy where these textures can be found.

MA 37.5 Wed 16:00 POT/0351

Acoustically-driven manipulation of magnetic textures in epitaxial ferromagnetic thin-films — •João Pedro Leite Gomes, Jens Herfort, and Alberto Hernández-Mínguez — Paul-Drude-Institut für Festkörperelektronik - Leibniz-Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, 10117 Berlin, Germany

Recent advances in information technology have driven the research towards more reliable storage devices, while striving for ever higher memory densities. One drawback of current spintronic technologies for information recording is the need for large spin-polarized currents to access/write information in magnetic materials, leading to less energy-efficient devices. An alternative proposal to achieve controlled magnetization switching is to make use of the magnetoelastic (ME) interaction, for example, through the excitation of surface acoustic waves (SAW) in piezoelectric substrates.

In this contribution, we report SAW-driven manipulation of domain walls (DWs) in epitaxial ferromagnetic thin-films with both cubic and uniaxial magnetic anisotropies along well-defined crystalline directions. Micromagnetic simulations model the physical mechanism by which the tickling magnetic field generated by the strain modulation, via the ME interaction, can result in the local switching of the DWs. We discuss how much SAWs are a feasible approach to achieve magnetization switching and/or promote DW pinning in single crystal ferromagnetic thin-films.

MA 37.6 Wed 16:15 POT/0351

Control of helix orientation in chiral magnets via lateral confinement — •Maurice Colling[1], Mariia Stepanova[1], Mario Hentschel[2], Erik Lysne[1], Kasper Hunnestad[1], Naoya Kanazawa[3], Yoshinori Tokura[3,4], Jan Masell[4,5], and Dennis Meier[1] — [1]Department of Materials Science and Engineering, NTNU Norwegian University of Science and Technology, Trondheim, Norway — [2]Physics Institute and Research Center SCoPE, University of Stuttgart, Stuttgart, Germany — [3]Department of Applied Physics, University of Tokyo, Tokyo, Japan — [4]RIKEN Center for Emergent Matter Science (CEMS), Wako, Japan — [5]Institute of Theoretical Solid State Physics, Karlsruhe Institute of Technology, Karlsruhe, Germany

Helimagnetic materials offer a versatile platform for spin-based device concepts due to their long-range, tunable spiral order. This talk demonstrates control of the helimagnetic propagation vector q via geometrical confinement, using FeGe as a model DMI-driven chiral magnet. Micromagnetic simulations based on the nonlinear sigma model show that open boundaries generate a chiral surface twist that acts as an effective surface anisotropy selecting the helix orientation. This behavior is captured well by an analytical model derived from the DMI boundary condition. Magnetic force microscopy on focused ion beam structured FeGe confirms the predicted orientation and establishes geometry-controlled helimagnetic order as a robust mechanism for steering DMI-stabilized spin-spiral states. The concept provides a route to device-level control of chiral magnetic textures.

MA 37.7 Wed 16:30 POT/0351

Magnetization dynamics of twists in (anti-)ferromagnetic insulators — Patricia Oehrl[1,2], Mathew James[3], Luca Maranzana[4], Andreas Bauer[2], Denis Mettus[2], Christian Pfleiderer[2], Christian Back[2], Sergey Artyukhin[4], Hans Huebl[1,2], and •Aisha Aqeel[3] — [1]Walther-Meißner-Institut, 85748 Garching, Germany — [2]Technical University of Munich, 85748 Garching, Germany — [3]University of Augsburg, 86159 Augsburg, Germany — [4]Quantum Materials Theory, Italian Institute of Technology, Via Morego 30, Genoa, Italy

Magnetic insulators hosting noncollinear spin textures display a remarkable variety of static and dynamic phenomena. In chiral systems such as Cu2OSeO3, the lack of inversion symmetry gives rise to helices and skyrmions stabilized by Dzyaloshinskii-Moriya interactions [1]. By contrast, in centrosymmetric compounds like CuSeO3, complex antiferromagnetic spiral states can emerge purely from competing symmetric exchange interactions, providing an intriguing platform to explore magnetism without intrinsic chirality. In this talk, I will present our preliminary results on dynamic excitation of these textures in chiral Cu2OSeO3 and centrosymmetric CuSeO3 magnets using magnetic resonance spectroscopy [2].

MA 37.8 Wed 16:45 POT/0351

Extraordinary return point memory in ferrimagnetic materials — •Tamer Karaman[1], Kai Litzius[1], Aladin Ullrich[1], Riccardo Battistelli[1], Manas Patra[1,2], Raluca Boltje[1], Miela Gross[2], Steffen Wittrock[2], Krishnanjana Joy[1], Daniel Metternich[2], Sebastian Hoffman[1], Timo Schmidt[1], Daniel Perez[3], Manuel Valvidares[3], Sebastain Wintz[2], Manfred Albrecht[1], and Felix Büttner[1,2] — [1]University of Augsburg, Germany — [2]Helmholtz-Zentrum Berlin, Germany — [3]ALBA Synchrotron Light Source, Spain

Magnetic domains and domain walls are promising information carriers, widely explored for racetrack memory [1] and other mobility applications [2]. In this study, we demonstrate deterministic magnetic-domain nucleation in rare-earth transition-metal (RE-TM) ferrimagnetic systems. Remarkably, the as-grown domain configuration serves as an intrinsic template that reappears with 100% return-point memory after repeated out-of-plane magnetic-field cycling. Even more surprisingly, the full domain pattern can be toggle switched using extremely small in-plane fields near 0 mT, while the overall domain morphology remains unchanged. These findings point to new opportunities in cryptography and other technologies requiring deterministic pattern reproducibility, and they highlight the importance of further exploring properties of RE-TM ferrimagnets. MA 37.9 Wed 17:00 POT/0351

Microscale coexistence of magnetic phases compatible with the Kagome spin-ice rule in HoAgGe — •Manuel Zahn[1,2], Kan Zhao[3], Philipp Gegenwart[1], Sándor Bordács[4], and István Kézsmárki[1] — [1]Center for Electronic Correlation and Magnetism, University of Augsburg, Augsburg, Germany — [2]Norwegian University of Science and Technology, Trondheim, Norway — [3]School of Physics, Beihang University, Beijing, China — [4]Department of Physics, Budapest University of Technology and Economics, Budapest, Hungary

HoAgGe realizes kagome spin-ice with a series of fractionalized magnetization plateau states for applied in-plane magnetic fields [1]. Corresponding magnetoresistance and Hall effect reveal a hysteresis at the plateau states, indicating field-history dependent occupation of magnetic domains with opposite chirality and Berry curvature [2].

In the presented study, we investigate the microscale magnetic patterns, using low-temperature atomic force microscopy to visualize possible phase coexistence. By studying different crystal cuts and varying magnetic fields using a vector magnet, we reconstruct the full 3D magnetic texture of phase coexistence. Our results provide insights into the interplay of geometrical, topological and frustrated properties of spin ice materials and demonstrate pathways for external manipulation of magnetic textures in highly-frustrated systems.

Ultrafast light-induced spin and orbital moment in nonmagnetic band insulators from RT-TDDFT — •Andri Darmawan, Markus E. Gruner, and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen

Recently dynamical multiferroicity was predicted in $SrTiO_3$ as well as $KTaO_3$ [1-2] and subsequently observed experimentally in $SrTiO_3$ [3], employing THz circularly polarized pulse. This is particularly intriguing as $SrTiO_3$ and $KTaO_3$ are nonmagnetic band insulators with d^0 occupation at Ti and Ta. Here, using real-time time-dependent density functional theory (RT-TDDFT) as implemented in the Elk code we employ optical circularly polarized laser pulses to investigate laser-induced spin and orbital moment in $SrTiO_3$ and $KTaO_3$. We study systematically the dependence on the laser parameters and find that duration and frequency of the pulse strongly influence the behavior of the light-induced spin and orbital magnetic moment in both $SrTiO_3$ and $KTaO_3$. While in $SrTiO_3$ the induced orbital momentum predominates, at certain frequencies $KTaO_3$ exhibits both substantial light-induced spin moment and orbital moment.

Funding by DFG within CRC1242 (project C02) and computational time at magnitUDE, amplitUDE are gratefully acknowledged.

Interfacial magnon generation drives ultrafast spin dynamics in Gd — •Corvin Krohn[1], Ekaterina Bobrova[1], Tim Amrhein[1], Dominic Lawrenz[1], Niko Pontius[2], Christian Schüssler-Langeheine[2], Martin Weinelt[1], and Nele Thielemann-Kühn[1,2] — [1]Freie Universität Berlin, Berlin, Germany — [2]Helmholtz-Zentrum Berlin, Berlin, Germany

Previous time-resolved photoemission [1] and x-ray magnetic circular dichroism (XMCD) [2] experiments investigating 4*f* magnetization dynamics in Gadolinium (Gd) showed conflicting results, with demagnetization timescales of 14 ps [1] and 0.7 ps [2], respectively.

Within an XMCD study at the FemtoSlicing facility, we could now show that intrinsic dynamics in Gd is slow. For a thin Gd film, however, where the pump laser directly excites the non-magnetic substrate as well, generation of magnons at the metal-substrate interface drives the ultrafast demagnetization.

In the next step we aim to identify magnons as m_s state excitations within the Gd 4*f* electronic ground level, using time-resolved x-ray absorption spectroscopy.

Revealing signatures of magnetic dynamics in the electronic structure will provide insights into the correlated electronic and magnetic structure of 4*f* metals.

MA 38.3 Wed 15:30 POT/0361

Probing ultrafast dynamics of artificial antiferromagnets by soft-x-ray diffraction — •Jasmin Jarecki[1], Martin Borchert[1], Stefan Eisebitt[1,2], and Daniel Schick[1] — [1]Max-Born-Institut für Nichtlineare Optik & Kurzzeitspektroskopie, Berlin, Germany — [2]Institut für Optik & Atomare Physik, TU Berlin, Germany

Ordering phenomena in solids encode key information about microscopic interactions and subsystem coupling. In magnetic materials, magnetic and structural order can be strongly coupled, yet the corresponding periodicities may exhibit different characteristic lengths. This calls for methods capable of simultaneously probing lattice and spin degrees of freedom to disentangle phonon and spin dynamics.

Using on- and off-resonant ultrafast x-ray diffraction (UXRD) in the soft-x-ray regime, we investigate the coupled structural and magnetic dynamics of a Fe/Cr superlattice (SL), an artificial antiferromagnet in which adjacent Fe layers adopt alternating magnetization directions for the chosen Cr spacer thickness. By tracking the structural and magnetic SL Bragg peaks, we study photon-energy- and fluence-dependent dynamics via their transient peak positions and intensities. While the structural peak shift and the magnetic peak intensity follow the expected behavior, the magnetic peak shift deviates markedly from the structural response and, in particular, does not exhibit the anticipated linear fluence dependence. These findings highlight the strong intercoupling between depth-dependent sample dynamics and depth-dependent probing, underscoring the need for careful analysis and modeling to reliably extract microscopic dynamics from UXRD.

MA 38.4 Wed 15:45 POT/0361

Double-pulse all-optical magnetization re-switching of GdFe — Rahil Hosseinifar[1], Felix Steinbach[2], Ivar Kumberg[1], José Miguel Lendínez[3], Sangeeta Thakur[1], Sebastien E. Hadjadj[1], Jendrik Gördes[1], Chowdhury S. Awsaf[1], Mario Fix[4], Manfred Albrecht[4], Florian Kronast[5], Unai Atxitia[3], Clemens von Korff Schmising[2], and •Wolfgang Kuch[1] — [1]Freie Universität Berlin, Berlin, Germany — [2]Max-Born-Institut, Berlin, Germany — [3]ICMM-CSIC, Madrid, Spain — [4]Universität Augsburg, Augsburg, Germany — [5]Helmholtz-Zentrum Berlin, Berlin, Germany

The reversible helicity-independent switching of the magnetization direction of ferrimagnetic materials like GdFe by individual sub-ps optical laser pulses bears the potential to accelerate magnetic data storage. We present a systematic Kerr-microscopy domain-imaging study of a 10 nm $Gd_{26}Fe_{74}$ film after excitation with two laser pulses with a certain time delay in between. Our results show that when the fluence of the first pulse is adjusted just above the threshold of single-pulse switching, a second pulse with about 60% of the fluence of the first pulse, arriving only 4 ps later, can already switch the magnetization back [1]. Atomistic spin dynamics simulations reproduce the experimental results and show that under these conditions the magnetizations of the Fe and Gd sublattices have already moved sufficiently away from zero when the second pulse hits the sample, a prerequisite for fast re-switching.

MA 38.5 Wed 16:00 POT/0361

Light-induced ultrafast magnetization dynamics driven by chiral phonons — •Shiqi Hu and Sangeeta Sharma — Max-Born Institute for Nonlinear Optics and Short Pulse Spectroscopy,Berlin,Germany

The pursuit of high-speed, low-power information processing is driving advanced research into ultrafast laser control of magnetic order. Going beyond conventional approaches that rely on heterojunctions for spin-current injection, this work demonstrates direct manipulation of magnetism in bulk materials

through intrinsic interactions. Using circularly polarized laser excitation, we generate THz chiral phonons in the non-collinear antiferromagnet Mn3Sn with a Kagome lattice. The angular momentum of these phonons produces an effective magnetic field, inducing coupled in-plane and out-of-plane spin precession that reorients the magnetic octupole. This reorientation, in turn, modulates the topological properties of Weyl points. Spin*orbit coupling and the rotational motion of chiral phonons are shown to be essential to this mechanism. We attribute the observed spin dynamics to a competition between the phonon-induced effective field*favoring ferromagnetic alignment*and the intrinsic antiferromagnetic spin interactions in the Kagome lattice. These findings open a new pathway for controlling magnetic topology.

MA 38.6 Wed 16:15 POT/0361

Exploring the ultrafast change of antiferromagnetic and ferromagnetic order in a Mn_2Au/Py bilayer — •Jendrik Gördes[1], Markus Weissenhofer[1,2], Sangeeta Thakur[1], Chowdhury S. Awsaf[1], Marcel Walter[1], Lorenzo Grilli[1], Deeksha Gupta[3], Niko Pontius[3], Christian Schüssler-Langeheine[3], Peter M. Oppeneer[2], Martin Jourdan[4], and Wolfgang Kuch[1] — [1]Freie Universität Berlin, Berlin, Germany — [2]Uppsala University, Uppsala, Sweden — [3]Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — [4]Johannes Gutenberg-Universität Mainz, Mainz, Germany

Antiferromagnetic (AFM) materials are promising candidates for future data storage devices. One noteworthy material is Mn_2Au, a metallic collinear AFM that can be electrically switched [1]. We report on the time-resolved change of AFM and ferromagnetic (FM) order of a Mn_2Au/permalloy (Py) bilayer after excitation with 800 nm fs laser pulses by X-ray magnetic linear and circular dichroism (XMLD and XMCD) in resonant soft X-ray reflectivity at the Mn and Fe L_3 edges. We observe an ultrafast loss and an exceptionally fast recovery of the AFM order within a few ps, much faster than the recovery of the adjacent FM order. Local and non-local mechanisms are considered in simulations using an atomistic spin model. The presented research highlights the fast dynamics of AFM layers for spintronic applications. [1] J. Železný, H. Gao, K. Výborný et al., PRL 113, 157201 (2014)

MA 38.7 Wed 16:30 POT/0361

Intrinsic timescales of ferro- and antiferromagnets in ultrafast demagnetisation — •Tobias Dannegger[1], Stephan Wust[2], Paul Herrgen[2], Martin Aeschlimann[2], Benjamin Stadtmüller[3], and Ulrich Nowak[1] — [1]Fachbereich Physik, Universität Konstanz, Konstanz, Germany — [2]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, Kaiserslautern, Germany — [3]Experimentalphysik II, Institute of Physics, University of Augsburg, Germany

For small deviations from the ground state, the spin dynamics of a magnetically ordered material can be described within linear spin-wave theory. There is a well known difference between the intrinsic timescales, given by the eigenfrequencies, of ferro- and antiferromagnets, the latter being approximately two orders of magnitude faster. Here, we present a systematic investigation, based on atomistic spin dynamics simulations, of how ferro- and antiferromagnetic ordering affects the intrinsic timescales of the magnetic order parameter far away from equilibrium, such as in ultrafast light-induced quenching experiments. We find that the speed advantage of antiferromagnets persists in the strongly non-equilibrium regime, but with some striking qualitative differences for very large excitations, where antiferromagnets slow down while the ferromagnetic quenching efficiency increases again.

15 min break

MA 38.8 Wed 17:00 POT/0361

Field-tuning of ultrafast magnetization fluctuations in $Sm_{0.7}Er_{0.3}FeO_3$ — •Julius Schlegel[1], Marvin Alexander Weiss[1], Daniel Anić[1], Emil Steiner[1], Franz Stefan Herbst[1], Makoto Nakajima[2], Takayuki Kurihara[3], Alfred Leitenstorfer[1], Sebastian T.B. Goennenwein[1], and Ulrich Nowak[1] — [1]Department of Physics, University of Konstanz, Germany — [2]Institute of Laser Engineering, Osaka University, Japan — [3]Department of Basic Science, The University of Tokyo, Japan

The missing stray field and the vanishing net magnetization make it challenging to investigate antiferromagnetic dynamics experimentally. Nevertheless, thermal magnetization fluctuations persist in antiferromagnets and can be exploited to gain insights into their dynamics [1].

In this work, we investigate these fluctuations in the canted antiferromagnet $Sm_{0.7}Er_{0.3}FeO_3$ under the influence of an external magnetic field [2]. Using femtosecond noise-correlation spectroscopy combined with atomistic spin-dynamics simulations, we examine the spin noise in the vicinity of the magnetic reorientation transition.

We demonstrate that the external magnetic field suppresses characteristic features of critical fluctuations, such as a diverging noise amplitude. Moreover, it enhances the quasi-ferromagnetic magnon frequency near the reorientation transition. Our results offer a means to tune ultrafast spin fluctuations via experimentally accessible external parameters.

MA 38.9 Wed 17:15 POT/0361

Large strain contribution to the laser-driven magnetization response of magnetostrictive $TbFe_2$ — •Constantin Walz[1], Fried-C. Weber[1,2], Steffen-P. Zeuschner[1], Karine Dumesnil[3], Alexander von Reppert[1], and Matias Bargheer[1,2] — [1]Institut für Physik und Astronomie, Universität Potsdam, Potsdam, Germany — [2]Helmholtz-Zentrum Berlin, Berlin, Germany — [3]Institut Jean Lamour, Université de Lorraine, Nancy, France

Rare Earth-Iron compounds ($REFe_2$ with $RE = \mathrm{Tb}, \mathrm{Dy}, \mathrm{Tb_{0.3}Dy_{0.7}}$) are well known for their giant (inverse) magnetostriction, exhibiting lattice-constant changes exceeding 10^{-3} at saturation. While they are widely used as ultrasonic transducers in the MHz regime, their ultrafast magnetization dynamics remain less explored.

We investigate the strain-driven magnetization dynamics in $TbFe_2$ using time-resolved magneto-optical Kerr effect (trMOKE) and optical reflectivity measurements. The delayed strain response in the trMOKE signal indicates a true magnetic origin of these features, ruling out instantaneous changes of the optical constants. In addition, we show that glass-capped sample structures efficiently transduce unipolar strain pulses, which we use to calibrate the contribution of quasi-static-strain-induced magnetization dynamics to the total signal. Modeling with a Landau-Lifshitz-Gilbert equation including a time-dependent magneto-elastic field reproduces the observations and demonstrates that strain can even provide the dominant contribution to the laser-driven magnetization dynamics.

MA 38.10 Wed 17:30 POT/0361

All-optical stochastic switching of magnetisation textures in Fe3Sn2 — •Andras Kovacs[1], Jonathan Weber[2], Michalis Charilaou[3], Rafal Dunin-Borkowski[1], and Sascha Schaefer[2] — [1]Ernst Ruska-Centre, Forschungszentrum Jülich, Germany — [2]Regensburg Center for Ultrafast Nanoscopy, University of Regensburg, Regensburg, Germany — [3]Department of Physics, University of Louisiana at Lafayette, USA

We utilize femtosecond optical pulses to alter the helicity of the magnetic spin configuration in dipolar skyrmions formed in the kagome magnet Fe3Sn2 in the absence of an external magnetic field and at room temperature. In situ Lorentz transmission electron microscopy is used to visualise the light-induced stochastic switching process of chiral Néel caps, while the internal Bloch component of the dipolar skyrmions remains unchanged. To corroborate the spin states and the light-induced magnetisation dynamics, micromagnetic modelling and simulations of the resulting electron phase shift maps are conducted to elucidate the spin rearrangement induced by individual femtosecond optical pulses [1]. We acknowledge the scientific support to D. Kong, L. Prodan, V. Tsurkan, A. Schroder, N. Kiselev, I Kezsmarki, A. Tavabi and the financial support to EU grant No. 856538. [1] A. Kovacs etal, Comm. Mater. 6, 223 (2025)

MA 38.11 Wed 17:45 POT/0361

Nonlinear spin and orbital Rashba–Edelstein effects induced by a femtosecond laser pulse: Simulations for Au(001) — Oliver Busch, •Franziska Ziolkowski, Börge Göbel, Ingrid Mertig, and Jürgen Henk — Martin-Luther-Universität Halle-Wittenberg, 06099 Halle, Germany

Rashba-type spin-orbit coupling gives rise to distinctive surface and interface phenomena, such as spin-momentum locking and spin splitting. In nonequilibrium conditions, it manifests e.g., as the Rashba–Edelstein effect, where an electric current generates a net spin or orbital polarization perpendicular to the current direction. While the steady-state behavior of these effects is well studied, their dynamics on ultrafast timescales remain largely unexplored.

We theoretically investigate the ultrafast spin and orbital Edelstein effects on an Au(001) surface, induced by femtosecond laser excitation [1]. These effects are intrinsic and inherently nonlinear. We simulate the ultrafast electron dynamics in response to the laser pulse by using a real-space tight-binding model combined with unitary time evolution of the density matrix.

Our results reveal pronounced differences between the spin and orbital responses and quantify the resulting charge, spin, and orbital currents, including laser-induced spin and orbital Hall effects. These findings provide insights into ultrafast angular momentum transfer mediated by the light-matter interaction and offer guidance for the design of next-generation spintronic and orbitronic devices.

MA 38.12 Wed 18:00 POT/0361

Impact of Structural Imperfections on the Ultrafast Orbital Hall Effect in Metallic Nanoribbons — •Theresa Albrecht, Franziska Ziolkowski, Börge Göbel, Ingrid Mertig, Jürgen Henk, and Samir Lounis — Institut für Physik, Martin-Luther-Universität, D-06099 Halle

The ultrafast orbital Hall effect (UOHE) arises when a femtosecond laser pulse drives a transient orbital current. We investigate how structural defects affect the UOHE in a Cu nanoribbon [1]. Using Evolve, a real-space tight-binding framework for finite systems [2], we simulate the laser-induced electron dynamics and

compute the orbital angular momentum (OAM) and its associated currents with atomic resolution. Defects significantly alter the OAM landscape: while defect-free ribbons exhibit pronounced edge accumulation, imperfections redistribute OAM toward defect sites and progressively suppress edge signatures as their number increases. Furthermore, we analyze the phase relation between the p- and d-orbital contributions to the OAM in interface geometries. Our results reveal the pivotal influence of defects on ultrafast orbital transport and dynamics.

MA 38.13 Wed 18:15 POT/0361

Pump-induced out-of-equilibrium magnetism in the Mott insulator CuO — •Katja Sophia Moos[1,2], Yun Yen[2], Gian Parusa[1,2], Arnau C. Romaguera[3], Elia Razzoli[3], Hiroki Ueda[3], and Michael Schüler[1,2] — [1]Department of Physics, University of Fribourg, 1700 Fribourg, Switzerland — [2]Center for Scientific Computing, Theory and Data, Paul Scherrer Institute, 5232 Villigen PSI, Switzerland — [3]Center for Photon Science, Paul Scherrer Institute, 5232 Villigen PSI, Switzerland

Understanding ultrafast magnetism requires tracking energy flow among coupled electronic, spin, and lattice subsystems. Using time-resolved resonant diffuse scattering combined with complementary X-ray techniques and quantum-kinetic simulations, we reveal microscopic pathways of pump-induced demagnetization in the antiferromagnetic Mott insulator CuO. Above-bandgap photoexcitation creates non-thermal magnons across the Brillouin zone within tens of femtoseconds, followed by magnon-magnon scattering driving quasi-thermalization within picoseconds. Magnetic recovery occurs via magnon-phonon coupling on nanoseconds, constrained by dispersion mismatches imposing intrinsic bottlenecks. Our momentum-resolved quantum Boltzmann simulations establish a hierarchical energy-transfer framework beyond phenomenological multi-temperature models, reproducing key features of the experiments. This approach provides design principles for controlling non-equilibrium magnetic states and highlights time-resolved resonant diffuse scattering as a power tool for ultrafast quantum materials research.

MA 38.14 Wed 18:30 POT/0361

Ultrafast spin and pure spin currents — •Deepika Gill, Sam Shallcross, and Sangeeta Sharma — Max-Born-Institut für Nichtlineare Optik und Kurzzeitspektroskopie, Max-Born-Strasse 2A, 12489, Berlin, Germany

Pure spin currents, the flow of spin in the absence of charge flow, represent a promising route toward energy efficient next-generation electronics [1]. Creating such currents often involves designed nano-structures, which can be challenging to create in experiment. Here, relying only on intrinsic material properties, we shift the design to the light pulse via two schemes: (1) via anti-symmetric laser pulses [2] and (2) via composite light pulses that generate pure spin current by tailoring spin density occupation in momentum space [3]. We provide realistic material examples including WSe2 and calculate the ultra-fast spin current response both via state-of-the-art time density function theory as well as Wannier parameterized tight-binding calculations.

MA 39.1 Wed 18:00 P2

Observation of negative orbital torque from Vanadium — •Jose Omar Ledesma Martin[1], Nikhil Vijayan[1], Durgesh Kumar[1], Ao Du[1], Lei Gao[2], Zijie Xiao[2], Hai I. Wang[2], Rahul Gupta[1], Gerhard Jakob[1], Sachin Krishnia[1], Yuriy Mokrousov[1,3], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Germany — [2]Max Planck Institute for Polymer Research, Germany — [3]Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Germany

Vanadium is predicted to exhibit a large orbital Hall effect. This effect is measured using ST-FMR, second-harmonic Hall, and THz emission, and all techniques reveal a negative orbital torque, in contrast to previous predictions and measurements that report a positive sign. The consistency in the results suggests the intrinsic origin of the OHE in our V samples. The torque magnitude depends strongly on the choice of ferromagnet: FeCoB/V, sensitive mainly to SHE-driven currents, shows only a weak response, whereas Ni/V, which efficiently converts OHE-driven currents, exhibits a torque nearly seven times larger. The torque increases with V thickness while remaining negative, and the extracted parameters indicate a large negative orbital Hall conductivity and long orbital diffusion length. Our results show that V generates strong orbital Hall currents with minimal spin Hall contribution and that itinerant interfacial orbital currents play a decisive role in determining both the efficiency and the sign of the torque (1).

MA 39.2 Wed 18:00 P2

Transport and spin torque in van der Waals heterostructures — •Nils Stüber[1], Sadeed Hameed[1], Aditya Kumar[1], Xinran Wang[1], Durgesh Kumar[1], Aravind Puthirath Balan[1], and Mathias Kläui[1,2] — [1]Institute of Physics, Johannes Gutenberg-Universität, Mainz, Germany — [2]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway

Graphene serves as an ideal spin-transport channel due to its long spin relaxation times and possible near-ballistic transport. In Ni/Gr heterostructures, the strength of the Spin Hall effect can be tuned via gate voltage, enabled by the Dirac-cone band structure.

In this work, we investigate spin-current generation in graphene induced by proximity-driven spin-orbit coupling (SOC) from epitaxially grown Ni(111). The SOC arises from hybridization between the graphene*s π-electrons and the Ni 3d orbitals.

We perform spin-torque ferromagnetic resonance (ST-FMR) to study the dependence of the spin-current signal on the Ni thickness and to identify the origin of the generated spin current. Additionally, THz emission experiments were carried out to detect the inverse Spin Hall effect in graphene, revealing a significantly different signal compared to CoFe/Gr heterostructures.

MA 39.3 Wed 18:00 P2

Tuning Spin-Charge Conversion at the hybrid heavy-metal/ organic semiconductor interface via Doping — Parul Devi[1], •Devamrutha I S[1], Zhitian Ling[2], Ashish Moharana[1], David Anthofer[1], Tomasz Marszalek[2], and Angela Wittmann[1] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz, Deutschland — [2]Max-Planck-Institut für Polymerforschung, Mainz, Deutschland

Spintronics, the way forward to device miniaturization, leverages electron spin rather than charge. Though inorganic materials were predominantly given more attention in spin transport studies, organic semiconductor (OSC)/magnetic hybrid interfaces are quickly gaining interest, owing to the flexibility, scalability, and structural tunability of organic materials. Here, we probe the role of the charge carrier concentration of the OSC on the spin injection and spin-charge conversion efficiency in hybrid heterostructures via spin pumping. For this, we probe the inverse spin Hall effect (ISHE) in a ferrimagnetic insulator/ heavy-metal/ OSC heterostructure and systematically dope the conjugated polymer PBTTT with F4-TCNQ. We observed that the ISHE amplitude in the heavy metal increases by a factor of 4 upon adsorption of the PBTTT layer while doping reduces the signal. These results open the door to charge doping as an effective tool to control spin injection across hybrid interfaces.

MA 39.4 Wed 18:00 P2

Chirality controlled quantum transport in kagome AV3Sb5 — •Li Cheng and Qun Yang — Max Planck Institute of Microstructure Physics

Kagome metals AV3Sb5 exhibit a rich interplay among charge-density waves (CDWs), structural chirality, unconventional superconductivity, and anomalous Hall transport. Recent theoretical progress shows that layer-dependent phase shifts between CDW wave vectors can generate helical stacking and chiral electronic structures, while experiments reveal strong correlations between chirality and anomalous charge transport. In parallel, distorted kagome compounds display intertwined CDW and magnetic orders with enhanced tunability under external stimuli.

Motivated by these developments, this project aims to establish a predictive first-principles framework that connects CDW chirality with spin/orbital polarization as well as anomalous transport, and to uncover the microscopic mechanisms driving anomalous Hall responses in kagome systems. We further propose to explore pressure, strain, and temperature as external knobs for switching chirality and controlling emergent electronic and magnetic functionalities.

MA 39.5 Wed 18:00 P2

Tunable Topological Spin Pump in the XXZ Chain via Incommensurate Boundary Drives. — •Anshuman Tripathi[1], Mircea Trif[2], and Thore Posske[1] — [1]I. Institute for Theoretical Physics, University of Hamburg, Hamburg, Germany — [2]International Research Centre MagTop, Institute of Physics, Polish Academy of Sciences, Warsaw, Poland

We investigate an interacting XXZ spin-1/2 chain driven quasiadiabatically at its boundaries by two incommensurate phase drives. The independently evolving

phases result in a quasi-periodic trajectory on a two-dimensional torus, which generates a robust topological spin pump in the ground state. We show that the pumped spin is determined by an effective Chern number defined over the drive-phase torus, whose value is set by the number of degeneracy points enclosed by the trajectory. These degeneracy points increase systematically with the chain length and can be tuned through the exchange anisotropy, providing direct control of the topological pumping strength. Our results demonstrate that incommensurate multi-tone driving enables a versatile and robust realization of topological pumps in interacting quantum spin chains.

MA 39.6 Wed 18:00 P2

Ab-initio calculated linear, quadratic and cubic magneto-optic Kerr effect spectra — •Martin Zeman[1], Maik Gaerner[2], Robin Silber[3], Martin Veis[1], Timo Kuschel[2,4], and Jaroslav Hamrle[1,5] — [1]Charles University Prague, Czech Republic — [2]Bielefeld University, Germany — [3]VSB - Technical University of Ostrava, Czech Republic — [4]Johannes Gutenberg University Mainz, Germany — [5]Czech Technical University, Prague, Czech Republic

The cubic magneto-optic Kerr effect originates from higher-order symmetry terms in cubic crystals. Using density-functional theory within WIEN2k, we calculate the linear, quadratic, and cubic MOKE contributions. First, the permittivity tensor is calculated for different magnetization orientations using the Kubo formula (linear response theory). Then, the individual contributions are separated using expected dependence on the magnetization direction, as predicted by the symmetry. Here we limit to ferromagnetic materials of cubic symmetry, bcc Fe, fcc Co, fcc Ni, and Heusler compounds Co_2FeSi and AuMnSb, whose magneto-optic response is described by principal spectra K, G_s, $2G_{44}$, and ΔH. Surprisingly, the strength of the cubic contribution ΔH is of similar order as the quadratic ones G_s, $2G_{44}$, which has also been confirmed by experimentally [1,2].

MA 39.7 Wed 18:00 P2

Application of 3D Nano-Lithography in Magnetism — •Jana Kredl[1], Christian Denker[1], Cornelius Fendler[2], Julia Bethune[1], Nina Meyer[1], Theresa Brinker[1], Finn-F. Stiewe[1], Tobias Kleinke[1], Chris Badenhorst[1], Alena Rong[1], Robin Silber[3], Mark Doerr[1], Raghvendra Palanakar[1], Toni Hache[6], Neha Jah[1], Uwe T. Bornscheuer[1], Marcel Kohlmann[1], Hauke Lars Heyen[1], Michaela Lammel[4], Alexander Paarmann[5], Andy Thomas[4], Robert Blick[2], Jakob Walowski[1], Michaela Dalcea[1], and Markus Muenzenberg[1] — [1]University of Greifswald, Germany — [2]University of Hamburg — [3]VSB-Technical University of Ostrava, Czech Republic — [4]IFW Dresden, Gemany — [5]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [6]Helmholtz-Zentrum Dresden-Rossendorf, Germany

3D 2-Photon-Lithography, originally developed for 3D photonic crystals, opens a wide range of new possible applications in many fields, e.g. life sciences, microoptics and mechanics. We will present our recent applications of 3D 2-Photon-lithography and show 3D evaporation masks for in-situ device fabrication using different deposition angles, infra-red laser light focusing lenses directly fabricated on optical fibers, tunnel structures for guiding growth of neurons [1], pillars for investigation of cell mechanics and master-mold fabrication for Polydimethylsiloxane (PDMS) micro-fluidic channels. Based on our experience we will discuss possible applications in magnetism. [1] C. Fendler et al., Adv. Biosys. 5 (2019) doi: 10.1002/adbi.201970054

MA 39.8 Wed 18:00 P2

Mapping the Interaction Field in Artificial Spin Ices — •Brindaban Ojha, Matías P. Grassi, and Vassilios Kapaklis — Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden

Artificial spin ice (ASI) consists of lithographically patterned nanomagnet arrays that interact through dipolar coupling. Although these interactions can be tuned by adjusting nanomagnet dimensions, periodicity, and thickness, their detailed distribution and influence on magnetization reversal remain incompletely understood. We study square ASI structures with nanomagnet widths corresponding to aspect ratios (length/width) of 3 and 4.5, while keeping the length fixed at ~450 nm, and probe their interaction fields using First-Order Reversal Curve (FORC) analysis. ASI with an aspect ratio of 4.5 shows a single central peak in the FORC distribution, whereas the aspect-ratio-3 system displays both a central peak and an asymmetric 'boomerang'-shaped feature. To understand these signatures, we perform micromagnetic simulations using MuMax. After relaxation from a random state, lower-aspect ratio ASI develops multidomain or vortex-like states, while higher-aspect-ratio ASI stabilizes in single-domain configurations due to enhanced shape anisotropy. The simulations confirm that the central FORC peak corresponds to single-domain switching in the higher-aspect ratio ASI, whereas the 'boomerang' feature arises from an intermediate S-shaped reversal mode in the lower-aspect ratio system. These results demonstrate how geometry governs interaction-field distributions and reversal mechanisms in ASI.

MA 39.9 Wed 18:00 P2

Element- and Depth-Selective Magnetometry of Buried Magnetic Layers by MCD-HAXPES at PETRA III — •Andrei Gloskovskii[1], Christoph Schlueter[1], and Gerhard Fecher[2] — [1]Photon Science / DESY, Hamburg — [2]Max Planck Institute for Chemical Physics of Solids, Dresden

Magnetic circular dichroism (MCD) in hard X-ray photoelectron spectroscopy (HAXPES) provides direct element-specific access to magnetization in deeply buried layers. The MCD signal follows a simple $\cos(\theta)$ dependence on the angle between the X-ray polarization vector and the sample magnetization. Depth-selective magnetic sensitivity is achieved by exploiting near-total-reflection and waveguide excitation geometries, where the depth resolution is controlled by shaping the spatial intensity profile of the incident hard X-ray field inside the multilayer structure. In both cases, the probing depth is tuned by redistributing the X-ray excitation field inside the sample rather than by changing the emission angle or the kinetic energy of the photoelectrons. Using Co-based alloys as model systems, we show that MCD-HAXPES provides element- and depth-resolved magnetic contrast in complex multilayer stacks. The method is particularly powerful for disentangling interface and bulk magnetization in buried heterostructures. In addition to the methodological aspects, this contribution also presents an overview of recent user activities at beamline P22 (PETRA III), where an increasing number of external user groups have successfully applied MCD-HAXPES for depth-resolved magnetic studies and have already published a broad range of high-impact results.

MA 39.10 Wed 18:00 P2

Interferometric measurements of Yittrium-Iron-Garnet cantilevers — Sumiya Saleem[1], •Richard Boucher[1], Seth Kaufman[1], and Georg Schmidt[1,2] — [1]Martin-Luther-Universität Halle-Wittenberg Insitut für Physik, Halle, Germany. — [2]Interdisziplinäres Zentrum für Materialwissenschaften, Martin-Luther-Universität Halle-Wittenberg, Halle, Germany.

Interferometric effects provide a sensitive detection of displacement, including those related to the resonance oscillations of cantilevers. We fabricate Yttrium-Iron-Garnet (YIG) cantilevers using a room-temperature pulsed laser deposition of amorphous YIG, lift-off method, followed by an anneal in oxygen yielding single-crystal structures [1]. By combining these in an interferometer built on the basis of the work of Pernpeitner [2] and Jörg [3] we have looked at the resonance frequency dependence on YIG cantilever length in the micrometre range, which will be compared with the work of Seo [4], various theoretical models, and COMSOL simulations, showing excellent agreement with theoretical results. We further show that these cantilevers can be driven to a non-linear regime, indicated via a characteristic Duffing non-linearity at high driving powers.

MA 39.11 Wed 18:00 P2

Spin-lattice coupling as a source of chiral phonons in cubic magnets — •Yelyzaveta A. Borysenko, Daniel Schick, and Ulrich Nowak — Department of Physics, University of Konstanz, 78457 Konstanz, Germany

Hybrid spintronic device concepts can be implemented based on angular momentum, as this can be transferred over significant distances and effectively exchanged between different quasiparticles. The understanding, control, and effective generation of angular momentum is crucial for such applications.

The creation and manipulation of chiral phonons introduces an additional degree of freedom, as they can couple to other quasiparticles in a chirality-selective manner as well as transfer angular momentum obtained from magnons. Chiral phonons mainly occur in materials with inversion-symmetry breaking, although recent works proved that they can be also generated in materials preserving this symmetry due to spin-lattice coupling [1], which was also experimentally demonstrated with ultrafast demagnetization in a nickel thin film [2].

In this work, we linearize the coupled equations of motion for the spin and lattice degrees of freedom assuming a coupling term of anisotropy type. We describe the appearance of chiral phonons induced by spin-lattice coupling comparing cubic ferromagnets and antiferromagnets, calculate angular momentum of the modes and discuss the chirality selective coupling of magnon and phonon bands.

MA 39.12 Wed 18:00 P2

Optical manipulation of spin based AC-nanooscillators — •Niklas Dornquast[1], Kevin Jäckel[1], Jakob Walowski[1], Tim Böhnert[2], and Markus Münzenberg[1] — [1]University of Greifswald, Germany — [2]The International Iberian Nanotechnology Laboratory (INL), Portugal

With the steady rise of artificial intelligence and the end of Moore's law, a novel approach for computational capabilities arises to fulfill the ever-increasing demand, while keeping energy consumption low. The research field of spintronics provides new possibilities for such energy-efficient technology by also utilizing the transport of electron spin in addition to charge transport, opening up operation processing in a higher Gigahertz frequency range. Devices

that realize such utilization of electron spin are, for example, spintronic AC-nanooscillators such as Spin-Torque-nanooscillators (STNOs) and Spin-Hall-nanooscillators (SHNOs). Additionally, these types of nanooscillators have the prospect of being used in a whole new computer architecture based on the human brain, called "neuromorphic computing". We investigate the effects of femtosecond laser pulses (<100 fs) of different polarities on such nanooscillators by optimizing the lasers' parameters to increase oscillation efficiency as well as manipulate the oscillation frequency optically.

MA 39.13 Wed 18:00 P2

Cubic magneto-optic Kerr effect in (001)-oriented thin films at grazing incidence of light — •Marius Krause[1], Maik Gaerner[1], Robin Silber[2], Jaroslav Hamrle[3], and Timo Kuschel[1,4] — [1]Bielefeld University, Germany — [2]VSB - Technical University of Ostrava, Czech Republic — [3]Charles University Prague, Czech Republic — [4]Johannes Gutenberg University Mainz, Germany

We investigate the cubic magneto-optic Kerr effect (CMOKE) in thin films of cubic crystal structures. CMOKE is proportional to third order in magnetization ($\propto M^3$) and was recently observed in Ni(111) thin films with 45° incidence of light [1]. At this angle of incidence, no CMOKE could be observed for (001)-oriented Ni thin films so far. However, we could observe a distinct CMOKE signal in Ni(001) at grazing incidence. Similar behaviour is found in other materials with (001)-oriented cubic crystal structure, indicating that grazing-incidence CMOKE is a more general feature of this crystal orientation. In this contribution, we present first experimental results of grazing-incidence CMOKE and discuss the incidence-angle dependence of CMOKE for different materials and crystal orientations. Our findings open new possibilities for CMOKE-based characterization of materials with (001)-oriented crystal structures.

MA 39.14 Wed 18:00 P2

Generation of Floquet-like sidebands in spin-wave systems induced by surface accustic waves — •Tim Vogel, Matthias Wagner, Björn Heinz, and Philipp Pirro — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau

The interaction between spin waves (SWs) and surface accoustic waves (SAWs) offers promising opportunities for advanced magnonic and spintronic applications. In this work, we investigate the generation of Floquet-like frequency combs in the GHz spin-wave spectrum with low-frequency SAWs in the MHz range as the Floquet-drive. We study the excitation of these states by coupling SAWs of different frequencies and incidence angles to SWs in both Damon-Eshbach and backward-volume geometry. We further explore these effects in multiple material systems to validate an analytical model describing the modified spin-wave dispersion under SAW driving. Our results contribute to a deeper understanding of magnon-phonon interactions and the conditions under which Floquet-like states emerge.

We acknowledge funding by the European Union via Horizon Europe project MandMEMS, Grant No. 101070536.

MA 39.15 Wed 18:00 P2

Growth and magnetic characterization of freestanding single-crystalline SrRuO3 /La0.7Sr0.3MnO3 oxide bilayers — •Diana Rata, Lilly Patschinsky, Elin Vocks, Alexander Much, Oleksandr Dolynchuk, Antonia Rieche, and Kathrin Dörr — Institute of Physics, Martin Luther University Halle*Wittenberg, 06099 Halle, Germany

We report the successful fabrication of freestanding epitaxial SrRuO3 /La0.7Sr0.3MnO3 (SRO/LSMO) heterostructures. LSMO and SRO layers were first prepared by PLD on a water-soluble sacrificial oxide Sr3Al2O6 (SAO), which was epitaxially grown on a SrTiO3 (100) substrate, followed by selective release and transfer of the membranes onto SiO2 wafers. The structure was characterized by X-ray diffraction. Our findings reveal that the epitaxial growth and strain of SAO layer is strongly affected by the subsequent growth condition (e.g., oxygen partial pressure) of upper oxide layers and influences strongly the quality and integrity of the oxide membranes. Magnetic characterization show that the freestanding SRO/LSMO membranes retain the key magnetic signatures of their corresponding bilayers. Notably, in the case of freestanding single-layer SrRuO3, we observe an enhancement of the magnetic response compared to its epitaxial single layer, suggesting strain relaxation and reduced substrate clamping as important factors. These results highlight the potential of freestanding oxide membranes for flexible integration and for exploring strain-decoupled magnetic phenomena in functional single-crystalline freestanding oxide bilayers.

MA 39.16 Wed 18:00 P2

Magnetic Anisotropy in Ordered and Disordered CoPd Alloys: A First-Principles Study — •Christian Maas, Michael Czerner, and Christian Heiliger — Institute for Theoretical Physics, Justus Liebig University Giessen

Understanding the magnetic anisotropy in magnetic materials is crucial for designing devices like sensors or data storage. In this work, we present ab initio density functional theory calculations of the magnetocrystalline anisotropy of $Co_xPd_{(1-x)}$ alloys with varying concentrations as well as $L1_0$ like $[CoPd]_x[PdCo]_{(1-x)}$ structures. We also show results for ordered layer structures with different thicknesses of Co and Pd layers. For our calculations, we employ the relativistic screened Korringa-Kohn-Rostoker Green's function method. The alloys are treated within the coherent potential approximation. Additionally, we explore the magnetic anisotropy of thin $Co_xPd_{(1-x)}$ films, considering both the magnetocrystalline and shape anisotropy.

MA 39.17 Wed 18:00 P2

Tailoring magnetic textures and investigation of magnetization processes in 3D via geometrical transformation — •Aman Singh[1], Timo Schmidt[2], Ivan Soldatov[1], Manfred Albrecht[2], Rudolf Schäfer[1], and Volker Neu[1] — [1]Leibniz IFW Dresden, D-01069 Dresden, Germany — [2]Institute of Physics, University of Augsburg, D-86159 Augsburg, Germany

Control over magnetic domains and domain walls is crucial for developing magnetic systems and devices. Here, we use a simple technique that uses a self-assembled reversible geometrical transformation from a flat 2D state to a rolled-up 3D state and back to the 2D state to create periodic up-down magnetization patterns in TbFe by applying a homogeneous magnetic field in the 3D state. We present how the magnetization patterns can be deterministically tailored simply by selecting the magnitude and direction of the applied magnetic field in the 3D state, which would otherwise require much more elaborate processes. This approach further provides a unique pathway to access and visualize magnetization processes in 3D by investigating the imprinted domains in the unrolled state of material magnetized at various fields in the 3D state. We further show that the overall 3D magnetization evolution can be reconstructed from recoil measurements in the 2D state when combined with the intrinsic anisotropy of the material. Finally, we discuss how this platform can be extended to investigate anisotropy changes in magnetostrictive materials, opening new possibilities for studying and engineering 3D magnetic states through reversible shape transformation.

MA 39.18 Wed 18:00 P2

Exploring spin reorientation and structural stability in distorted kagome metal — •Jayjit Kumar Dey[1], Tomke Glier[2], Sourav Chowdhury[1], Mouli Roy-Chowdhury[3], Subhajit Nandy[1], Amir-Abbas Haghighirad[4], Dmitry Reznik[2], and Moritz Hoesch[1] — [1]Deutsches Elektronen-Synchrotron (DESY), Hamburg, Germany — [2]University of Colorado Boulder, Boulder, CO, USA — [3]Université Grenoble Alpes, CEA, CNRS, Grenoble INP, SPINTEC, Grenoble, France — [4]Karlsruhe Institute of Technology, Karlsruhe, Germany

Distorted kagome metals have emerged as fertile platforms for investigating the interplay between geometrical frustration, magnetoelastic coupling, and exotic electronic states. In this work, we investigate the magnetic anisotropy and spin-reorientation behavior of TbAgGe and DyAgGe using X-ray magnetic circular dichroism (XMCD) and X-ray magnetic linear dichroism (XMLD) at the rare-earth M4,5-edges. XMCD reveals strong magnetocrystalline anisotropy and highlights the gradual evolution of 4f-moment orientation under applied magnetic field. Complementary XMLD measurements provide direct evidence of exchange-driven spin arrangement and local crystal field anisotropy. The robustness of the hexagonal crystal framework is evidenced by Extended X-ray absorption fine structure (EXAFS) and Raman spectroscopy, with no evidence of symmetry breaking despite noticeable shifts in bond angles and interlayer spacing. These results establish spin dynamics and structural stability in distorted kagome systems.

MA 39.19 Wed 18:00 P2

More is not always better: the case of $Mn_{0.56}Ge_{0.09}Sb_{0.23}Te$ — Tijmen Groot[1], Marie Tardieux[1], Laura T. Corredor[2,3], Manaswini Sahoo[4], Anja U.B. Wolter[4], and •Anna Isaeva[1,2,3] — [1]University of Amsterdam, The Netherlands — [2]TU Dortmund University, Germany — [3]Research Center Future Energy Materials and Systems, Germany — [4]Leibniz IFW Dresden, Germany

In the quest to optimize magnetic topological materials within the $(MnX_2Te_4)(X_2Te_3)_n$ family [1], Mn enrichment appears to be a viable strategy that enhances the ferrimagnetic ground state and the Curie temperature. We recently reported the most Mn-rich phases derived from $MnSb_2Te_4$, achieving T_C = 58-73 K [2-3], nearly satisfying one key requirement for potential applications.

Our further attempts to tune T_C show that not only Mn richness but also lattice symmetry plays a key role. Here we present the cubic, Mn-rich compound $Mn_{0.56}Ge_{0.09}Sb_{0.23}Te$ ($Fm\bar{3}m$, a = 5.9320(2) Å), as identified by powder and single-crystal XRD, SEM/EDX, and DC susceptibility. Due to the statistical disorder of Mn, Ge, and Sb over the cationic sites, it loses ferrimagnetic order in favor of an A-type antiferromagnetic arrangement with a low T_N = 25 K. This ground state is also supported by DFT+U calculations across a wide range of plausible compositions.

MA 39.20 Wed 18:00 P2

Magnetic Domain Structure of Erbium thin films — •Ujjval Mishra, Patrick Härtl, and Matthias Bode — University of Würzburg, Experimental Physics 2, Am Hubland, D-97074 Würzburg, Germany

Rare-earth metal (REM) films exhibit diverse magnetic behaviors governed by the indirect RKKY coupling of localized $4f$ moments, leading to complex long-range order. Building on prior studies of REM surface magnetism [1-5], we investigate the magnetic properties of epitaxial Erbium (Er) thin films. Er, a heavy rare-earth element with two unpaired $4f$ electrons, crystallizes in a hexagonal close-packed structure and remains paramagnetic above T_N = 85 K. Below T_C = 20 K, it adopts a conical ferromagnetic phase with the cone axis parallel to the c direction and a semi-cone angle of 29.6° at 6 K [6].

Spin-polarized scanning tunneling microscopy (SP-STM) reveals a complex domain structure in Er(0001) films epitaxially grown on W(110). At 4.5 K, domain walls are predominantly pinned to structural defects, while external magnetic fields around 2 T induce a maze-like contrast, confirming their magnetic origin. These findings highlight the intricate coupling between structural defects and magnetic domain evolution in Er(0001) thin films.

First-principles study of Mn mono- and bilayers on the Ta(001) surface — •Leo Kollwitz, Tim Drevelow, and Stefan Heinze — Institute of Theoretical Physics and Astrophysics, Kiel University, Leibnizstraße 15, 24098 Kiel, Germany

The magnetic order in ultrathin $3d$ transition-metal films on surfaces can be strongly influenced by the substrate. A prominent example is a Mn monolayer on W(001), in which the prototypical antiferromagnetic Mn exhibits strong ferromagnetic exchange coupling [1]. Deposition of an additional Mn layer, however, leads to a checkerboard antiferromagnetic order in the surface layer, while the magnetic moment of the Mn interface layer is quenched moment [2]. Here, we study the magnetism in Mn mono- and bilayers on the Ta(001) surface by density functional theory (DFT) via the Fleur code [3]. Surprisingly, the Ta substrate leads to a very similar behavior of magnetic order in the Mn mono- and bilayer as on the W(001) surface, contrary to the trend observed for Fe monolayers [4]. Our DFT calculations show a strong dependence of the magnetic moments of the lower Mn layer on the interlayer distance as well as the magnetic configuration. Based on the DFT results we parameterize an atomistic spin Hamiltonian.

MA 39.22 Wed 18:00 P2

prospects of studying circularly polarised phonons in 2D magnetic materials — •Hanna Shirin Pulikkal Hamza[1], Lukas Nöding[1], Helya Alaei[1], Ahmed Hassanien[1], Mashood Tariq Mir[1], Zdeněk Sofer[2], Jochen Mikosch[1], Thomas Baumert[1], and Arne Senftleben[1] — [1]Institute of Physics,University of Kassel, 34132 Kassel, Germany — [2]UCT Prague

It has been proposed that circularly polarised phonons can induce transient magnetisation in materials when driven by ultrafast laser pulses via the atomistic scale Barnett effect. In this ongoing study, we want to directly link the observation of circular atomic motion with magnetisation in 2D Van der Waals room temperature ferromagnetic materials. We have recently induced circularly polarised coherent phonons by a pair of femto-second laser pulses in a non-magnetic material namely graphite and detected the resulting lattice dynamics using Ultrafast Electron Diffraction (UED). In this contribution, we will review the results on graphite and show our recent progress in exfoliating ferromagnetic 2D materials. Furthermore, we will explore magnetisation measurements of our microscopic samples using Kerr microscopy and vibrating sample magnetometry.

MA 39.23 Wed 18:00 P2

D-wave Chiral Phonons from Electron-Phonon Coupling — •Dimos Chatzichrysafis[1] and Alexander Mook[1,2] — [1]Johannes Gutenberg Universität, Mainz — [2]University of Münster

Chiral phononics, the field of study of phonons carrying finite orbital angular momentum has recently attracted wide interest due to its rich, versatile physics and potential applications.

In search of mechanisms to generate unconventional phonon orbital angular momentum textures, we demonstrate theoretically that d-wave chiral phonons can emerge even in the absence of electronic spin order. We show that by considering an electronic system hosting a d-wave orbital angular momentum texture, non-relativistic electron-phonon coupling leads to the formation of d-wave chiral phonons.

In this way we expand the potential platforms of chiral phononics and offer application routes unique to d-wave textures, such as orbital phonon splitters.

MA 39.24 Wed 18:00 P2

Phonon Pumping Experiments — •Jeremias Mütschele, Luise Holder, Michaela Lammel, Richard Schlitz, and Sebastian T. B. Goennenwein — Department of Physics, University of Konstanz, Konstanz, Germany

Phonons carrying angular momentum have recently attracted significant attention in the field of spintronics, as they are considered promising candidates for information carriers that do not require electrical currents. The coupling of phonons to spin-wave excitations (magnons) opens up opportunities to manipulate them, and consequently the transmitted information, via magnon-phonon interactions. However, engineering such hybrid quasiparticles, known as magnon-phonon-polaritons, remains a major experimental challenge. To gain deeper insight into the properties of magnon-phonon-polaritons, we investigate phonon pumping from a ferromagnetic thin film into a paramagnetic bulk crystal under various geometrical configurations. We find that our approach enables the selective excitation and analysis of distinct magnon-phonon-polariton modes. This could open a pathway to tailor phonon-based information transport.

MA 39.25 Wed 18:00 P2

Thorium-229 as a Chiral Phonon Detector — •Martin Pimon[1], Kjeld Beeks[2], Thorsten Schumm[2], and Andreas Grüneis[1] — [1]Institute of Theoretical Physics, TU Wien, Vienna, Austria — [2]Institute of Atomic and Subatomic Physics, TU Wien, Vienna, Austria

The thorium-229 isotope features an exceptionally low-energy nuclear metastable excited state 8.4 eV above the ground state. This property makes it a viable candidate for probing level splitting in nuclear sub-levels using modern high-precision laser spectroscopy methods.

Magnetic interactions play a significant role in this level splitting, highlighting the potential of thorium-229 as a novel atomic-sized detector for the magnetic moment of chiral phonons. Moreover, the electric field gradient from the surrounding crystal lattice introduces additional level splitting, providing insights into structural properties.

By incorporating thorium atoms into an ionic crystal, our proposed technique enables the direct observation of both magnetic and electric interactions from within the crystal itself. This approach leverages high sensitivity to phonon-related phenomena, presenting a promising avenue for detecting chiral phonons.

In this poster, we will review the contributions to nuclear level splitting and explore the challenges and benefits of utilizing the thorium-229 nucleus as a detector for chiral phonons.

MA 40: Focus Session: Chiral phonons and crystals coupled to magnetic order II

Conventional magnetism arises from electron spin and orbital angular momentum, forming the basis of spintronics and orbitronics. Recent advances, however, have revealed that magnetism is also intimately linked to the chirality and angular momentum of the crystal lattice itself, often mediated by circular lattice vibrations known as chiral or axial phonons. These discoveries have uncovered novel mechanisms of spin and phonon transport and enabled direct access to phonon chirality and angular momentum as fundamental physical quantities. These developments prompt a re-examination of angular momentum coupling in solids, including well-established phenomena such as the Einstein-de Haas and Barnett effects, as well as the role of phonon angular momentum in the equilibrium state of magnetic materials. Chiral and axial phonons emerge as a powerful new platform for controlling magnetic order and dynamics, bridging lattice, spin, and angular momentum physics. This focus session aims to highlight recent breakthroughs in phonon angular momentum and magnetism and to connect the rapidly expanding field of chiral phononics with the broader magnetism community, spanning both experimental and theoretical perspectives.

As part of this focus session, we offer an excursion to the high-field THz user facilities at HZDR with an introduction to the planned Dresden Advanced Light Infrastructure (DALI). See MA 32 for details.

Magnetic order induced chiral phonons in a ferromagnetic Weyl semimetal — •Luyi Yang — Tsinghua University, Beijing, China

Chiral phonons are vibrational modes in a crystal that possess a well-defined handedness or chirality, typically found in materials that lack inversion symmetry. Here we report the discovery of chiral phonon modes in the kagome ferromagnetic Weyl semimetal $Co_3Sn_2S_2$, a material that preserves inversion symmetry but breaks time-reversal symmetry. Using helicity-resolved magneto-Raman spectroscopy, we observe the spontaneous splitting of the doubly degenerate in-plane E_g modes into two distinct chiral phonon modes of opposite helicity when the sample is zero-field cooled below the Curie temperature, in the absence of an external magnetic field. As we sweep the out-of-plane magnetic field, this E_g phonon splitting exhibits a well-defined hysteresis loop directly correlated with the material's magnetization. The observed spontaneous splitting reaches up to 1.27 cm^{-1} at low temperatures, progressively diminishes with increasing temperature, and completely vanishes near the Curie temperature. Our findings highlight the role of the magnetic order in inducing chiral phonons, paving the way for novel methods to manipulate chiral phonons through magnetization and vice versa. Additionally, our work introduces new possibilities for controlling chiral Weyl fermions using chiral phonons.

MA 40.2 Thu 10:00 HSZ/0002

The effect of lattice vibrations on the Curie temperature — •Thorben Pürling[1,2,3] and Stefan Blügel[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [2]Institute for Theoretical Physics, RWTH Aachen University, 52074 Aachen, Germany — [3]Science Institute and Faculty of Physical Sciences, University of Iceland, 107 Reykjavík, Iceland

Lattice vibrations, or phonons, are important degrees of freedom that are excited in every magnet operating at finite temperatures. This is particularly true for magnets used in practical applications, which typically operate above room temperature. When predicting critical temperatures – a key property of magnets – from *ab initio* calculations lattice vibrations are typically neglected in favor of fluctuations only in the magnetic degrees of freedom. Conversely, in experiments at room temperature the lattice does contribute to the thermal properties of the system. We aim to close the gap between theory and experiment at room temperature by taking lattice vibrations into account explicitly. We present a numerical method based on the atomistic spin model and showcase how the lattice vibrations can be integrated out to an effective spin Hamiltonian that inherently depends on lattice fluctuations.

We acknowledge funding from the ERC grant 856538 (project "3D MAGIC") and DFG through SFB-1238 (project C1).

MA 40.3 Thu 10:15 HSZ/0002

Universal phonon angular momentum Hall effect — •Daniel Bustamante Lopez[1,2], Verena Brehm[2], and Dominik Juraschek[2] — [1]Boston University, Boston, MA, USA — [2]Eindhoven University of Technology, Eindhoven, Netherlands

The phonon angular momentum Hall effect was recently proposed as a phononic analogue of the spin and orbital Hall effects. Here, we demonstrate that a temperature gradient universally drives a transverse flow of phonon angular momentum in harmonic lattices. Using an exact Green's function method together with nonequilibrium molecular dynamics, we obtain closed-form expressions for the local phonon angular momentum density, bond-resolved current, and a corresponding conductivity kernel that ties them to spatial temperature variations. The Hall response originates from bath-induced mode mixing encoded in off-diagonal phonon correlations and does not require lattice chirality, Berry curvature, or inversion-symmetry breaking. It persists in the most simple centrosymmetric geometries, including square and honeycomb lattices. We predict robust edge accumulation and a tunable Hall angle for phonon angular momentum in various materials with quantitative agreement between analytic theory and simulations. Our results establish the phonon angular momentum Hall effect as a universal channel for transverse angular-momentum transport in crystalline solids.

MA 40.4 Thu 10:30 HSZ/0002

Phonon Angular Momentum Transfer Torque — •Verena Brehm[1], Daniel Bustamante Lopez[2], Shu Zhang[3], and Dominik Juraschek[1] — [1]Department of Applied Physics and Science Education, Eindhoven University of Technology, Eindhoven, Netherlands — [2]Department of Physics, Boston University, Boston, USA — [3]Okinawa Institute of Science and Technology, Okinawa, Japan

Angular momentum can be carried by a variety of (quasi)particles, including magnons, photons, and phonons, whose interplay has recently opened new directions in spintronics and optoelectronics. In this talk, we demonstrate the transfer of angular momentum from a phononic system to a magnetic system via an interfacial transfer torque, which we call the Phonon Angular Momentum Transfer Torque (PAMTT). We estimate the magnitude of phonon angular momentum originating from different mechanisms, among them the recently discovered phonon angular momentum Hall effect, and explore the possible magnetization dynamics that can be induced by the resulting PAMTT. Our analysis shows that both the precessional and relaxation components of the PAMTT can be detected as shifts in frequency and broadening of the linewidth in ferromagnetic resonance (FMR) experiments.

MA 40.5 Thu 10:45 HSZ/0002

The phonomagnet: Spontaneous order of phonon angular momentum — •Maike Fahrensohn and Matthias Geilhufe — Condensed Matter and Materials Theory Division, Department of Physics, Chalmers University of Technology, 41258 Göteborg, Sweden

Magnetism arises from the collective order of electron spin and orbital angular momentum. Here, we introduce a new type of magnetism, which appears due to spontaneous order of the phonon angular momentum. We consider a Hamiltonian containing an interaction term that couples the phonon angular momentum to the electronic spin density. Using an imaginary-time Dyson expansion, we evaluate the spin partition function and obtain an effective phonon Hamiltonian.

To first order in the coupling strength, this approach yields a Zeeman-like term, which couples the electronic magnetization to the phonon angular momentum and leads to a spin-induced bias of phonon chirality.

To second order, we obtain a bilinear interaction between ionic angular momentum modes on different sites, mediated by the Matsubara spin susceptibility. Decomposing the tensor into isotropic and anisotropic parts, we identify emergent phononic analogues of the Heisenberg (isotropic), Γ-model (symmetric, anisotropic), and Dzyaloshinskii-Moriya (antisymmetric, anisotropic) interactions.

Similarly to the conventional Heisenberg model for electronic spins, our model exhibits a phase transition in which ions spontaneously develop angular momentum at elevated temperatures.

Thermal Hall Effects of Magnons and Phonons — •Alexander Mook — Universität Münster

Thermal Hall transport in insulating magnets provides a powerful probe of topology, interactions, and spin-lattice coupling in charge-neutral quantum matter. I will discuss the magnon thermal Hall effect arising from Berry curvature in altermagnets, and show how symmetry and band geometry control transverse heat currents carried by spin waves [1]. Going beyond single-particle pictures, I highlight recent theoretical results demonstrating that magnon-magnon interactions can generate intrinsic thermal Hall responses even in topologically trivial magnon bands [2]. I then turn to magnetoelastic systems, where magnon-phonon coupling produces hybrid excitations whose combined Berry curvature and scattering processes can strongly enhance or even invert the thermal Hall signal [3,4]. Together, these results establish thermal Hall transport as a genuinely many-body phenomenon governed by topology, interactions, and spin-lattice hybridisation.

MA 40.7 Thu 11:45 HSZ/0002

Electrical conductivity from the axial phono-magnetic effect — •Natalia Shabala and Matthias Geilhufe — Department of Physics, Chalmers University of Technology, 412 96 Gothenburg, Sweden

Axial, or circularly polarized phonons, are characterized by the collective vibrations of atoms in circular patterns. These phonons have been shown to induce large magnetization in a phenomenon referred to as the phono-magnetic effect [1,2]. The mechanism behind this effect is believed to be the electron-phonon interaction. In combination with circular polarization of phonons this interaction leads to the time-reversal symmetry breaking and causes splitting of electronic energy levels. In this work, we aim to study the effect of this splitting on other physical phenomena. In particular, we are interested in the electrical conductivity, which can be studied through the Hubbard model. Additionally, we investigate whether the time-reversal symmetry breaking leads to the emergence of the anomalous Hall effect, as can be expected in 2D materials.

MA 40.8 Thu 12:00 HSZ/0002

Magnetic field induced pseudo angular momenta, chiral phonons, and anomalous EP interactions in some Weyl semimetals — Vladimir Gnezdilov[1], Florian Büscher[2], •Peter Lemmens[2], Angela Möller[3], Dirk Wulferding[4], Claudia Felser[5], and Chandra Shekar[5] — [1]ILTPE, Kharkiv, Ukraine — [2]IPKM, TU-BS, Braunschweig — [3]Dept. Chemistry, JGU, Mainz — [4]Dept. Physics and Astr., Sejong Univ., Korea — [5]MPI-CPfS, Dresden

Applying magnetic fields excite phonon chirality and induce angular momenta due to the time-reversal breaking [1]. This allows to study effects usually restricted to the boundary of the Brillouin zone. We show such results for several Weyl semimetals [2] with uncommon spin-phonon interactions and discuss novel possibilities for the transfer and interaction between the angular momenta of photons and phonons [3].

Phonon Polariton Hall Effect — •Omer Yaniv[1] and Dominik Juarschek[1,2] — [1]Tel Aviv University, Tel Aviv, Israel — [2]Eindhoven University of Technology, Eindhoven, Netherlands

The phonon Hall effect conventionally describes the generation of a transverse heat current in an applied magnetic field. In this work, we extend the effect to hybrid light matter excitations and demonstrate theoretically that phonon polaritons, formed by coupling optical phonons with terahertz radiation, support transverse energy flow when coherently driven in an applied magnetic field. Using the example of PbTe, which exhibits strongly coupled phonon polaritons, we show that the magnetic field splits the phonon-polariton branches into left and right-handed circular polarization, obtaining unequal group velocities. We derive the energy current operators for propagating phonon polaritons and show how their mixed phononic-photonic nature enables controllable transverse phonon-polariton transport in the terahertz regime. Our results demonstrate bending of light through a phonon polariton Hall effect, which provides a route towards terahertz polaritonic devices.

MA 40.10 Thu 12:30 HSZ/0002

Phonon angular momentum in ultrafast demagnetization and hybrid quasiparticles — •Markus Weissenhofer[1], MS Mrudul[1], Philipp Rieger[1], Luca Mikadze[1], Ulrich Nowak[2], and Peter M. Oppeneer[1] — [1]Uppsala University, Uppsala, Sweden — [2]Universität Konstanz, Konstanz, Germany

Transfer and manipulation of angular momentum is a key aspect in spintronics. Recently, it has been shown that angular momentum transfer between spins and phonons is possible even on ultrashort timescales [1]. To contribute to the understanding of this transfer, we investigate spin-phonon coupling using two different fully ab-initio based methods [2,4]. Using Ehrenfest nuclear dynamics simulations combined with time-dependent density functional theory, we demonstrate that after ultrafast demagnetization of FePt optical phonons carrying finite angular momentum are created [2]. In addition, we show how a novel framework [3] can be used to calculate magnon-phonon coupling parameters and hybridization from first principles, revealing the existence of chiral phonons in Fe arising from a chirality-selective magnon-phonon coupling [4].

Towards a Physics-Informed Deep Learning Model for Parameterizing the Magnetism in 4f based Single-Molecule Magnets — •Zayan Ahsan Ali and Oliver Waldmann — Physikalisches Institut, Universität Freiburg, Germany

Single-molecule magnets (SMMs) have attracted interest in recent decades for their intriguing magnetic behavior and potential applications in quantum computing and spintronics. 4f based SMMs stand out because lanthanide ions can provide large magnetic anisotropies. However, the ligand environments that govern their magnetic properties involve up to 27 ligand-field parameters, while common experimental data such as temperature dependent magnetic susceptibility measured on powdered samples are comparatively featureless. Inferring ligand field parameters from such data is therefore a highly over-parameterized inverse problem. Machine learning approaches have shown promise in addressing this challenge [1]. Two central difficulties are identification of physically relevant regions of the ligand field parameter space and learning of a highly complex one-to-many mapping. This work presents a machine learning framework tailored to overcome both obstacles. It is shown that an informative training data set can be constructed via active learning with uncertainty sampling, and that incorporating the energy spectrum as an intermediate representation significantly improves the learnability of the high dimensional inverse mapping. The resulting architecture is found to be capable of predicting multiple possible ligand field parameter sets.

Graphene-based quantum heterospin graphs — Gabriel Martínez-Carracedo[1], Amador García-Fuente[1], László Oroszlány[2], •László Szunyogh[3], and Jaime Ferrer[1] — [1]Universidad Oviedo, Spain — [2]Eötvös Loránd University, Budapest, Hungary — [3]Budapest University of Technology and Economics, Hungary

Harnessing quantum-regime functionalities without relying on rare-earth elements represents an important step toward developing globally accessible quantum technologies. In this contribution, we investigate a range of low-dimensional open quantum spin systems constructed from magnetic nanographene structures containing spin-1/2 and spin-1 triangulenes and/or olympicenes. These graphene nanostructures act as localized spins and can be effectively modeled using a quantum bilinear*biquadratic Heisenberg Hamiltonian. We compute the energy spectrum and the quantum numbers associated with the low-energy eigenstates. We identify a double degeneracy in the total spin quantum number S of the first excited state in three-leg spin graphs (3-LSGs) and in other heterospin nanostructures. This degeneracy depends on both the number of sites and the spin species, and arises from a swapping-transformation symmetry of the Hamiltonian. Numerical simulations further show that this degeneracy remains largely robust in $N = 7$ spin-1 3-LSGs under realistic perturbations relevant to experimental conditions. [1]

MA 42.3 Thu 10:00 HSZ/0004

Femtosecond spin-state switching dynamics of Fe(II) complexes condensed in thin films — •Manuel Gruber[1], Lea Kämmerer[1], Gérald Kämmerer[1], Laurent Mercadier[2], Andreas Scherz[2], Felix Tuczek[3], Peter Kratzer[1], Uwe Bovensiepen[1], and Heiko Wende[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany — [2]European XFEL, Schenefeld, Germany — [3]Institute for Inorganic Chemistry, Kiel University, Germany

Significant progress has been made in tailoring spin-crossover films, driven by their potential for technological applications. However, studies of ultrafast switching in such films remain limited compared to their solution-phase counterparts. Here, we investigated photoinduced spin-state switching in a molecular film at room temperature, using the new capabilities offered by X-ray free-electron lasers. The sub-picosecond transition from the $S = 0$ low-spin state to the $S = 2$ high-spin state is tracked via transient changes in the Fe L_3 X-ray absorption edge. Our results reveal the involvement of an intermediate state in the switching dynamics [Kämmerer et al., ACS Nano 18, 34596 (2024)].

Financial support from CRC 1242 is gratefully acknowledged.

MA 42.4 Thu 10:15 HSZ/0004

Chirality-induced spin selectivity without intrinsic spin-orbit coupling: Role of non-equilibrium molecular orbital moment — •Sumit Ghosh[1] and Daniel E. Bürgler[2] — [1]The Institute of Physics of the Czech Academy of Sciences, 16200 Prague, Czech Republic — [2]Peter Grünberg Institut (PGI-6), Forschungszentrum Jülich GmbH, 52428 Jülich, Germany

We present an alternative theory of chirality induced spin selectivity (CISS) that does not require any intrinsic spin orbit coupling (SOC). The proposed mechanism is based on the formation of circulating currents in the molecular rings. In each ring, this current generates a non-equilibrium molecular orbital moment (MOM) which interacts with the spin of an injected electron, giving rise to CISS. The direction of the MOM is governed by the gauge field that arises from the chirality-induced structural distortion of the molecule. Being non-relativistic in nature, the gauge field induced MOM can be stronger than the effect generated by SOC. The presence of such a gauge field also overcomes the hurdle posed by Onsager's reciprocity. Finally we demonstrate that a non-equilibrium MOM can also form in the absence of the gauge field. However only the presence of the gauge field can produce the experimentally observed crossing I-V curve which is a characteristics of the CISS effect.

MA 42.5 Thu 10:30 HSZ/0004

Magnetocaloric effect of the centered-square, centered-hexagon, and double-pyramidal spin models — •Hamza Meel and Jürgen Schnack — Bielefeld University, Faculty of Physics, Bielefeld, Germany

Molecular magnetocalorics have been proposed as a replacement to ^{3}He for cryogenic applications, however the search for the best compound for such an application is still ongoing. Specifically, magnetic molecules exhibiting a high adiabatic entropy change in the kelvin and sub-kelvin range are sought after. Such an entropy change could for instance be achieved by a molecule whose ground state is highly degenerate. We investigate three frustrated systems, the centered square, the centered-hexagon, and the double-pyramidal spin models. Their figures of merits and their magnetocaloric effect are discussed.

MA 42.6 Thu 10:45 HSZ/0004

Exchange-biased toroidal moments in a family of homochiral Cu_6Ln_3 complexes studied by high-field EPR — •Jan Arneth[1], Deepanshu Chauhan[2], Sagar Paul[3], Bapan Jana[2], Wolfgang Wernsdorfer[3], Maheswaran Shanmugam[2], Gopalan Rajaraman[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Department of Chemistry, Indian Institute of Technology Bombay, India — [3]Physikalisches Institut, Karlsruhe Institute of Technology, Germany

The vortex-like arrangement of the individual magnetic moments renders single-molecule toroics (SMT) promising candidates for application in quantum computing, molecular spintronics and the development of magneto-electric coupling in multiferroic devices. Here, we report the magnetic investigation of a family of heterobimetallic nonanuclear Cu_6Ln_3 (Ln = Y,Gd,Dy) clusters, featuring a homochiral Cu_3-Ln_3-Cu_3 triangular core, using combined theoretical *ab-initio*, ac and dc susceptibility, μ-SQUID and high-field EPR studies. Numerical analysis of our experimental data allow for the determination of the microscopic spin Hamiltonian parameters, which reveal an antiferromagnetic inter-triangular coupling between the two spin-frustrated Cu_3 units. In particular, Cu_6Dy_3 exhibits both single-molecule magnet (SMM) and SMT behaviour with a non-magnetic ground state persisting up to magnetic fields as high as $B \simeq 1.3$ T. The large excitation gap is found to result from the ferromagnetic Cu-Dy exchange interaction coupling the toroidal Dy_3 unit with the adjacent Cu_3 triangles.

Fully Quantum-Mechanical Simulations of Spin Crossover Behaviour in an Iron(II) Complex — •Ethan Crawford, Solveig Felton, and David Wilkins — Queen's University Belfast, Belfast, Northern Ireland

Spin-crossover (SCO) complexes change spin state when exposed to external stimuli such as light, temperature or pressure, allowing them to be used as sensors or magnetic memory devices. Predicting with precision when a crossover occurs would bring the technology closer to fruition, but it remains a significant challenge. Single-point energy calculations using Density Functional Theory (DFT) have been employed with limited accuracy, because they neglect the vibrational and other entropic contributions present at finite temperatures. Furthermore, a given calculation setup is not necessarily transferable to another complex. We trained a committee neural network potential (c-NNP) using data generated via Ab Initio Molecular Dynamics for an Iron (II) SCO complex. Two c-NNPs were trained, to model both the highest and lowest spin states respectively, encompassing all intramolecular interactions. The models were systematically improved using the query by committee approach. These systems were extended from a single complex to a bulk system combining the c-NNPs with a classical forcefield to account for the intermolecular interactions. The spin state for each complex is individually assigned to simulate experimental transitions. During the transition window, neither model can accurately predict the behaviour of the complex, but combining the three forcefields should replicate experimental behaviour.

MA 42.8 Thu 11:30 HSZ/0004

Symmetric finite-temperature Lanczos method for anisotropic magnetic molecules — •Jürgen Schnack — Bielefeld University, Faculty of Physics, Bielefeld, Germany

The finite-temperature Lanczos method (FTLM) constitutes a valuable approximation scheme for Hilbert space problems that exceed the dimension tractable by complete numerical diagonalization [1,2]. Several large magnetic molecules have been successfully modeled using FTLM [3]. It has been noted earlier that the method converges best for problems where the z-component of total spin commutes with the Hamiltonian. For anisotropic Hamiltonians the convergence is much poorer [4]. Here, we discuss conceptional improvements [5] as well as realizations on nowadays supercomputing architectures that employ CPUs as well as GPUs.

MA 42.9 Thu 11:45 HSZ/0004

Investigation of Magnetic Properties of Ce-Doped Ni-Based Composites as Near Infrared Absorbers Based on Soft-XAS and XMCD Measurements — •Timuçin Emre Tabaru[1], Ali Karatutlu[2], Iremnur Duru[1], and M. Fatih Kilicaslan[3] — [1]Department of Electrical Electronics Engineering, Sivas University of Science and Technology, 58000 Sivas, Turkey — [2]National Nanotechnology Research Center (UNAM), Bilkent University, Ankara 06800, Türkiye — [3]Department of Engineering Fundamental Sciences, Sivas University of Science and Technology, 58000 Sivas, Turkey

In this study, the X-ray Magnetism Circular Dichroism (XMCD) spectra of Ni-based composites produced by melt spinning and rapid solidification with ~75% Ni, ~10% Cr, ~8% Si, ~5% Fe, ~2% B, and 1% Ce doping were determined according to different Fe and Cerium (Ce) contents using soft X-ray absorption spectroscopy (XAS) at the HESEB beamline at the Synchrotron-Light For Experimental Science And Applications In The Middle East (SESAME). The L2 and L3 edges of Ni, Fe, and Ce were investigated for both Ce-doped and undoped samples. The areas under the XAS and XMCD spectra obtained from these measurements were determined, and the spin and orbital magnetic momenta of each sample were calculated. The results confirmed that the materials mentioned exhibit paramagnetic properties, in agreement with the literature. Ni-based composite doped with Ce demonstrated enhanced broadband infrared (IR) absorption, reaching a maximum efficiency of 93% in the 3-5 μm mid-IR window and maintaining over 80% absorption across the entire 3-15 μm spectral range.

MA 42.10 Thu 12:00 HSZ/0004

Magnetic Hexagonal Nanoferrite-Based Electrode: Structural Characterization and Electrochemical Detection of Caffeine in Drinks — •Sajjad Hussain — The Begum Nusrat Bhutto Women University, Sukkur, Sindh, Pakistan

Caffeine is a pharmacologically active alkaloid that is frequently incorporated into a wide range of food and beverage formulations. V-type hexagonal ferrite nanoparticles (SrSnFe*O**-NPs) were prepared through a sol*gel-based green auto-combustion route and analyzed using a range of advanced characterization techniques, including X-ray diffraction (XRD), X-ray absorption fine structure (XAFS), scanning electron microscopy (SEM), atomic force microscopy (AFM), Brunauer*Emmett*Teller (BET) surface area analysis, and vibrating sample magnetometry (VSM). The V-type hexaferrite exhibits a single-phase crystalline structure with an average crystallite size exceeding 30 nm. The local atomic structure was confirmed using XAFS analysis, while the surface morphology and particle size were examined through SEM and AFM. BET was used to confirm the surface area 209.6 m*/g. The magnetic studies revealed soft magnetic behavior. Furthermore, the synthesized V-type hexagonal ferrites were employed to modify a glassy carbon electrode (GCE), developing SrSnFe*O**-NPs/GCE for the electrochemical sensing of caffeine. Cyclic voltammetry studies revealed conductive and diffusion-controlled behavior, with the SrSnFe*O**-NPs/GCE demonstrating high sensitivity and selectivity for caffeine detection (linear ranges: 0.5 to 80 *M; detection limits: 0.025 *M, while the LOQ was 0.078 *M.

Strain control of three-dimensional magnetic nanostructures — •José Claudio Corsaletti Filho, Mohammad Sedghi, Elina Zhakina, Markus König, Elena Gati, and Claire Donnelly — Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

The study of nanoscale objects in three-dimensions has led to new discoveries and opportunities for technological development. Recent studies have shown that the magnetic landscape of 3D nanostructures can be controlled by geometrical effects, enabling innovations in design and magneto-mechanical devices. Consequently, a method to reversibly tune the properties of a three-dimensional nanostructure is highly desirable. Strain represents a particularly promising approach, as it directly influences the geometry. Indeed, while strain has been extensively applied to magnetic thin films for the tuning of global material properties, there the substrate restricts global strains to 0.7-1%. In this work, we describe how we strained 3D magnetic nanostructures and map out their geometrical changes through in situ electron microscopy. We are able to achieve ultimate strains of up to 20%, but we also identify regimes associated with the elastic and plastic deformations of 3D nanostructures with different geometries. By determining the mechanical properties of the nanowires, we obtain the fundamental insight to achieving reversible tuning of the geometry - and therefore the magnetic properties - of 3D nanostructures. Such reversible tuning will be of key interest for future technological applications.

MA 43: Spin-Dependent Phenomena in 2D

Invited Talk MA 43.1 Thu 9:30 POT/0112

Defect-Induced Phase Transitions in the 2D Magnetic Semiconductor CrSBr — •Shengqiang Zhou — Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

As an air-stable van der Waals magnetic semiconductor, CrSBr has attracted great research interest due to its exceptional optical, electronic, and magnetic properties [1]. Below its Néel temperature of 132 K, CrSBr exhibits a typical A-type antiferromagnetic order consisting of antiferromagnetically coupled ferromagnetic monolayers [1, 2]. In this talk, I will present the magnetic phase transition from antiferromagnetic to ferromagnetic order in CrSBr induced by ion irradiation [3, 4]. We observe the emergence and subsequent suppression of the ferromagnetic phase in CrSBr as the irradiation fluence increases. Structural analysis combined with first-principles calculations suggests that the formation of interstitials promotes ferromagnetic coupling between the layers. At moderate irradiation fluences, the Curie temperature gradually decreases, reflecting the impact of crystalline degradation. Surprisingly, at even higher irradiation fluences, CrSBr does not amorphize but instead transforms into a new crystalline phase. These findings indicate that, by precisely tuning irradiation parameters and employing lithography techniques, one can selectively modulate the induced ferromagnetism in CrSBr in terms of magnetization strength, critical temperature, and spatial distribution. Res., 3, 2400053 (2024)

MA 43.2 Thu 10:00 POT/0112

Electric-field tunable valley excitons in proximity coupled WSe_2/CrI_3 heterostructures — Felix Hellenkamp[1], •Yiheng Li[1], Marc Schütte[1], Kenji Watanabe[2], Takashi Taniguchi[3], Lutz Waldecker[1], Christoph Stampfer[1,4], and Bernd Beschoten[1] — [1]2nd Institute of Physics and JARA-FIT, RWTH Aachen University, Germany — [2]National Institute for Materials Science, Tsukuba, Japan — [3]International Center for Materials Nanoarchitectonics, NIMS — [4]PGI-9, Forschungszentrum Jülich, Jülich, Germany

Two-dimensional (2D) transition metal dichalcogenides have attracted significant interest due to their unique optical properties. The possibility to address the K and K' valley selectively via σ^+ and σ^- polarized light enables optical initialization and readout of the valley degree of freedom. The valley degeneracy can be lifted via magnetic proximity coupling to a 2D magnet such as CrI_3. However, in the heterostructures the resulting exciton splitting lacks tunability, limiting its applicability in device architectures that demand adjustable valley splitting. Our work shows a large tunability of the exciton splitting in a WSe_2/CrI_3 heterostructure via external displacement fields. Reflection contrast measurements show a displacement field induced change in the exciton resonance energy which is asymmetric with respect to the excitons at the K and K' valleys, leading to a 35% increase in exciton splitting at a displacement field of -0.4V/nm. We attribute the change in resonance energy to a reduction in the optical bandgap, caused by a displacement-field-induced modification in the band alignment.

MA 43.3 Thu 10:15 POT/0112

Atomic-scale visualization of quasi-one-dimensional structure and magnetic-field-tunable electronic statesin CrSBr — •Keda Jin[1,2], Tobias Wichmann[1,3], F. Stefan Tautz[1,3], Felix Lüpke[1,4], Jose Martinez-Castro[1,2], and Markus Ternes[1,2] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich — [2]Institut für Experimentalphysik II B, RWTH Aachen, 52074 Aachen — [3]Institut für Experimentalphysik IV A, RWTH Aachen, 52074 Aachen — [4]Institute of Physics II, Universität zu Köln, 50937 Köln

The anisotropic two-dimensional (2D) van der Waals magnet CrSBr is famous for hosting a quasi-one-dimensional (1D) electronic structure, but its direct visualisation has remained elusive.

Using low-temperature scanning tunnelling microscopy and spectroscopy, we present the atomic-scale characterisation of this quasi- 1D conduction bands in monolayer CrSBr on $NbSe_2$. Our measurements reveal a spatial anisotropy in the local density of states, confirming the existence of conduction bands that are flat along one crystallographic direction but dispersive along the perpendicular direction. Moreover, we demonstrate that an applied magnetic field reconstructs its electronic structure, showcasing strong magneto-electronic coupling. Our work provides the real-space visualisation of the long-predicted electronic anisotropy and establishes its potential for developing magnetically-tunable low-dimensional electronic devices.

MA 43.4 Thu 10:30 POT/0112

Origin of Exchange Bias in Compensated and Orthogonal Spin Interfaces in vdW Heterostructures — •Aditya Kumar[1], Aravind Balan[1], Patrick Reiser[2], Sadeed Hameed[1], Thibaud Denneulin[3], Rafal E. Dunin-Borkowski[3], Patrick Maletinsky[2], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Staudinger Weg 7, 55128 Mainz, Germany — [2]Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland — [3]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons and Peter Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany

Van der Waals heterostructures formed by mechanical stacking can create atomically flat, defect-free interfaces, yet exhibit exchange bias in expected compen-

sated and orthogonal spin configurations. This work investigates the underlying spin-pinning mechanisms in heterostructures of out-of-plane ferromagnet Fe_3GeTe_2 interfaced with c-type out-of-plane antiferromagnet $MnPS_3$ and in-plane a-type antiferromagnet CrSBr. Using NV magnetometry and STEM holography imaging, we reveal distinct exchange bias origins: the spin reorientation transition in $MnPS_3$ induces large, robust exchange bias, while orthogonal coupling at the Fe_3GeTe_2/CrSBr interface generates circular flux closure domains that produce switchable exchange bias. [1] A. P. Balan et al., Advanced Materials 36, 2403685 (2024). [2] A. Kumar et al., Small 21, e06284 (2025).

MA 43.5 Thu 10:45 POT/0112

Spin-polarized scanning tunneling microscopy of antiferromagnetic spin ordering in a topological Hall material — Alexina Ollier[1,2], Valeria Sheina[1,2], Seik Pak[4], Corina Urdaniz[1,2], Muskan Sande[1,3], Soonhyung Lee[1,2], Lei Fang[1,2], Christoph Wolf[1,2], Woonghee Cho[6], Pyeongjae Park[7], Andreas Heinrich[1,3], Je-Geun Park[6], Moon jip Park[4,5], and •Won-Jun Jang[1,2] — [1]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Seoul, Korea — [2]Ewha Womans University, Seoul, Korea — [3]Department of Physics, Ewha Womans University, Seoul, Korea — [4]Department of Physics, Hanyang University, Seoul, Korea — [5]Research Institute for Natural Science and High Pressure, Hanyang University, Seoul, Korea — [6]Department of Physics and Astronomy, Seoul National University, Seoul, Korea — [7]Materials Science and Technology Division, Oak Ridge National Laboratory, Tennessee, USA

We report spin-polarized scanning tunneling microscopy measurements on Co1/3TaS2. STM images acquired with a conventional tip reveal the triangular atomic lattice of the surface, whereas SP-STM uncovers additional symmetry features directly linked to the spin-polarized electronic structure of TaS2 arising from the triple-Q magnetic order. The spin-dependent contrast observed with the SP tip confirms the presence of spin-polarized van Hove singularities, a hallmark of the non-coplanar magnetic state. These results demonstrate that SP-STM can directly probe the modified electronic structure arising from chiral magnetic textures in non-coplanar magnets.

MA 43.6 Thu 11:00 POT/0112

Super-Moiré Spin Textures in Twisted 2D Antiferromagnets — •King Cho Wong[1], Ruoming Peng[1], Eric Anderson[2], Jackson Ross[3], Adam Wei Tsen[4], Elton Santos[3], Xiaodong Xu[2], and Joerg Wrachtrup[1] — [1]3rd Physics Institute, University of Stuttgart, Stuttgart, Germany — [2]University of Washington, Seattle, USA — [3]University of Edinburgh, Edinburgh, UK — [4]University of Waterloo, Canada

Stacking two-dimensional (2D) layered materials offers a platform to engineer electronic and magnetic states. In general, the resulting states - such as Moiré magnetism - have a periodicity at the length scale of the Moiré unit cell. Here, we study magnetic order in twisted double bilayer chromium triiodide (tDB CrI3) by means of scanning nitrogen-vacancy microscopy. We observe long-range magnetic textures extending beyond the single Moiré unit cell, which we dub a super-Moiré magnetic state. At small twist angles, the size of the spontaneous magnetic texture increases with twist angle, opposite to the underlying Moiré wavelength. The spin-texture size reaches a maximum of about 300 nm in 1.1° twisted devices, an order of magnitude larger than the underlying Moiré wavelength. The vector field maps suggest the formation of antiferromagnetic Neel-type skyrmions spanning multiple Moiré cells. The twist angle dependent study combined with atomistic simulations suggests that magnetic competition between the Dzyaloshinskii-Moriya interaction, magnetic anisotropy, and exchange interactions produces the super-Moiré spin orders.

MA 44: Focus Session: Curvilinear magnetism: Magnetics with nanoscale curved geometries (joint session MA/TT)

The behaviour of any physical system is determined by the order parameter whose distribution is governed by the geometry and topology of the physical space of the object, in particular its dimensionality and curvature. Specifically, spin textures, static and dynamic magnetic responses become sensitive to bends and twists in physical space. In this respect, curvature effects emerged as a novel tool to tailor magnetic properties and responses relying on geometric deformations. In magnetism, coupling between geometry of a magnet and magnetic order parameter brings about novel responses of curved thin films, nanowires and nanoparticles and enforces topological constraints on the number and type of magnetic solitons living in a curved space. Curvatures can force a geometry-driven local interactions like Dzyaloshinskii-Moriya interaction (DMI) and anisotropy as well as novel non-local chiral symmetry breaking effects, which were confirmed experimentally using electron holography studies of magnetic cap-shaped structures. Advances in experimental techniques (fabrication and tomographic characterization) allow validating theoretically predicted effects and apply them for functional devices as was demonstrated with geometrically twisted 3D racetracks. Recent highlights of the community include experimental proof of curvature stabilised skyrmions, explorations of curvilinear altermagnets, tailoring magnetic solitons in curvilinear 2D magnets, curvilinear magnetoelectrics, use of curvilinear magnetic architectures to tune superconducting transport, and magnetoionic manipulation of magnetic states in nanostructures to name just a few representative topics, which will be covered at the focused symposium.

2D and 3D racetracks: Interplay of geometric and magnetic chiralities — •Stuart Parkin — Max Planck Institute for Microstructure Physics, Halle (Saale), Germany — Martin Luther University Halle-Wittenberg

Magnetic Racetrack Memory (RTM) is a unique memory-storage device that relies on the current driven motion of multiple domain walls along magnetic conduits that can be arranged either horizontally (2D) or vertically (3D). It has great potential as a high performance, non-volatile memory that has enormous data storage capacity compared to today*s memory technologies. Atomically engineered 2D magnetic racetracks in the form of synthetic antiferromagnets allow for very high current induced motion of nanoscopic chiral domain walls[1]. Recently we have shown that 2D RTM can be scaled to dimensions that are technologically relevant with widths of just ~50 nm[2]. 3D racetracks would allow for the highest density memories. Using a state-of-the-art multi-photon super-resolution lithography system we form 3D scaffolds of arbitrary shapes on which the racetracks can be subsequently deposited. We discuss 3D racetracks that are formed with clockwise and anticlockwise chiral twists and curved cross-sections. The interplay between the geometrical chirality and the spin chirality of the individual domain walls allows for domain wall diode devices [3]. [1] S. S. P. Parkin, S.-H. Yang, Nat. Nanotechnol. 2015, 10, 195. [2] J.-C. Jeon, A. Migliorini, J. Yoon, J. Jeong, S. S. P. Parkin, Science 2024, 386, 315. [3] A. M. A. Farinha, S.-H. Yang, J. Yoon, B. Pal, S. S. P. Parkin, Nature 2025, 639, 67.

Invited Talk MA 44.2 Thu 10:00 POT/0151

Combined MFM/KPFM at the Ultimate Sensitivity Limit for Probing Curvature-Engineered Micromagnetic States — •Emily Darwin[1], Reshma Peremadathil Pradeep[1,2], Luca Berchialla[3], Daniel Rotthardt[1,2], Ales Hrabec[3], and Hans Hug[1,2] — [1]Empa, Swiss Federal Laboratories for Materials Science and Technology, 8600 Dübendorf, Switzerland — [2]Department of Physics, University of Basel, 4056 Basel, Switzerland — [3]aul Scherrer Institut PSI, 5232 Villigen, Switzerland

Curved substrates offer a promising route for tailoring the magnetic properties of multilayer systems, potentially stabilizing topologically non-trivial spin textures such as skyrmions. However, local variations in surface inclination can significantly affect growth conditions, altering crystallographic orientation or even disrupting the multilayer architecture.

In this study, we investigate a Pt/Co/Ru multilayer deposited on a polymer substrate patterned with nanoscale semispherical bumps using a combined single-pass Magnetic Force Microscopy (MFM) and Frequency-Modulated Kelvin Probe Force Microscopy (FM-KPFM) technique. Our system achieves

unprecedented sensitivity to both magnetic and electrostatic interactions. We find that steep, near-vertical walls at the perimeter of hemispherical features locally disorder the multilayer stack, resulting in distinct changes in the contact potential difference. This disruption facilitates magnetic flux return and enables the formation of circular magnetic domains aligned with the external magnetic field on the dome tops.

Invited Talk MA 44.3 Thu 10:30 POT/0151

Curvilinear magnetism in superconducting spintronics — •Sol Jacobsen — Center for Quantum Spintronics, Norwegian University of Science and Technology NTNU, Trondheim, Norway

Replacing semiconductor-based computational components with superconducting elements can give an energy saving of two orders of magnitude. To harness this, we need precise control of the interaction between superconducting and magnetic components. Geometric curvature controls the superconducting transition by affecting spin relaxation and precession in superconductor-magnet heterostructures [1]. To functionalize this in devices, we can dynamically alter the curvature by inducing bending-strain. This can for example lead to electrically controlled superconducting spin-valves, current-reversal, and chirality-dependent ground states in triplet-SQUIDs [1-3]. In this presentation, I will discuss how real-space geometric curvature provides new pathways for manufacturing and controlling the interaction between superconductivity and magnetism in wires and thin films, and anticipate future developments in the field.

Advanced Control of Magnetic Nanostructures via Metasurface Engineering and Voltage-Driven Functionalities — •Anna Palau — Institut de Ciència de Materials de Barcelona (ICMAB-CSIC)

Understanding and manipulating magnetic micro- and nanostructures are fundamental to advancing technologies in data storage, spintronics, and magnetic sensing. Magnetic metasurfaces have recently attracted significant interest for their ability to locally configure magnetic field distributions and overcome limitations of traditional magnetic imaging techniques. In this work, we demonstrate how metasurfaces enable precise control of vortex motion, coercive fields, and saturation behaviour in magnetic nanostructures without altering their intrinsic anisotropy [1]. We show that metasurfaces can overcome magnetic field constraints in X-ray Photoemission Electron Microscopy (XPEEM), enabling high-resolution imaging of magnetisation states under conditions previously inaccessible. Additionally, we explore electric-field-driven ionic migration as a complementary route for voltage-controlled, non-volatile modulation of magnetic and superconducting properties [2], highlighting new opportunities for energy-efficient control and advanced characterisation. Invited Talk MA 44.5 Thu 11:45 POT/0151

Magnetic tomography of noncollinear spin textures in curvilinear geometries — •Sandra Ruiz-Gomez — ALBA Synchrotron, Barcelona, Spain

Three-dimensional nanomagnetic systems offer a unique platform for discovering and controlling complex spin textures. Recent advances in 3D nanofabrication, magnetic characterization techniques, and micromagnetic modeling are now enabling precise control of curvature, torsion, and geometry at the nanoscale, opening new routes for engineering spin textures in three-dimensional architectures.

In this talk, I will present our latest results on how geometrical design and 3D architecture can be exploited to tailor the energy landscape of domain walls, manipulate their topological properties, and guide their motion from straight nanowires to more complex curved cylindrical and tubular geometries. By combining state-of-the-art fabrication techniques with high-resolution imaging and theoretical analysis, we identify how curvature can be harnessed to stabilize complex spin textures, enabling deterministic control over their dynamics.

Overall, this work highlights how 3D nanomagnetism can be leveraged to access new regimes of topological control, with implications for next-generation spintronic devices, robust information carriers, and reconfigurable magnetic architectures.

MA 44.6 Thu 12:15 POT/0151

Transferred magnetic nanomembranes for curvilinear magnetism and spintronics — •Olha Bezsmertna[1], Oleksandr Pylypovskyi[1], Rui Xu[1], Mykola Vinnichenko[2], Andrea Sorrentino[3], Daniel Wolf[4], Axel Lubk[4], Peter Fischer[5,6], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [2]Institute for Ceramic Technologies and Systems IKTS, 01277 Dresden, Germany — [3]Alba Light Source, MISTRAL beamline, Cerdanyola del Vallès 08290, Spain — [4]Leibniz Institute for Solid State and Materials Research, 01069 Dresden, Germany — [5]University of California, Santa Cruz, United States — [6]Lawrence Berkeley National Laboratory, Berkeley, United States

The functionality of the magnetic nanomembranes can be extended through controlled transfer processes and geometric design. We show that advanced giant magnetoresistive thin films can be reliably transferred onto various substrates using green chemistry, preserving their structural integrity and magnetic performance, thus enabling mechanically conformal devices for applications where low weight, flexibility, and durability are essential [1]. With the developed technique, we demonstrate fabrication of curvilinear hierarchical magnetic nanotemplates and their subsequent transfer to an appropriate handling support enabling high-resolution transmission microscopy investigations (electron- and x-ray-based) of the impact of geometric curvature on complex magnetic states [2].

MA 44.7 Thu 12:30 POT/0151

Magnetic solitons in spherical maghemite nanoshells — •Oleksandr V. Pylypovskyi[1], Gaspare Varvaro[2], Davide Peddis[2,3], Priyanka Mishra[4], Carmine Autieri[4], Filipp N. Rybakov[5], Denis D. Sheka[6], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., 01328 Dresden, Germany — [2]CNR-Istituto di Struttura della Materia, 00015 Roma, Italy — [3]Universitá degli Studi di Genova, 1-16146 Genova, Italy — [4]International Research Centre Magtop, Institute of Physics, Polish Academy of Sciences, 02668 Warsaw, Poland — [5]Uppsala University, Uppsala SE-751 20, Sweden — [6]Taras Shevchenko National University of Kyiv, 01601 Kyiv, Ukraine

Topology of the shape of magnetic nanoarchitecture makes a major impact on global properties of its magnetic textures [1,2]. Here, we present a fabrication of maghemite spherical shells and a theoretical analysis of magnetic solitons they host in equilibrium. The ferrimagnetic shells with a radius and shell thickness of about 4 nm and 1.4 nm have a radial easy axis that favors skyrmionic textures. Their ground state corresponds to a 3D onion state with the change of the radial component of magnetization at the equator. In this presentation, we will also report on the localization of magnetic solitons on spherical shells.

MA 44.8 Thu 12:45 POT/0151

Coherent Spin Waves in Curved Ferromagnetic Nanocaps of a 3D-printed Magnonic Crystal — •Kilian Lenz[1], Huixin Guo[2], Mateusz Golebiewski[3], Ryszard Narkowicz[1], Jürgen Lindner[1], Maciej Krawczyk[3], and Dirk Grundler[2] — [1]Inst. of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Germany — [2]School of Engineering, Institute of Materials,Laboratory of Nanoscale Magnetic Materials and Magnonics, École Polytechnique Fédérale de Lausanne, Switzerland — [3]Institute of Spintronics and Quantum Information, Adam Mickiewicz University, Poznań, Poland

In this work we present ferromagnetic resonance measurements and simulations of a 3D magnonic crystals embedded in an on-chip microresonator. It was realized by two-photon lithography of a 3D woodpile structure and atomic layer deposition of a 30-nm-thin Ni film. Operated near 14 and 24 GHz, the microresonator output revealed numerous coherent magnons with distinct angular dependencies reflecting the underlying face-centered cubic lattice. The micromagnetic simulations show that some of the edge modes are localized at the curved nanocaps and that they remain robust against changes of the field orientation. These cap modes exhibit an unexpected phase evolution. The findings advance the development of functional microwave circuits with 3D magnonic crystals and strengthen their visionary prospects for edge-dominated magnon modes.

MA 45: Magnetic Relaxation and Gilbert Damping

Time: Thursday 9:30–11:00 Location: POT/0351

MA 45.1 Thu 9:30 POT/0351

Nonlinear magnon-magnon coupling in a ferrimagetic YIG sphere at cryogenic temperatures — •Johannes Weber[1,2], Richard Schlitz[3], Sebastian T. B. Goennenwein[3], Matthias Althammer[1,2], and Hans Huebl[1,2,4] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]TUM School of Natural Sciences, Technische Universität München, Garching, Germany — [3]Department of Physics, University of Konstanz, Konstanz, Germany — [4]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

Yttrium ion garnet (YIG) is known for its low magnetic damping properties, which are optimized in single crystalline YIG spheres, making it a potent candidate for nonlinear magnonics. The magnetic spectrum shows numerous so called Walker modes. Here, we present two-tone pump and probe microwave spectroscopy measurements of the magnetization dynamics of a 250 μm YIG sphere. The data shows signatures of three-magnon scattering, when the drive exceeds the first order Suhl instability threshold. We quantitatively analyze the underlying non-linearity for different Walker modes. These experiments enable a pathway for probing quantum signatures in magnetic systems.

MA 45.2 Thu 9:45 POT/0351

Evidence of relativistic field-derivative torque in nonlinear THz response of magnetization dynamics — •Arpita Dutta[1], Pratyay Mukherjee[6], Swosti P. Sarangi[1], Somasree Bhattacharjee[6], Christian Tzschaschel[2,3], Debankit Priyadarshi[3], Kouki Mikuni[4], Takuya Satoh[4,5], and Ritwik Mondal[6] — [1]NISER Bhubaneswar, HBNI, Jatni, India — [2]Max-Born Institute, Berlin, Germany — [3]ETH Zurich, Switzerland — [4]Institute of Science Tokyo, Japan — [5]Quantum Research Center for Chirality, Okazaki, Japan — [6]IIT (ISM) Dhanbad, India

The selective addressing of spins by THz electromagnetic fields via Zeeman torque is one of the most successful means of controlling magnetic excitations. Here, we show that the conventional Zeeman torque on the spin is not sufficient, rather an additional relativistic field derivative torque is essential to realize the observed magnetization dynamics. We accomplish this by exploring the ultrafast nonlinear magnetization dynamics of a ferrimagnetic garnet when excited by two co-propagating THz pulses. Having identified the Kaplan-Kittel mode at 0.48 THz, resulting from the exchange interaction, we drive this to a nonlinear regime. We find that the observed nonlinear trace of the magnetic response cannot be mapped to the magnetization precession induced by the Zeeman torque, while the Zeeman torque supplemented by an additional FDT follows the experimental evidences.

MA 45.3 Thu 10:00 POT/0351

Quantum Landau-Lifshitz-Gilbert equation — •Yuefei Liu — Nordita, Stockholm University and KTH Royal Institute of Technology, SE-10691 Stockholm, Sweden — Center for Quantum Spintronics, Department of Physics, NTNU, Norwegian University of Science and Technology, NO-7491 Trondheim, Norway

The classical Landau-Lifshitz-Gilbert (LLG) equations describe magnetization dynamics. Extending them to quantum systems is difficult, but we introduce an effective equation that is considered as a quantum analog of LLG equation [PRL 133, 266704 (2024)]. It reproduces classical features for ferromagnetically coupled spin-1/2 dimers, yet deviates strongly in antiferromagnetic and entangled cases, suggesting a new paradigm beyond Lindblad-type master equations.

MA 45.4 Thu 10:15 POT/0351

Temperature dependence of volume and interface contributions to the magnetic damping of Permalloy thin films — Verena Ney[1], Kilian Lenz[2], Fabian Ganss[2], René Hübner[2], Jürgen Lindner[2], and •Andreas Ney[1] — [1]Johannes Kepler Universität, Linz, Österreich — [2]Helmholtz-Zentrum Dresden-Rossendorf, Deutschland

The magnetic damping of $Ni_{80}Fe_{20}$ (Permalloy, Py) thin films has been reported to be lowest when sandwiched in Al cap and spacer layers [1]. Here we study the Gilbert damping parameter α as a function of Py layer thickness via temperature- and frequency-dependent ferromagnetic resonance (FMR) experiments. The full FMR dataset allows to separate the Gilbert-like contributions to the FMR linewidth from non-Gilbert-like ones like two magnon scattering processes. In addition, the Py thickness series allows to deconvolute α into its respective bulk and interfacial contributions and their respective temperature dependencies. While the bulk contribution monotonously decreases with temperature from 0.0061(1) down to 0.0054(1), the interfacial contribution shows a subsequent increase at low temperature. The remaining bulk contribution, which is only of resistivity-like character, can be considered to reflect the intrinsic magnetic damping properties of Py thin films, while the interface contribution contains both resistivity- and conductivity-like contributions [2].

[1] V. Ney et al. Phys. Rev. Materials **8**, 124410 (2024)
[2] V. Ney et al. Phys. Rev. Materials (submitted, 2025)

MA 45.5 Thu 10:30 POT/0351

Thickness-dependent modulation of magnetization dynamics in ultralow-damping Co_2MnSi Heusler alloys measured by ultrafast TR-MOKE — •Levi Geier[1], Anulekha De[1], Anna Maria Friedel[1,2], Philipp Pirro[1], Martin Aeschlimann[1], and Georg von Freymann[1,3] — [1]RPTU University Kaiserslautern-Landau — [2]Institut Jean Lamour, UMR CNRS 7198, Université de Lorraine, 54000 Nancy, France — [3]Fraunhofer Institute for Industrial Mathematics ITWM, Kaiserslautern

We measure the laser-induced ultrafast demagnetization and subsequent damped precession of the magnetization dynamics in Co_2MnSi Heusler alloys of varying thicknesses (4 nm - 18 nm). The study is performed by a time-resolved magneto-optical Kerr effect (TR-MOKE) setup based on an all-optical pump-probe approach. An ultralow effective damping down to an effective Gilbert damping constant $\alpha = 0.004$ is measured for the 18-nm-thick sample, which increases with decreasing applied magnetic field and increasing pump fluence. We attribute this trend to the generation of incoherent magnons in addition to the coherent magnons after excitation by the laser pulse. Moreover, we observe a strong dependence of the effective damping parameter on the film thickness. The effective damping decreases significantly with increasing film thickness, presumably due to two-magnon scattering. Interestingly the quenching of the magnetization during the demagnetization does not change significantly with pump fluence.

MA 45.6 Thu 10:45 POT/0351

Systematic Theory of Real-Time Atomistic Spin Dynamics — •Sarah Damerow and Michael Potthoff — I. Institute of Theoretical Physics, University of Hamburg

We present a systematic response-theoretical approach for deriving indirect interactions and novel couplings in the effective dynamics of classical spins coupled to generic lattice-fermion models. Via a systematic twofold expansion of the exact time evolution operator, namely in the coupling strength and in the retardation time, one identifies a rich variety of spin-, orbital-, and site-dependent contributions to the equations of motion. These include the familiar Ruderman–Kittel–Kasuya–Yosida and the Dzyaloshinskii–Moriya interactions. Additional anisotropic terms, different types of Gilbert damping and of geometrical spin torques, as well as various spin-inertia terms emerge. While the order of expansion suggests the order of magnitude of the effects, symmetry analysis allows for their classification. The practical feasibility of the approach is demonstrated with numerical results obtained for a Chern insulator.

Spin-Disorder-Induced Angular Anisotropy in Polarized Magnetic Neutron Scattering — Ivan Titov, •Venus Rai, and Andreas Michels — Department of Physics and Materials Science, University of Luxembourg, 162A Avenue de la Faiencerie, 1511 Luxembourg

We experimentally report a hitherto unseen angular anisotropy in the polarized small-angle neutron scattering (SANS) cross section of a magnetically strongly inhomogeneous material [1]. Based on an analytical prediction using micromagnetic theory, the difference between the spin-up and spin-down SANS cross sections is expected to show a spin-disorder-induced anisotropy. The effect is particularly pronounced in inhomogeneous magnetic materials, such as nanoporous ferromagnets, magnetic nanocomposites, or steels, which exhibit large nanoscale jumps in the saturation magnetization at internal pore-matrix or particle-matrix interfaces. Analysis of the experimental neutron data constitutes a method for determining the exchange-stiffness constant. Our results for the nuclear-magnetic interference terms contained in the polarized magnetic neutron scattering cross section might also be of relevance to other neutron techniques.

MA 46.2 Thu 9:45 POT/0361

Beam focusing with nested mirror optics(NMO) at RESEDA — •Florian Schönleitner[1,2], Denis Mettus[2], Johanna Jochum[2], and Christian Pfleiderer[1,2] — [1]Physik-Department, Technische Universität München, Germany — [2]Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, Garching, Germany

The RESEDA(REsonance Spin Echo for Diverse Applications) instrument is a spectrometer that can use the MIEZE(Modulated IntEnsity with Zero Effort) method, a variant of neutron spin echo(NSE) that uses radio frequency(RF) spin flippers instead of static magnetic fields and that can measure samples that depolarise the beam. As a next step for improving the experimental setup it was proposed that nested mirror optics should be integrated to focus the beam at varios components of the instrument. Focusing the beam at the sample might allow measurements of samples with smaller sizes, such as samples in a diamond anvil cell. It also might allow for measurements at higher scattering angles, as it could reduce phase aberrations for the MIEZE method. Focusing the beam at the RF-flippers allows to build smaller AC-coils, leading to higher accessible frequencies, and consequently might lead to a better energy resolution of the spectrometer. In order to create an efficient setup that does not introduce additional artifacts, careful consideration of all effects caused by inserting NMO is necessary. Here we will present preliminary results of the simulations of NMO integration and discuss their potential.

MA 46.3 Thu 10:00 POT/0361

Towards Halbach spheres - Icosahedral symmetry is not just cool anymore — •Ingo Rehberg[1] and Peter Blümler[2] — [1]Experimental Physics, University of Bayreuth, Germany — [2]Institute of Physics, University of Mainz, Germany

Halbach spheres [e.g.1] are an ideal theoretical solution for generating homogeneous magnetic fields. Experimentally, a continuous magnetisation profile is difficult to realise, and the inaccessibility of the sphere's interior favours the use of Halbach rings [2,3]. An alternative is to arrange discrete magnets on the surface of a sphere. Regular polyhedra with a high degree of symmetry are well suited to approximate spherical Halbach configurations [3,4]. Icosahedral symmetry is especially effective at producing uniform magnetic fields (4th order saddle points).

Shaken, not stirred: Using vibrations for sub-10nm resolution scanning X-ray microscopy imaging — •Simone Finizio, Benjamin Watts, Benedikt Rösner, and Jörg Raabe — Paul Scherrer Institut, Villigen PSI, Switzerland

In order to fully exploit the significantly higher coherent photon flux offered by the novel diffraction-limited light sources for high-resolution imaging, scanning microscopy techniques need to tackle imaging overheads and the unavoidable vibrations at the nanometric scales, both hindering the achievement of sub-10nm resolutions in routine conditions.

In most scanning microscopy endstations, significant effort and expense is dedicated to fight these unavoidable vibrations. In this work, we propose to stop fighting vibrations, and instead harness their potential to provide a uniform sampling at the nanoscale. This is achieved by relaxing the positioning precision requirements and sampling the position of the sample with a fast (10 kHz) clock, significantly above the mechanical eigenfrequencies of the sample assembly. An image is then created by binning the recorded positions and photon counts according to a user-defined pixel size. With this method, the routine imaging of sub-10nm features could be demonstrated.

MA 46.5 Thu 10:30 POT/0361

Magnetic interactions and magnetic field distributions in van der Waals heterostructures with Fe_3GeTe_2 — •Joachim Dahl Thomsen[1], Qianqian Lan[1], Eva Duft[1], Zdeněk Sofer[2], Nikolai Kiselev[3], and Rafal Dunin-Borkowski[1] — [1]Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Jülich, Jülich, Germany — [2]Department of Inorganic Chemistry, University of Chemistry and Technology Prague, Prague, Czech Republic — [3]Peter Grünberg Institute and Institute for Advanced Simulations, Forschungszentrum Jülich, Jülich, Germany

Magnetic van der Waals (vdW) materials are promising for memory and logic applications because their properties are highly tunable and they integrate readily into heterostructures that exploit proximity and interlayer effects. However, depth-resolved imaging of interlayer coupling is challenging in plan-view, where contrast is integrated through the sample. Here we use cross-sectional Fe_3GeTe_2 (FGT)/graphite/FGT heterostructures to probe coupling between vertically stacked FGT layers across separations of 0-110 nm. We use Lorentz TEM and off-axis electron holography to visualize the domain structure and map the magnetic field inside and outside the vdW heterostructures, resolving how the interaction evolves with spacer (graphite) thickness. We find that domain alignment between FGT flakes is set by their separation, and that a weak interaction persists even at a separation of 110 nm. These measurements provide design guidance for vdW heterostructure devices that rely on controlled interlayer interactions between magnetic textures.

Electronic correlations and non-colinear spins driving chirality-induced spin selectivity — Jacek Herbrych[1], Nicole Naber[2], and •Maria Daghofer[2] — [1]Wroclaw University of Science and Technology, Wroclaw, Poland — [2]FMQ, Universität Stuttgart, Stuttgart, Germany

Starting from a non-interacting p-orbital model for helical organic molecules, we look at the impact of onsite Hubbard and Hund's-rule interactions. We find that they can induce an orbital-selective Mott transition as well as a block spiral with non-colinear helical magnetic order. We then investigate the resulting chiral bands and find them to be partially spin polarized, a manifestation of p-wave magnetism. Using density-matrix renormalization group, cluster perturbation theory and Monte-Carlo methods, we find that small spin-orbit coupling together with strong correlations robustly leads to spin-polarized bands, even at moderately high temperature and for short correlation lengths. We thus propose this combination as an explanation of chirality-induces spin selectivity and also discuss the interplay of such non-colinear spin patterns with magnetised leads.

MA 47.2 Thu 15:15 HSZ/0002

Chiral phonon-electron interaction in altermagnets — •Armando Consiglio[1], Giancarlo Panaccione[1], and Domenico Di Sante[1,2] — [1]CNR-Istituto Officina dei Materiali (IOM), Unità di Trieste, Strada Statale 14, km 163.5, 34149 Basovizza (TS), Italy — [2]Department of Physics and Astronomy, University of Bologna, 40127 Bologna, Italy

The recent discovery of altermagnetism has opened new frontiers in condensed matter physics, bridging the behaviour of collinear antiferromagnets and ferromagnets. Altermagnetic materials exhibit zero net magnetization while hosting spin-split electronic bands, suggesting novel couplings between lattice and electronic degrees of freedom with potential implications for chiral phonon formation and magneto-phononic effects. In this study, we focus on MnTe and CrSb and present two main results. First, we identify signatures of chiral phonons in the presence of altermagnetic order. Second, we analyze the coupling between these chiral phonon modes and the low-energy electronic states of the compounds, revealing new magneto-phononic interactions. The work provides insight into the interplay between spin order and lattice dynamics in altermagnetic materials, highlighting their potential for novel spintronic and phononic functionalities.

MA 47.3 Thu 15:30 HSZ/0002

Spin polarized optical excitation in altermagnetic RuO_2 — •Paul Herrgen[1], Luca Haag[1], Stephan Wust[1], Marius Weber[1], Akashdeep Akashdeep[2], Mathias Kläui[2], Gerhard Jakob[2], Hans Christian Schneider[1], Benjamin Stadtmüller[3], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany — [3]Institute of Physics, University of Augsburg, 86159 Augsburg, Germany

Altermagnetic materials open new avenues for spintronic applications in compensated magnets due to the spin-split band structure. This unconventional electronic configuration enables access to spin-polarized, all-optical excitation despite the absence of a net magnetization.

In this work, we experimentally probe optically induced spin polarization in the altermagnetic material candidate RuO_2 [1]. The out-of-plane Néel vector of the system allows for the detection of the induced spin polarization via polar magneto-optical Kerr effect (MOKE) measurements. In light of the ongoing debate surrounding the altermagnetic nature of RuO_2, we conducted a systematic study across a range of film thicknesses. Our results show that altermagnetic behavior is observable only in the thinnest films, while increasing thickness leads to a progressive suppression of the characteristic altermagnetic response.

MA 47.4 Thu 15:45 HSZ/0002

Non-collinear achiral altermagnetic semiconductor — •Mengli Hu[1], Mikel Iraola[1], Paul McClarty[2], Jeroen van den Brink[1,3], and Maia G. Vergniory[4,5] — [1]Leibniz Institute for Solid State and Materials Research, IFW Dresden, Helmholtzstraße 20, 01069 Dresden, Germany — [2]Laboratoire Léon Brillouin, CEA, CNRS, Université Paris-Saclay, CEA-Saclay, 91191 Gif-sur-Yvette, France — [3]Würzburg-Dresden Cluster of Excellence Ct.qmat, Technische Universitat Dresden, 01062, Dresden, Germany — [4]Département de Physique et Institut Quantique, Université de Sherbrooke, Sherbrooke, J1K 2R1 Québec, Canada. — [5]Donostia International Physics Center, 20018 Donostia-San Sebastian, Spain

Altermangnets (AMs) constitute a novel family of magnetic materials characterized by the absence of net magnetization and the presence of spin-polarized band structures. Whereas AM phases were initially proposed in collinear structures, the recently discovered noncollinear chiral AMs stand out for their distinct hedgehog spin texture and multifunctionality in spintronics. In this work, we deepen the characterization of these systems by constructing a Landau theory for noncollinear achiral AMs. Furthermore, we demonstrate that the achiral symmetry of the crystal is reflected in the spin texture in reciprocal space, which presents only spatial-even multipoles. These multipoles, distinguished from those in collinear AMs via the high-order secondary order parameters, can couple to many phenomena. Our results suggest non-collinear achiral AMs as a promising platform for spintronics applications due to the potential to achieve various spin textures.

MA 47.5 Thu 16:00 HSZ/0002

Circular Dichroism in Resonant Photoelectron Diffraction on Altermagnetic MnTe Films — •Lena Hirnet, Marco Dittmar, Maximilian Ünzelmann, and Friedrich Reinert — Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ctd.qmat, Universität Würzburg, Germany

Altermagnets have lately attracted great attention combining antiferromagnetic spin alignment in real space with a momentum-dependent spin polarization of the electronic states in the band structure. One of the proposed altermagnet work horse materials is MnTe [1,2]. Recently, it has been theoretical predicted that the circular dichroism observed in resonant photoelectron diffraction patterns serves as a direct probe of the altermagnetic sublattice texture [3]. Here, we present resonant photoemission experiments conducted at soft x-ray photon energies corresponding to the Mn $L_{2,3}$ absorption edge. In the corresponding photoelectron diffraction pattern, we can identify the scattering processes of electrons — photoexcited from the Mn-3d states — with the surrounding sublattice atoms. In particular, we find Mn-Mn and Mn-Te forward-scattering peaks and will discuss their dichroic texture which compares very well with the theoretical calculations [3].

MA 47.6 Thu 16:15 HSZ/0002

Atomic altermagnetism — •Rodrigo Jaeschke-Uiergo[1], Venkata K. Bharadwaj[1], Warlley Campos[2], Ricardo Zarzuela[1], Nikolaos Biniskos[3], Rafael M. Fernandes[4], Tomáš Jungwirt[5], Jairo Sinova[1], and Libor Šmejkal[2,6,1,5] — [1]Johannes Gutenberg Universität, Mainz, Germany — [2]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [3]Charles University, Prague, Czech Republic — [4]University of Illinois Urbana-Champaign, Urbana, USA — [5]Czech Academy of Sciences, Prague, Czech Republic — [6]Max Planck Institute for Chemical Physics of Solids, Dresden Germany

Altermagnetism has recently been verified experimentally in MnTe and CrSb, which feature two sublattices with antiparallel magnetic dipole moments. In this talk, I will introduce the concept of atomic altermagnetism, a form of ferroic higher-order partial waves of the atomic spin density. Using spin-symmetry analysis and a partial-wave decomposition of first-principles spin densities, we demonstrate such non-dipolar spin order in MnTe, CrSb and KV_2Se_2O, where it coexists with the Néel order. In the Mott insulator Ba_2CaOsO_6, we uncover a striking case of pure atomic altermagnetism, which is entirely absent of dipolar sublattice order. These results show that altermagnetism can occur without Néel order. Finally, I will show that KV_2Se_2O and Ba_2CaOsO_6 are predicted to host giant spin-splitter angles of up to 42° and 26°, respectively demonstrating that strong altermagnetic responses can emerge without requiring the staggered Néel order of local dipole moments.

MA 47.7 Thu 16:45 HSZ/0002

High-field magnetotransport and quantum oscillations in altermagnetic CrSb — •Sajal Naduvile Thadathil[1,2], B. V. Schwarze[1], T. Kotte[1], M. Uhlarz[1], C. Muller[3,4], P. Ritzinger[3,4], K. Vyborny[3], T. Speliotis[5], J. Pospisil[4], R. G. Hernandez[6], H. Reichlova[3], D. Kriegner[3], J. Wosnitza[1,2], and T. Helm[1] — [1]Dresden High Magnetic Field Laboratory (HLD-EMFL), HZDR, Germany — [2]Institute of Solid-State and Materials Physics, TU Dresden, Germany — [3]Institute of Physics ASCR, Czech Republic — [4]Charles University, Czech Republic — [5]Institute of Nanoscience and Nanotechnology, Greece — [6]Universidad del Norte, Colombia

Within the family of altermagnets, CrSb is a metallic, collinearly ordered material that exhibits particularly strong symmetry-induced spin splitting in its band structure. In this study, we combine electrical magnetotransport measurements up to 70 T on microfabricated single-crystalline CrSb with first-principles calculations to investigate its Fermi surface. Our experiments reveal a non-saturating magnetoresistance and nonlinear Hall resistivity consistent with multiband charge transport. Notably, we report the observation of Shubnikov-de Haas quantum oscillations in CrSb. Band-structure calculations, when compared with our measurements, accurately reproduce the expected Fermi-surface geometry. These results confirm the predicted electronic band structure of CrSb, establish robust multi-charge-carrier transport at high fields, and highlight the importance of high-field experiments for mapping electronic band structures of altermagnets.

MA 47.8 Thu 17:00 HSZ/0002

Altermagnetism in RuO_2? An experimental study on strain and stoichiometry in heterostructures — •Maik Gaerner[1], Niklas Schmolka[1], Alexander Weissbach[2], Joachim Wollschläger[2], Karsten Rott[1], Jan Schmalhorst[1], Martin Wortmann[3], and Günter Reiss[1] — [1]Bielefeld University, Germany — [2]Osnabrück University, Germany — [3]Bielefeld University of Applied Sciences and Arts, Germany

RuO_2 is a widely studied altermagnetic candidate material, but its magnetic ground state remains actively debated. While some studies find little to no evidence of altermagnetic order in RuO_2 thin films [1,2], others report on clear signatures of altermagnetism [3]. Strain and stoichiometry are widely regarded as key parameters for electronic and magnetic properties of RuO_2 [4,5].

Here, we analyze the impact of strain as well as stoichiometry on the appearance of altermagnetic order in RuO_2. Therefore, we investigate RuO_2 heterostructures, probing e.g. spin-torques and tunnel magneto-resistance. Through an accompanying, systematic X-ray photoelectron spectroscopy study, we analyze the thermal instability of oxidation states in the near surface region to elucidate the role of process temperature in the production of heterostructures.

MA 47.9 Thu 17:15 HSZ/0002

Altermagnetic non-reciprocal magnon transport in insulating d-wave orthoferrites — •Jonas Köhler[1], Edgar Galindez-Ruales[1], Shixun Cao[2], Ulrich Nowak[3], Gerhard Jakob[1], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany. — [2]Materials Genome Institute, Institute of Quantum Science and Technology, International Center for Quantum and Molecular Structures, Shanghai University, 99 Shangda Road, Shanghai, 200444, China. — [3]Fachbereich Physik, Universität Konstanz, Universitätsstr. 10, Konstanz, 78457, Germany.

Altermagnetic materials have recently been predicted to host unique magnonic phenomena, including chiral magnon modes, anisotropic magnon lifetimes, and spin transport without additional symmetry breaking by magnetic fields [1].

We present non-local transport in the insulating rare-earth orthoferrites $LuFeO_3$ and $YFeO_3$. We observe a non-zero magnon spin-transport signal for the Spin-Hall-injected magnons, indicating a field-free spin-biased magnon transport. Using thermal excitation via the Spin-Seebeck effect, we observe a strong directional dependence. The signal in the $\Gamma - U$ direction has the opposite sign from the one in the $\Gamma - U'$ direction, while it vanishes along and perpendicular to the easy axis, suggesting a suppression along those crystallographic directions. This shows the altermagnetic spin split magnons, and we can reproduce the observation with an atomistic spin dynamics model.

MA 47.10 Thu 17:30 HSZ/0002

Magnetic structure and the detwinning effect under applied magnetic field in the altermagnet α-MnTe — •Feihao Pan[1], Yishui Zhou[1], Sabreen Hammouda[1], Yinghao Zhu[1], Soohyeon Shin[1], Karin Schmalzl[2], Wolfgang Schmidt[2], Eric Ressouche[3], Oscar Ramon Fabelo Rosa[4], and Yixi Su[1] — [1]Jülich Centre for Neutron Science (JCNS) at the Heinz Maier-Leibnitz Zentrum (MLZ), Forschungszentrum Jülich, Lichtenbergstrasse 1, D-85747 Garching, Germany — [2]Jülich Centre for Neutron Science (JCNS) at ILL, Forschungszentrum Jülich, F-38000 Grenoble, France — [3]IRIG, CEA and Université Grenoble Alpes, CEA Grenoble, F-38054 Grenoble, France — [4]Institut Laue-Langevin, 71 avenue des Martyrs, 38042 Grenoble Cedex 9, France

Altermagnetism has garnered significant interest due to spin splitting without relativistic spin-orbit coupling and its promising applications in spintronics. We have recently carried out a detailed single-crystal neutron diffraction study of α-MnTe under applied in-plane magnetic field. We found that a moderate field can generate a strong detwinning effect of magnetic domains. The determination of the magnetic structure of α-MnTe, carried out under both the twined and detwinned conditions, allows us to conclude that the magnetic moment of Mn is indeed colinearly ordered and is uniquely aligned along the crystallographic [1,1,0] direction. This important finding can pave the way for future investigations of altermagnetic phenomena, such as chiral magnon splitting and unconventional spin transport, in α-MnTe under almost detwinned conditions via a wide range of experimental probes.

MA 47.11 Thu 17:45 HSZ/0002

Altermagnetism from the point of view of Mössbauer spectroscopy and other local probes — •Felix Seewald[1], Tillmann Weinhold[1], Cornelius Herrmann[1], Jan Friedrichsen[1], Domenic Nowak[2], Rowena Wachtel[2], Rajib Sarkar[1], Sabine Wurmehl[2], and Hans-Henning Klauss[1] — [1]IFMP, TUD Dresden University of Technology — [2]Leibniz Institute for Solid State and Materials Research, IFW, Dresden

Altermagnetism has emerged as a hot topic of interest in solid state magnetism during recent years. Altermagnets combine a compensated antiferromagnetic structure with spin-split electronic bands. [1, 2]

We want to discuss what one can learn about altermagnetism from (nuclear) local probe spectroscopy, focusing mainly on Mössbauer spectroscopy (MBS) and NMR/NQR.

Depending on the type of altermagnet and the easy axis of the antiferrromagnetic order, local probes can prove or disprove the altermagnetic order. For d-wave altermagnets in Mössbauer spectroscopy and NMR/NQR studies the interplay between the local electric field gradient and the local magnetic hyperfine field may directly differentiate the altermagnetic sites.

We wull discuss Mössbauer spectroscpy as well as NMR/NQR studies on candidates FeF_2, FeF_3, $La_2O_2FeMnOSe_2$ and furthermore highlight the challenges and restrictions they are connected with.

MA 48.1 Thu 15:00 HSZ/0004

Linear and nonlinear zero-field spin waves in transversally magnetised low-damping, half-metallic Co_2MnSi waveguides — •Anna Maria Friedel[1,2], Moritz Bechberger[1], Björn Heinz[1], Sébastien Petit-Watelot[2], Stéphane Andrieu[2], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Institut Jean Lamour, UMR CNRS 7198, Université de Lorraine, 54000 Nancy, France

We report on zero-field spin waves in the linear and nonlinear regime propagating over tens of micrometers in transversally magnetised Co_2MnSi waveguides. The remanent configuration is stabilised by the intrinsic cubic magnetocrystalline anisotropy of the $L2_1$-ordered Heusler compound, which enables an operation in the favourable Damon-Eshbach geometry, yielding large spin wave group velocities and propagation lengths associated with the large saturation magnetisation $M_s \approx 1000\,\mathrm{kA/m}$ and the low Gilbert damping $\alpha \leq 10^{-3}$ in the half-metallic, $L2_1$-ordered Co_2MnSi. The cubic anisotropy not only allows for a reconfigurable remanent geometry and stable remanent operation, but also impacts the nonlinear magnetisation dynamics, yielding for instance a first order instability suppression range over several GHz. Investigating the linear and nonlinear dynamics in microstructured waveguides in remanence by Brillouin light scattering, this study consolidates the great interest in the half-metallic Co_2MnSi particularly for hybrid magnonic-spintronic applications at zero external bias fields.

MA 48.2 Thu 15:15 HSZ/0004

Long-range propagating paramagnon-polaritons in organic free radicals — •Sebastian Knauer[1], Roman Verba[2], Rostyslav O. Serha[1,3], Denys Slobodianiuk[2], David Schmoll[1,3], Andreas Ney[4], Sergej O. Demokritov[5], and Andrii V. Chumak[1] — [1]Faculty of Physics, University of Vienna, 1090 Vienna, Austria. — [2]V. G. Baryakhtar Institute of Magnetism of the NAS of Ukraine, 03142 Kyiv, Ukraine. — [3]Vienna Doctoral School in Physics, University of Vienna, 1090 Vienna, Austria. — [4]Institut für Halbleiter- und Festkörperphysik, Johannes Kepler Universität, 4040, Linz, Austria. — [5]Institute for Applied Physics, University of Münster, 48149 Münster, Germany.

Magnetic materials can host magnons below their Curie or Néel temperature, whereas in their paramagnetic phase, only short-range paramagnons are observed. We show that the organic free radical TEMPO supports long-range coherent spin dynamics well above its Néel temperature. Using all-electrical propagating spin-wave spectroscopy with on-chip microwave lines and external fields, we observe coherent excitations up to 23 GHz with group velocities above 100 $\mathrm{km\,s^{-1}}$ over 8 mm, exceeding calculated paramagnon velocities. Dispersion and pulse-propagation modelling identify these modes as paramagnon-polaritons, hybrid spin-photon excitations guided by the TEMPO column. This establishes organic free radicals as tunable paramagnetic magnonic media for microwave circuitry, spintronics, and high-frequency classical and quantum information processing [1].

Nonlinear frequency mixing in spin-wave transducers — •Matthias Wagner, Felix Kohl, Björn Heinz, and Philipp Pirro — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern- Landau, D-67663 Kaiserslautern, Germany

The demand for higher data transmission rates and high level of miniaturization has drawn attention to spin waves as a potential platform for building future radio frequency devices. So far, a lot of research has been carried out in optimizing prototype devices solely relying on continuous single-frequency operation. Nevertheless, the question how spin-wave transducers perform when real, multi-frequency signals are applied still is an open research subject that is especially relevant in the high-power regime where nonlinear spin-wave scattering leads to intermixing of frequency components within the passband. In this study, we quantify the nonlinear distortions caused by two-tone signals in spin-wave transducers by measuring relevant parameters, such as the 1-dB compression point and the third-order intercept point. Our results enable direct comparison between spin-wave based devices and conventional RF technology at the application level.

MA 48.4 Thu 15:45 HSZ/0004

Temperature-dependent characterization of spin-wave transducers — •Julien Schäfer, Björn Heinz, and Philipp Pirro — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern- Landau, D-67663 Kaiserslautern, Germany

In radiofrequency technology, spin-wave-based (SW) communication building blocks, such as limiters and isolators, offer a low-energy alternative to traditional electronic devices. These magnonic communication devices consist of micrometer-sized antenna pairs that allow for tuning of the bandwidth and the frequency range through antenna shaping and adjustment of the applied magnetic field. Especially their compact size makes magnonic circuits attractive for on-chip integration, aiming to replace bulky electronic counterparts in crowded surroundings, such as cryostats and satellites. Following the objective to expand the SW transducer applicability to low-temperature environments, we study the propagation of SWs at various temperatures ranging from room temperature to 2 K. Understanding the impact of temperature-dependent variations in magnetic material parameters, including saturation magnetization and SW lifetime, on dispersive propagation characteristics is essential for engineering suitable devices. Our research provides insight into temperature-dependent insertion loss and isolation, consequently validating the applicability of SW transducers beyond room temperature conditions.

MA 48.5 Thu 16:00 HSZ/0004

Uniaxial strain response of antiferromagnetic magnons — •Manuel Knauft, Arthur von U.-S. Schwark, Matteo Minola, and Bernhard Keimer — Max Planck Institute for Solid State Research, Stuttgart, Germany

With the suggested paradigm shift away from conventional transistors towards lower loss devices, magnonics has attracted considerable attention in recent years. Generation, manipulation and detection of magnons are prerequisites for successful integration into microstructured chips. One potential phase space pa-

rameter to control magnon behavior is strain. In particular, in antiferromagnetic iridates with perovskite structure, it has recently been shown that the magnon energy can be varied by as much as 40% with small uniaxial strain of about 0.1% [1]. These ideas can also be extended to spatially inhomogeneous strain environments. We will demonstrate ideas of guiding magnons through bending single crystals and show results of finite element simulations and confocal Raman scattering.

Antiferromagnetic magnon condensation — •David Angster[1], Tobias Dannegger[1], Ulrich Nowak[1], and Verena Brehm[2] — [1]University of Konstanz, Germany — [2]Eindhoven University of Technology, Netherlands

The Bose-Einstein condensation (BEC) is a phase transition of a boson gas in which the ground state becomes macroscopically occupied below a critical temperature. BEC of bosonic quasiparticles, such as magnons, has been realised experimentally through active pumping of their density above a threshold value, since their number is not conserved in thermal equilibrium. This non-equilibrium magnon BEC was first demonstrated by Demokritov et al. [1]. Here, we present atomistic spin dynamics (ASD) simulations of antiferromagnetic hematite. The pumping of high-energy magnon modes triggers magnon redistribution via scattering processes that ultimately lead to condensation in the ground state, visible as an overproportional and non-thermal occupation of the low-frequency modes. Exploiting the non-linearity of ASD, we explore the key characteristics of BEC formation [2]: 1. a pumping threshold, 2. the spontaneous emergence of coherence, and 3. the shift of the magnon chemical potential.

High-Resolution Field Mapping of Parametric-Instability Thresholds in YIG Films: Fine Structure and Magnon-Phonon Hybridization — •Tamara Azevedo[1], Rostyslav O. Serha[2], Yannik Kunz[1], Matthias R. Schweizer[1], Vitaliy I. Vasyuchka[1], Mikhail Kostylev[3], Burkard Hillebrands[1], and Alexander A. Serga[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Faculty of Physics, University of Vienna, 1090 Vienna, Austria — [3]Faculty of Physics, University of Western Australia, 6009 Perth, Australia

Parametric electromagnetic pumping of magnons is a central technique for exciting and amplifying spin waves. Determining the parametric-instability threshold where the supplied energy compensates intrinsic magnon damping is essential for understanding and controlling this process. Using a highly sensitive automated measurement scheme based on quasi-continuous-wave excitation from a vector network analyzer and a microstrip resonator, we determined the instability threshold in tangentially magnetized yttrium-iron-garnet (YIG) films as a function of the external field $\mathbf{H}_0$ with unprecedented magnetic-field resolution. For parallel pumping, the threshold power exhibits distinct features originating from magnon hybridization with transverse and longitudinal phonons, as well as fine structure caused by the competitive excitation of thickness modes. These results highlight the dynamics specific to parallel parametric pumping that govern the onset of instability and provide crucial insight for efficient magnonic devices.

MA 48.8 Thu 17:00 HSZ/0004

Stability of a magnon Bose-Einstein condensate under two-tone pumping — •Franziska Kühn[1], Lars Schiesser[1], Matthias R. Schweizer[1], Vitaliy I. Vasyuchka[1], Georg von Freymann[1,2], Mathias Weiler[1], Burkard Hillebrands[1], and Alexander A. Serga[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Fraunhofer Institute for Industrial Mathematics ITWM, Fraunhofer Platz 1, 67663 Kaiserslautern, Germany

In our work we investigate the stability of magnon Bose-Einstein condensates (BEC) in yttrium-iron-garnet films under two-tone pumping. First, to create a magnon BEC, the magnon gas is populated above the thermal level by external injection of magnons through parametric pumping. For flexible control of the excitation conditions, we employ a broadband microstrip antenna, allowing continuous tuning of the pumping frequencies. Second, after the magnon BEC is formed, its stability is tested by disturbing it with a second pumping pulse at a lower frequency. By shaking the magnon system without generating additional magnons, we aim to properly identify stability conditions of the magnon BEC in a time-varying environment. The measurements are performed using wave vector resolved Brillouin light scattering spectroscopy as an optical detection method for magnons. This research was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation)-TRR 173/3-268565370 Spin+X (Project B04 and B13).

MA 48.9 Thu 17:15 HSZ/0004

Modelling spin-wave interference with electromagnetic leakage in micron-scaled spin-wave transducers — •Felix Kohl[1], Björn Heinz[1], Matthias Wagner[1], Christoph Adelmann[2], Florin Ciubotaru[2], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern- Landau, D-67663 Kaiserslautern, Germany — [2]imec, Kapeldreef 75, 3001 Heverlee, Belgium

Utilization of spin-wave transducers for radio-frequency signal processing provides significant potential due to intrinsic tunability, scalability and nonlinearity. However, such components can exhibit passband ripples, distortions in their transmission band, diminishing their operation and functionality. In this work, we experimentally identify the interference with the electromagnetic crosstalk (EM) as a major source of passband ripples and provide a simple analytic model to predict its impact on device operation. The results are in good agreement with the experimental observation. In addition, we test multiple transducer geometries to identify operational regimes and minimize the EM impact. Finally, the effect of nonlinear device operation on the interference with the EM is addressed, which is of relevance for the exploitation of the spin-waves intrinsic nonlinear traits.

MA 48.10 Thu 17:30 HSZ/0004

Avoided Crossings of Magnon Modes and Superconducting Lumped Element Resonator in YIG Microplatelet — •Seth W. Kurfman[1], Anoop Kamalasanan[1], Karl Heimrich[1], Philipp Geyer[1], Frank Heyroth[2], Kwangyul Hu[3], Tharnier Puel[3], Michael Flatté[3,4], and Georg Schmidt[1,2] — [1]Martin Luther Universität Halle-Wittenberg Institut für Physik, Halle, Germany — [2]Interdisziplinäres Zentrum für Materialwissenschaften, Halle, Germany — [3]University of Iowa Department of Physics and Astronomy, Iowa City, Iowa (USA) — [4]Eindhoven University of Technology Department of Applied Physics, Eindhoven, The Netherlands

Yttrium iron garnet (YIG) has been considered for decades as a gold standard material for magnonics due to its low-loss magnonic properties, and has successfully been used to demonstrate strong-coupling in macroscopic device geometries [1-4]. However, strong coupling of magnons in truly sub-10 micron YIG structures to date has not yet been realized. Here, we demonstrate the use of a YIG microplatelet placed on superconducting lumped element LC resonator to achieve strong coupling between numerous magnon modes and the LC resonator photons. These experimental findings are qualitatively backed by micromagnetic simulations and analytical calculations to identify the magnon modes corresponding to the experimentally observed anti-crossings in the microwave transmission signal.

MA 48.11 Thu 17:45 HSZ/0004

Auto-oscillations and directional magnonemission induced by spin current injection into large magnetic volumes — •R. Schlitz[1,2], V. E. Demidov[3], M. Lammel[1], S. O. Demokritov[3], and P. Gambardella[2] — [1]Department of Physics, University of Konstanz, Konstanz, Germany — [2]Department of Materials, ETH Zurich, Zurich, Switzerland — [3]Institute of Applied Physics, University of Muenster, Muenster, Germany

Magnons are quantized excitations of the magnetization texture in ordered magnets, which can be used to transport spin information. In magnetic insulator/heavy metal bilayers angular momentum conversion from the electrical to the magnonic domain allows to electrically generate and detect magnon spin currents in the magnetic layer [1]. Recent studies showed, that in the nonlinear regime the changes of the nonlocal transport allow to also obtain information on the transported magnon manifold [2,3]. We show that local modifications of the magnon dispersion in the nonlinear regime can sensitively affect nonlocal magnon transport, giving rise to a strong enhancement of the number of specific low energy magnons. Considering the role of nonlinear relaxation processes, the nonlocal transport can be understood in terms of the nonequilibrium modification of the magnon dispersion. Our results showcase that nonlocal transport measurements are a sensitive probe to unravel changes to the magnon manifold [4].

MA 49.1 Thu 15:00 POT/0112

Scalable magnetoreceptive e-skin for high-resolution interaction towards undisturbed extended reality — •Pavlo Makushko[1], Jin Ge[1], Gilbert Santiago Cañón Bermúdez[1], Oleksii Volkov[1,5], Yevhen Zabila[1], Stanislav Avdoshenko[2], Rico Illing[1], Leonid Ionov[3], Martin Kaltenbrunner[4], Jürgen Fassbender[1], Rui Xu[1], and Denys Makarov[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf e.V., Dresden, Germany — [2]Leibniz Institute for Solid State and Materials Research Dresden, Dresden,Germany — [3]University of Bayreuth, Bayreuth, Germany — [4]Johannes Kepler University, Linz, Austria — [5]Goethe-Universität Frankfurt, Frankfurt am Main, Germany

Electronic skins seek to go beyond the natural human perception, e.g., by providing magnetoperception to detect magnetic fields. However, realizing magnetoreceptive e-skin with spatially continuous sensing over extended areas is challenging due to escalating circuit complexity and power consumption with increasing sensing resolution or interactive area. Here, by incorporating the GMR effect and electrical resistance tomography, we achieve continuous sensing of magnetic trigger across an area up to $120 \times 120\,mm^2$ with a sensing resolution of better than 1 mm [1]. A simplified circuit design enables optically transparent, mechanically compliant, and vapor/liquid permeable devices, that can be conveniently applied onto any surface including human skin. These achievements pave the way to numerous applications, including undisturbed recognition of fine-grained gesture touchless interaction. [1] P. Makushko et al., Nat Commun 16, 1647 (2025).

MA 49.2 Thu 15:15 POT/0112

Probing the magnetic order in a ferromagnetic monolayer — •Paritosh Karnatak[1], Andriani Vervelaki[1], Katharina Kress[1], Boris Gross[1], Daniel Jetter[1], Menghan Liao[2,3], Ritadip Bharati[2,3], Fengrui Yao[2,3], Ignacio Gutierrez[2,3], Kenji Watanabe[4], Takashi Taniguchi[5], Alberto Morpurgo[2,3], and Martino Poggio[1,6] — [1]Department of Physics, University of Basel, Basel, Switzerland — [2]Department of Quantum Matter Physics, University of Geneva, Geneva, Switzerland — [3]Group of Applied Physics, University of Geneva, Geneva, Switzerland — [4]Research Center for Functional Materials, National Institute for Material Science, 1-1 Namiki, Tsukuba 305-0044, Japan — [5]International Center for Materials Nanoarchitectonics, National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan — [6]Swiss Nanoscience Institute, University of Basel, Basel, Switzerland

Understanding magnetism in two-dimensional (2D) van der Waals (vdW) magnets requires nanoscale local probes. Scanning SQUID microscopy (SSM), with ~100 nm resolution, enables direct imaging of magnetic structures in mono- and few-layer materials. Using SSM, we investigate the magnetic behavior of $CrPS_4$, a weakly anisotropic vdW interlayer antiferromagnet. Monolayer $CrPS_4$ shows no remanence and a zero coercive field, unlike thicker odd layers that exhibit 20-50 mT coercivity and nearly 100% remanence.

These layer-dependent studies reveal the role of interlayer coupling and dimensionality on magnetic responses. Our findings provide insights into mechanisms driving long-range magnetic order in 2D.

MA 49.3 Thu 15:30 POT/0112

SQUID-on-lever scanning probe for magnetic imaging with sub-100-nm spatial resolution — Timur Weber[2], •Daniel Jetter[1], Martino Pogio[1], and Dieter Kölle[2] — [1]Department of Physics, University of Basel, 4056 Basel, CH — [2]Physikalisches Institut, University of Tübingen, 72076 Tübingen, Germany

Scanning superconducting quantum interference device (SQUID) microscopy is a magnetic imaging technique combining high field sensitivity with nanometer-scale spatial resolution. We demonstrate a scanning probe that combines the magnetic and thermal imaging with the tip-sample distance control and topographic contrast of a non-contact atomic force microscope. We pattern the nanometer-scale SQUID, including its weak-link Josephson junctions, via neon or helium focused ion beam milling on a niobium coated cantilever. These SQUID-on-lever probes overcome many of the limitations of existing devices, achieving spatial resolution better than 100 nm, magnetic flux sensitivity of $0.3\ \mu\Phi_0/\sqrt{\mathrm{Hz}}$, operation in magnetic fields up to about 0.5 T and the incorporation of a third Josephson junction for shifting its phase. Its advanced functionality, high spatial resolution, and the ease of use of a cantilever-based scanning probe, extends the applicability of scanning SQUID microscopy to a wide range of magnetic, superconducting, and quantum Hall systems. We demonstrate magnetic imaging of skyrmions at the surface of bulk Cu2OSeO3. Analysis of the SQUID's point spread function yields a full-width-half-maximum of 71 nm that allows to image modulated magnetization patterns with a period of 65 nm.

MA 49.4 Thu 15:45 POT/0112

Magneto-Mechanical Resonator with Stimulus-Responsive Hydrogel for pH Sensing — •Nora Timm[1], Jonas Faltinath[2,3], Bruno Kluwe[1], Jonas Schumacher[1], Pascal Stagge[1], and Tobias Knopp[1,2,3] — [1]Fraunhofer Research Institution for Individualized and Cell-based Medical Engineering IMTE, Lübeck, Germany — [2]Section for Biomedical Imaging, University Medical Center Hamburg-Eppendorf, Hamburg, Germany — [3]Institute for Biomedical Imaging, Hamburg University of Technology, Hamburg, Germany

Magneto-mechanical resonators (MMRs) offer a promising platform for passive and wireless sensing. We present a novel chemical sensor by integrating a miniaturized MMR (2 mm×2 mm×7 mm) with a pH-responsive poly(2-hydroxyethyl methacrylate) (pHEMA) hydrogel functionalized with acrylic acid. In our implementation, the stimulus-responsive hydrogel modulates the distance between two permanent magnets through reversible volumetric changes in response to pH variations. One magnet serves as the stator and the other as the rotor of the MMR that is excited into torsional oscillations by external magnetic fields. Since the resonance frequency depends on magnet separation, frequency analysis of the inductively detected signal enables pH sensing. We demonstrate the sensor's response to pH variations in the range of pH 5-7 with observable shifts in resonance frequency of more than 40 Hz, which corresponds to a relative shift of more than 12 %. This proof-of-concept establishes hydrogel-integrated MMR sensors as a viable approach for wireless chemical sensing.

MA 49.5 Thu 16:00 POT/0112

Deep learning enabled wearable magnetoelectronics — •Guannan Mu, Rui Xu, Proloy T. Das, Jan Schmidtpeter, Lin Guo, Oleksandr Pylypovskyi, Andreas Knüpfer, Rico Illing, Olha Bezsmertna, and Denys Makarov — Helmholtz-Zentrum Dresden-Rossendorf e.V., 01328 Dresden, Germany

A wide variety of magnetic field sensors is already integrated into human-machine interfaces in wearable electronics [1,2]. However, the currently available interfaces are limited in the number of recognizable gestures and operation distance. To overcome these limitations, we integrate deep learning into two magnetic interaction platforms. First, we employ a flexible magnetoresistive sensor for user-definable temporal multipattern classification. Furthermore, we realize a compact LSTM-enabled wearable magnetic-interaction system integrated into a wrist-worn platform that incorporates a planar Hall magnetoresistive sensor, enabling a single sensor to recognize multiple predefined gestures and achieving a high classification accuracy of 99.4 % at a long range interaction distance of 12 cm, highlighting the potential of deep learning-enhanced magnetic sensing to expand functionality and enable long-range magnetic interaction recognition in smart wearable interfaces.

Eco-sustainable printed magnetoresistive sensors — •Lin Guo, Xiaotao Wang, Proloy Taran Das, Yevhen Zabila, Ihor Veremchuk, Rui Xu, and Denys Makarov — Helmholtz-Zentrum Dresden-Rossendorf e.V., 01328 Dresden, Germany

Magnetoresistive sensors (MR), capable of non-contact detection of magnetic fields and consequently relative motion, have been extensively used across a broad spectrum of applications[1].Meanwhile, the massive deployment of magnetoresistive sensor arise the sustainability concerns from two aspects: 1. Carbon footprint in fabrication. 2. Electronics waste issue at the end of their lifetime.

Here, we propose the printed eco-sustainable magnetoresistance sensors. First, the recyclable printed MR sensors is developed based on a polyepichlorohydrin binder[2]. The hazardous MR ([Co/Cu]50) fillers are realized a close loop recycle once after the sensor lifetime. Further, we develop a healable and recyclable printed MR sensor via a full biomaterial gelatin-choline-citric acid ionogel. The additional healable capability extends the service time of the printed MR sensors and the full biomaterial binder decreased the carbon footprint. Finally, we developed a fully green printed magnetoresistance with Fe@Fe3O4 core-shell particles as functional filler, carboxymethyl cellulose as matrix binder, and water as solvents. Given that the skill-fully engineered magnetic structure and spin dependent transport, the printed sensors exhibit the remarkable low field magnetoresistance and sensitivity.

MA 49.7 Thu 16:30 POT/0112

Mechanically Flexible High-Resolution Planar-Hall Effect Sensors — •Proloy Taran Das, Jan Schmidtpeter, Pavlo Makushko, Yevhen Zabila, Conrad Schubert, and Denys Makarov — Helmholtz-Zentrum Dresden-Rossendorf e.V., Institute of Ion Beam Physics and Materials Research, Bautzner Landstrasse 400, 01328 Dresden, Germany

Planar Hall effect (PHE) magnetic field sensors are attractive for applications requiring sub-nanoTesla resolution and vector field sensing [1,2]. In this presentation, we will discuss a comparative investigation of rigid and flexible PHE devices, linking their thin-film design and substrate mechanics to performance in sensitivity, linearity, and low-frequency noise. We show that flexible PHE sensors [3], fabricated as bi- and tri-layer elements on polymer substrates, maintain linear response under bending and achieve a magnetic field resolution to a few nT/*Hz at 10 Hz. The performance, rivalling that of rigid silicon-based references, is attained through careful tuning of unidirectional and uniaxial anisotropy through exchange bias, shape and growth effects and a synchronous demodulation readout. The results underscore the potential of PHE sensors for high-resolution biomagnetic sensing and robotics.

MA 49.8 Thu 16:45 POT/0112

Probing nuclear spin dynamics in a single-atom magnet using Landau-Zener transitions — •Seunghyeok Jang[1,4], Valeria Sheina[1,3], Luciano Collazo[1,3], Georg A. Traeger[5], Denis Jankovic[1,3], Alexina Ollier[1,3], Muskan Sande[2,3], Sejong Kahng[4], Andreas Heinrich[2,3], and Won-jun Jang[1,3] — [1]Center for Quantum Nanoscience, Institute for Basic Science (IBS) — [2]Departure of Physics, Ewha Woman University — [3]Ewha Woman University — [4]Departure of Physics, Korea University — [5]Physik, Georg-August-Universitat Gottingen

Single-atom magnets provide a unique platform to probe quantum dynamics driven by hyperfine interactions. Holmium atoms on MgO thin films constitute a model system with exceptionally long-lived electronic states and well-resolved avoided level crossings, enabling electron-spin inversion via Landau-Zener (LZ) tunneling. Here, using spin-polarized scanning tunneling microscopy, we perform single-shot measurements of LZ tunneling events on 2-monolayer (ML) MgO at millikelvin temperatures, observing nuclear-spin polarization and resolving a ~10 peV gap at the avoided level crossing. We further measure the nuclear-spin lifetimes on both 2 ML and 3 ML MgO by applying LZ transitions twice in a pump-probe scheme. On 3 ML MgO, the lifetime reaches several hundred seconds, representing an enhancement of roughly two orders of magnitude compared with 2 ML. The exceptionally long nuclear-spin lifetime highlights single Ho atoms on MgO as a promising platform for quantum information processing based on coupled electron-nuclear spin states.

MA 49.9 Thu 17:00 POT/0112

Sensing Electric Currents in an a-IGZO TFT-Based Circuit Using a Quantum Diamond Microscope — •Pralekh Dubey[1], Mayana Yousuf Ali Khan[2], Lakshmi Madhuri P[3], Ashutosh Kumar Tripathi[3], Phani Kumar Peddibhotla[1], and Pydi Ganga Bahubalindruni[2] — [1]Department of Physics, Indian Institute of Science Education and Research, Bhopal — [2]Department of Electrical Engineering and Computer Science, Indian Institute of Science Education and Research, Bhopal — [3]National Centre for Flexible Electronics, Indian Institute of Technology, Kanpur

Quantum diamond microscopy (QDM), based on nitrogen-vacancy centers in diamond, provides a new approach for non-invasive magnetic imaging and diagnostics of electronic circuits under ambient conditions. By detecting magnetic fields generated by on-chip currents, QDM can probe device regions inaccessible to conventional electrical methods. It enables reconstruction of current density maps with sub-micron spatial resolution and sensitivity down to sub-microampere currents. Here, we employ a home-built QDM to map current flow in amorphous indium-gallium-zinc oxide (a-IGZO) thin-film transistor (TFT) circuits, a key technology for flexible and transparent electronics. As a demonstration, we map magnetic fields produced by current flowing through an a-IGZO TFT-based current mirror circuit. The corresponding current density was reconstructed, enabling direct visualization of current pathways. This study establishes QDM as a novel and powerful diagnostic tool for evaluating oxide-semiconductor circuits and emerging technologies.

MA 50: Bulk Materials: Soft and Hard Permanent Magnets

Time: Thursday 15:00–17:15 Location: POT/0151

MA 50.1 Thu 15:00 POT/0151

Ag-induced hardening and enhanced magnetic performance in SPS-consolidated CoCrFeMnNi high-entropy alloys — •Emmanouil Kasotakis[1], Ivan Tarasov[1], Tatiana Smoliarova[1], Hamed Shokri[2], Bilal Gökce[2], Michael Farle[1], and Natalia Shkodich[1] — [1]Faculty of Physics and Center of Nanointegration (CENIDE), University of Duisburg-Essen, Duisburg, 47057 Germany — [2]Chair of Materials Science and Additive Manufacturing, School of Mechanical Engineering and Safety Engineering, University of Wuppertal, Wuppertal, 42119 Germany

Nanocrystalline CoCrFeMnNi-Agx (x = 0; 1; 2.5; 5.5 at. %) high-entropy alloy (HEA) powders, produced via rapid two-step high-energy ball milling (HEBM) in Ar [1], were consolidated into ferromagnetic (Tc ~ 80 K) bulk samples by spark plasma sintering (SPS) at 700 K and 1000 K. Ag-free CoCrFeMnNi sintered at 1000 K formed a single-phase fcc alloy with uniform elemental distribution and a Vickers microhardness (HV0.2) of 2.4 GPa. Ag addition created distinct powder microstructures, from Ag-segregated regions (1 and 2.5 at. %) to uniform Ag distribution (5.5 at. %), increasing HV0.2 by 12% (to 2.7 GPa) in SPS-consolidated HEAs. In-field annealing (up to 700 K, 9 T) enhanced magnetization (M), coercivity (Hc), and remanence (Mr). CoCrFeMnNi-Agx (x = 5.5 at. %, 700 K) showed a tenfold rise in M (9 T, 310 K) to 40.2 Am2/kg, Hc = 46 kA/m, and Mr = 12.1 Am2/kg. We acknowledge DFG support (project ID: FA209/27-1).

MA 50.2 Thu 15:15 POT/0151

Transition-Metal-Induced Uniaxial Anisotropy in Fe_3Y — •M. Nur Hasan[1], Santa Pile[2], Rafael M. Vieira[1,3], Alexander Kovacs[2], Samuel RJ Holt[4], Martin Lang[4], Swapneel Pathak[4], Andrea Petrocchi[4], Hans Fangohr[4], Thomas Schrefl[2], and Heike C. Herper[1] — [1]Uppsala University, Sweden — [2]University for Continuing Education Krems, Austria — [3]Luleå University of Technology, Sweden — [4]MPSD, Hamburg, Germany

The rising demand for sustainable energy increases the need for rare-earth-free high-performance permanent magnets. The intermetallic compound Fe_3Y is a promising candidate due to its high saturation magnetization and Curie temperature. However, its intrinsic easy-plane magnetocrystalline anisotropy (MCA) hinders its use as a permanent-magnet material. Here, we combine first-principles density functional theory, spin-dynamics and micromagnetic simulations to explore mechanisms for reorienting the MCA toward a desired uniaxial direction through selective transition-metal doping. Our results show that Fe-site substitution, particularly with V, Zn, Nb, and Ta reverses the MCA to a uniaxial, reaching values up to 2 MJ/m^3, while the Curie temperature remains unaffected by these dopants. Micromagnetic simulations reveal dopant-specific hysteresis trends and indicate that the systems maintain stability in low-temperature regimes.

MA 50.3 Thu 15:30 POT/0151

Magnetic imaging of interaction domains in nanocrystalline Nd-Fe-B by X-rays — P. Klassen[1], D. Günzing[2], A. Aubert[3], B. Eggert[1], T. Feggeler[2,4], •L. Kämmerer[1], G. Kämmerer[1], F. Maccari[3], J. Neethijaran[5], A. Ditter[2], D. Shapiro[2], H. Wende[1], K. Skokov[3], O. Gutfleisch[3], C. Donnelly[5], and K. Ollefs[6] — [1]Uni. Duisburg-Essen and CENIDE, GER — [2]LBNL, ALS, CA US — [3]Mat. Sc., TU Darmstadt, GER — [4]BNL, NSLS-II, NY US — [5]MPI-CPfS, Dresden, GER — [6]KIP, Uni. Heidelberg, GER

Nd-Fe-B magnets play a key role in sustainable energy conversion due to their high energy density. We provide insights into the magnetic domain structure of nanocrystalline Nd-Fe-B magnets obtained by X-ray ptychographic coherent diffractive imaging. The magnetic interaction domains of nanocrystalline Nd-Fe-B magnets with different compositions and grain structures ($Nd_2Fe_{14}B$ and $Nd_{15}Fe_{78}B_7$ melt spun ribbons and hot-deformed Nd-Fe-B from MQU-F) are shown and correlated to its microstructure. The soft X-ray imaging at the Fe L_3 edge provides detailed insights into the complex magnetic structure within the magnets, down to individual grains in the nanometer regime (10 nm). With 3D X-ray ptycho-tomography imaging we investigate the nature and local character of the domain wall in the hot-deformed Nd-Fe-B and correlate it to the microstructure in the material. Misalignment in magnetization of individueal grains from the interaction domain direction can be seen. We gratefully acknowledge funding from the DFG via the CRC/TRR 270 and used resources of the Advanced Light Source (contract no. DE-AC02-05CH11231).

MA 50.4 Thu 15:45 POT/0151

Nanoscale origins of coercivity in Cu-modified Sm(Co,Zr)6.7 alloys with globular 1:5/2:17 nanostructure — •Burcak Ekitli[1], Alex Aubert[1], Xinren Chen[2], Konstantin Skokov[1], Fernando Maccari[1], Esmaeil Adabifiroozjaei[3], Leopoldo Molina-Luna[3], Baptiste Gault[2], and Oliver Gutfleisch[1] — [1]Functional Materials, TU Darmstadt, 64287 Darmstadt, Germany — [2]Max-Planck-Institut for Sustainable Materials, 40237 Düsseldorf, Germany — [3]Advanced Electron Microscopy, TU Darmstadt, 64287 Darmstat, Germany

Sm-Co permanent magnets are commercially available in two main forms: the SmCo5 nucleation type and the more complex Sm(Co,Fe,Cu,Zr)7-7.5 (2:17-type), where coercivity is controlled by domain-wall pinning linked to a Cu concentration gradient within a cellular nanostructure. In this work, we investigate the Sm(CobalCuyZr0.023)6.7 composition to examine how Cu content affects microstructure and magnetic performance. HRSEM, TEM, and atom probe tomography reveal a previously unreported globular nanostructure, consisting of nanoscale 2:17 regions embedded in a continuous 1:5 matrix. Coercivity increases with Cu concentration and reaches up to 2 T when the Cu gradient is sufficiently strong. This underscores the superior efficiency of the cellular structure, which achieves comparable coercivity with less Cu. However the globular structure provides more stable coercivity at elevated temperatures (>700 K). These results connect microstructure and thermal stability, guiding new designs for high-temperature Sm-Co magnets.

MA 50.5 Thu 16:00 POT/0151

Unraveling the Magnetic Interactions of Nanocrystalline Rare-Earth-Lean Nd-Fe-B Powder and the Influence of Additive Manufacturing on the Magnetic Properties — •Priyatosh Sahoo[1], Lukas Schäfer[1], Kilian Schäfer[1], Franziska Scheibel[1], Esmaeil Adabifiroozjaei[1], Rebekka Hlawaty[1], Enrico Bruder[1], Philipp Gabriel[2], Anna Ziefuss[2], Stephan Barcikowski[2], Leopoldo Molina-Luna[1], Karsten Durst[1], Oliver Gutfleisch[1], and Konstantin Skokov[1] — [1]TU Darmstadt, Germany — [2]Universität Duisburg-Essen, Germany

MQP-S powder is a promising material for Laser Powder Bed Fusion (PBF-LB/M) thanks to its excellent flowability and hard magnetic properties. It shows enhanced remanence despite an isotropic microstructure, indicating exchange-spring-like behavior. However, PBF-LB/M processing fully melts the powder, erasing its initial microstructure and possibly affecting magnetic interactions. This study explores how PBF-LB/M parameters influence both density and magnetic performance in MQP-S magnets. Selected samples were characterized using Henkel and Thamm-Hesse plots, First-Order Reversal Curves (FORC) and magnetic domain imaging give insides about the global and local magnetic properties and interaction. A comparative analysis between the initial powder and the additively manufactured samples shows distinct magnetic coupling behaviors linked to the changing microstructure, providing new insights into the relationships among processing, microstructure, and properties in these magnets.

MA 50.6 Thu 16:15 POT/0151

Accelerating Sm-Fe-V Phase-Diagram Mapping via an Active-Learning Pipeline — •Aaron Dextre, Alex Aubert, Konstantin Skokov, Oliver Gutfleisch, and Pelin Tozman — Technische Universität Darmstadt

Sm1Fe12-based compounds are promising candidates to replace Nd-Fe-B, yet realizing their potential requires specific microstructures where grains are isolated by a low-melting-point phase. To locate the specific phase equilibria required for this coexistence, we developed an active-learning framework to accelerate the mapping of the Sm-Fe-V phase diagram. Integrating Neural Networks and Random Forests, our ensemble model iteratively directed the synthesis and annealing of target alloys to refine phase boundaries efficiently. After six cycles, we determined that the 1:12 phase is stable over a broader V range, while the target two-phase field is more confined than previously reported. These findings revise the Sm-Fe-V equilibria and demonstrate active learning*s utility in magnetic materials discovery.

MA 50.7 Thu 16:30 POT/0151

A new look at the magnetic properties of $DyCo_5$ — Alena Vishina[1], Konstantin Skokov[2], Hiroki Tsuchiura[3], Patrik Thunström[1], Alex Aubert[2], Oliver Gutfleisch[2], Olle Eriksson[1,4], and •Heike C. Herper[1] — [1]Uppsala University, Uppsala, Sweden — [2]Technische Universität Darmstadt, Germany — [3]Tohoku University, Sendai, Japan — [4]WISE-Wallenberg Initiative Materials Science, Uppsala University

Rare earth (RE) intermetallics such as $RECo_5$ impress with a huge variety of magnetic properties arising from the interplay of RE 4f and transition metal 3d orbitals. Our recent study provides new insights in $DyCo_5$.[1] Measurements were carried our on single crystals in applied fields up to 14T. We employed a multiscale modelling theory combining dynamical mean field theory (as implemented in the LMTO code RSPt) and atomistic spin-dynamics (UppASD) simulations with the effective spin model for RE compounds to understand the origin of the experimental findings.

Our multiscale method allows to explain the experimentally observed magnetisation anisotropy as well as the behaviour around the magnetic compensation point. For $DyCo_5$, both experiment and theory, show that the compensation is incomplete and field dependent. Furthermore, key experimental features - such as the saturation behaviour at high fields and the evolution of the magnetic moment at different temperatures - are successfully reproduced.

MA 50.8 Thu 16:45 POT/0151

Orbital magnetic moment and magnetocrystalline anisotropy of Fe_2AlB_2 — •Nicolas Josten[1], Benedikt Eggert[1], Benedikt Beckmann[2], Anna Semisalova[1], Ralf Meckenstock[1], Konstantin Skokov[2], Hanna Pazniak[3], Thierry Ouisse[3], Katharina Ollefs[1], Heiko Wende[1], Oliver Gutfleisch[2], Michael Farle[1], and Ulf Wiedwald[1] — [1]Faculty of Physics and Center for Nanointegration (CENIDE), University Duisburg Essen, Germany — [2]Functional Materials, Institute of Materials Science, Technical University of Darmstadt, Germany — [3]LMGP, Grenoble INP, CNRS, Université Grenoble Alpes, France

Fe_2AlB_2 is a ferromagnet known for its considerably high magnetocrystalline anisotropy (1 MJ·m^{-3} at 10 K [1]), tunable Curie-temperature around ambient temperature (stoichiometric T_C = 291 K [1]) and magnetocaloric effect of moderate size (ΔT_{ad}(2 T) = 2.2 K [2]). It can be easily synthesized out of earth-abundant and low-cost elements. Here we combine X-ray magnetic circular dichroism (XMCD) and ferromagnetic resonance (FMR) measurements on single crystals to determine the orbital moment and correlate it with the high magnetocrystalline anisotropy. Additional magnetometry measurements along the principal crystallographic directions show the development of anisotropy across the ferromagnetic to paramagnetic phase transition.

MA 50.9 Thu 17:00 POT/0151

Enabling Ce Substitution in Nd-Fe-B Magnets for Wind Turbines via the 2-Powder Method — •Chi-Chia Lin[1,2], Konrad Opelt[1], Abdullatif Durgun[2], Imants Dirba[2], and Oliver Gutfleisch[2] — [1]Fraunhofer IWKS, Hanau, Germany — [2]TU Darmstadt, Darmstadt, Germany

Wind turbines contain Nd-Fe-B magnets weighing up to several tonnes. As deployment accelerates, demand for Nd rises, increasing supply risk and cost. Ce substitution can reduce critical-RE usage but degrades performance due to inferior intrinsic properties of $Ce_2Fe_{14}B$, formation of detrimental phases, and microstructural degradation.

We present a 2-powder method (2PM) enabling substantial Ce substitution without geometry constraints. A coarser (Ce,Nd)-Fe-B main powder is blended with a finer Nd-Fe-B powder and conventionally sintered, producing a uniform core-shell structure in which Nd-enriched shells magnetically harden $RE_2Fe_{14}B$ grain surfaces. Relative to single-powder processing at identical overall composition, 2PM boosts coercivity, remanence, and energy product by increasing local anisotropy fields at grain surfaces and optimizing grain-boundary chemistry. In addition, we introduce a hybrid segmented magnet that positions the 2PM Ce-substituted segment between Nd-Fe-B segments, extending local magnetic hardening to a bulk macroscopic effect and enhancing demagnetization resistance while concentrating Nd only where peak coercivity is required.

Together, 2PM and hybrid segmentation offer a scalable route to thrift Nd with abundant Ce toward wind-turbine performance targets.

MA 51: Spin Transport and Orbitronics, Spin-Hall Effects II (joint session MA/TT)

Time: Thursday 15:00–17:00 Location: POT/0361

MA 51.1 Thu 15:00 POT/0361

Spin-pumping and induced magnetic polarization in permalloy/platinum heterostructures — •Verena Ney[1], Kilian Lenz[2], Fabrice Wilhelm[3], René Hübner[2], Fabian Ganss[2], Andrei Rogalev[3], Jürgen Lindner[2], and Andreas Ney[1] — [1]Johannes Kepler Universität Linz, Österreich — [2]Helmholtz Zentrum Dresden-Rossendorf, Deutschland — [3]ESRF, Grenoble, Frankreich

Spin pumping is the transfer of angular momentum across interfaces into a non-ferromagnetic material driven by the precessing magnetization of an adjacent ferromagnet. Using ferromagnetic resonance (FMR) the presence of spin pumping can be evidenced by an increase of the Gilbert damping parameter α [1]. Here we study platinum-permalloy (Pt/Py) heterostructures using temperature-dependent broadband FMR. A clear increase of α is seen in a temperature range from 10 to 300 K when Pt and Py are in direct contact. The temperature dependence of the spin-pumping contribution can be derived by comparing with an Al-sandwiched Py reference film from [2]. Surprisingly, upon insertion of a thin Al spacer layer between Pt and Py the increase in α is suppressed. X-ray magnetic circular dichroism at the Pt L_3-edge reveals a clear magnetic polarization in Pt/Py whereas it is absent when a spacer layer of only 2 nm of Al is inserted.

The induced polarization of Pt can thus be associated with spin pumping, while non-polarized Pt in proximity to Py shows an almost identical $\alpha(T)$ behavior as the Py reference sample in [2].

Single and double spin Hall anomalous Hall and Hanle effects in Pt/YIG and Ta/YIG bilayers — •Akashdeep Akashdeep, Duc Minh Tran, Mathias Kläui, Gerhard Jakob, and Timo Kuschel — Johannes Gutenberg University Mainz, Germany

Anomalous Hall effect data of heavy metal / magnetic insulator bilayers, such as $Pt/Y_3Fe_5O_{12}$ (YIG), are commonly explained by magnetoresistance effects that are quadratically depending on the spin Hall angle (SHA) [1-4]. This is because they usually consist of two spin Hall processes as for example valid for spin Hall magnetoresistance [1,2]. In addition, S. Zhang et al. predicted theoretically a single spin Hall process combined with interfacial spin-dependent scattering which results in a linear SHA dependence [5] not reported experimentally so far.

In this contribution, we present anomalous Hall effect results for Pt/YIG and Ta/YIG with opposite sign in SHA of Pt and Ta. Thus, we can probe even and odd SHA dependencies. For thin Pt and Ta thicknesses, we observe results that are even in the SHA which is consistent with experimental literature. However, we found an odd SHA dependence for thicker heavy metal layers which is only partially mentioned in theory. We will present the separation of the effects and discuss the impact of the SHA on the individual effect contributions.

MA 51.3 Thu 15:30 POT/0361

Current-induced spin and orbital polarization in the ferroelectric Rashba semiconductor GeTe — •Sergio Leiva-Montecinos[1], Libor Vojáček[2], Jing Li[2], Mairbek Chshiev[2], Laurent Vila[2], Ingrid Mertig[1], and Annika Johansson[3] — [1]Martin-Luther-Universität Halle-Wittenberg, Germany — [2]Univ. Grenoble Alpes, CEA, CNRS, Grenoble, France — [3]Max Planck Institute of Microstructure Physics, Halle (Saale), Germany

The Edelstein effect is a promising mechanism for generating spin and orbital polarization from charge currents in systems without inversion symmetry. In ferroelectric materials, such as Germanium Telluride (GeTe), the combination of bulk Rashba splitting and voltage-controlled ferroelectric polarization provides a pathway for electrical control of the sign of the charge-spin conversion [1, 2].

In this work [3], we investigate current-induced spin and orbital magnetization in bulk GeTe using Wannier-based tight-binding models derived from *ab initio* calculations and semiclassical Boltzmann theory. Employing the modern theory of orbital magnetization, we demonstrate that the orbital Edelstein effect surpases its spin counterpart by one order of magnitude. Moreover, the orbital Edelstein effect remains largely unaffected in the absence of spin-orbit coupling, highlighting its distinct physical origin compared to the spin Edelstein effect.

Orbital contribution to g-tensor from first-principles modern theory — •Garima Ahuja[1], Mirco Sastges[2,3], Dongwook Go[4], Shobhana Narasimhan[1], Yuriy Mokrousov[2,3], and Stefan Blügel[2,5] — [1]Theoretical Sciences Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Bengaluru, India — [2]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, Jülich, Germany — [3]Institute of Physics, Johannes Gutenberg University Mainz, Mainz, Germany — [4]Department of Physics, Korea University, Seoul, South Korea — [5]Institute for Theoretical Physics, RWTH Aachen University, Aachen, Germany

The electronic g-factor, which measures how angular momentum couples to magnetic fields, is a key descriptor of magnetic behavior in solids. In crystalline materials, the orbital contribution to the g-factor can significantly modify its value. In this talk, we present a first-principles framework for computing g-factors, based on multiband perturbation theory with the DFT-Wannier approach, to reveal microscopic origins of the orbital contribution, highlighting the roles of local and non-local orbital currents. We resolve both orbital and spin responses, determine the full g-tensor, and show how interband couplings and band geometry shape the g-tensor across the Brillouin zone. g-tensor plays a key role in quantum technologies, where qubit coherence and control depend on accurate knowledge of magnetic response. We present our findings for some interesting bulk and 2D systems, offering a predictive route for engineering magnetic responses in materials relevant to quantum computing, spin-orbitronics, and spectroscopy.

MA 51.5 Thu 16:00 POT/0361

Inherent Electro-Optic Kerr Rotation — •Erlend Syljuåsen[1], Alireza Qaiumzadeh[1], Rembert Duine[2,3], and Arne Brataas[1] — [1]Center for Quantum Spintronics,Trondheim, Norway — [2]Institute for Theoretical Physics, Utrecht University, The Netherlands — [3]Department of Applied Physics, Eindhoven University of Technology, The Netherlands

Static electric-field–induced Kerr rotation of reflected light is used to probe symmetry breaking, electronic properties, and transport phenomena as the spin and orbital Hall effects. In this talk, we uncover a previously overlooked contribution to the electric-field–induced Kerr rotation, arising from the interplay of matter, the static electric field, and the magnetic component of light. This contribution remains nonzero even in isotropic nonmagnetic homogeneous materials, making this effect inherent to any such Kerr measurement. We present analytical expressions for both two-dimensional layers and semi-infinite bulk metals, and find within the relaxation-time approximation signal magnitudes directly relevant for experiments.

MA 51.6 Thu 16:15 POT/0361

Thermally Activated Spin Transport in a Multiferroic $LiCu_2O_2$/Pt Heterostructure — •Mathew James, Ankita Nayak, István Kézsmárki, and Aisha Aqeel — University of Augsburg, 86159 Augsburg, Germany

Multiferroics, in which electric and magnetic orders are coupled, are potential materials for low-power spintronic devices. $LiCu_2O_2$ is a Type II multiferroic material known to exhibit spiral (non-collinear) spin ordering below its antiferromagnetic transition temperature, $T_N \approx 23$ K [1]. In this material, the magnetic Cu^{2+} ions form double chains along the crystallographic b-axis, resulting in a double-leg spin-ladder configuration.

In this study, we use the Spin Seebeck Effect (SSE) as an electric probe to investigate the thermally activated magnetic response of $LiCu_2O_2$ across different magnetic configurations. In the SSE, a temperature gradient across a magnetic insulator generates non-equilibrium magnons that carry a spin current. This spin current is converted into a measurable voltage in a heavy-metal layer deposited on top of the insulator, via the Inverse Spin Hall Effect [2]. Our preliminary results indicate that the SSE voltage is sensitive to the spiral ordering in $LiCu_2O_2$. References: [1]S. Park, et al., Phys. Rev. Lett., 98, 5 (2007). [2]K. Uchida et al., Nature, vol. 455, no. 7214, (2008).

MA 51.7 Thu 16:30 POT/0361

Current-induced orbital dynamics in magnetic oxides — •Mahmoud Zeer[1], Marjana Ležaic[1], Dongwook Go[1,2], Leonid Pourovskii[3], Stefan Blügel[1,4], Mathias Kläui[2], Olena Gomonay[2], and Yuriy Mokrousov[1,2] — [1]Peter Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Institute of Physics, Johannes Gutenberg-University Mainz, 55099 Mainz, Germany — [3]CPHT, CNRS, École polytechnique, Institut Polytechnique de Paris, 91120 Palaiseau, France — [4]Institute of Theoretical Physics, RWTH Aachen University, 52074 Aachen, Germany

Magnetic oxides provide an ideal platform for exploring orbital de- grees of freedom emerging from strong orbital angular momentum and spin-orbit coupling. The resulting unquenched orbital moments en- able rich orbital-transport phenomena, particularly in antiferromag- netic systems. In this work, we investigate current-induced orbital dy- namics in representative transition-metal oxides using first-principles calculations in both bulk and thin-film geometries. We identify siz- able orbital response and highly efficient orbital-to-spin conversion mechanisms, which give rise to substantial torque components on the magnetic sublattices [1]. In addition, we analyze the contributions of dipole, quadrupole, and octupole magnetic moments to the overall orbital response. Our findings establish magnetic oxides as a promis- ing and realistic platform for harnessing orbital degrees of freedom for next-generation spin-orbital technologies. [1] S. Krishnia, C. Schmitt, M. Zeer et al., under review.

Disentangling angular momentum transport in ferromagnet-diamagnet structures via suspended systems — •Fiona Sosa Barth[1,2], Matthias Grammer[1,2], Richard Schlitz[3], Tobias Wimmer[1,2], Janine Gückelhorn[1,2], Luis Flacke[1,2], Sebastian T.B. Goennenwein[3], Rudolf Gross[1,2,4], Hans Huebl[1,2,4], Akashdeep Kamra[5], and Matthias Althammer[1,2] — [1]Walther-Meißner-Institut, BAdW, Garching, Germany — [2]School of Natural Sciences, TUM, Garching, Germany — [3]Department of Physics, University of Konstanz, Konstanz, Germany — [4]Munich Center for Quantum Science and Technology, München, Germany — [5]RPTU Kaiserslautern-Landau, Kaiserslautern, Germany

Spintronics relies on the transfer of angular momentum between electrons and solid state excitations such as magnons and phonons. In our recent work, we demonstrate angular momentum transfer between two ferromagnetic strips on diamagnetic substrates [1]. A DC current on one of the strips is converted into a non-equilibrium magnon accumulation, which transfers angular momentum to the magnonic system of the second FM strip, detected electrically by the inverse processes. In this work, we investigate how the nature of this angular momentum transport is affected by the substrate. We first examine how SiOx, SiN and

SiN/SiOx layers on Si substrates impact the transport response, and then study the effect in freestanding ferromagnetic strips fully decoupled from the substrate. This allows us to separate potential dipolar from phononic contributions to the coupling between the FM strips. [1] R. Schlitz et al., Phys. Rev. Lett. 132, 256701 (2024)

Coupling between spin waves and excitons in CrSBr bilayers — •Luis Rolf Gieselmann, Thorsten Deilmann, and Michael Rohlfing — Institute of Solid State Theory, University of Münster, Germany

CrSBr is a layered van der Waals semiconductor characterized by its peculiar magnetic structure, possessing ferromagnetic ordering within and antiferromagnetic ordering between its layers.

The antiparallel alignment of spins in neighboring layers directly affects the excitonic properties of the material, as interlayer transitions of electrons and holes are thus optically forbidden in the magnetic ground state. External manipulation of the spins, however, produces partially parallel alignments between layers and thus enables excitations of interlayer excitons.

Such excitonic effects have previously been studied for canting by an external magnetic field. In our work, we have considered an alternative, namely canting of the spins induced by spin waves within CrSBr bilayers. The spin wave behavior of the material is studied using coherent states and then employed in a simple model Hamiltonian to calculate the change of excitonic energies.

MA 52.2 Thu 15:00 P4

Holstein-Primakoff Expansions and the Goldstone Theorem for Ferromagnetic Spin Chains — •Hendrik Wächter, Fred Hucht, and Jürgen König — University of Duisburg-Essen, Faculty of Physics, Duisburg, Germany

A common approach to investigate collective magnetic excitations is to represent spins as bosons. A popular representation that achieves this is the Holstein-Primakoff transformation, which comes at the cost of introducing square roots containing the occupation number operator to the spin ladder operators. For many applications, it is preferable to expand these square roots in power series. Typically, this is done by a Taylor series expansion in powers of $1/S$, sacrificing essential virtues of the Holstein-Primakoff transformation by coupling to an unphysical Hilbert space. We consider Newton series expansions as an alternative [1]. Ferromagnetic spin chains are used to compare the efficacy of both expansions, focusing on ground-state and low-energy excitation properties, notably including Goldstone modes. Matrix product states and the density-matrix renormalization group method are used to obtain highly accurate numerical results. We find that the Newton series expansion up to a finite order respects the existence of gapless spin excitations within the relevant Hilbert space.

MA 52.3 Thu 15:00 P4

Local Spin Seebeck Effect in Hematite — •Florian Kraft[1], Maximilian Thiel[1], Katharina Lasinger[1,2], Matthias R. Schweizer[1], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, Germany — [2]Clarendon Laboratory, Department of Physics, University of Oxford, United Kingdom

Antiferromagnets such as hematite (α-Fe_2O_3) are key candidates for spintronic and magnonic devices due to their ultra-low magnetic damping and vanishing stray fields. However, the inherent compensation of magnetic moments makes probing the magnetic order challenging.

We employ the Local Spin Seebeck Effect (LSSE), generated by focused laser heating of an α-Fe_2O_3/Pt bilayer, to spatially resolve thermal spin currents. Our measurements are performed at room temperature, where hematite orders in a weak ferromagnetic state, characterized by an intrinsic net magnetization (**m**). In our r-cut single crystal, the crystallographic c-axis is obliquely aligned relative to the surface plane, thus enabling us to vary the in-plane and oblique components of **m** and the Néel vector **n** by rotating the external magnetic field.

The local heat-to-spin conversion mechanism is analyzed through the field and field-angle dependence of the LSSE signal. We place particular emphasis on alignments close to the in-plane projection of the c-axis, as this direction maximizes the competition between the magnetic field and intrinsic anisotropies. Resolving the contributions of the in-plane and oblique components of **m** and **n** is critical for understanding magnon transport in complex antiferromagnetic systems.

MA 52.4 Thu 15:00 P4

Entanglement and Dissipation in Quantum Spin Systems — •Jakob Wagner, Daniel K. J. Boness, and Wolfgang Belzig — Department of Physics, University of Konstanz, D-78457 Konstanz, Germany

Squeezing in quantum systems allows the reduction of quantum fluctuations in one observable of interest at the cost of enhanced uncertainty in its conjugate. Spin systems common in magnonics naturally exhibit squeezing [1, 2]. Generally, dissipation changes the amount of squeezing, possibly also amplifying it [3, 4]. Here, we relate the effects of dissipation in spin systems to linearized bosonic systems. We extend previous considerations by assuming a general linear system-bath coupling. Associating the position coordinate of the bosonic system with spin fluctuations in one direction, as well as the momentum coordinate with the orthogonal direction we demonstrate the equivalence of the Landau-Lifschitz-Gilbert equation to an unconventionally damped harmonic oscillator. We demonstrate several coupling dependent effects like control of the squeezing direction and modified entanglement properties. Our results thus give new controls over decoherence in magnonic systems via engineered dissipation.

Demidov[2], Steffen Michaelis de Vasconcellos[1], and Rudolf Bratschitsch[1] — [1]Institute of Physics and Center for Nanotechnology(CeNTech), UniversityofMünster — [2]InstituteofAp- plied Physics, University of Münster — [3]Center for Soft Nanoscience, University of Münster — [4]Kirchhoff-Institute for Physics, Heidelberg University

Magnons hold the promise for novel computing architectures due to their low power consumption. Recently, magnonic YG waveguides have been demonstrated using a maskless silicon ion-implantation technique [1]. Here, we examine how silicon ion implantation modifies the structural, optical, and magneto-optical properties of YIG thin films. Our findings establish design guidelines for YIG improved spin-wave manipulation for magnonic integrated circuits. Reference: [1] J. Bensmann, et al., Nat. Mater. 24, 1920-1926 (2025).

MA 52.6 Thu 15:00 P4

Linear Spin Wave Theory for Resonant Inelastic X-ray Scattering — •Paul Hille and Maurits W. Haverkort — Institute for Theoretical Physics, Heidelberg University, 69120 Heidelberg

Magnon excitations provide a key window into the collective magnetic behavior of correlated materials. While inelastic neutron scattering (INS) has long been the standard technique to map magnon dispersion relations and intensities, in recent years, resonant inelastic X-ray scattering (RIXS) has grown into a complementary technique to measure dispersing magnetic excitations. Within the RIXS process one can not only excite single magnons but also multiple magnetic excitations with a single photon.

The central goal of this work is to extend existing linear spin wave theory (LSWT) routines for INS to handle multi-magnon excitations characteristic of RIXS spectra. This is combined with an effective RIXS scattering operator incorporating the resonant energy and light polarisation dependence. We obtain a general and extensible computational framework that enables RIXS modeling for realistic magnetic materials within LSWT. Furthermore, quantitative comparison with experimental RIXS data enables assessment of the validity of treating magnons as non-interacting quasiparticles.

MA 52.7 Thu 15:00 P4

Electric Control of Magnon Phase via the Aharonov–Casher Effect — •Gabriel Schwöbel[1], Rostyslav O. Serha[2], Matthias R. Schweitzer[1], Vitaliy I. Vasyuchka[1], Mathias Weiler[1], Burkard Hillebrands[1], and Aleksander A. Serga[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, Kaiserslautern, Germany — [2]Faculty of Physics, University of Vienna, Vienna, Austria

A promising approach toward nonreciprocal magnon phase manipulation is offered by the Aharonov–Casher effect—a mechanism whereby particles or quasiparticles with a magnetic moment acquire an additional phase when traveling through an electric field. While this effect has been theoretically predicted for magnons, direct experimental confirmation is still lacking. Additionally, electric fields also influence magnetic systems through the magnetoelectric effect by modifying the magnetization.

Our experiments demonstrate that the Aharonov–Casher effect and magnetoelectric contributions can be independently quantified and unambiguously distinguished. By applying an in-plane electric field to a perpendicularly magnetized YIG film, we achieve controlled manipulation of the phase of the forward-volume magnetostatic spin waves. The resulting phase shifts depend on both the propagation direction and the polarity of the applied electric field, demonstrating electric-field tunability of magnon transport and offering a pathway toward nonreciprocal phase control in magnonic systems.

MA 52.8 Thu 15:00 P4

Femtosecond noise correlation spectroscopy of magnon fluctuations in bismuth doped yttrium iron garnet — •C. Runge[1], F. S. Herbst[1], M. A. Weiss[1], N. Beaulieu[2], J. B. Youssef[2], A. Leitenstorfer[1], M. Lammel[1], R. Schlitz[1], and S. T. B. Goennenwein[1] — [1]Department of Physics, University of Konstanz, Germany — [2]LabSTICC, CNRS, Université de Bretagne Occidentale, France

Magnetic systems exhibit a rich variety of dynamic phenomena on ultrafast timescales, which are of both fundamental and technological interest. For example, magnons, the quanta of spin waves, are discussed as promising candidates for information carriers due to their ability to propagate without charge transport. Femtosecond noise correlation spectroscopy (FemNoC) has been established [1] as a time-resolved optical technique that directly probes the local magnetization correlation function of a spin system. Thus, FemNoC is sensitive to incoherent magnetization dynamics like thermal magnons or random telegraph switching in the anisotropy landscape and allows to distinguish them by their respective correlation characteristics [1]. Here, we apply FemNoC to bismuth doped yttrium iron garnet. We investigate the magnon population of the sample both in thermal equilibrium and excited by ferromagnetic resonance. Introducing a quantitative model we can fit both regimes and determine the number of magnons induced by the resonant drive.

MA 52.9 Thu 15:00 P4

Active noise spectroscopy of magnon-photon polaritons — •Lars Nikolas Hess, Philipp Schwenke, Vitaliy Vasyuchka, Kevin Künstle, and Mathias Weiler — Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

Microwave (MW) cavities offer a wide range of applications for exciting ferromagnetic resonance (FMR) in solid-state magnets [1]. Due to the interaction of resonant MW photons with the magnonic excitations of a magnetic sample, their coupling behaviour can be studied in detail [2]. In this study, we use a MW cavity designed to operate in the frequency range from 500 MHz to 600 MHz to investigate the thermally excited MW photons and their coupling to magnons in the ferrimagnetic insulator $Y_3Fe_5O_{12}$ (YIG). To this end, a 2 *m thick YIG film is positioned inside the cavity. The resonant coupling between the MW photons and the YIG FMR is realised. An active feedback loop inspired by a similar setup for surface acoustic wave resonators [3] is implemented to specifically amplify the thermal photons in the MW cavity, that couple to the magnetic excitations in YIG. The resonator used in combination with the active amplification process makes it possible to determine characteristic parameters of the coupled systems without the use of an external MW source.

MA 52.10 Thu 15:00 P4

Low-temperature-compatible iron garnet films grown by liquid phase epitaxy — Jamal Ben Youssef[1], Nathan Beaulieu[1], Richard Schlitz[2], Davit Petrosyan[3], •Michaela Lammel[2], and William Legrand[4] — [1]LabSTICC-CNRS, Université Bretagne Occidentale, Brest — [2]Department of Physics, University of Konstanz, Konstanz — [3]Department of Materials, ETH Zurich, Zurich — [4]CNRS, Institute Néel, Université Grenoble Alps, Grenoble

Integrating thin epitaxial yttrium iron garnet (YIG) - one of the prototypical material systems in the field of magnonics, owing to its record-low damping of the magnetization dynamics - into hybrid (quantum) systems promises a platform to study the interaction of magnons with other (quasi)particles. However, up to now the usability of YIG in such devices is limited due to the losses occurring at low temperatures due to the paramagnetic gadolinium gallium garnet (GGG) substrate, and eventually Gd intermixing in the first layers. To circumvent this problem, we use liquid phase epitaxy (LPE) to grow ultrathin films of strained YIG on a commercial diamagnetic substrate, yttrium scandium gallium garnet (YSGG) [arXiv:2509.06242]. We investigate their magnetization dynamics between 3 K and 300 K, and compare them to films grown on paramagnetic GGG. We demonstrate that our LPE YIG on YSGG substrates features a ferromagnetic resonance linewidth below 1 mT at 3 K, together with a very weak temperature and frequency dependence of the losses. Therewith, the growth of YIG/YSGG by LPE provides a straightforward approach for the fabrication of YIG thin films for low-temperature investigations.

MA 52.11 Thu 15:00 P4

Magnetoacoustic interaction in Yttrium-Iron-Garnet / Aluminium-Scandium-Nitride heterostructures — •Kaya Gauch[1], Kevin Künstle[1], Yannik Kunz[1], Agne Žukauskaite[2,3], Stephan Barth[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzisch Tech nische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Fraunhoferr Institute for Electron Beam und Plasma Technology FEP, 01277 Dresden, Germany — [3]Institute of Solid State Electronics, Technische Universität Dresden, 01062 Dresden, Germany

The magnetoelastic interaction between surface acoustic waves (SAWs) and spin waves (SWs) has attracted considerable attention in recent years. Magnetoelastic excitation of SWs is particularly promising in low-damping ferrimagnets such as yttrium iron garnet (YIG). Electri cal excitation of SAWs necessitates a piezoelectric layer, such as ZnO [1]. Here, we investigate magnetoelastic interactions in a heterostruc ture consisting of a YIG/GGG bilayer coated with a piezoelectric AlScN thin film. The coupling between SAWs and SWs is characterized using micro-focused Brillouin light scattering (BLS) spectroscopy and vector network analyzer (VNA) measurements. In addition, the ob served magnetoelastic interaction is benchmarked against the coupling in the more established ZnO/YIG/GGG heterostructure. [1] Ryburn et al., Phys. Rev. Appl. 23, 034062 (2025)

MA 52.12 Thu 15:00 P4

Distinctive Propagation of Phonon-mediated Magnons in YIG/GGG — •Youngseon Soon[1], Moojune Song[1], Phuoc Cao Van[2], Jinhyun Baek[1], Byong-Guk Park[3], Jong-Ryul Jeong[2], Albert Min Gyu Park[1], and Kab-Jin Kim[1] — [1]Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 34141, Republic of Korea — [2]Department of Materials Science and Engineering, Chungnam National University, Daejeon 34134, Republic of Korea — [3]Department of Materials Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon 34141, Republic of Korea

Magnonic systems enable information processing via collective spin excitations and couple efficiently to other quasiparticles. We study magnetostatic surface spin waves (MSSWs) coupled to standing acoustic waves in a 200-nm YIG film on GGG. Using two microwave antennas and VNA measurement, we observe 3.5 MHz periodic modulation in transmission spectra arising from magnetoelastic interaction. As the magnon wave vector k increases, these phononic signatures weaken and eventually vanish, reflecting both the k-dependence of the coupling and the momentum selectivity of antennas. Phonon-mediated magnon modes emerge at lower frequencies than directly excited MSSWs and propagate much farther, providing a low-k channel for long-distance spin-wave transport without acoustic resonators. These distinctive features highlight the wavevector-dependent magnon-phonon hybridization and demonstrate that both coupling strength and propagation behavior can be engineered through excitation geometry.

MA 52.13 Thu 15:00 P4

Broadband Floating-Electrode SAW Transducers for Magnetoelastic Spin-Wave Excitation in CoFeB thin films — •Kawa Noman[1], Ryusuke Hisatomi[2], Kotaro Taga[2], Teruo Ono[2], Vitaliy Vasyuchka[1], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Kyoto University, Institute for Chemical Research,Kyoto,Japan

Microwave filters based on surface acoustic wave (SAW) devices exhibit low insertion loss and enable wideband operation in the GHz range. In this study, we microfabricate custom-designed floating-electrode in terdigital transducers (FE-IDTs) on piezoelectric LiNbO3 substrates, whose unique geometry with additional electrically floating metal fin gers enhances electromechanical coupling and broadband SAW exci tation [1]. We then deposit a 10 nm CoFeB thin film by DC mag netron sputtering within the SAW propagation path. We investigate the magnetic-field dependence of the SAW-driven magnetoelastic spin-wave resonance using vector network analysis. Systematic variation of the electrode material, aperture, and duty cycle reveals a rich spec trum of high-amplitude Rayleigh modes at odd and even harmonics of FE-IDT excitation. Moreover, we observe clear signatures of SAW-driven magnetoelastic excitation of spin-waves in CoFeB. High-amplitude SAWs enable non linear magnon generation [2].

MA 52.14 Thu 15:00 P4

Backward volume spin waves in ion-implanted magnonic YIG waveguides — •Sven Niehues[1], Jannis Bensmann[1], Robert Schmidt[1], Kirill O. Nikolaev[2], Dimitri Raskhodchikov[1], Shraddha Choudhary[1], Richa Bhardwaj[1], Shabnam Taheriniya[1,3,4], Akhil Varri[1,3], Ahmad El Kadri[1], Johannes Kern[1], Wolfram H. P. Pernice[1,3,4], Sergej O. Demokritov[2], Vladislav E. Demidov[2], Steffen Michaelis de Vasconcellos[1], and Rudolf Bratschitsch[1] — [1]Institute of Physics and Center for Nanotechnology (CeNTech), University of Münster — [2]Institute of Applied Physics, University of Münster — [3]Center for Soft Nanoscience, University of Münster — [4]Kirchhoff-Institute for Physics, Heidelberg University

Magnonics offers a promising alternative approach to conventional information processing due to the low-energy nature of spin waves and distinctive features such as nm-scale wavelengths. Recently, the fabrication of dispersion-tunable magnonic waveguides and a large-scale spin-wave network with 198 crossings have been demonstrated using a newly developed maskless silicon ion implantation technique [1]. Here, we show that backward volume spin waves (BVSW) propagate in silicon-ion implanted waveguides written into YIG thin films. Using time-resolved Faraday rotation spectroscopy, we extract the dispersion relation, the mode profile and damping of the BVSWs. Our results demonstrate the versatility of silicon-ion implanted magnonic waveguides, offering a promising route toward magnonic integrated circuits. Reference: [1] J. Bensmann, et al. Nat. Mat. 24, 1920-1926 (2025).

MA 52.15 Thu 15:00 P4

Quantum Geometry of Magnons — •Sidhartha Chatterjee[1], Andreas Haller[1], Peter P. Orth[2], and Thomas L. Schmidt[1] — [1]University of Luxembourg — [2]Saarland University

We develop a theoretical framework for magnon dynamics in a one-dimensional antiferromagnetic Heisenberg chain that includes next-nearest-neighbour Dzyaloshinskii-Moriya interaction (DMI) and a position-dependent magnetic field applied along the easy axis. This combination leads to a spin spiral ground state. The collective excitations above the ground state are magnons, spin-1 bosonic modes. We perform the Holstein-Primakoff transformation to obtain the magnon Hamiltonian, which is quadratic in nature. For the diagonalisation, we use the Bogoliubov transformation, and we show that the quantum geometric tensor of magnons naturally exhibits symplectic structure. This geometric structure yields corrections to the semiclassical equations of motion for magnon wave packets, resulting in anomalous velocity terms and metric-driven contributions. Overall, the framework provides a systematic route for incorporating geometric effects and symplectic structure into magnon dynamics, where no particle number conserving framework exists, and offers a pathway for engineering transport phenomena in magnetic materials through the direct manipulation of the quantum geometry of their collective excitations.

MA 52.16 Thu 15:00 P4

Impact of Magnetic Ground State on the Generation of an All-Magnonic Frequency Comb — •Alexandra Schrader, Chris Körner, Rouven Dreyer, and Georg Woltersdorf — Martin Luther University Halle-Wittenberg

We have observed the emergence of a magnonic frequency comb in extended Permalloy films as well as in microstructures of Permalloy and CoFeB. Since the frequency comb generation appears to be a unique feature of softmagnetic materials at very low bias fields (below 2 mT), we anticipate a strong correlation between the static ground state and the emerging dynamics. In the case of microstructures, the higher harmonic generation is indeed connected to the non-uniform domain structure at the edges.

However, the presence of these edge effects reduces the frequency multiplication efficiency. In this work, stripes of different aspect ratios are investigated to bridge the gap between extended layers and microstructures. This allows to explore the correlation between the static magnetization pattern obtained in Kerr microscopy and the generation of the frequency comb revealed via SNS-MOKE and NV-center microscopy. Both static and dynamic features are complemented by micromagnetic simulations.

MA 52.17 Thu 15:00 P4

Surface Acoustic Wave Generation and Detection in AlScN/GGG Heterostructures — •Karl Heimrich[1], Seth Kurfman[1], Frank Heyroth[2], Katrin Lehmann[2], Fabian Lofink[3], and Georg Schmidt[1,2] — [1]Martin Luther Universität Halle-Wittenberg Institut für Physik, Halle, Germany — [2]Interdisziplinäres Zentrum für Materialwissenschaften, Halle, Germany — [3]Frauenhofer ISIT, Itzehoe, Germany

Surface acoustic waves (SAWs) can be excited and detected in piezoelectric materials using interdigitated transducers (IDTs). In magnetostrictive materials, particularly with low-loss magnetic properties (e.g. Yttrium-Iron-Garnet, YIG), the coupling between SAWs and magnons provides unique opportunities for device applications. Different groups have already successfully demonstrated the coupling of ferromagnetic resonance with acoustic surface waves [1, 2, 3, 4]. Even the coupling to the low loss material YIG has been shown[3, 5]. Here we demonstrate the use of an Aluminium-Scandium-Nitride (AlScN)/Gallium-Gadolinium-Garnet (GGG) heterostructure to excite and detect SAWs that propagate in a pure GGG surface, offering the possibility to couple into micropatterned or even suspended YIG structures [6].

MA 52.18 Thu 15:00 P4

Magnon-phonon coupling in suspended nanostructure — •Giovanni Del Bufalo[1,2], Matthias Grammer[1,2], Johannes Weber[1,2], and Hans Huebl[1,2,3] — [1]Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — [2]TUM School of Natural Sciences, Technische Universität München, Garching, Germany — [3]Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

High-overtone bulk acoustic wave resonators were among the first mechanical systems explored in the quantum regime, enabling studies of vacuum fluctuations and non-classical states. Integrating magnetic thin films with these resonators creates hybrid magneto-phononic excitations through magnetoelastic coupling, allowing energy exchange between phonons and magnons. Beyond energy transfer, these hybrid modes can inherit angular momentum from their constituent excitations, raising a fundamental question: how is angular momentum transferred and shared between phonons and magnons in such systems? We address this by implementing a suspended silicon membrane as a bulk acoustic wave resonator, coupled to a 40nm $Co_{25}Fe_{75}$ metallic film. Using broadband ferromagnetic resonance spectroscopy at cryogenic temperatures, we quantify the magnon-phonon coupling strength and assess its implications for angular momentum transfer and magnetization damping. Our results highlight the potential of this device architecture for probing spin-mechanical interactions and advancing hybrid quantum systems that combine magnetic and mechanical degrees of freedom.

MA 52.19 Thu 15:00 P4

Characterization of spin-Hall nano-oscillators — •Christine Strickler, Moritz Bechberger, Julien Schäfer, Björn Heinz, and Philipp Pirro — Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, D-67663 Kaiserslautern, Germany

Within the research field of spintronics, spin-Hall nano-oscillators (SHNOs) have emerged as promising candidates for building blocks in neuromorphic computing. These devices typically consist of a bi layer comprising a ferromagnetic (FM) and a heavy metal (HM) layer. Typically, a direct charge current is applied to the HM, which injects a spin current into the FM via the spin Hall effect, exerting spin orbit torques that can counteract the natural damping of the FM and thereby excite coherent auto-oscillations. We perform ferromagnetic resonance spectroscopy on fabricated full-film bilayer systems to opti mize the material stack in terms of FM-layer thickness and FM/HM interface quality. The materials selected for this study are CoFeB and NiFe as FM and Pt and W as HM, which leads to four potential ma terial stacks. The optimized stacks are fabricated in several SHNO geometries and sizes to investigate their properties concerning mode spectrum and threshold current for auto-oscillation via Brillouin light scattering spectroscopy. This study of SHNO fabrication paves the way for further investigation into such structures and their potential coupling phenomena.

MA 52.20 Thu 15:00 P4

Frequency-dependent parametric injection of magnons in yttrium iron garnet — •Lars Schiesser, Franziska Kühn, Matthias R. Schweizer, Vitaliy Vasyuchka, Alexander A. Serga, and Mathias Weiler — Fachbereich Physik and Landesforschungszentrum OPTIMAS, RPTU Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

Parametric generation of magnons in low-damping yttrium iron garnet (YIG) films offers a flexible approach to excite magnons across a broad range of wavenumbers, enabling the creation of high magnon densities, which are essential for the preparation of magnon gases preceding condensation phenomena. Using parallel parametric pumping driven by a broadband stripline antenna, we investigate the frequency dependence of pumping thresholds and the ensuing nonlinear scattering processes. By tuning both the external magnetic field and the pumping frequency, we selectively control the initial position of parametrically injected magnons in momentum space and thus define the starting conditions for subsequent multi-magnon scattering dynamics. Time-resolved Brillouin light scattering (BLS) spectroscopy is employed for the direct observation of the temporal and spectral evolution of the magnon population.

These frequency characteristics provide the basis for the implementation of pumping schemes with arbitrary waveforms, which will enable the realization of complex, tailored excitation signals, opening new pathways for the precise control of nonlinear magnon dynamics.

MA 52.21 Thu 15:00 P4

Spatially-Localized Second Harmonic Generation via Spin Wave Concentration in Patterned YIG Structures — •Marc Eger[1], Stephanie Lake[1], Philipp Geyer[1], Seth Kurfman[1], Rouven Dreyer[1], and Georg Schmidt[1,2] — [1]Martin-Luther-Universität Halle-Wittenberg Insitut für Physik, Halle, Germany — [2]Interdisziplinäres Zentrum für Materialwissenschaften, Martin-Luther-Universität Halle-Wittenberg, Halle, Germany

The anisotropic dispersion and inherent non-linearity of (magnetostatic) spin waves in thin films and confined structures provide unique opportunities for

implementation in next-generation radio-frequency devices [1]. A particular challenge remains in establishing effective and useful means to locally generate and subsequently exploit higher harmonics without extraneous non-linear losses [2]. In order to compensate these losses, one method to achieve this is to focus low-intensity spin waves in a low-loss magnetic material to a localised region far from the exciting antenna. This can be done, for example, with deterministically tuning the dispersion relation by modifying film thickness along with a geometric confinement through standard patterning processes. Here we compare micromagnetic simulations and experimental results obtained by frequency- and spatially-resolved SNS MOKE [3] within passive, lithographically-patterned YIG funnel structures, wherein we demonstrate second harmonic generation of magnons.

MA 52.22 Thu 15:00 P4

Enhancing Mechanical Stability of Heusler Alloys via the Powder-in-Tube Method — •T. Niehoff[1,2], L Beyer[3,4], J. Puy[5], J. Freudenberger[3,4], O. Gutfleisch[5], J. Wosnitza[1,2], F. Scheibel[5], and T. Gottschall[1] — [1]Dresden High Magnetic Field Laboratory (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Institut für Festkörper- und Materialphysik, TU Dresden, Dresden, Germany — [3]Leibniz-Institut für Festkörper- und Werkstoffforschung IFW, Dresden, Germany — [4]TU Bergakademie Freiberg, Freiberg, Germany — [5]Institute of Materials Science, Technical University of Darmstadt Darmstadt, Germany

We address the long-standing problem of mechanical fatigue in Heusler-based elastocaloric and multicaloric materials by applying the Powder-in-Tube (PIT) method to stabilize the material inside a steel shell. This significantly enhances mechanical robustness. Under cyclic loading up to 100,000 cycles and high-load tests, PIT samples retain their structural integrity, showing only minor, non-critical end cracks while the core remains thermally connected to the shell. Even after plastic deformation, the Heusler core stays intact. Magnetization before and after cycling exhibits only minimal changes, confirming durability, and magnetocaloric measurements demonstrate excellent thermal coupling between core and metal shell. Overall, the PIT method extends the operational lifetime of Heusler alloys by orders of magnitude and allows independent optimization of mechanical stability and caloric performance.

MA 52.23 Thu 15:00 P4

Significant Enhancement of Magnetocaloric Performance of LaFe12B6 via Microstructure Optimization — •Protyasha Prachurja, Wei Liu, Alex Aubert, Benedikt Beckmann, Konstantin Skokov, and Oliver Gutfleisch — Institute of Materials Science, Technische Universität Darmstadt, Darmstadt, Germany

Light rare-earth magnetocaloric (MC) materials are appealing because of their abundance and reduced criticality risks [1]. Within this group of materials, LaFe12B6 - a first-order MC compound - undergoes a phase transition around 36 K, making it a potential candidate for hydrogen liquefaction applications [2]. However, its pronounced MC effect emerges only under relatively high magnetic fields (>5 T), which restricts its performance at lower fields [3]. This limitation is linked to its antiferromagnetic ground state and the presence of secondary phases in the microstructure. We carried out a systematic optimization of the synthesis conditions to improve phase purity and magnetocaloric properties. We found that annealing at 1383 K for 24 hours with a 3% La excess reduced the secondary phase content from 13.2 to 7.7 wt.% and sharpened the first-order transition. Consequently, the peak magnetic entropy change increased significantly from -1 to -10 J/kgK under a 5 T field. References: [1] Wei Liu et al. J. Phys. Energy, 2023, 5.3, 034001; [2] L.V.B. Diop; O. Isnard; J. Rodríguez-Carvajal Phys. Rev. B, 2016, 93.1, 80; [3] L.V.B. Diop; O. Isnard J. App. Phys., 2016, 119.21, 213904. MA 52.24 Thu 15:00 P4

Superconducting magnetic system for magnetocaloric hydrogen liquefaction — •C. Estillac Leal Silva[1,2], T. Platte[4], M. Strassheim[1,3], T. Niehoff[1,3], C. Salazar-Meija[1], J. Wosnitza[1,3], and T. Gottschall[1] — [1]Dresden High Magnetic Field Laboratory (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf Dresden, Germany — [2]TU Bergakademie Freiberg, Freiberg, Germany — [3]Institüt für Festkörper und Materialphysik, TU Dresden, Dresden, Germany — [4]Magnotherm Solutions GmbH, Darmstadt, Germany

As hydrogen's importance in the clean-energy sector continues to expand, improving its liquefaction efficiency becomes crucial, since the liquid form provides high volumetric energy density for storage and transport. Traditional compression systems, however, remain both costly and energy-intensive, prompting interest in magnetic refrigeration as an alternative process. This approach employs the adiabatic temperature variation of magnetocaloric materials in an Active Magnetocaloric Regenerator (AMR) to reach the final cooling stage required for hydrogen liquefaction. Achieving large temperature spans requires large variations in the magnetic field. In addition, higher operating frequencies are needed to reach greater cooling powers. Therefore, a magnetic system capable of sustaining high fields while supporting rapid cycling, whether through linear or rotary motion of the magnetocaloric material, is necessary. This presentation discusses the development of a superconducting magnetic system meeting these requirements, targeting a concentrated 5-7 T field which enables a sharp field change.

MA 52.25 Thu 15:00 P4

MnCrNiGeSi high-entropy alloy: structural, magnetic and magnetocaloric properties — •Atakan Tekgül[1] and Kağan Şarlar[2] — [1]Uludag University, Bursa, Turkey — [2]Karamanoglu Mehmetbey University, Bursa, Turkey

This study investigates the structural, magnetic, and magnetocaloric properties of two rare-earth-free high-entropy alloys, $Mn_{20}Cr_{14}Ni_{33}Ge_{25}Si_5$ and $Mn_{24}Cr_{10}Ni_{33}Ge_{25}Si_8$, produced by arc melting. Rietveld refinement of X-ray diffraction data confirms that both alloys crystallize in an orthorhombic Pnma structure. Increasing the Mn content from 20% to 24% strengthens the ferromagnetic exchange interactions, resulting in an enhancement of the saturation magnetization (43.8->56.7 $Am^{-1}kg^{-1}$) and an upward shift of the Curie temperature (361->387 K). Isothermal magnetization measurements and Arrott plot analyses reveal a second-order magnetic phase transition. The magnetocaloric effect, calculated via the Maxwell relation, yields a magnetic entropy change of 2.1 $Jkg^{-1}K^{-1}$ for the alloy with 20% Mn and 3.6 $Jkg^{-1}K^{-1}$ for the Mn-rich alloy under a magnetic field of 2 T. The combination of low hysteresis, high Curie temperature, and enhanced entropy change demonstrates that Mn-enriched Mn-Cr-Ni-Ge-Si HEAs offer promising performance for environmentally friendly, high-temperature magnetic refrigeration. These results confirm that compositional tuning, particularly Mn substitution, is an effective route for optimizing the magnetocaloric response in rare-earth-free HEAs.

MA 52.26 Thu 15:00 P4

Spin structure analysis on Fe_2AlB_2 powder and single-crystals — •Joachim Landers[1], Niels Kubitza[2], Soma Salamon[1], Ulf Wiedwald[1], Christina Birkel[2,3], and Heiko Wende[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen — [2]Department of Chemistry and Biochemistry, TU Darmstadt — [3]School of Molecular Sciences, Arizona State University

The MAB phase Fe_2AlB_2 exhibits ferromagnetic ordering below the Curie temperature $T_C \approx 290$ K, showing a strong magnetocaloric effect close to room temperature, which makes it a promising candidate for magnetic cooling applications. We utilize Mössbauer spectroscopy under high magnetic fields to analyze the spin structure and ferro- to paramagnetic phase transition of Fe_2AlB_2 microparticle powders. Field- and temperature-dependent measurements on an Fe_2AlB_2 single-crystal sanded down to appropriate thickness for transmission experiments are used as reference and allow for specific characterization along easy and hard magnetic directions with regards to magnetic alignment. Funding by the DFG via CRC/TRR 270 (project number 405553726, subprojects B02, B03, and B05) is gratefully acknowledged. We thank T. Ouisse and H. Pazniak (LMGP, Grenoble) for providing single crystals.

MA 52.27 Thu 15:00 P4

Combining X-ray absorption spectroscopy with a multifunctional probe to decipher first-order phase transitions — •Benedikt Eggert[1], Alex Aubert[2], Shingo Yamamoto[3], Ana Kurtanidze[3,4], Thomas Herrmannsdörfer[3], Oliver Gutfleisch[2], Kurt Kummer[5], Nick Brookes[5], Jochen Wosnitza[3,4], Katharina Ollefs[6], Konstantin Skokov[2], and Heiko Wende[1] — [1]University Duisburg-Essen — [2]TU Darmstadt — [3]HZDR, HLD-EMFL — [4]TU Dresden — [5]ESRF — [6]KIP, University Heidelberg

Here, we present a new instrumental setup designed for the investigation of magnetostructural phase transition, installed within the high field magnet at beamline ID32 of the European Synchrotron Radiation Facility in Grenoble, France. With these newly established setups, we can perform dichroic X-ray absorption spectroscopy, while accessing other subsystems via bulk probes (e.g., lattice expansion or change in electrical resistivity) within a temperature range from 4 K to 650 K in the soft X-ray regime.

Here, we will show first experimental results from La(Fe,Si)13 during the field and temperature-induced magnetostructural phase transition showcasing some of the possibilities.

Funding by the BMFTR under Grant BMBF-Projekt05K2022, and the Deutsche Forschungsgemeinschaft via CRC/TRR 270 HoMMage (Project-ID 405553726) is gratefully acknowledged. We thank the ESRF for the allocation of beamtime.

MA 52.28 Thu 15:00 P4

Magnetic and transport properties of compensated ferrimagnetic Heusler alloys at finite-temperature predicted by *ab inito* spin fluctuation theory — •Shogo Yamashita[1], Esita Pandey[1], Gerhard Fecher[1], Claudia Felser[1], and Atsufumi Hirohata[1,2] — [1]Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany. — [2]Center for Science and Innovation in Spintronics, Tohoku University, Sendai, Japan

Fully compensated ferrimagnets have been attractive for spintronics because their net zero magnetization suppresses stray fields, enabling high-density memory integration. Among them, Heusler alloys which have 24 valence electrons are of particular interest since they can exhibit both half-metallicity with 100 % spin polarization at the Fermi level and fully compensated ferrimagnetism. However, a fully compensated half metallic Heusler alloy $Mn_{1.5}V_{0.5}FeAl$ reported previously has a Curie temperature below room temperature, limiting its device applications. To find alternatives, we investigated $Mn_2Co_{0.5}V_{0.5}Al(Ga)$, which is regarded as a mixture of half-metallic $Mn_2VAl(Ga)$ and $Mn_2CoAl(Ga)$ exhibiting high Curie temperature, with 24 valence electrons. Using an *ab inito* spin-fluctuation theory based on the coherent potential approximation and disordered local moments, we examined its electronic structure, magnetic properties, and spin conductivities at finite-temperature. In this presentation, we will also discuss possible future control in the properties.

MA 52.29 Thu 15:00 P4

Broadly tunable compensation in ferrimagnetic MnFeVAl Heusler alloy — •Esita Pandey[1], Shogo Yamashita[1], Edouard Lesne[1], Gerhard Fecher[1], Claudia Felser[1], and Atsufumi Hirohata[1,2] — [1]Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany — [2]Tohoku University, Sendai, Japan

Zero-moment spintronic systems are highly desirable, as they minimize stray fields while maintaining stability against external magnetic perturbations. Unlike antiferromagnets, compensated ferrimagnets offer an ideal solution, combining a net-zero magnetic moment with spin-polarized conduction [1-3]. In this study, we demonstrate the realization of a near-zero-moment state in Mn1.5V0.5FeAl Heusler alloy thin films with a wide tunable compensation range. Films of varying thickness were fabricated on thermally oxidized Si substrates with a W buffer layer using simultaneous triple-target sputtering in an ultra-high-vacuum system. Structural analysis via X-ray diffraction shows that the W underlayer is stabilized in the body-centered cubic (bcc) α-phase with (110) orientation, while the Heusler films exhibit pronounced [110] texture and a lattice parameter close to bulk values. Magnetometry measurements reveal that the samples are magnetically isotropic and exhibit an exceptionally low saturation magnetization at RT. These results position MnFeVAl films as promising candidates for thermally stable, stray-field-free spintronic devices with robust spin-polarized transport. Reference: [1] V. Baltz et al., Rev. Mod. Phys. Vol. 90, No. 1 (2018); [2] A. Hirohata, Magnetochemistry 8, 37 (2022); [3] R. Stinshoff et al., Phys. Rev. B 95, 060410(R) (2017).

MA 52.30 Thu 15:00 P4

Halbach 2.0 - Creating homogenous fields with finite size magnets — •Peter Blümler[1] and Ingo Rehberg[2] — [1]Institute of Physics, University of Mainz, 55128 Mainz, Germany — [2]Institute of Physics, University of Bayreuth, 95440 Bayreuth, Germany

Homogeneous magnetic fields can be generated with permanent magnet arrangements, most notably Halbach rings made of idealized, infinitely long magnetic rods. However, this classical concept is limited when using real, finite magnets. To address this, three-dimensional configurations have been investigated. Optimal single and stacked rings of point dipoles are identified, offering greater field strength and homogeneity than traditional Halbach designs and earlier numerical estimates.

A central innovation is the "focused configuration" (I.R. & P.B., Phys. Rev. Appl. 23 (2025) 064029), where dipoles are tilted out of the ring plane, producing highly homogeneous fields shifted away from the magnet plane. Rotating multiple tilted rings relative to each other further improves homogeneity, though at the cost of a fixed field direction (still confined to the transverse plane).

Experiments with cuboid magnets confirm the theoretical predictions, showing that these configurations overcome finite-magnet limitations and provide enhanced field strength and homogeneity. All configurations can be explored and exported for 3D printing using a dedicated Python GUI (https://zenodo.org/records/15064360).

MA 52.31 Thu 15:00 P4

Towards Sustainable NdFeB Magnets Using Advanced Recycling — •Aybike Paksoy[1], Amrita Khan[1], Abdullatif Durgun[1], Mario Schönfeldt[2], Hasan Mahmudul[2], Iliya Radulov[2], Imants Dirba[1], and Oliver Gutfleisch[1] — [1]Functional Materials, Technical University of Darmstadt, Darmstadt, Germany — [2]Fraunhofer IWKS, Fraunhofer Research Institution for Materials Recycling and Resource Strategies, Hanau, Germany

NdFeB permanent magnets exhibit the highest maximum energy product (BH)max at room temperature, making them important for many technologies essential to the clean energy transition. However, their reliance on critical rare earth elements raises significant environmental, economic, and geopolitical challenges [1]. Consequently, increasing attention has been directed toward the recycling of end-of-life NdFeB permanent magnets. Enhancing the sustainability of rare earth permanent magnets and reducing their criticality are key requirements for environmentally responsible products. The magnetic properties of NdFeB magnets are strongly governed by their microstructure. Recycling routes can alter grain size, crystallographic texture, and defect density, which in turn influence magnetic performance. In this work, advanced recycling strategies are explored with the aim of producing sustainable NdFeB magnets while preserving their functional properties. [1] M. Schönfeldt et al., J. Alloys and Compounds (2023) https://doi.org/10.1016/j.jallcom.2023.168709

MA 52.32 Thu 15:00 P4

Resource efficient recycling and additive manufacturing of Nd-Fe-B magnets — •Amrita Khan[1], Lukas Schäfer[1], Priyatosh Sahoo[1], Iliya Radulov[2], Mahmudul Hasan[2], Konstantin Skokov[1], Igor Lubomirsky[3], and Oliver Gutfleisch[1] — [1]TU Darmstadt, Darmstadt, Germany — [2]Fraunhofer IWKS, Hanau, Germany — [3]Weizmann Institute of Science, Rehovot, Israel

Recycling Nd-Fe-B magnets is crucial for maintaining a sustainable supply of rare-earth elements for clean energy applications while significantly reducing the environmental impact and energy footprint. Additive manufacturing (AM) is a promising production route for functional magnetic materials, especially for achieving high geometric complexity, energy-efficient processing, and waste minimization. In this work, the PBF-LB/M process is used to directly produce permanent magnets, which are not yet optimized with regard to magnetic performance. The recycling of Nd-Fe-B scrap magnets and powder production is a critical step for successful processing via PBF-LB/M. In this study, different recycling processes are investigated: (i) hydrogen decrepitation, (ii) electrolytic decrepitation, and (iii) ultrasonic atomization, which are characterized regarding their particle size distribution, morphology, and flowability. The goal is to identify the influence of the powder properties on the PBF process and the resulting magnetic performance of additively manufactured magnets. This work was supported by the Volkswagen-Stiftung through the project MagCycleAM (9D878 Project No. 0071952-00).

MA 52.33 Thu 15:00 P4

Inverse garnet/Pt heterostructures by lateral crystallization — •Christian Holzmann[1], Stephan Glamsch[1], David Stein[1], Maximilian Mihm[1], Aladin Ullrich[1], Richard Schlitz[2], Michaela Lammel[2], Johannes Boneberg[2], and Manfred Albrecht[1] — [1]Institute of Physics, University of Augsburg, 86159 Augsburg, Germany — [2]Department of Physics, University of Konstanz, 78457 Konstanz, Germany

Rare-earth iron garnet thin films are known for their low Gilbert damping, insulating nature, and tunable magnetic properties. These favorable properties are mostly limited to single-crystalline films grown on specific substrates like GGG, which limits their applications [1]. To expand the functionallity of garnet thin films, we grow a thulium iron garnet film on a thin Pt layer by means of lateral crystallization. The Pt layer is sputter-deposited on a GSGG substrate, followed by garnet deposition by PLD. Hereby, a hole pattern in the Pt layer - either created naturally by thermal dewetting or artifically patterned - acts as crystallization seed. While the as-grown film is amorphous, post-deposition annealing at 700°C results in a lateral garnet crystallization rate of about 1 um/min and a single-crystalline garnet film on top of the Pt layer. This garnet film exhibits similar properties to an epitaxially grown film, including Gilbert damping as low as 0.008 [2]. Therefore, the lateral crystallization of garnet films opens up new possibilities to combine garnet and metal films for spintronic devices.

FMR in chiral Mn_2TiO_4 — •Amruthavarshini Anand[1], Rajendra Loke[1], Ahmed Rasheed[1], Agustinus Agung Nugroho[2], and Joachim Hemberger[1] — [1]Institute of Physics II, University of Cologne, 50937 Cologne, Germany — [2]Institut Teknologi Bandung, Bandung 40116, Indonesia.

Ferromagnetic resonance (FMR) is a powerful technique for probing the dynamic magnetic properties of materials. In this study, we investigate FMR in Mn_2TiO_4, an inverse spinel tetragonal oxide. When Mn occupy full of tetrahedrally coordinated A site and half of B site, the space group $P4_322$, posses a chiral axis along c. Which via spin orbit coupling influences the magnetic resonance.

FMR measurements performed across different frequencies and magnetic field orientations allow us to extract resonance fields, linewidths, damping parameters, and magnetic anisotropy constants. Analysis of the FMR data using Kittel fitting enables determination of the frequency-field relationship, effective magnetization, and g-factors, while linewidth fitting provides quantitative values of the Gilbert damping parameter. And we also performed a FMR configuration with circularly polarized microwave excitation to enhance sensitivity to chiral magnetic effects and enable a more comprehensive investigation of the system's frequency- and field-dependent behaviour.

MA 52.35 Thu 15:00 P4

Magnetic interactions in compositionally complex and high entropy perovskites BaIn1-xMxO3-δ (M = Fe, Co, Sn, Ti) — •Auguste Stanionyte[1], Laura T. Corredor[2], Richard Matyšek[2,3], Anja U. B. Wolter[4], Giuditta Perversi[3], and Anna Isaeva[1,2] — [1]University of Amsterdam, The Netherlands — [2]TU Dortmund University and Research Center Future Energy Materials and

Systems, Germany — [3]Maastricht University, The Netherlands — [4]Leibniz IFW Dresden, Germany

High configurational entropy exerts unprecedented effects on a material's phase stability and functional properties and raises questions about possible interrelationships between the two.[1] In our recent work, the BaIn1-xMxO3-δ series were obtained as phase-pure cubic perovskites where Co, Fe, Sn, Ti and In share the B-site in increasing configurational entropy.[2] The present study investigates the magnetic behavior of these compounds. We observe antiferromagnetic-like behavior in the M(T) curves below 20 K, and varying levels of hysteresis in the M(H) experiments at 2K. Specific heat measurements show a field-dependent magnetic entropy release at low temperatures, but neutron diffraction rules out long-range order. With AC susceptibility measurements showing a shift in transition temperatures for higher frequencies, the study so far indicates a glassy magnetic structure with clusters. Altogether, our experimental results give an intriguing look into the emergent properties of such complex and disordered structures, but the exact microscopic mechanism remains to be uncovered. MA 52.36 Thu 15:00 P4

FMR in chiral Mn_2TiO_4 — •Amruthavsarshini Anand[1], Rajendra Loke[1], Ahmed Rasheed[1], Agustinus Agung Nugroho[2], and Joachim Hemberger[1] — [1]Institute of Physics II, University of Cologne, 50937 Cologne, Germany — [2]Institut Teknologi Bandung, Bandung 40116, Indonesia.

Ferromagnetic resonance (FMR) is a powerful technique for probing the dynamic magnetic properties of materials. In this study, we investigate FMR in Mn_2TiO_4, an inverse spinel oxide. The magnetic Mn^{2+} ions occupy tetrahedrally coordinated (A) sites and half of octahedrally coordinated (B) sites. The space group $P4_322$ possesses a chiral axis along c, which via spin orbit coupling influences the magnetic resonance.

FMR measurements performed across different frequencies allow us to extract resonance fields and linewidths for different crystal orientations. The data can be analysed using Kittel's formula revealing magnetic anisotropy constants and g-factor, while linewidth fitting provides quantitative values of the Gilbert damping parameter. We also utilise circularly polarized microwave excitation to directly address chirality and the resulting non-reciprocity of the magnetic response.

MA 52.37 Thu 15:00 P4

Emergent electromagnetic inductance of nontrivial magnetic textures in $SrRuO_3/SrIrO_3$ bilyers — •Ludwig Scheuchenpflug[1], Sebastian Esser[2], Robert Gruhl[1], Max Hirschberger[2,3], and Philipp Gegenwart[1] — [1]Universität Augsburg, Lehrstuhl für Experimentalphysik VI — [2]Department of Applied Physics, University of Tokyo, Japan — [3]RIKEN Center for Emergent Matter Science, Japan

Emergent electromagnetic induction (EEMI) by current-driven spin dynamics was proposed and observed in the spin helix magnet $Gd_3Ru_4Al_{12}$ [1], where the (current-nonlinear) imaginary impedance at kHz frequency was associated with the motion of helical spin structures.

To explore the possibility of EEMI arising from current-driven dynamics of nontrivial magnetic structures, we fabricated and microstructured epitaxial thin film bilayers of ferromagnetic $SrRuO_3$ and paramagnetic $SrIrO_3$ on STO. This bilayer system is suspected to host DMI-stabilized Néel-skyrmions, indicated by the topological Hall-effect (THE) [2]. We observe in AC-measurements a large and current-linear imaginary impedance at low temperatures over broad current density and frequency ranges, signaling the EEMI of nontrivial textures.

SQUID magnetometry of weakly diamagnetic samples using custom 3D-printed sample holders — •Thomas Kerschenbauer, Luca Bischof, and Rüdiger Klingeler — Kirchhoff Institut for Physics, Heidelberg, Germany

Magnetization studies of weakly diamagnetic samples by means of SQUID magnetometers using conventional sample holders often produce background signals comparable to the sample signal. Therefore, accurate background measurement and subtraction processes are necessary, which are challenging with conventional sample holders. Here, we present high-resolution magnetization data on representative diamagnetic samples, including the aromatic compounds naphthalene and anthracene. We obtained these results through SQUID measurements using custom sample holders designed for the Quantum Design MPMS 3 with SLA 3D printing technology. This offers a versatile and cost-effective solution for manufacturing improved sample holders. These sample holders allow us, e.g., to improve the positioning of the sample, which requires high precision for background subtraction. It also allows for flexibility in sample shape, size, and orientation. These improvements can be used to study weakly magnetic materials and enable measurements that are limited by background signals of conventional sample holders.

MA 52.39 Thu 15:00 P4

Quantitative Distance Calibration and Magnetic Noise Imaging with Scanning NV Magnetometry — •Nikhita Khera, Ephraim Spindler, Kristin Kuehl, and Elke Neu Ruffing — RPTU in Kaiserslautern, Rheinland Pfalz, Germany

Nitrogen-vacancy (NV) enters in diamond are widely used as quantum sensors for nanoscale magnetometry and the study of spin dynamics. As part of ongoing work using a Scanning NV Magnetometer, we report progress towards quantitatively calibrated scanning NV measurements and applications to low-magnetisation systems. A central part of this work is the calibration if the sensor sample distance for scanning NV tips, which is essential for reliable spatial resolution. Using perpendicular magnetic anisotropy (PMA) reference sample, we perform distance calibration and aim to determine the NV orientation in the tip. When combined with complementary approaches such as reverse AFM to determine the NV position within the tip, this enables access to the full three-dimensional localisation of the quantum sensor. Beyond calibration, we explore magnetic fluctuations in antiferromagnetic insulators by measuring the NV spin relaxation times T1, giving insight into their local magnetic noise and spin dynamics. We also use scanning NV magnetometers to map stray fields - from exfoliated 2D- hematite flakes revealing nanoscale field structures associated with antiferromagnetic domain structures, and from 3-D printed nickel microstructures. Altogether, this work pushes forward scanning NV magnetometry and showcases its use across a variety of magnetic materials.

MA 52.40 Thu 15:00 P4

User-Interactive Magnetic Field Characterization Employing a 3D Printer as a Three-Axis Motor Stage — •Daniel Feser[1,2], Nikolai Weidt[1,2], Nikita Popkov[2,3], Rico Huhnstock[1,2], and Arno Ehresmann[1,2] — [1]Institute for Physics and CINSaT, University of Kassel, Heinrich-Plett-Str. 40, 34132 Kassel, Germany — [2]AIM-ED, Joint Lab of Helmholtzzentrum für Materialien und Energie, Berlin (HZB) and University of Kassel, Hahn-Meitner-Platz 1, 14109, Berlin, Germany — [3]Intelligent Embedded Systems, University of Kassel, Wilhelmshöher Allee 71-73, 34121, Kassel, Germany

This project presents a flexible, user-interactive system for three-dimensional magnetic field mapping that repurposes a consumer-grade 3D printer as a precise three-axis positioning platform. A teslameter probe is mounted in a custom-designed and 3D-printed printhead, ensuring stable and accurate field measurements. The printer is controlled through Python-generated G-code, with device coordination handled via the Tango server framework. This system allows users to manually configure scan volumes, adjust measurement parameters, and safely map magnetic fields around sensitive samples while avoiding collisions. The acquired magnetic field data are processed and displayed as heatmaps, enabling intuitive analysis of spatial field variations. Overall, the platform demonstrates a low-cost, adaptable approach to magnetic field characterization using accessible hardware and open-source software.

A metallic p-wave magnet with commensurate spin helix — Rinsuke Yamada[1], •Jan Masell[2,3], Moritz M. Hirschmann[3], and Max Hirschberger[1,3] — [1]The University of Tokyo, Tokyo, Japan — [2]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — [3]RIKEN Center for Emergent Matter Science (CEMS), Wako, Japan

Antiferromagnetic states with a spin-split electronic structure give rise to spintronic, magnonic and electronic phenomena despite (near-)zero net magnetization. Even-parity spin-split magnets (d, g-wave) can be collinear and are known as altermagnets. Odd-parity magnets (p, f-wave) may be termed antialtermagnets and need co-planar magnetic order.[1] In this talk, we present our recent experimental realization of a metallic p-wave magnet, the simplest odd-parity spin-split magnet. [2] The magnetic texture is a coplanar spin helix whose magnetic period is an even multiple of the chemical unit cell, as revealed by X-ray scattering experiments. This texture breaks space-inversion symmetry but approximately preserves time-reversal symmetry up to a half-unit-cell translation, thereby fulfilling the symmetry conditions for p-wave magnetism. Consistent with theoretical predictions, our p-wave magnet shows a characteristic anisotropy in the electronic conductivity. Spin-orbit coupling and a tiny spontaneous net magnetization further break time-reversal symmetry, resulting in a giant anomalous Hall effect.

MA 54.2 Fri 9:45 HSZ/0002

Giant Faraday Effect of magnon-polarons in the magnetoelectric altermagnet Fe2Mo3O8 — •Kirill Vasin[1], Sandor Bordács[2], Lilian Prodan[1], Vladimir Tsurkan[3], Istvan Kézsmárki[1], and Joachim Deisenhofer[1] — [1]University of Augsburg, Augsburg, Germany — [2]Budapest University of Technology and Economics, Budapest, Hungary — [3]Moldova State University, Chisinau, Republic of Moldova

We investigate magnetic circular dichroism of magnon-polarons in the polar altermagnet candidate $Fe_2Mo_3O_8$ using time-domain terahertz magnetospectroscopy. From linearly polarized measurements in Faraday geometry we reconstruct right- and left-circular transmission, revealing hybrid magnon-phonon branches which are fully circularly polarized below the Néel temperature. These magnon-polarons are both electric- and magnetic-dipole active and produce exceptionally large Faraday rotations in the terahertz range, with Verdet constant up to $\sim 4100^{\circ}/T/cm$. A suggested minimal circular-birefringent dielectric model captures both the magnitude and field dependence of the response.

MA 54.3 Fri 10:00 HSZ/0002

Mn4As3: a structure-search prediction of altermagnetism in a tetragonal Mn-As compound — •Bo Tai[1], Yu Zhu[1], Weikang Wu[2], and Xiaolong Feng[1] — [1]Max Planck Institute for Chemical Physics of Solids, Nöthnitzer Straße 40, 01187 Dresden, Germany — [2]Key Laboratory for Liquid-Solid Structural Evolution and Processing of Materials, Ministry of Education, Shandong University, Jinan 250061, China

We predict that 2D Mn4As3 is a dynamically stable altermagnetic Mn-As compound obtained from an ab initio structure search. The search identifies a tetragonal P4/mmm structure as the lowest-energy configuration, and confirming its dynamical stability. Using first-principle calculation, we find 2D Mn4As3 (P4'/mm'm) breaks PT symmetry while preserving zero net magnetization, realizing an altermagnetic state. Spin-resolved band structures reveal characteristic momentum-dependent spin splitting: spin-up and spin-down bands are split along Γ-X and Γ-Y but remain degenerate along Γ-M, leading to a Fermi-surface spin texture with a d-wave-like pattern of spin splitting. Berry-curvature and transport calculations further show that rotating the magnetic moment (Néel vector) direction provides effective control over both the anomalous Hall conductivity and the positions of band crossings near the Fermi level. These results establish structure-searched Mn4As3 as a dynamically stable altermagnet and a promising platform for magnetization-direction control of Berry-phase transport in Mn-pnictides.

MA 54.4 Fri 10:15 HSZ/0002

Antichiral surface states in altermagnets — •Sopheak Sorn — Institute for quantum materials and technology, Karlsruhe Institute of Technology, Karlsruhe, Germany — Institute of theoretical solid state physics, Karlsruhe Institute of Technology, Karlsruhe, Germany

Altermagnets host symmetry-protected nodal lines and nodal planes in their band structures. In this talk, I will show how nodal lines in d-wave altermagnets give rise to unusual surface states that are antichiral. Antichiral surface states on two opposite surfaces of a slab geometry propagate parallel to one another, in contrast to the antiparallel propagation direction of chiral surface states. I demonstrate the presence of antichiral surface states using a tight-binding model. The antichiral character and many important features of the antichiral surface states are explained using a mapping from the altermagnetic model to Su-Schrieffer-Heeger chains: the topological index and the bulk-boundary correspondence of the latter explain the antichiral surface states. This work indicates that altermagnets are one of the few quantum materials that can support such antichiral surface states.

Quantum Entanglement Signatures of Altermagnetism — •Mahsa Seyed Heydari, Wolfgang Belzig, and Sebastián A. Díaz — Universität Konstanz

In two-sublattice magnets in an antiferromagnetic configuration, the notion of two-mode squeezing is equivalent to quantum entanglement between the sublattice spins[1]. It has been shown that the logarithmic negativity is linearly related to the squeezing parameter. Altermagnets are a particular class of magnets which have a vanishing total magnetisation but a peculiar spin-polarization texture in momentum space. Using a simple model an altermagnet [2], we determine the magnon spectrum of an altermagnet and show that particular entanglement features witness the altermagnetic nature. Hence, we show that quantum magnonics offers a route towards distinguishing altermagnets from simple antiferromagnets, which is a difficult experimental task to date.

MA 54.6 Fri 10:45 HSZ/0002

Persistent altermagnetic spin polarisation — •Warlley H. Campos[1], Florette C. F. Mbognou[1], Anna B. Hellenes[2,3], Jan Priessnitz[1], and Libor Šmejkal[1,3] — [1]Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany — [2]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany — [3]Institute of Physics, Czech Academy of Sciences, 162 00 Praha 6, Czech Republic.

Altermagnets exhibit d-, g-, or i-wave collinear spin polarisation of nonrelativistic exchange origin [1]. Relativistic spin-orbit coupling (SOC) is commonly considered to generate noncollinear spin textures in reciprocal space. Here, we demonstrate that collinear, persistent altermagnetic spin polarisation (PASP) in the full Brillouin zone is possible even in the presence of strong SOC. By combining spin and magnetic layer group analysis, we identify two distinct classes of PASP: one materialising on top of strong exchange spin splitting, and the other accompanying a typically weaker [2], relativistic spin splitting. We then perform *ab initio* calculations to realise the strong and weak types in Lieb-lattice [3-5] and cuprate altermagnets [1], respectively. Finally, we discuss experimental indication of weak PASP in MnTe [2]. PASP could enable strong spintronics currents with long spin lifetimes and efficient spin accumulation [5].

Spin Orbit Coupling Affecting the Presence of Altermagnetism in $La_2O_2TM_2OSe_2$, TM={Fe, Mn, $Fe_{0.5}Mn_{0.5}$} — •Tillmann Weinhold[1], Cornelius Herrmann[1], Domenic Nowak[2], Rowena Wachtel[2], Felix Seewald[1], Rajib Sarkar[1], Sabine Wurmehl[2], and Hans-Henning Klauss[1] — [1]Institute of Solid State and Materials Physics, IFMP, TUD Dresden University of Technology — [2]Leibniz Institute for Solid State and Materials Research, IFW, Dresden

Altermagnets are a recently discovered type of solid with magnetic order leading to zero net magnetization while providing spin-splitting effects of electron bands of up to multiple eV.

While hundreds of possible candidates have been found by analyzing proposed crystal and magentic structures, only few of them could be experimentally proven to be altermagnets by now.

By the use of local probe techniques we were able to precisely determine the magnetic structure of $La_2O_2Fe_2OSe_2$, a compound isostructural to two proposed altermagnets, namely $La_2O_2FeMnOSe_2$ and $La_2O_2Mn_2OSe_2$.

A comparison of these conclusions with upcoming results of the other two compounds can give strong indications or possibly even experimental verification of whether the magnetic phase of these materials is altermagnetic.

MA 54.8 Fri 11:30 HSZ/0002

Ultrafast carrier dynamics in the g-wave altermagnet $CoNb_4Se_8$ — •Alexander Schmid[1], Gregor Zinke[1,2], Resham B. Regmi[3], Luca Haag[2], Tobias Eul[1], Hans C. Schneider[2], Nirmal J. Ghimire[3], Martin Aeschlimann[2], and Benjamin Stadtmüller[1] — [1]University of Augsburg — [2]RPTU University Kaiserslautern-Landau — [3]University of Notre Dame, USA

Altermagnets have sparked considerable interest as a new type of compensated magnet with an unconventional spin splitting in momentum space that is rooted in the crystal and spin group symmetries of these materials.

In the manifold of altermagnetic candidates, intercalated transition metal dichalcogenides such as $CoNb_4Se_8$ have been identified as altermagnetic materials with characteristic g-wave spin splitting below 168 K. [1]

In our work, we used time- and momentum-resolved photoemission to gain insight into the ultrafast dynamics of the layered altermagnetic $CoNb_4Se_8$. Specifically, we focus on the ultrafast carrier dynamics near the characteristic spin-split bands at the M-point of the band structure, both in the altermagnetic and paramagnetic phases. This direct comparison allows us to uncover the impact of the spin and nodal plane structure of altermagnets on the ultrafast charge and spin carrier scattering. Our findings will be a vital first step toward understanding the optical response of altermagnets on ultrafast timescales.

MA 54.9 Fri 11:45 HSZ/0002

Emergent d-wave surface altermagnetism in G-type Heusler antiferromagnets V_3Al and V_2TiSi — •Ersoy Sasioglu, Ingrid Mertig, and Samir Lounis — Institute of Physics, Martin Luther University Halle-Wittenberg, 06120 Halle (Saale), Germany

Antiferromagnets that preserve combined inversion and time-reversal symmetry (PT) necessarily exhibit spin-degenerate electronic bands in the absence of spin-orbit coupling. Using density-functional theory, we show that asymmetric surface terminations of centrosymmetric G-type Heusler antiferromagnets lift the PT symmetry and give rise to an exchange-driven, nonrelativistic d-wave spin splitting, a mechanism we term *surface altermagnetism*. In the antiferromagnetic semimetal V_3Al, an experimentally established compound with $T_N \approx 700$ K, and in the antiferromagnetic semiconductor V_2TiSi, the interior layers of the slab retain the conventional compensated G-type order and spin-degenerate electronic structure, whereas inequivalent surface terminations induce pronounced d-wave spin splittings and metallic surface states localized on the outer transition-metal layers that decay exponentially toward the bulk. These results demonstrate that surface altermagnetism arises purely from lattice-symmetry breaking at asymmetric terminations, providing a robust, exchange-driven route to engineer spin-polarized metallic surface states in high-temperature G-type antiferromagnets without invoking spin-orbit coupling.

MA 54.10 Fri 12:00 HSZ/0002

P-wave magnetism with helical order — •Jaafar Ansari[1] and Libor Šmejkal[1,2,3] — [1]Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — [2]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [3]Institute of Physics, Academy of Sciences of the Czech Republic, Prague, Czech Republic

The emergent class of magnetic materials exhibiting p-wave [1] spin polarization represents a critical frontier in condensed matter physics for holding considerable promise for advanced spintronic architectures. Examples have been studied in commensurate and incommensurate p-wave structures with asymmetric spin polarizations [2-4]. This work presents a systematic theoretical classification of systems capable of realizing this unique band-structure symmetry, which is rooted in spin group theory. Our study focuses on helimagnets that do and do not generate p-wave order. By ab initio calculations we investigate the role played by broken inversion symmetry, noncollinearity of the spins, and the robustness of the p-wave polarisation against spin-orbit interaction. Our analysis characterizes the conditions under which the nominal p-wave symmetry is maintained, partially suppressed or entirely lost, and identifies material candidates. [1] Hellenes, A. B., et. al, arXiv.2309.01607 (2023), [2] Chakraborty, A., et al., Nat Commun 16, 7270 (2025), [3] Kim, S.-J, et. al., Adv. Sci. 11, 2307306 (2024), [4] Alvarez, N., Phys. Rev. B 112, 024404 (2025)

MA 54.11 Fri 12:15 HSZ/0002

Evidence for spin split bands in RuO_2 investigated by ultrafast magnetization dynamics — •Kevin Jäckel[1], Holger Grisk[1], Niklas Dornquast[1], Jakob Walowski[1], Markus Münzenberg[1], Maik Gaerner[2], Günter Reiss[2], and Timo Kuschel[2,3] — [1]University of Greifswald, Germany — [2]Bielefeld University, Germany — [3]Johannes Gutenberg University Mainz, Germany

In the search for new materials suitable for spintronic applications, the recently discovered altermagnets open up novel paths of research. In our work we focus on the proposed d-wave altermagnetic material RuO_2 by measuring its magnetic response to circularly polarized ultrashort laser pulses. Hereby we propose a way to link its ultrafast demagnetization dynamics, which are accessed by employing time-resolved magneto-optical Kerr effect measurements, to other, well established material systems such as semiconducting GaAs or topological insulators [1]. Therefore, we measure both the real and imaginary parts of the Kerr rotation, which are the Kerr angle and the Kerr ellipticity related to magnetic circular birefringence and dichroism. We see a strong, transient response, which scatters on a femtosecond timescale and can be described by the Raman coherence time.

MA 55: Skyrmions III

Time: Friday 9:30–12:45 Location: HSZ/0004

MA 55.1 Fri 9:30 HSZ/0004

RC circuit based on magnetic skyrmions — •Ismael Ribeiro de Assis, Ingrid Mertig, and Börge Göbel — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany

Skyrmions are nanosized magnetic whirls attractive for spintronic applications due to their innate stability. They can emulate the characteristic behavior of various spintronic and electronic devices such as spin-torque nano-oscillators, artificial neurons and synapses, logic devices, diodes, and ratchets. Here, we show that skyrmions can emulate the physics of an RC circuit-the fundamental electric circuit composed of a resistor and a capacitor-on the nanosecond time scale. The equation of motion of a current-driven skyrmion in a quadratic energy landscape is mathematically equivalent to the differential equation characterizing an RC circuit: the applied current resembles the applied input voltage and the skyrmion position resembles the output voltage at the capacitor. These predictions are confirmed via micromagnetic simulations. We show that such a skyrmion system reproduces the characteristic exponential voltage decay upon charging and discharging the capacitor under constant input. Furthermore, it mimics the low-pass filter behavior of RC circuits by filtering high frequencies in periodic input signals. Since RC circuits are mathematically equivalent to the leaky-integrate-fire (LIF) model widely used to describe biological neurons, our device concept can also be regarded as a perfect artificial LIF neuron.

MA 55.2 Fri 9:45 HSZ/0004

Accelerating Skyrmion-Based Computing via Oscillating Magnetic Fields — •Yuean Zhou[1], Thomas B. Winkler[2], Grischa Beneke[1], Fabian Kammerbauer[1], Robert Frömter[1], Giovanni Finocchio[3], Johan H. Mentink[2], Davi R. Rodrigues[4], and Mathias Kläui[1] — [1]Institut für Physik, Johannes Gutenberg-Universität Mainz, Germany — [2]Radboud University, Institute for Molecules and Materials, Netherlands — [3]Department of Mathematical and Computer Sciences, Physical Sciences and Earth Sciences, University of Messina, Italy — [4]Department of Electrical and Information Engineering, Politecnico di Bari, Italy

Skyrmion-based unconventional computing architectures, including stochastic, reservoir, and probabilistic computing [1], rely on stochasticity and dynamical transitions. However, pinning effects restrict mobility in realistic device geometries. To stably enhance the dynamics, we apply an additional oscillating out-of-plane magnetic field [2], and quantify the skyrmion motion in confined geometries using Markov State Models constructed from skyrmion trajectories recorded by Kerr microscopy. The diffusion enhancement shows a distinct maximum around 25 Hz and tapers off on either side, suggesting a stochastic-resonance-driven mechanism. Micromagnetic simulations qualitatively reproduce the resonance peak, supporting this interpretation. Controlled periodic driving thus provides an effective route to boost skyrmion dynamics for unconventional computing. [1] T.B. Winkler et al., arXiv:2508.19623 (2025) [2] R. Gruber et al., Adv. Mater. 2208922 (2023)

MA 55.3 Fri 10:00 HSZ/0004

Dipolar Skyrmion Continuum Mechanics — •Kilian Leutner[1], Klaus Raab[1], Grischa Beneke[1], Duc M. Tran[1], Sachin Krishnia[1], Robert Frömter[1], and Mathias Kläui[1,2] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany — [2]Center for Quantum Spintronics, Norwegian University of Science and Technology, 7491 Trondheim, Norway

Magnetic skyrmions–topological quasiparticle spin textures–offer a platform for both fundamental physics and applications [1]. In multilayer films, micrometer-scale skyrmions can emerge from dipolar interactions, and describing the long-timescale behavior of an ensemble requires multiscale modeling. We extend the Thiele equation by treating the skyrmion radius as a dynamic variable and derive the forces governing changes in both position and size from micromag-

netic theory. As a novel approach to describe ensemble dynamics, we develop a continuum-mechanics framework in which individual skyrmions are replaced by macroscopic fields such as density, velocity, and radius. The equation of state required for this description–relating pressure and density in the basic case–is calculated using dipolar-lattice theory [2]. We validate these two theoretical frameworks by examining how a spin-orbit torque compresses a skyrmion lattice in a Ta/CoFeB/MgO wire in an experiment. The continuum-mechanics model provides deeper insight into dipolar skyrmion ensembles as a hyperelastic medium composed of interacting particles of variable size.

MA 55.4 Fri 10:15 HSZ/0004

Magnetoresistance and Planar Hall Effect in Noncollinear Magnets — •Juba Bouaziz[1,2], Hiroshi Ishida[3], Hiroshi Katsumoto[1], and Stefan Blügel[1,4] — [1]Peter Grünberg Institut, Forschungszentrum Jülich, 52425 Jülich — [2]Faculty of Physics, University of Duisburg-Essen, 47057 Duisburg — [3]College of Humanities and Sciences, Nihon University, Tokyo — [4]Institute for Theoretical Physics, RWTH Aachen University, 52062 Aachen

Magnetotransport measurements are widely used to probe magnetic structures. We study how noncollinear magnetism modifies magnetoresistance (MR) and the planar Hall effect (PHE). In the weak-coupling limit, and using a multiple-scattering expansion of the electron current for Rashba-mediated conduction electrons [1], we show that noncollinearity introduces additional contributions to both MR and PHE. These arise from tilted magnetic moments and include a chiral MR term determined by the chirality of the magnetic structure. We also identify a noncollinear magnetoresistance (NCMR) contribution that persists even without Rashba spin-orbit interaction. Finally, we analyze the form and magnitude of these effects for different nanostructures, including magnetic trimers and topological spin textures such as skyrmions.

MA 55.5 Fri 10:30 HSZ/0004

Reorientation of skyrmion lattice with local magnetic field gradients — •Duc Tran[1], Edoardo Mangini[1], Elizabeth Jefremovas[1], Dennis Meier[2,3], Robert Frömter[1], and Mathias Kläui[1,2] — [1]Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany — [2]Centre for Quantum Spintronics, NTNU, 7491 Trondheim, Norway — [3]Faculty of Physics, University of Duisburg-Essen, 45057 Duisburg, Germany

We present a minimally invasive approach for nucleating and manipulating skyrmion lattices in soft CoFeB multilayers using single-pass MFM. By matching the scan-line spacing to the domain periodicity, we drive reversible transitions from stripe domains to isolated skyrmions and locally ordered lattices using the field gradient generated by the magnetic tip. Skyrmion positions are used to calculate the local orientational order parameter ψ_6, allowing quantitative assessment of lattice order[1]. Repeated scanning leads to a systematic increase in $\langle|\psi_6|\rangle$, revealing a progression from a disordered configuration toward a well-ordered hexagonal lattice. We show that the lattice orientation can be directly controlled by altering the scanning direction, as verified through both real-space analysis and fast Fourier transforms. This technique enables on-demand creation, rearrangement, and deletion of metastable skyrmions, offering unprecedented control over lattice symmetry, ordering, and orientation[2].

MA 55.6 Fri 10:45 HSZ/0004

Static and dynamic spin texture manipulation in Fe/Gd multilayers — Tim Titze[1], Sabri Koraltan[2,4], Timo Schmidt[3], Mailin Matthies[1], Florian Bruckner[2], Claas Abert[2], Amalio Fernández-Pacheco[4], Dieter Suess[2], Claus Ropers[5], Manfred Albrecht[3], Stefan Mathias[1], and •Daniel Steil[1] — [1]Georg-August-Universität Göttingen — [2]University of Vienna — [3]University of Augsburg — [4]Technical University of Vienna — [5]Max-Planck Institute for Multidisciplinary Sciences, Göttingen

Topological spin textures can be created, annihilated and manipulated in Fe/Gd multilayers using adiabatic and non-adiabatic external stimuli like temperature, magnetic fields and ultrashort light pulses. In this talk, I will show various ways to control magnetic spin textures statically and dynamically in $[Fe(0.35\ nm)/Gd(0.40\ nm)]_{160}$ multilayers, combining time-resolved magneto-optical Kerr spectroscopy with micromagnetic simulations and static magnetic imaging techniques. In particular, I will discuss different pathways for skyrmion creation [1,3], the use of in-plane fields as an additional control knob [4], as well as tailoring the skyrmion breathing mode using a two pulse excitation sequence [2].

MA 55.7 Fri 11:15 HSZ/0004

Effects of interlayer Dzyaloshinskii-Moriya interaction on the shape and dynamics of magnetic twin-skyrmions — •Tim Matthies[1], Levente Rózsa[2,3], Roland Wiesendanger[1], and Elena Vedmedenko[1] — [1]University of Hamburg, Hamburg, Germany — [2]Wigner Research Centre for Physics, Budapest, Hungary — [3]Budapest University of Technology and Economics, Budapest, Hungary

Magnetic skyrmions have been proposed as promising candidates for storing information due to their high stability and easy manipulation by spin-polarized currents. Here, we study how these properties are influenced by the interlayer Dzyaloshinskii-Moriya interaction (IL-DMI), which stabilizes twin-skyrmions in magnetic bilayers. We find that the spin configuration of the twin-skyrmion adapts to the direction of the IL-DMI by elongating or changing the helicities in the two layers. Driving the skyrmions by spin-polarized currents in the current-perpendicular-to-plane configuration, we observe significant changes either in the skyrmion velocity or in the skyrmion Hall angle depending on the current polarization. These findings unravel further prospects for skyrmion manipulation enabled by the IL-DMI.

MA 55.8 Fri 11:30 HSZ/0004

Current-Induced Skyrmion Dynamics and Diffusion — •Leonie-Charlotte Dany, Maarten Brems, Simon Fröhlich, Tobias Sparmann, Fabian Kammerbauer, Sachin Krishnia, Peter Virnau, and Mathias Kläui — Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany

Magnetic skyrmions, nanoscale chiral spin textures with particle-like behavior, are promising candidates for information storage and unconventional computing due to their robustness and efficient current-driven motion [1-3]. In Ta/CoFeB/MgO multilayers, we investigate the transition of current-driven skyrmion motion from creep, through depinning, to the viscous flow regime driven by a unipolar, pulsed current. By varying current density, pulse width, and frequency, we demonstrate how external stimulation overcomes pinning potentials and enables skyrmions to enter into a regime characterized by linear velocity-current relations, i.e., the viscous flow regime. Additional studies with an alternating, net-zero current drive reveal an exponential increase of the diffusion coefficient with current density, while higher frequencies suppress diffusion following a power-law dependence. These findings provide quantitative insight into controlling skyrmion mobility and diffusion, essential for spintronic device design [4].

MA 55.9 Fri 11:45 HSZ/0004

Correlating on-the-fly Electrical and Optical Skyrmion Readout — •Grischa Beneke[1], Kilian Leutner[1], Nikhil Vijayan[1,2], Fabian Kammerbauer[1], Duc Minh Tran[1], Sachin Krishnia[1], Johannes Güttinger[2], Armin Satz[2], Robert Frömter[1], and Mathias Kläui[1] — [1]Institute of Physics, Johannes Gutenberg University Mainz, Germany — [2]Infineon Technologies Austria AG, Austria

Magnetic skyrmions, topologically stabilized spin textures, are promising candidates for memory devices and non-conventional computing due to their stability, non-linear interactions, and low-power manipulation. However, reliable electrical readout of individual skyrmions remains a fundamental challenge, as current magnetic tunnel junction and anomalous Hall effect techniques fail to reliably detect single moving skyrmions. Our approach leverages thermally activated skyrmions, where a low constant drive current simultaneously drives skyrmion motion and the Hall voltage necessary for detection. We demonstrate reliability through real-time correlation between Hall voltage signals and direct Kerr microscopy imaging. Two consecutive Hall crosses enable skyrmion velocity determination in accordance with Kerr microscopy videos [1]. We present an analytical formula for the skyrmion AHE readout signal, demonstrating scalability from micrometer to nanometer dimensions. These advances establish a robust platform for skyrmion-based sensors, counters, and unconventional computing systems requiring precise individual skyrmion control and detection. [1] G. Beneke et al., Accepted for publication in Appl. Phys. Lett., arXiv:2508.15519 (2025).

MA 55.10 Fri 12:00 HSZ/0004

CNN-Based Classifier for Automated Identification of Magnetic States in Spin Dynamics Simulations — •Amal Aldarawsheh[1], Ahmed alia[2], and Stefan Blügel[1] — [1]Peter Grünberg Institute Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany — [2]Institute for Advanced Simulation (IAS-7), Forschungszentrum Jülich, 52425 Jülich, Germany

The identification and classification of different magnetic states are essential for understanding the complex behavior of magnetic systems. Traditional approaches that rely on handcrafted features or manual inspection often fall short, particularly when dealing with subtle or topologically complex spin textures. In this study, we present an automated deep learning model that employs an

EfficientNetV1B0 Convolutional Neural Network to classify nine distinct magnetic states, including both FM and, for the first time, AFM spin textures such as AFM skyrmions and AFM stripe domains. The spin configurations are generated through atomistic spin dynamics simulations using the *Spirit* code, then visualized with VFRendering to produce RGB images, which serve as inputs to the classification model. To train and evaluate the model, we created a new dataset of manually labeled RGB images. Experimental results show that the proposed model achieves an accuracy and F1-score of 99%, significantly outperforming established deep learning baselines.

MA 55.11 Fri 12:15 HSZ/0004

Exchange striction model calculations for the skyrmion-containing compound $Gd_3Ru_4Al_{12}$ — •Justus Grumbach[1], Martin Rotter[2], and Mathias Doerr[1] — [1]Institut für Festkörper- und Materialphysik, Technische Universität Dresden, 01062 Dresden, Germany — [2]McPhase Project, Sestiere Cannaregio 2904, 30121 Venezia, Italy

For the compound $Gd_3Ru_4Al_{12}$, we measured the complete dilatometric tensor, enabling a refinement of the phase diagrams in all crystallographic directions (see also the talk by M. Doerr). The most prominent feature is a lattice effect indicating a coupling of skyrmions to the crystal lattice, as previously evidenced by a docking of the propagation vector onto the crystal lattice. In the simulations, an approach for calculating the exchange striction was implemented that takes volume-influences into account and is particularly suitable for Gd-based compounds. Major aspects supporting our experimental results could be reproduced. The presentation will outline the full simulation process - from modeling, through the calculation of general magnetostrictive effects, to the influence of skyrmions - and conclude with a discussion of the volume effect in the skyrmion phase.

MA 55.12 Fri 12:30 HSZ/0004

Volume effect in Gd-containing skyrmion compounds — •Mathias Doerr[1], Justus Grumbach[1], and Maximilian Hirschberger[2] — [1]Technische Universität Dresden, Germany. — [2]University of Tokyo and RIKEN Center for Emergent Matter Science, Japan.

Skyrmions with a smaller characteristic wavelength are currently investigated in centrosymmetric compounds. The interplay between skyrmion lattices (SkL) and underlying crystallographic structures offers the possibility to determine the stability region of skyrmions by dilatometric measurements (thermal expansion and forced magnetostriction). Magnetostriction measurements on the two hexagonal metallic compounds $Gd_3Ru_4Al_{12}$ with a planar breathing kagome lattice and the triangular lattice magnet Gd_2PdSi_3 show a volume change (plateau phase) in the stability region of the skyrmion lattice, indicating the need for an unstrengthened crystal lattice for the formation of skyrmions. Another important result of our investigations was the refinement of the H-T phase diagrams for both investigated materials. The key results of the measurements were verified using a mean field calculation (see talk by J. Grumbach).

MA 56: Focus Session: (Anti)ferroic states – Magnetic and magnetoelectric III (joint session FM/MA)

chair: Morgan Trassin (ETH Zurich, CH)

This focus session explores recent advances in understanding and control of (anti)ferroic states. Emphasis will be placed on theoretical modelling, advanced characterization techniques, and the engineering of emergent properties for use in nano-electronic devices. The session aims to bridge fundamental research with emerging device-relevant functionalities, bringing together experimental, and theoretical perspectives on ferroic materials.

Time: Friday 9:30–11:30 Location: BEY/0E40

See FM 23 for details of this session.

MA 57.1 Fri 9:30 POT/0112

Angle-dependent magnetization reversal in perpendicular-anisotropy garnet films — •Senyin Zhu, Hanxu Zhang, Xianjie Wang, and Bo Song — Harbin Institute of Technology, Harbin 150001, China

Rare-earth-doped iron garnet (RIG) films with perpendicular magnetic anisotropy (PMA) offer a useful platform for studying angle-dependent magnetization reversal. The hysteresis behavior of Bi/La-doped thin RIG films was measured for magnetic-field orientations ranging from the in-plane direction, defined as 0°, to the out-of-plane direction at 90° and further up to 140°, enabling the identification of two distinct reversal regimes. For field orientations close to the film plane (0-50°), the reversal is governed by a continuous rotation of the magnetization, consistent with a uniform-state instability leading to a second-order phase transition. For field orientations close to the film normal (50-140°), the reversal is driven by domain nucleation with irreversible jumps, which is the characteristic signature of a first-order phase transition. The reversal mechanisms are consistent with the rotation- and nucleation-dominated processes known from metallic films.[1,2] In garnet film systems, however, the angular ranges at which these processes occur are shifted with respect to metallic films, most likely due to their stress-controlled perpendicular anisotropy and the larger exchange lengths.[1] O. Hovorka, A. Berger, and L. Fallarino, Phys. Rev. B 94, 064408 (2016). [2] R. Salikhov, F. Samad, L. Fallarino et al., Phys. Rev. B 110, 024417 (2024).

MA 57.2 Fri 9:45 POT/0112

Tailoring Magnetic Anisotropy Energy (MAE) with ion irradiation on Fe (110) — •Gabriel Gray[1], Kilian Lenz[1], Aleksandra Lindner[1], Fabian Ganss[1], Jürgen Fassbender[1], René Hübner[1], Rodolfo Gallardo[2], Pedro Landeros[2], and Jürgen Lindner[1] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, Dresden, Germany — [2]Universidad Técnica Federico Santa María, Department of Physics, Valparaíso, Chile

Our research focuses on the changes in Magnetic Anisotropy Energies (MAE) in epitaxially grown Fe (110) thin films. We aim to create spatially defined regions with tunable magnetic anisotropies, modified through local ion implantation, in order to engineer spin textures and establish controllable spin-wave channels within the ferromagnetic thin film.

The Fe films were irradiated with Cr ions at varying kinetic energies and fluences. Subsequent magnetic characterization was performed using ferromagnetic resonance, while structural characterization was done by x-ray diffractometry, transmission electron microscopy and energy-dispersive x-ray spectroscopy.

Our results reveal a clear correlation between ion fluence and modifications in uniaxial magneto-crystalline anisotropy, while cubic anisotropy and the effective magnetization remain largely unaffected.

MA 57.3 Fri 10:00 POT/0112

Perpendicular magnetic anisotropy in Pt/Co/Cu heterostructures — •Anastasios Markou[1] and Ioannis Panagiotopoulos[2] — [1]Physics Department, University of Ioannina, 45110 Ioannina, Greece — [2]Department of Materials Science and Engineering, University of Ioannina, 45110 Ioannina,Greece

Magnetic multilayers with perpendicular magnetic anisotropy (PMA) formed by interfacing ferromagnetic layers with heavy-metal spin-orbit-coupled layers have received significant attention due to their tunable magnetic interactions and potential for stabilizing room-temperature topological magnetic textures. Inserting a 3d metal, such as Cu, at the interface between the ferromagnet and the heavy metal can break the symmetry of the adjacent interfaces and give rise to non-compensated asymmetric interactions, enhancing the chiral character of the system [1].

Here, we report on the magnetic properties of magnetron sputtered $[Pt/Co/Cu]_7$ multilayers with optimized deposition parameters to achieve high-quality interfaces and tunable PMA. We show that the magnetic properties can be tuned by varying the thickness of the 3d elements. PMA is observed over a broad range of Co and Cu thicknesses, demonstrating the crucial role of the Pt/Co interface, while the adjacent Cu layer provides an additional degree of freedom to tailor the effective interfacial anisotropy and magnetic coupling. These interfacial contributions are found to govern key properties such as coercivity, loop squareness, and the overall magnetization reversal behavior.

MA 57.4 Fri 10:15 POT/0112

Large Microstructure-Dependent Magneto-Ionic Effects in Nanocrystalline Fe-Ni alloys — •Anna Ullrich[1], Florin Leo Hambeck[1], Raphael Kohlstedt[2,3], Sandra Schiemenz[4], Daniel Wolf[4], and Karin Leistner[1,3,4] — [1]Institute of Chemistry, Chemnitz University of Technology, Germany — [2]Institute of Physics, Chemnitz University of Technology, Germany — [3]Research Center MAIN, Chemnitz University of Technology, Germany — [4]Leibniz IFW Dresden, Germany

Magneto-ionic effects offer voltage-driven, energy-efficient control of magnetic properties via electrochemical reactions or ion migration.[1] Most studies focus on Co- or Fe-based systems,[2] recent research has reported similar effects in Ni,[3] prompting exploration in industrial relevant Fe-Ni alloys. We investigated magneto-ionic control in electrodeposited Fe-Ni thin films across the full compositional range using in situ MOKE microscopy.[4] Near-equiatomic films with mixed fcc/bcc phase and ultrafine grains show up to −90 % coercivity reduction at ~ 1 V. In situ Raman spectroscopy and structural characterization attribute the effect to dense grain boundaries and heterogeneous surface oxides, facilitating voltage-induced surface oxide reduction and magnetic softening. Our findings highlight the importance of microstructure in enhancing magneto-ionic functionality, providing guidelines for designing materials for sensing, actuation, and neuromorphic computing. Mater. 2025, e00654.

MA 57.5 Fri 10:30 POT/0112

Two-component anomalous Hall and Nernst effects in anisotropic $Fe_{4-x}Ge_xN$ thin films — •Jakub Vít[1], Petr Levinský[1], Robin K. Paul[2], Imants Dirba[2], and Karel Knížek[1] — [1]Institute of Physics, Prague, Czechia — [2]TU Darmstadt

50-500 nm thin films of $Fe_{4-x}Ge_xN$ (x=0–1) were fabricated onto MgO substrates by magnetron sputtering. The Hall and Nernst effects were measured, complemented with structural and magnetic characterizations, electron microscopy and DFT calculations. Fe_4N is cubic, whereas a small tetragonal distortion is found in $Fe_{4-x}Ge_xN$ films for x>0.35. The tetragonal samples with x=0.8 and 1 show two-component behavior in the Hall and Nernst effect hysteresis loops, which can be analyzed as a sum of positive and negative loops with different saturation fields. This unusual behavior is due to a combination of several factors: (1) Co-existence of two different crystallographic orientations in the tetragonal thin films. (2) Opposite sign of the anomalous Hall&Nernst effects (AHE&ANE) for the direction of magnetization along the a and c-axis. (3) Strong easy-plane magnetic anisotropy, responsible for different saturation fields for a and c-axis.

The maximum ANE was determined to be 0.9 V/K for x=0 at room temperature, and -0.85 V/K for x=1 at T=50 K. The rapid increase of ANE for Fe_3GeN from low temperatures indicates that, were it not for its low T_C (≈100 K), it could surpass ANE of Fe_4N. This observation is consistent with our theoretical assumptions and motivates further research of doped Fe_4N for which ANE enhancement is predicted by DFT calculations. (Preprint of this research: [arXiv 2511.14305])

MA 57.6 Fri 10:45 POT/0112

Voltage control of exchange bias in coupled spin-valve heterostructures — •Markus Gössler[1], Jonas Zehner[1,2], Rico Huhnstock[3], Falk Röder[2,4], Rico Ehrler[1], Olav Hellwig[1,5], Arno Ehresmann[3], and Karin Leistner[1] — [1]TU Chemnitz, Germany — [2]IFW Dresden, Germany — [3]University of Kassel, Germany — [4]IPF Dresden, Germany — [5]HZDR Dresden, Germany

Exchange bias can be described as a unidirectional magnetic anisotropy that arises at the interface of a ferromagnet and an antiferromagnet, which is commonly used to pin magnetization in magnetic devices. Typically, exchange bias is initiated only once via a field cooling procedure and cannot be easily modified thereafter. Here, we demonstrate the voltage control of exchange bias in a coupled spin-valve heterostructure via a magneto-ionic (i.e. electrochemical) approach. This is accomplished in a sputtered IrMn/Fe/Au/Fe/FeOx layer structure by modifying the Fe/FeOx top layer thicknesses via voltage-triggered electrochemical reduction/oxidation in an alkaline electrolyte.[1] Magnetic interlayer coupling between the exchange-biased (untreated) Fe layer and the top Fe layer through the Au spacer allows controlling exchange bias in this system by a top layer modification only. The reversibility in our heterostructures is significantly improved compared to the direct magneto-ionic treatment of exchange-biased Fe layers. Furthermore, by tailoring the layer structure we also demonstrate a reversible switching between single-step and double-step hysteresis loops,[1] which could pave the way for magnetic field sensors with adjustable sensitivity.

MA 58.1 Fri 9:30 POT/0151

Prototype for Magnetic Multiscale Modelling Suite (MaMMoS) — •Hans Fangohr[1], Samuel RJ Holt[1], Martin Lang[1], Swapneel Pathak[1], Andrea Petrocchi[1], Wilfried Hortschitz[2], Santa Pile[2], Alena Vishina[3], M Nur Hasan[3], Georgia A Marchant[3], Timoteo Colnaghi[4], Christina Winkler[4], Jonas Winkler[5], Nora Dempsey[6], Thomas G Woodcock[5], Andreas Marek[4], Heike C Herper[3], and Thomas Schrefl[2] — [1]MPSD, Hamburg, Germany — [2]UWK, Krems, Austria — [3]Uppsala University, Sweden — [4]MPCDF, Garching, Germany — [5]IFW, Dresden, Germany — [6]Institute Neel, Grenoble, France

Magnetic materials require multiscale modelling across electronic, atomistic, micromagnetic and device levels. MaMMoS provides a unified Python framework that links these steps and avoids manual data translation. Based on ground-state magnetic parameters from DFT databases, it computes their temperature dependence using atomistic spin-dynamics, and passes them directly to micromagnetic solvers for modelling hysteresis and switching. Common analysis tools (e.g., coercivity, remanence) are included, and benchmarking and optimisation are possible. Planned extensions include machine-learning based modules to replace simulations with faster, approximate estimates. We present the current prototype to attract early adopters and invite community feedback.

MA 58.2 Fri 9:45 POT/0151

A Fourier-Space Approach to Physics-Informed Magnetization Reconstruction from Nitrogen-Vacancy Measurements — •Alexander Setescak[1], Florian Bruckner[1], Dieter Suess[1], Young-Gwan Choi[2,3], Hayden Binger[2], Lotte Boer[2], Claire Donnelly[2], Uri Vool[2], and Claas Abert[1] — [1]University of Vienna, Vienna, Austria — [2]Max Planck Institute for the Chemical Physics of Solids, Dresden, Germany — [3]University of Ulsan, Ulsan, Republic of Korea

Reconstructing complex magnetization textures from nitrogen-vacancy (NV) magnetometry stray-field measurements presents a challenging inverse problem. In this work, we introduce a physics-informed method that addresses this by incorporating the full micromagnetic energy directly into the variational formulation.

Built on a PyTorch backend, our forward model integrates an auto-differentiable micromagnetic framework with FFT-based stray-field calculations and Fourier-space upward continuation. This enables efficient gradient-based optimization via the adjoint method and allows the sensor-sample distance to be treated as an optimization parameter. By doing so, we eliminate the experimental uncertainty arising from unknown NV implantation depths and surface oxidation layers.

Validation on synthetic data demonstrates high-fidelity reconstruction of spin textures and precise sensor height estimation. Furthermore, when applied to experimental NV measurements of the van der Waals magnet $Fe_{3-x}GaTe_2$, the framework reconstructs skyrmion bubbles that are consistent with theoretical micromagnetic behavior.

MA 58.3 Fri 10:00 POT/0151

First principals calculation of current-induced spin-transfer and spin-orbit torques — •Tamás Véber[1], László Oroszlány[1,2], Zoltán Tajkov[1,3], Marcell Sipos[1], and Branislav K. Nikolic[4] — [1]Eötvös Loránd University, Budapest, Hungary — [2]Wigner Research Centre for Physics, Budapest, Hungary — [3]HUN-REN Centre for Energy Research, Budapest, Hungary — [4]University of Delaware, USA

The study of two dimensional magnetic materials - especially those possessing strong spin-orbit coupling - has great promise both in terms of providing new theoretical discoveries, as well as practical applications like smaller and more energy efficient magnetoresistive RAM (MRAM) technologies. The theoretical study of such systems has been well-established in recent decades. However, no single ecosystem exists in which all the simulation and post-processing steps can be performed in a cohesive way. We aim to fill this gap by providing a chain of cross-compatible software for this purpose - and where it is possible, do this in the form of open-source libraries. In this work we lay out such an implementation for obtaining current-induced spin torques - like spin-transfer torque (STT) and spin-orbit torque (SOT) - in the linear response regime from ab initio results. We demonstrate this method on a set of magnetic two dimensional few-layer materials, comparing our results with the literature.

MA 58.4 Fri 10:15 POT/0151

Multi-spin Hamiltonians from symmetry considerations — •Levente Rózsa — HUN-REN Wigner Research Centre for Physics, Budapest, Hungary — Budapest University of Technology and Economics, Budapest, Hungary

Spin Hamiltonians are central to modeling magnetic materials. These Hamiltonians must reflect the symmetry of the underlying crystal [1]. Going beyond the most extensively studied two-spin interaction terms, for example the introduction of the isotropic biquadratic exchange interaction, has proven successful in describing special types of magnetic ordering in classical and quantum magnets. Four-spin generalizations of the anisotropic Dzyaloshinsky-Moriya interaction have also been proposed [2,3].

Here, we present a general formalism for deriving symmetry-adapted multi-spin interactions up to arbitrary order in the spin Hamiltonian. This method provides an alternative to perturbative expansions [2] which become difficult to tract as the number of spins and the complexity of the interactions increases. We identify all possible interaction terms containing four spins, and describe their transformation properties under rotations. We propose procedures for deriving these interactions from first-principles calculations, and for calculating the magnetic ground states stabilized by them.

MA 58.5 Fri 10:30 POT/0151

Above-Room-Temperature Magnetism in the Fe3GeTe2 and Fe3GaTe2 monolayer — •Anjali Jyothi Bhasu[1], Bendegúz Nyári[1], László Oroszlány[2], László Udvardi[1], and László Szunyogh[1] — [1]Department of Theoretical Physics, Budapest University of Technology and Economics, Budafoki ut 8., HU-1111 Budapest, Hungary — [2]Department of Physics of Complex Systems, Eötvös Loránd University, 1117 Budapest, Hungary

Room-temperature ferromagnetism that remains robust at the nanoscale is a key requirement for next-generation spintronic and information storage technologies. Using density-functional methods, we investigate monolayers of the van der Waals magnets Fe3GeTe2 and Fe3GaTe2, both of which exhibit magnetic ordering under ambient conditions. We compute the magnetic interaction parameters using the LKAG torque formalism as well as the spin-cluster expansion combined with the relativistic disordered local moment formalism. Special emphasis is placed on how these interactions vary with the Hubbard parameter U, which controls electron-electron correlations within the DFT+U framework. We then estimate the energetically favored magnetic structure by evaluating the Fourier transform of the tensorial coupling matrices. The order-disorder transition temperatures are obtained from large-scale Monte Carlo simulations, and we find that the simulated transition temperatures depend sensitively on the value of U.

MA 58.6 Fri 10:45 POT/0151

Micro and macroscopic quantum details of complex spin-textures — •Wenhan Chen[1,2], Sangeeta Sharma[1,3], and John Kay Dewhurst[2] — [1]Max-Born-Institut (MBI) im Forschungsverbund Berlin e.V,Max-Born-Str 2A, Berlin — [2]Max-Planck-Institut für Mikrostrukturphysik, Halle (saale) — [3]Freie Universität Berlin, Berlin

Studying large-scale systems from first principles remains challenging because conventional DFT becomes prohibitively expensive. The recently proposed ultra-long-range DFT (ULR-DFT) aims to address this systematically while retaining full quantum-mechanical detail.

In our preliminary work, ULR-DFT successfully reproduces micrometre-scale ferromagnetic domains and domain walls, while also providing quantum-level information such as band structures and response functions. Applied to B20 chiral magnets, it captures helical states and skyrmion textures in agreement with experiments. Overall, ULR-DFT is promising for both fundamental research and device modelling, including band-structure engineering for spintronic applications.

Automated Defect Detection in Magnetic Imaging Data Using Latent Measures and U-Net Segmentation — •Ross Knapman[1,2], Nasim Bazazzadeh[1,3], Kübra Kalkan[1], Atreya Majumdar[1], and Karin Everschor-Sitte[1] — [1]Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany — [2]Institute of Mechanics, Faculty of Engineering, University of Duisburg-Essen, 45141 Essen, Germany — [3]Radiology Department, Massachusetts General Hospital, 175 Cambridge St., Boston, MA 02114, USA

Detecting and characterising local inhomogeneities is essential for understanding and optimising magnetic materials. We present an automated framework that combines physics-based latent measures with deep convolutional segmentation for robust defect identification in magnetic imaging data. Time-resolved micromagnetic simulations with randomly distributed defects are used to compute three per-pixel descriptors: temporal mean, temporal standard deviation, and a latent-entropy measure that quantifies local dynamical complexity [1,2]. Each measure serves as input to a U-Net architecture trained for pixel-level segmentation of defect regions. Performance is evaluated under additive and multiplicative noise to test robustness. This approach demonstrates how integrating physics-motivated feature construction with deep learning enables reliable automated analysis of magnetic textures and defect landscapes in simulation and experiment.

MA 58.8 Fri 11:30 POT/0151

Dynamical mean-field theory for spin systems at finite temperature: cluster extension — •Przemyslaw Bieniek[1], Timo Grässer[2], and Götz Uhrig[1] — [1]Condensed Matter Theory, TU Dortmund University, Otto-Hahn-Str. 4, 44227 Dortmund, Germany — [2]Institute of Molecular Physical Science, ETH Zürich, Vladimir-Prelog-Weg 1-5/10, 8093 Zürich, Switzerland

Dynamical mean-field theory (DMFT) is an established numerical technique for approximately solving fermionic many-body problems. It maps the full quantum system to an impurity problem and uses a self-consistency condition to connect back to expectation values of the original model. In recent years, a method inspired by DMFT applicable to spin systems (spinDMFT) was developed. It is in agreement with numerical techniques and has already proven successful in explaining nuclear magnetic resonance experiments. However, it was derived only in the case of infinite temperature.

Based on spinDMFT, we develop a dynamical mean-field theory for spin systems at finite temperatures. The algorithm computes spin correlations in imaginary time. It maps the spin system to a single-site problem with a time-dependent mean field and uses a self-consistency condition to connect the values of the mean-field to quantum expectation values. The single-site approach is extended to a cluster algorithm, allowing for the computation of nonlocal expectation values. We benchmark the algorithm by comparing the resulting correlations with numerical approaches. We discuss the potential applications of the method and possible extensions.

MA 58.9 Fri 11:45 POT/0151

A Computational Framework for Bare and Interacting Longitudinal Susceptibility in Magnetic Materials — •Rohit Pathak[1], Vladislav Borisov[1,2], Mikhail I. Katsnelson[2,3], Anna Delin[4,5], and Olle Eriksson[1,2] — [1]Uppsala University, Sweden — [2]Wallenberg Initiative Materials Science for Sustainability, Uppsala, Sweden — [3]Radboud University, Netherlands — [4]KTH Royal Institute of Technology, Sweden — [5]Wallenberg Initiative Materials Science for Sustainability, Stockholm, Sweden

We present a computational framework for calculating the non-interacting and interacting spin susceptibilities in magnetic materials using the Relativistic Spin-Polarized Toolkit (RSPt) [1]. The ground-state electronic structure is obtained from self-consistent DFT calculations, followed by the computation of site-resolved Matsubara Green's functions, whose convolution yields the bare susceptibility. The interacting χ^{zz} is evaluated by solving the ADA–TDDFT Dyson equation $K = (1 - XU)^{-1}X$, based on previously developed theory [2]. Applications to bcc Cr, $BaFe_2As_2$, and FeSe show that the calculated $\chi(\mathbf{q})$ peaks reproduce the known magnetic ordering vectors. This framework enables systematic exploration of spin-density-wave phenomena in correlated electron systems.

MA 58.10 Fri 12:00 POT/0151

Proximity-Induced Magnetic Phases in CrI3 Monolayers Coupled to Transition-Metal Dichalcogenide Monolayer — •Zoltan Tajkov[1], Laszlo Oroszlany[1], Amador Garcia Fuente[2], Jaime Ferrer[2], Jaroslav Fabian[3], and Daniel Pozsar[1] — [1]Eotvos Lorand University, Budapest, Hungary — [2]University of Oviedo, Oviedo, Spain — [3]University of Regensburg, Regensburg, Germany

We investigate the emergence of altered magnetic phases in a CrI3 monolayer induced by proximity effects with WTe2. Using density functional theory (DFT) calculations within the SIESTA framework, we analyze the magnetic properties via a novel approach for extracting the magnetic exchange interaction and on-site anisotropy tensors in extended Heisenberg spin models, explicitly incorporating relativistic effects. This method, based on the Liechtenstein-Katsnelson-AntropovGubanov torque formalism, evaluates energy variations upon infinitesimal spin rotations. Our results provide insight into how a 2D magnet is influenced when coupled to a material with strong spin-orbit coupling. Additionally, we explore the impact of varying twist angles, considering the incommensurability of the CrI3 and WTe2 unit cells.

MA 58.11 Fri 12:15 POT/0151

Acoustic Wave Group Velocity under Magnetic Field — •Dominik Legut[1,2], Ievgeniia Korniienko[1], and Pablo Nieves[3] — [1]IT4Innovations, VSB-TU Ostrava, Ostrava, Czechia — [2]Charles University, Prague, Czechia — [3]University of Oviedo, Oviedo, Spain

Recently, we derived a spin-lattice model for ferromagnetic cubic crystals[1]. Then we analyzed the effect of the magneto-elasticity on the group velocities for high symmetry directions[2]. Here we present a different approach to determine the group velocity of the acoustic waves in any crystals and under the effects an external magnetic field for cubic and hexagonal symmetry. The group velocity is obtained by calculating Christoffel matrix elements and their partial derivative with respect to the phase velocity direction, and inserting them in an analytical expression for the group velocity. The effect of that external magnetic field is computed through the induced effective corrections to the elastic tensor which depend on the magnetic susceptibility tensor and the magnetoelastic constants. We present examples of dry sandstone, cubic CoPt and hcp Co to show complex landscapes of fractional change in group velocity as a function of ray direction, as well as a field dependence consistent with the Simon effect[3]. We have developed web-based applications where these effects can be analyzed and visualized in 3D[4].

machine learning prediction of magnetic ordering in chiral induced multiferroic hybrid MOFs — •Gayathri Palanichamy, Biplab Sanyal, and Jonas Fransson — Materials Theory Division, Angstrom Laborartory, Uppsala Univesity, Sweden

Chiral hybrid metal organic frameworks with Ruddlesden Popper type halide layers provide a versatile platform for engineering multiferroicity by combining molecular chirality with transition metal magnetism. In this work, we develop a machine learning framework to identify multiferroic candidates in systems where chiral A-site organic molecules break inversion symmetry to induce ferroelectricity, while B-site transition metal centers govern magnetic ordering. First principles calculations confirm that the chiral distortion stabilizes a spontaneous polarization, and selected compositions exhibit coexisting ferroelectricity and ferromagnetism. To efficiently explore this large chemical and structural space, we construct feature descriptors capturing molecular chirality, distortion modes, metal ligand coordination metrics, and octahedral connectivity. Random Forest and Deep Neural Network models are trained to classify magnetic ground states (FM, AFM A, AFM C, AFM G) and achieve an R* score of 0.94, enabling reliable prediction of magnetic ordering across diverse chiral MOFs. Our approach also identifies previously unexplored chiral Ruddlesden Popper candidates with potential multiferroic behavior. This work establishes a data driven strategy toward building a chiral magnetic MOF repository, providing design principles for future spintronic and multifunctional materials.

Magnetization dynamics in RMn_6Sn_6 crystals investigated by broadband ferromagnetic resonance spectroscopy — •Philipp Schwenke[1], David Weffling[1,3], Kyle Fruhling[2], Vitaliy Vasyuchka[1], Fazel Tafti[2], and Mathias Weiler[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Department of Physics, Boston College, Chestnut Hill, MA 02467, USA — [3]Present address: Department of Physics and Materials Science, University of Luxembourg, L-4362 Esch-sur-Alzette, Luxembourg

The RMn_6Sn_6-material family is known for hosting complex magnetic orders [1]. Their Kagome and triangular lattices give rise to an unconventional band structure forming flat bands and Dirac cones leading to significant anomalous Hall- and Nernst-effects [2,3]. In this study, we investigate the magnetization dynamics of $ErMn_6Sn_6$ and $YbMn_6Sn_6$. We track characteristic phase transitions of the materials and the accompanying signatures in the magnetization dynamics over temperature. We find that the phase transitions are in agreement with previous results, while the spin dynamical signatures have not been discussed before. This study highlights the potential of using broadband ferromagnetic resonance spectroscopy to investigate the magnetic properties in RMn_6Sn_6

Anisotropic magnon transports in van der Waals altermagnetic and ferromagnetic insulators — •Qirui Cui — Department of Applied Physics, School of Engineering Sciences, KTH Royal Institute of Technology, AlbaNova University Center, SE-10691 Stockholm, Sweden

Based on state-of-the-art first-principles calculations and model analysis [Nat. Rev. Phys. 5, 43-61 (2023)], we report the spin Seebeck effect (SSE) and spin Nernst effect (SNE) in vdW altermagnetic and ferromagnetic insulators, which are entirely independent of magnetic fields and spin-orbit coupling [Phys. Rev. B 108, L180401 (2023)]. In altermagnetic monolayers Cr2Te2O and Cr2Se2O, the breaking of combined symmetries of space inversion P, time reversal T, and translation τ, while preserving the combined symmetry of mirror M and τ, renders magnons with anisotropic spin-momentum locking, i.e., altermagnetic magnons. Interestingly, this spin-momentum locking gives rise to the SSE and SNE, with very efficient generation of longitudinal and transverse spin currents when the thermal gradient is aligned with and deviates from the main crystal axes, respectively. Moreover, anisotropic magnon dispersions are also realized in synthesized ferromagnetic monolayers CrPS4 and CrSBr, arising from C4 symmetry breaking-induced anisotropic exchange couplings [Adv. Funct. Mater. 35, 2407469 (2025)]. Consequently, without the magnetic field, the anisotropic SSE and the SNE emerge. These nontrivial magnonic transports can be further manipulated by the temperature and gate current.

Magnon Shake-Up Enabling Quantum Features and Devices — •Vahid Azimi Mousolou — Department of physics and astronomy, Uppsala University

Shake-up effects, based on the sudden approximation and many-body quantum dynamics, reveal fundamental aspects of quantum systems and have broad applications in molecular spectroscopy and electronic structure analysis. Here, we present magnon shake-up patterns within magnetic systems [1], highlighting their significance in generating and detecting magnon entanglement and squeezing. This study offers new insights into shake-up phenomena in quantum magnonics and paves the way for novel developments in quantum technology.

MA 59.4 Fri 10:15 POT/0361

Optical vortex generation by magnons with spin-orbit-coupled light — •Ryusuke Hisatomi[1,2], Alto Osada[3], Kotaro Taga[1], Haruka Komiyama[1], Takuya Takahashi[1], Shutaro Karube[1,2], Yoichi Shiota[1,2], and Teruo Ono[1,2] — [1]Institute for Chemical Research, Kyoto University, Uji, Japan — [2]Center for Spintronics Research Network, Institute for Chemical Research, Kyoto University, Uji, Japan — [3]Center for Quantum Information and Quantum Biology (QIQB), Osaka University, Toyonaka, Osaka, Japan

Magneto-optic effects are generally described as the interaction between spin systems and collimated light (paraxial light). However, in many real-world systems studied in magneto-optics research, light focused by an objective lens (non-paraxial light) is utilized, which inherently exhibits optical spin-orbit coupling. Such spin-orbit-coupled light possesses a longitudinal electric-field component. Recently, we found that the interaction between spin-orbit-coupled light and collective spin dynamics (i.e., magnons) leads to optical vortex scattering, and we developed a theoretical framework to reproduce this phenomenon. The result provides the first step toward a comprehensive magneto-optics study incorporating optical vortices.

MA 59.5 Fri 10:30 POT/0361

Magnetization dynamics in YIG optomechanical crystals — •Matthias Grammer[1,2], Jonny Qiu[3], Sebastian Sailler[4], Sebastian T.B. Goennenwein[4], Matthias Althammer[1,2], Stephan Geprägs[1], Michaela Lammel[4], Eva Weig[3], and Hans Huebl[1,2] — [1]Walther-Meißner-Institut, BAdW, Garching, Germany — [2]School of Natural Sciences, TUM, Garching, Germany — [3]School of Computation, Information and Technology, TUM, Garching, Germany — [4]Department of Physics, University of Konstanz, Konstanz, Germany

Efficient transduction between microwave and optical photons is a key requirement for future quantum network applications. Recent studies have focused on freestanding magnetic nanostructures such as optomechanical crystals (OMC) based on yttrium iron garnet (YIG). These devices allow for co-localizing magnonic, elastic and photonic exitations in a single nanostructure. While the optical properties of a YIG OMC have already been experimentally shown [1], its magnonic and phononic modes have so far only been explored

through simulations. In this talk, we present an experimental investigation of the magnetic modes in a YIG OMC. For our proof of principle study, we fabricated a non-suspended YIG OMC on a GGG substrate using sputtering and lift-off techniques. We investigate the collective magnon modes using spacially resoved micro-focused magneto-optical Kerr effect measurements and categorize the observed modes using micromagnetic simulations.

MA 59.6 Fri 10:45 POT/0361

Direct observation of magnetic vortex resonances on curvilinear surfaces — •Sabri Koraltan[1], Takeaki Gokita[1], Michal Krupinski[2], Sebastian Wintz[3], and Amalio Fernández-Pacheco[1] — [1]Insitute of Applied Physics, TU Wien, Vienna, Austria — [2]Institute of Nuclear Physics, Polish Academy of Sciences, Krakow, Poland — [3]Institute for Nanospectroscopy, Helmholtz-Zentrum Berlin, Berlin, Germany

Spin waves in magnonic systems offer energy-efficient alternatives to conventional electronics [1], with low-frequency magnetic vortex resonances being particularly relevant for microwave applications [2]. While planar magnetic vortices have been extensively studied [2], their dynamics in three-dimensional curvilinear architectures remain largely unexplored. Here, we present the direct experimental observation of vortex core gyration on a 3D curvilinear surface [3]. Using a stripline antenna on a SiN membrane, we excite self-assembled polystyrene spheres coated with NiFe, which host a vortex lattice state at remanence. Time-resolved scanning transmission X-ray microscopy (TR-STXM) at BESSY II [4] captures real-space, time-resolved dynamics, revealing complex spin-wave modes due to curvature-induced field gradients. Our results highlight the potential of curvilinear magnetic architectures for next-generation magnonic devices.

MA 59.7 Fri 11:15 POT/0361

Direction Selective Spin Waves Imaging in Microstructures — •Roméo Beignon[1], Chris Köerner[2], Rouven Dreyer[2], Zeling Xiong[3], Katrin Schultheiss[3], Helmut Schultheiss[3], Vincent Jacques[1], Georg Woltersdorf[2], and Aurore Finco[1] — [1]Laboratoire Charles Coulomb, Université de Montpellier, CNRS, Montpellier, France — [2]Martin Luther University Halle-Wittenberg, Halle, Germany — [3]Helmholtz-Zentrum Dresden-Rossendorf, Institut für Ionenstrahlphysik und Materialforschung, Dresden, Germany

Spin waves can be generated and manipulated at the nanoscale using patterned microstructures and magnetization features. Harnessing these effects is key to the development of magnonic devices. With scanning NV microscopy, we are able to image spin waves with a spatial resolution of about 50 nm. Simultaneously, we probe the stray field produced by non-uniform static magnetic textures hosted in the microstructures and explore their interactions with spin wave modes.

Here, we apply this technique to observe spin waves in Permalloy microstructures. We first investigate spin waves generated via scattering and measure their dispersion relation. Then, we show that the NV center is sensitive to the handedness of the circularly polarized field emitted by spin waves. We can thus selectively image spin waves propagating in different directions and study how they interact with the edges of the Py structure. Finally, we observe discrete magnon modes with high azimuthal indices in disks featuring a vortex state. These measurements open the way to understanding complex non-linear dynamic phenomena in magnetic microstructures.

MA 59.8 Fri 11:30 POT/0361

Time domain correlation spectroscopy of thermal and nonequilibrium magnons — •F. S. Herbst[1], M. A. Weiss[1], C. Runge[1], N. Beaulieu[2], J. B. Youssef[2], A. Leitenstorfer[1], M. Lammel[1], R. Schlitz[1], and S. T. B. Goennenwein[1] — [1]Department of Physics, University of Konstanz, Germany — [2]LabSTICC, CNRS, Université de Bretagne Occidentale, France

Yttrium iron garnet (YIG) is a prototypical material for spintronics and magnonics due to its low magnetic damping and high spin wave propagation velocities. The properties of coherently excited, standing spin waves are well understood. However, much less is known about the interplay between coherently excited magnons and incoherent fluctuations, as schemes simultaneously resolving both coherent and incoherent contributions in a single measurement are scarce. In this work, we probe bismuth doped YIG with femtosecond noise correlation spectroscopy (FemNoC), an optical technique probing magnetization dynamics in the time domain. This method enables us to simultaneously investigate both the thermal magnon noise background and the coherent magnon response induced by microwave excitation. Using a phenomenological model, we can fit both the waveform and amplitude of the experimental data. This step allows us to quantify and disentangle the respective contributions by their correlation signature. Consequently, FemNoC gives access to the absolute magnon number of a magnetic system in the time domain.

MA 59.9 Fri 11:45 POT/0361

Nonlinearly controllable magnonic mode-converter in a synthetic antiferromagnet — •Mujin You[1,2], Moojune Song[2], Jun Seok Seo[2], Sanghoon Kim[3], Yoichi Shiota[4], Teruo Ono[4], Se Kwon Kim[1], Albert M. Park[2], Kab-Jin Kim[2], Mathias Weiler[1], and Philipp Pirro[1] — [1]Fachbereich Physik and Landesforschungszentrum OPTIMAS, Rheinland-Pfälzische Technische Universität Kaiserlautern-Landau, Germany — [2]Department of Physics, Korea Advanced Institute of Science and Technology (KAIST), Korea — [3]Department of Nanosemiconductor Engineering, University of Ulsan, Korea — [4]Institute for Chemical Research, Kyoto University, Uji, Japan

Exploring and controlling nonlinear regimes enables new functionalities in hybrid magnonic systems, including phenomena such as nonlinear anticrossing gap closure and bistability in magnon dispersion. In this work, we observe mode hopping between acoustic and optic modes in a SAF, occurring at the magnetic field where the optic frequency becomes twice the acoustic frequency-consistent with a three-magnon interaction process. Based on this nonlinear mode-hopping behavior, we demonstrate an electrically tunable, nanoscale GHz-range mode-converter. These findings reveal a promising application via nonlinear coupling between acoustic and optic magnons in SAFs, paving the way for energy-efficient, reconfigurable magnonic devices.

MA 59.10 Fri 12:00 POT/0361

$\mathbb{Z}$ Topological Index for 3D Hamiltonians based on Lattice Gauge Theory — Nastaran Salehi and •Manuel Pereiro — Department of Physics and Astronomy, Uppsala University, Box 516, SE-751 20 Uppsala, Sweden

The characterization of topological phases in three-dimensional (3D) systems often requires extending concepts well-established in two dimensions (2D). We propose a robust method for calculating an integer topological invariant, akin to the Chern number, for 3D Hamiltonians with periodic boundary conditions. This approach utilizes conceptual elements derived from lattice gauge theory, defining the invariant over a discretized Brillouin zone (a 3-torus, T^3). By constructing U(1) link variables from the Bloch wavefunctions, we define a gauge-invariant quantity from Wilson loops over elementary 3D plaquettes (cubes) in k-space. The resulting topological index is an integer, reflecting the classification of principal fiber bundles $T^3 \times U(1)$ and related to the homotopy group $\pi_3(\mathbb{P}^2(\mathbb{R})) \cong \mathbb{Z}$. This method is general and computationally efficient, avoids issues with band degeneracies, and provides a unique integer invariant for each band. We adapt the method for magnetic Hamiltonians and showcase its effectiveness with two examples: firstly, a 3D Kagome lattice model, and secondly, a realistic material, Mn_3Se, for which the magnon spectra is obtained by employing electronic structure first-principles calculations.

MA 59.11 Fri 12:15 POT/0361

Second-Chern Topology of 3D Magnon Bands via a Field-Angle Pump — •Nastaran Salehi and Manuel Pereiro — Department of Physics and Astronomy, Uppsala University, Box 516, SE-751 20 Uppsala, Sweden

We present a general framework to realize second-Chern topology in three-dimensional (3D) bosonic Bogoliubov-de Gennes (BdG) bands by augmenting the Brillouin zone with a slow, cyclic control parameter, yielding a 4D manifold $\mathbf{T}^3 \times S^1$. Using the bosonic metric Σ_3 and paraunitary gauge, we define the non-Abelian Berry connection/curvature for isolated positive-norm band bundles and an integer invariant $C_2 \in \mathbf{Z}$. We prove that C_2 quantizes an adiabatic transport: across a slab, the pumped conserved quantity (spin for magnons) per 2π cycle is an *integer* set by C_2, and the corresponding current is proportional to $\dot{\phi}$. We introduce a stable lattice algorithm, based on Σ_3-polar link variables, that is gauge covariant and robust in the presence of degeneracies. For the sake of concreteness and pedagogical clarity, we carry out the full derivation in a kagome-based 3D magnet, where a field-angle cycle drives a topological spin flow detectable via inverse spin Hall voltages in Pt contacts on opposing faces. Although illustrated for magnons, the construction applies broadly to quadratic bosonic BdG systems, including phononic and photonic analogues.

Members' Assembly of the Metal and Material Physics Division

Wednesday 17:15–18:45 SCH/A251

- discussion of MM activities
- announcement of the poster awards
- exchange of ideas for the next DPG meeting

Sessions

– Invited Talks, Topical Talks, Tutorials, Contributed Talks, and Posters –

MM 1: Hands on tutorial: Linking Large Language Models with Digital Workflows for Materials Science Simulations (joint session MM/TUT)

Advanced computational simulations often require chaining several models and software packages together, a process that demands careful workflow management. In this tutorial you can gain hands-on experience with the Python based workflow environment pyiron (www.pyiron.org). Participants in the tutorial will be able to run all the examples shown in the presentation interactively on their own laptops. There is no need to install any code, just a standard web browser to explore the applications interactively.

Time: Sunday 16:00–18:15 Location: TRE/MATH

Tutorial MM 1.1 Sun 16:00 TRE/MATH

Hands on tutorial: Linking large language models with digital workflows for materials science simulations — •Jörg Neugebauer[1], Tilmann Hickel[1,2], and Ralf Drautz[3] — [1]Max Planck Institute for Sustainable Materials — [2]Bundesanstalt für Materialforschung und -prüfung — [3]ICAMS, Ruhr Universität Bochum

Advanced computational simulations now reliably predict material properties, but they often require chaining several models and software packages together, a process that demands expert knowledge and careful workflow management. Efficient, reproducible research therefore hinges on automated workflow tools that can handle this complexity. In this tutorial we introduce pyiron (www.pyiron.org), a Python based workflow environment for building and executing fully automated simulation pipelines. We show how complex simulations workflows can be constructed programmatically via Python code as well as via a flow-based graphical user interface. We further introduce how large language models (LLMs) can be embedded to streamline the "human in the loop" tasks. After a brief overview of pyiron's core concepts, we construct workflows for computing ab initio thermodynamic bulk phase diagrams. The necessary steps, such as density functional theory calculations, training ACE-based machine learning potentials, and exploring phase stability using foundational models like GRACE, are all performed within pyiron workflows. Participants will learn how to develop and integrate such workflows into their own materials science simulations, thereby enabling faster, more transparent, and more reproducible research.

MM 2: Invited Talk: Richard Hennig

Time: Monday 9:30–10:00 Location: SCH/A251

Invited Talk MM 2.1 Mon 9:30 SCH/A251

Deep-Learning and Generative AI for the Discovery of Electron-Phonon Superconductors — •Richard Hennig — University of Florida, Gainesville, Florida, USA

The search for new superconductors with higher critical temperatures, T_c, and critical fields, H_c, is limited by the cost of electron-phonon calculations and the vastness of compositional and structural space. To overcome both obstacles, we develop an integrated deep-learning workflow for conventional, electron-phonon-mediated superconductors.

First, we introduce BEE-NET, an ensemble of equivariant graph neural networks trained to predict the Eliashberg spectral function $\alpha^2F(\omega)$ and T_c directly from crystal structures, optionally augmented by the phonon density of states. Unlike traditional approaches that learn T_c directly, predicting $\alpha^2F(\omega)$ treats superconductors and non-superconductors on equal footing and, together with explicit phonon-spectrum information, leverages electron-phonon physics to improve predictions for rare superconducting materials. Embedded in a multi-stage screening pipeline that combines elemental substitution strategies with machine-learned interatomic potentials, BEE-NET scans over 1.3×10^6 candidate structures and down-selects to 741 dynamically and thermodynamically stable compounds with DFT-confirmed $T_c > 5$ K, including two experimentally realized new superconductors.

Finally, I will briefly show how guided diffusion models for crystal structures and our Open Materials Generation (OMatG) framework based on stochastic interpolants extend this physics-informed, data-driven approach to the generative design of new superconductors.

MM 3: Mechanical Properties and Alloy Design I

Time: Monday 10:15–12:45 Location: SCH/A215

MM 3.1 Mon 10:15 SCH/A215

Mechanical Properties of Disordered Fe-Co Nanoparticles — •Yarden Nathan — Technion, Haifa, Israel

We synthesized Fe- 50 at.% Co nanoparticles (NPs) via solid-state dewetting of Fe-Co bilayers deposited on a sapphire substrate at the temperature of 900 *C followed by slow cooling. By employing X-ray diffraction and electron diffraction in transmission electron microscope (TEM) we demonstrated that the NPs are fully disordered α-FeCo body centered cubic (BCC) phase. We demonstrated that the size and orientations of the disordered BCC NPs can be controlled by varying their fabrication parameters. Most of the NPs were faceted single crystals with their top (110) facet oriented parallel to the substrate. The mechanical properties of the NPs were measured by employing in-situ micro compression tests in the scanning electron microscope (SEM). The near-theoretical strength of α-FeCo NPs was demonstrated. We propose that the fully disordered NPs behave similarly to the defect-free NPs of pure metals. The plasticity of these NPs is controlled by the dislocation nucleation requiring near-theoretical stress. This mechanism explains the near-theoretical strength and the distinct "smaller is stronger" size effect observed in this metastable phase.

MM 3.2 Mon 10:30 SCH/A215

Role of Structural Hierarchy on Tensile Properties of Nanoporous Metals — •Wei-Che Chang[1], Yong Li[1], Henry Ovri[1], and Shan Shi[1,2] — [1]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany — [2]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, Hamburg, Germany

Nanoporous gold (NPG) is drawing significant attention as functional, lightweight material due to its low density, high surface area, and tunable structures. Despite the inherent ductility of bulk gold, NPG often exhibits brittleness under tension [1]. Recently, hierarchical nanoporous gold (HNPG) with multiple levels of well-defined porosities has attracted significant interest for its enhanced functional performance and improved compressive properties at reduced solid fraction [2]. However, whether these mechanical enhancements under compression also extend to tension, particularly whether structural hierarchy can mitigate the intrinsic brittleness of nanoporous networks under tension, remains an important open question. In this work, we introduce an in-situ micro-tensile setup for real-time observation of deformation and fracture behaviors in a scanning electron microscope (SEM). Our results show that the hierarchical structure improves ductility by a factor of five. The mechanism of tensile deformation is further revealed by molecular dynamics simulations.

MM 3.3 Mon 10:45 SCH/A215

Mechanical shielding of holes in elastic solids — •Kanka Ghosh and Andreas M. Menzel — Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Universitätsplatz 2, 39106 Magdeburg, Germany

Holes inside an elastic solid reduce its overall mechanical stiffness. We examine whether a stiff shell around the hole can act as a shield under external loading, maintaining overall mechanical properties of the solid as if the hole were absent. For this purpose, an isotropic, homogeneous, linearly elastic material, loaded uniformly under plane strain with low concentrations of holes is considered. Instead of changing the materials to conceal a hole, we suggest to adjust the thickness of the shell for given elasticity parameters. A corresponding analytical expression for the thickness of the shell is derived. We extend this idea to the atomistic level using molecular dynamics simulations of model Lennard-Jones solids. Consistency of the resulting shell thickness for mechanical shielding at the atomistic scale attests the robustness of our continuum elasticity predictions. The concept is crucial for light-weight construction without compromising elastic materials properties.

We acknowledge support of this work through the European Union (EFRE) and the State Saxony Anhalt through project no. ZS/2024/02/184030.

MM 3.4 Mon 11:00 SCH/A215

Synthesis and mechanical properties of multi-scale hierarchical Ni and Cu foams — •Ulrike Dette[1,2] and Shan Shi[1,3] — [1]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, 21073 Hamburg, Germany — [2]Institute of Materials Physics and Technology, Hamburg University of Technology, 21073 Hamburg, Germany — [3]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, 21502 Geesthacht, Germany

As functionalized materials gain importance and component miniaturisation advances, there is an increasing demand for optimized structured materials. This talk presents a novel and straightforward alloying-dealloying approach to fabricate metals such as Ni and Cu with two- and three-level hierarchical network structures. Due to the significant difference in vapour pressures between the target metals, vapor phase alloying (VPA) of a metal foam with Zn resulted in Zn-based intermetallic alloy foams. This is then followed by vapor phase dealloying (VPD) which removes Zn and creates a finer porosity, resulting in a second level. A subsequent VPA-VPD cycle produces a third hierarchical level. Compression tests on these hierarchical foams with varying solid fractions were performed to determine Young's modulus and strength. The experimental results align well with the predictions of our new scaling law.

15 min. break

MM 3.5 Mon 11:30 SCH/A215

Formation and properties of crystalline and amorphous high-entropy ZrTiTaMoWNi thin films using magnetron sputtering of a segmented target — •Anna Kornyushchenko[1,2], Vyacheslav Perekrestov[2], Marilena Tomut[1,3], Harald Rösner[1], Martin Peterlechner[4], and Gerhard Wilde[1,5] — [1]Institute of Materials Physics, University of Muenster, Muenster, Germany — [2]Laboratory of Vacuum Nanotechnologies, Sumy State University, Sumy, Ukraine — [3]GSI Helmholtz Center for Heavy Ion Research, 64291 Darmstadt, Germany — [4]Karlsruhe Institute of Technology, Laboratory for Electron Microscopy, 76131 Karlsruhe, Germany — [5]Herbert Gleiter International Institute, Liaoning Academy of Materials, Shenyang, China

Using direct current magnetron sputtering of a segmented target under conditions of thermodynamical equilibrium, single-phase bcc or amorphous ZrTiTaMoWNi high entropy alloy layers have been formed. The crystalline layers have been obtained in the form of nano-patterns, with crystal growth occurring preferentially on the basis of (310) crystallographic plane, which aligns parallel to the substrate surface. The amorphous layers have smooth surface, featureless morphology and demonstrate structural stability. TEM studies have shown that their crystallization into a single bcc phase occurs at the annealing temperature of 800 C. The microhardness of the amorph and the crystalline films has measured to be 10 GPa and 4.6 GPa, correspondingly. Resistance to impact of swift heavy Au ions irradiation with energies 4.8 MeV/u have been compared for amorph and crystalline layers.

MM 3.6 Mon 11:45 SCH/A215

Microstructural and Chemical Analysis on MoSiTi samples with PDC coating for High Temperature Application — •Ingrit Nurak[1], Daniela Camacho[2], Lukas Korell[3], Giorgia Guardi[1], Heike Störmer[1], Svetlana Korneychuk[1], Yolita M. Eggeler[1], Astrid Pundt[1], and Samuel A. Kredel[2] — [1]Karlsruher Institut für Technologie, Karlsruhe, Germany — [2]Technische Universität Darmstadt, Darmstadt, Germany — [3]Dechema Forschungszentrum, Frankfurt, Germany

MoSiTi material is of high interest for high temperature applications, such as Mo-20Si-52.8Ti [Schliephake et. al., 2019]. In this presentation, we investigate the combination of this material with a Cr-bond coat and a Si(Hf, Ta)BCN(O)-polymer derived ceramic (PDC) upper layer. The structural and chemical evolution of the layered material, depending on the specific synthetic routes used and additional thermal treatments will be addressed by using different scanning and transmission electron microscopy (SEM, TEM) techniques. TEM will be applied to the (i) polymer-derived ceramic nanocomposites coating, to the development of (ii) ultra-high temperature silicides and to the (iii) Cr bond coat layer. Heat treatments will be addressed at 1200˚C and 1400˚C both in air and in argon atmosphere. The experimental outcomes demonstrate that the Materialsystem exhibits the capacity to withstand temperatures of 1200˚C for an hour without delamination. Notwithstanding the application of heat treatment at 1400˚C, there is no oxygen penetration into the MoSiTi substrate occurred. Moreover, the PDC coating was found to remain partially amorphous.

MM 3.7 Mon 12:00 SCH/A215

Understanding Alloying Effects on Grain Boundary Adhesion in Nickel Alloys by Atomistic Simulation — •Aljoscha F. Baumann[1], Reyhaneh Ghassemizadeh[1], and Daniel F. Urban[1,2] — [1]Fraunhofer IWM, Freiburg, Germany — [2]Freiburger Materialforschungszentrum, Freiburg, Germany

When increasing the in-service performance of engineering metallic materials, interfaces such as phase or grain boundaries (GB) may act as the weakest links. For the nickel-base superalloy Alloy 718 intergranular cracking can be a relevant damage mechanism as a result of high-temperature fatigue in an oxygen-rich environment. The reliable prediction of adhesion and mechanical stability at grain boundary interfaces from atomistic calculations remains a challenge due to the high-dimensional parameter space of chemical compositions and GB structures. Recently developed machine learning interatomic potentials (MLIPs) such as GRACE offer a promising solution to explore this parameter space by combining high accuracy with computational efficiency. Here we use a MLIP to perform cleavage simulations on grain boundaries in fcc Ni with Cr and Fe as alloying elements at varying concentrations and statistical distributions. This approach provides a pathway for atomistic simulations towards a more comprehensive modelling of alloys and their interface mechanical properties, thereby providing insights into intergranular failure mechanisms. Our results can be used to parametrize traction separation laws used in finite element modelling, allowing for microstructure-sensitive modelling of fatigue crack formation and growth.

MM 3.8 Mon 12:15 SCH/A215

Phase stability and surface segregation in multinary noble-metal alloys: an atomistic study with universal models — •Quentin Bizot, Matous Mrovec, and Ralf Drautz — Interdisciplinary Centre for Advanced Materials Simulation (ICAMS), Ruhr-University Bochum, 44780 Bochum, Germany

Multinary alloys are complex solid solutions composed of several elements. They rarely behave like ideal solid solutions due to differences in phase stability, atomic size, and crystalline preferences. In bulk, short-range order can therefore be significant, leading to the formation of specific phases or distortions across the lattice. In addition to the effects in the volume, surface segregation affects the order and composition of the few first layers at the surface. A detailed understanding of these effects at the atomic scale is essential to predict and control the distribution and ordering of surface atoms, as well as their influence on material properties.

In this work, we investigate complex solid solutions based on noble metals with atomistic simulations demonstrating the formation of stable phases in the bulk as well as the segregation of specific elements at the surface. For this purpose, we used tailored GRACE model capable of describing interactions for 25 transition metals as well as universal GRACE models trained on diverse datasets.

MM 3.9 Mon 12:30 SCH/A215

First-principles study of aluminum alloy - polymer interfaces: From surface structures to adsorbate interactions — •Zhengqing Wei[1], Inna Plyushchay[2], Nebahat Bulut[1], Florian Lehmann[4], Philip Grimm[5,6], Maik Gude[4], Julia Hufenbach[5,6], and Sibylle Gemming[1,3] — [1]Inst. Physics, TU Chemnitz, Germany — [2]Natl. Taras Shevchenko University of Kyiv, Ukraine — [3]MAIN Center, TU Chemnitz, Germany — [4]ILK, TU Dresden, Germany — [5]IFW Dresden, Germany — [6]Inst. Materials Science, TU-BA Freiberg, Germany

Aluminum alloy surfaces face strict demands regarding extreme environmental conditions. The joining of aluminum alloy materials with engineering plastics enhances the overall resilience of composite. This study employs density functional theory (DFT) to model aluminum alloy surfaces while including electronic structure considerations. The surface stability was investigated as functions of alloying composition particularly on surfaces doped with Mg, Zr, and Si. The study includes the alloy's diffusion tendency, which shows that differential electron density variations occur simply at the outermost surface layer in contact with vacuum. Surface vacancy and migration barriers, and when the surface is bonded to the polymers, the interactions between atomic species of polymer side chains and aluminum alloy surfaces as well as surface vacancy sites were also analyzed. The modeled adsorbates on aluminum alloy surfaces provides modified local potential parameters for classical modeling of large-scale aluminum alloy–polymer surface and interfacial regions.

MM 4: Materials for the Storage and Conversion of Energy I

Time: Monday 10:15–13:00 Location: SCH/A216

Topical Talk MM 4.1 Mon 10:15 SCH/A216

Photoelectric properties of dislocations in SrTiO3 single crystals — •Marin Alexe — University of Warwick

Dislocations are one-dimensional crystallographic line defects traditionally regarded as detrimental to the functional properties of conventional semiconductors. However, it has been recently shown on Fe-doped SrTiO3 single crystals containing well-ordered, high-density dislocation structures that dislocations can significantly enhance photoconductivity. Local photoconductivity measurements using atomic force microscopy (AFM) revealed that regions surrounding dislocation cores exhibit up to a fourfold increase in photoconductivity compared with dislocation-free areas of the crystal. Furthermore, macroscopic in-plane surface measurements using microcontacts aligned along dislocation slip bands showed orders-of-magnitude enhancement in photoconductivity. This might be due a significant increase of the carrier density at the core of dislocation due to a to a non-chemical local doping induced by the strain or strain gradient.

These results provide unambiguous evidence that dislocations in oxide semiconductors can be beneficial for specific functional properties. The anisotropic enhancement of photoconductivity along dislocation cores highlights their potential as active elements in future one-dimensional oxide electronic and optoelectronic devices.

MM 4.2 Mon 10:45 SCH/A216

Defect-driven carrier dynamics in tantalum nitride photoelectrodes — •Lukas M. Wolz[1], Johannes Dittloff[1,2], Laura I. Wagner[1,2], Julius Kühne[1,2], Luc-Fabrice Tremel[1], Lina M. Todenhagen[1,2], Lissa Eyre[1,2], Felix Deschler[1,2,3], Ian D. Sharp[1,2], and Johanna Eichhorn[1] — [1]Physics Department, TUM School of Natural Sciences, Technische Universität München, Germany — [2]Walter Schottky Institute, Technische Universität München, Germany — [3]Institute for Physical Chemistry, Heidelberg University, Germany

Tantalum nitride (Ta_3N_5) is a widely studied semiconductor for solar-driven water splitting. Yet, experimentally realized efficiencies often remain below theoretical limits largely because native and impurity-related defect states alter charge carrier dynamics by promoting trapping and recombination. Here, we investigate how distinct defect properties in Ta_3N_5 thin films govern ultrafast photocarrier behavior using femtosecond transient absorption spectroscopy, complemented by photoluminescence (PL) and PL excitation measurements. Ta_3N_5 photoelectrodes were synthesized by annealing TaO_x, TaN_x, and Ta precursor films in NH_3, enabling systematic control over shallow and deep defect state concentrations. The controlled defect properties allow us to disentangle the roles of nitrogen vacancies and oxygen-related defects in shaping carrier dynamics. Our results reveal that deep defects function as efficient trapping and recombination centers for free carriers. Here, we correlate ultrafast spectroscopy with complementary optical and photoelectrochemical data.

MM 4.3 Mon 11:00 SCH/A216

Probing Defect-State Photoionization in Ta_3N_5 Thin Films via Photocurrent Excitation Spectroscopy — •Luc-Fabrice Tremel[1], Lukas M. Wolz[1], Johannes Dittloff[1,2], Ian D. Sharp[1,2], and Johanna Eichhorn[1] — [1]Physics Department, TUM School of Natural Sciences, Technische Universität München, Germany — [2]Walter Schottky Institute, Technische Universität München, Germany

Transition-metal nitrides are a highly interesting material space for solar-energy conversion due to their suitable bandgap for visible light absorption and high theoretical solar-to-hydrogen efficiencies. A prominent example is Ta_3N_5, which combines a bandgap of 2.2 eV with favorable band alignment for solar water splitting. In practice, however, its photoelectrochemical performance is strongly constrained by shallow and deep defects. Here, we use photocurrent excitation spectroscopy, complemented by power-dependent photocurrent measurements, to determine how these defect states shape the spectral photocurrent response of Ta_3N_5. By tracking photocurrent as a function of photon energy, light intensity, and applied potential, we distinguish the sharp band-edge transition from a broadened onset dominated by defect-assisted photoionization into the conduction band. These insights into the defect-controlled photoresponse of Ta_3N_5 provide guidance for improved fabrication strategies and the development of higher-performing nitride-based solar-fuel devices.

MM 4.4 Mon 11:15 SCH/A216

Piezoresponse force microscopy on substituted BaTiO3-relaxors — •Markus Kratzer[1], Philipp Fahler-Muenzer[2], Christian Maier[4], Klaus Reichmann[3], Marco Deluca[5], and Christian Teichert[1] — [1]Chair of Physics, Department of Physics, Mechanics and Electrical Engineering, TU Leoben, Leoben, Austria — [2]University of Warwick - Department of Physics, Coventry, United Kingdom — [3]Institute for Chemistry and Technology of Materials, Graz, Austria — [4]Materials Center Leoben GmbH, Leoben, Austria — [5]Silicon Austria Labs GmbH, Sandgasse 34, 8010 Graz, Austria

Relaxor ferroelectrics are key materials in electrostatic capacitors for energy storage but also for high-performance actuators and transducers. Classical relaxor ferroelectric systems often contain lead, which is environmentally unsound. Thus, lead free relaxors are highly desired. A promising route is via substituted barium titanate (BaTiO3). In this study we focus on B-site-substituted polycrystalline BaTiO3, where the central Ti ion in the perovskite lattice is partially substituted by Zr or Nb. In such systems, information on the microscopic ferroelectric domain structure is still lacking, even though detailed macroscopic characterization using a variety of techniques has been undertaken. We use piezoresponse force microscopy to investigate domain structure and local polarization switching at different temperatures and compositions. We find that temporal stabilization of domains with limited volume is still possible, even though long-range ferroelectric order is strongly supressed with increasing levels of substitution. This suggests the presence of residual highly unstable polar nanoregions.

MM 4.5 Mon 11:45 SCH/A216

Tunable TiO_xN_y Photoelectrodes for Efficient Solar Energy Conversion — •Sebastian Trautschold and Johanna Eichhorn — TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany

Oxynitrides have recently emerged as a versatile material class for photoelectrochemical energy conversion, offering a pathway to combine the stability of oxides with the visible-light absorption and favorable charge transport of nitrides. Their key advantage lies in the continuous tunability of optical and electronic properties via adjusting the O/N ratio. TiO_xN_y provides a particularly illustrative platform: while TiO_2 is limited by a wide bandgap and TiN is metallic, TiO_xN_y can be tuned into an intermediate semiconducting regime, enabling improved utilization of the solar spectrum without sacrificing transport.

Here, we deposit TiO_xN_y thin films by pulsed gas reactive sputtering, enabling precise stoichiometric control over a broad composition range. Post-annealing in ammonia and nitrogen is then used as an additional handle to tailor crystallinity, phase evolution, and defect chemistry. By correlating deposition and annealing parameters with structural, chemical, and optoelectronic characteristics - particularly bandgap and defect properties - we identify processing windows that optimize qualities relevant for solar harvesting. Our results demonstrate the strong sensitivity of TiO_xN_y to both growth kinetics and thermal treatment, and establish practical guidelines for engineering oxynitride photoelectrodes toward efficient and durable solar energy conversion systems.

MM 4.6 Mon 12:00 SCH/A216

In Situ Scanning Transmission Electron Microscopy Investigation of Solid-State Batteries Under Realistic Processing Conditions — •Thomas Demuth, Shamail Ahmed, and Kerstin Volz — Philipps Universität Marburg, Department of Physics and mar.quest, Marburg, Germany

Solid-state batteries promise safer energy storage with higher energy density compared to conventional lithium-ion batteries with liquid electrolytes. To ensure good ionic conductivity between the cathode active material (CAM) and solid electrolyte (SE), the interface area must be maximized. This can be achieved by co-sintering the materials at elevated temperatures. However, high-temperature treatment can induce secondary phase formation at the SE - CAM interface. To optimize material stability, a fundamental understanding of the materials' structure and the processes occurring at the interface are required. Here, in situ (scanning) transmission electron microscopy ((S)TEM) offers insights into nanoscale reaction processes. In our study, we have heated the CAM LiNiO2 (LNO) as a model system in an oxygen atmosphere, utilizing a closed gas cell heating holder, which enables heating the sample in a gaseous atmosphere of 1 bar to temperatures of up to 1000 °C. Using a scanning nanobeam mode allows rapid switching between live imaging for the observation of morphological changes and recording of 4D diffraction pattern datasets for structural analysis. Our findings indicate that the onset temperature for phase degradation is significantly higher in an oxygen atmosphere compared to vacuum, highlighting the importance of replicating realistic processing conditions.

MM 4.7 Mon 12:15 SCH/A216

Voltage-Dependent CEI Development on LMO Cathodes in-situ monitored via Langasite Microgravimetry — •Robert Löser and Guido Schmitz — University of Stuttgart, Stuttgart, Germany

Understanding the formation and evolution of the cathode-electrolyte interphase (CEI) is essential for improving the stability of high-voltage lithium-ion battery materials such as LiMn2O4 (LMO). In this work, we investigate the CEI formation and composition in-situ on sputtered LMO thin films using an electrochemical microbalance based on a Langasite (La3Ga5SiO14) resonator. Unlike conventional quartz crystal microbalances, Langasite substrates enable high-temperature annealing of sputtered oxide films while keeping their piezoelectric properties, making them uniquely suited for preparing crystalline cathode layers directly on the resonator surface. LMO films were cycled to different upper voltage cutoffs to investigate how oxidative potentials influence CEI formation. The coupled electrochemical-gravimetric data reveal clear voltage-dependent mass changes associated with electrolyte decomposition, surface reconstruction, and dissolution processes. By correlating frequency shifts with electrochemical signatures, we quantify the onset, magnitude, and reversibility of CEI species formation dependent of the upper voltage boundary. This study demonstrates that Langasite-based microgravimetry enables powerful, in-situ investigation of CEI evolution and interphase dynamics on annealed cathode films such as LMO, opening the way for systematic studies across a broader range of high-temperature processed electrodes.

Tuning electronic structure of CoNi LDHs via surface Fe doping for achieving effective oxygen evolution reaction — •Yunli Shi[1,2], Huaping Zhao[1], Junqi Li[2], and Yong Lei[1] — [1]Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — [2]School of Materials Science and Engineering, Shaanxi University of Science and Technology, Xian 710021, China

Cobalt and nickel based layered double hydroxides (LDHs) are promising oxygen evolution reaction (OER) catalysts, but their performance is limited by poor conductivity and low intrinsic catalytic activity. In this study, CoNi LDHs were used as a matrix, with iron sites introduced onto the surface via cation replacement (Fe-CoNi LDHs). Unlike ternary Fe-CoNi LDHs synthesized through conventional one-step methods, the iron sites in Fe-CoNi LDHs are primarily located on the surface and edges of nanosheets, ensuring abundant exposure of reactive sites. Surface doping was found to optimize the coordination environment and electronic structure, reducing the binding energy between reactants and active sites. As a result, Fe-CoNi LDHs exhibit an overpotential of only 260 mV at 10 mA cm**, demonstrating superior OER performance. This study elucidates the electronic structure and mechanism of enhanced activity, highlighting the potential of surface doping to advance electrocatalytic applications.

MM 4.9 Mon 12:45 SCH/A216

NiCo2O4/Fe3O4 Nanocomposite with a Sea Urchin-like Morphology as a High-Performance Dual-Functional Material for Advanced Lithium-Ion Batteries and Supercapacitors — •Amina Zafar, Amjad Nisar, and Mashkoor Ahmad — Pakistan Institute of Nuclear Science and Technology (PINSTECH), Islamabad, Pakistan

The development of advanced electrode materials with multifunctional electrochemical properties is critical for next-generation energy storage systems. In this study, mesoporous sea urchin-like nickel cobaltite/magnetite (NiCo2O4/Fe3O4) composite was synthesized and systematically investigated for lithium-ion batteries and supercapacitors. The resulting composite offers high specific surface area, improved conductivity, abundant active sites and favorable structural characteristics. DFT calculations reveal that the composite exhibits enhanced redox kinetics and improved charge transfer compared to pristine NiCo2O4, leading to superior electrochemical performance. As an anode for lithium-ion batteries, the NiCo2O4/Fe3O4 electrode delivers a high reversible capacity of around 730 mAh/g at 0.3 A/g with excellent cycling stability, retaining 87.1 % of its capacity after 1000 cycles. For supercapacitor, the electrode exhibits an enhanced specific capacitance of 1330 F/g at 1 A/g, outperforming both NiCo2O4 and Fe3O4. The assembled (NiCo2O4/Fe3O4//activated carbon) device achieved a specific capacitance of 221 F/g and an energy density of 69.6 Wh/kg, along with excellent cycling stability, retaining around 94 % capacitance after 8000 cycles.

Machine Learning for Materials Discovery: from Big Data to Predictive Insights — •Silvana Botti — Research Center Future Energy Materials and Systems and Interdisciplinary Centre for Advanced Materials Simulation, Ruhr University Bochum, Universitätsstraße 150, D-44801 Bochum, Germany

Machine learning (ML) models for materials science are rapidly evolving, driven by large-scale, high-quality datasets and innovative neural network architectures. This talk explores critical challenges in improving the accuracy and reliability of complex ML models, examining the interplay between the quality and quantity of training data and model performance across material properties. Recent advances have been marked by the creation of extensive FAIR databases, such as Alexandria (https://alexandria.icams.rub.de/), which provides over 7 million density-functional theory calculations spanning periodic compounds of various dimensionalities. These comprehensive datasets enable systematic investigation of the relationship between training data volume/quality and model accuracy.

MM 5.2 Mon 10:45 SCH/A251

Screening of high-entropy oxides as oxygen conductors for fuel cells — •Jesper R. Pedersen, Ciku Parida, Benjamin H. Sjølin, and Ivano E. Castelli — Department of Energy Conversion and Storage, Technical University of Denmark, Kgs. Lyngby 2800, Denmark

High-entropy materials are at the cutting edge of materials design and this work investigates their suitability for use in fuel cells. However, screening high-entropy materials is computationally demanding, especially for properties such as oxygen migration barriers which are critical for components used in fuel cell cathodes. We aim to address this challenge by fine-tuning the MACE foundation model to a generated database containing more than 400 nudged elastic band (NEB) calculations spanning the chemical space of double perovskites. We show this new model achieves accuracy similar to the DFT calculations not only on structural relaxations, but also for the more complex task of saddle-point discovery. This enables the continued rapid exploration of the chemical space beyond the initial screening, leading to new insights into factors governing oxygen migration in fuel cell cathodes.

MM 5.3 Mon 11:00 SCH/A251

Interpretable Bayesian Optimization for Autonomous Materials Discovery — •Akhil S. Nair[1,2], Lucas Foppa[1], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at the FHI of the Max Planck Society, Berlin, Germany — [2]Institut für Chemie und Biochemie, Freie Universität Berlin, Germany

Bayesian Optimization (BO) can accelerate materials discovery by exploring complex design spaces using surrogate models and acquisition functions [1]. Its efficiency, however, relies on identifying a small set of key parameters or features that are potentially correlated with the target property. Existing feature-selection methods often fall short, as they struggle to capture nonlinearities and interactions among features [2], limiting BO's performance in high-dimensional spaces. To overcome this challenge, we introduce the Sparse Adaptive Representation-based Bayesian Optimization (SARBO) framework, which integrates BO with the Sure-Independence Screening and Sparsifying Operator (SISSO) method [3]. By capturing the non-linear interactions, SARBO identifies the most relevant features and adaptively updates their selection during the BO cycles, ensuring the optimization is continuously guided by the features that matter most. We demonstrate SARBO's effectiveness through the simulated discovery of single-atom alloy catalysts for CO_2 activation.

Fantastic Polaronic Peaks and Where to Find Them: Learning Vibrational Spectra of a Disordered Energy Material — •Christoph Dähn[1], Yang Wang[2], Risov Das[2], Bettina V. Lotsch[2], Karsten Reuter[1], and Christian Carbogno[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]MPI für Festkörperforschung, Stuttgart

Vibrational Raman and infrared spectroscopy offers unique opportunities for characterizing microscopic structural and dynamical properties. For energy materials and in particular for solar batteries [1], a straightforward interpretation of such spectra is however hindered by the intrinsic structural and occupational disorder, which includes defects and polarons. At the same time, this also prevents their accurate *ab initio* simulation, which would require extensive calculations at a hybrid level of density-functional theory (DFT) in a multitude of disordered supercells. In this work, we discuss how machine-learning interatomic potentials trained on high-level DFT data can be used to capture the otherwise inaccessible vibrational dynamics. We demonstrate this approach for a

two-dimensional titanium niobate featuring partially occupied metal sites and polarons. By Monte Carlo sampling its configurational disorder, we are able to disentangle polaronic signatures and disorder induced contributions in the spectra. This reveals how local atomic environments control polaron stability and offers insights on how doping can be used to control charge retention in such compounds.

Leveraging data science technologies to enable AI-driven materials design — •Tilmann Hickel[1,2], Han Mai[2], Shankha Nag[1], Sarath Menon[3], Osamu Waseda[2], Liam Huber[1,2], Jan Janssen[2], and Jörg Neugebauer[2] — [1]Bundesanstalt für Materialforschung und -prüfung, Berlin, Germany — [2]MPI für Nachhaltige Materialien, Düsseldorf, Germany — [3]Ruhr University Bochum, Germany

The handling of materials data is of key importance in designing and producing engineering systems. Therefore, consortia such as NFDI MatWerk aim to develop a sustainable infrastructure for the digital representation of materials science and engineering. The goal is to seamlessly integrate decentralized data and metadata, experimental and computational workflows, and a materials ontology to maximize interoperability and reproducibility of materials data processing. Many AI techniques particularly benefit from structured workflows for data generation and exploitation. For example, the generation and application of machine-learning interatomic potentials becomes accessible for many materials scientists via workflow-management systems such as pyiron. In conjunction with semantic technologies and large-language models they allow to design and validate novel, complex workflows solutions in materials science. We will demonstrate these advantages in the context of atomistic approaches to chemo-structural couplings in metallic alloys. To this end, a high-throughput analysis of the segregation behaviour to grain boundaries will be introduced. Further, hydrogen solubility trends in alloys will be discussed. We will conclude future perspectives in materials informatics.

MM 5.6 Mon 12:15 SCH/A251

Unveiling the Core of Materials Properties via SISSO and Sensitivity Analysis: Use-case Demonstration for Perovskites — •Lucas Foppa and Matthias Scheffler — The NOMAD Laboratory at the Fritz Haber Institute of the Max Planck Society, Berlin, Germany.

Interpretable AI can help reveal the physical principles governing intricate material properties and functions. In particular, the sure-independence screening and sparsifying operator (SISSO) symbolic-regression approach identifies analytical expressions correlating a target materials performance to a small set of physical descriptive parameters, termed materials genes, selected from a vast pool of primary features. However, the identified genes influence the SISSO models to different degrees. Here, we use the gradient-based partial-effect sensitivity analysis to pinpoint the most influential genes, thus enhancing SISSO's interpretability and enabling deeper physical insights. This analysis also highlights that different combinations of genes can yield equally accurate descriptions of the correlation. The approach is demonstrated for the bulk properties of perovskites.

MM 5.7 Mon 12:30 SCH/A251

Towards automated calculation of phase diagrams with machine learning interatomic potentials — •Sarath Menon and Ralf Drautz — ICAMS, Ruhr University Bochum, Germany

Calculation of thermodynamic properties and phase diagrams through atomistic simulations provides valuable insights for the design and assessment of new materials. Accurate phase diagram prediction requires determining the Helmholtz and Gibbs free energies for relevant phases and understanding their dependence on thermodynamic state variables, yet conventional approaches remain technically complex and computationally demanding.

In this work, we introduce algorithms that streamline the computation of multicomponent phase diagrams. Relevant phases are identified using a combination of materials databases and machine learning interatomic potentials, and their free energies are computed with atomic cluster expansion potentials. Temperature and composition effects are assessed through non-equilibrium thermodynamic integration and alchemical sampling, including both vibrational and configurational entropy contributions.

We demonstrate the methodology by computing unary pressure-temperature and several binary temperature-composition phase diagrams as well as phase equilibria in ternary materials. We provide all corresponding computational tools. The workflows are designed to be independent of the interatomic potential and material system, supporting broader use and advancing the accessibility of thermodynamic phase diagram computation in atomistic simulations.

Transformation-induced plasticity in zirconia ceramics: simulations and experiments — •David Rodney — Insitut Lumière Matière, University of Lyon, France

Similar to steels, zirconia ceramics display transformation-induced plasticity (TRIP) through an stress-induced tetragonal-to-monoclinic phase transformation. However, the conditions under which TRIP occurs remain unclear, owing to the intrinsic complexity of the transformation, which involves multiple variants and intermediate phases, and to experimental and computational limitations. Experimentally, the transformation is difficult to track in situ and classical interatomic potentials do not capture zirconia's polymorphism.

We present a combined experimental and numerical study addressing these challenges. Experimentally, we perform in situ Laue micro-diffraction on ceria-doped zirconia micropillars compressed along different crystallographic directions. We replicate the same loading conditions in atomistic simulations using a neural-network interatomic potential (NNIP) trained on extensive DFT data and capable of describing the phase behavior of pure and ceria-stabilized zirconia.

Comparison between experiments, NNIP simulations, and DFT calculations provides new insights into the transformation mechanisms. The results clarify the origin of tetragonal stabilization by ceria and show that TRIP proceeds through a complex sequence of stable and metastable phases, including multiple monoclinic and orthorhombic structures, revealing a richer transformation landscape than previously recognized.

On-the-Fly Machine Learning of Interatomic Potentials for Elastic Property Modeling in Al-Mg-Zr Solid Solutions — •Lukas Volkmer[1], Leonardo Medrano Sandonas[1], Philip Grimm[2,3], Julia Kristin Hufenbach[2,3], and Gianaurelio Cuniberti[1,4] — [1]Institute for Materials Science and Max Bergmann Center of Biomaterials,TUD Dresden University of Technology — [2]Institute of Materials Science, Technische Universität Bergakademie Freiberg — [3]Leibniz Institute for Solid State and Materials Research Dresden — [4]Dresden Center for Computational Materials Science, TUD Dresden University of Technology

Aluminum-based alloys offer exceptional mechanical performance due to their low density, high specific strength, and strong resistance to oxidation and corrosion. In this work, we develop a scalable and transferable machine-learning interatomic potential (MLIP) capable of accurately predicting thermodynamic, mechanical, and microstructural properties across a broad concentration space of Al-Mg-Zr alloys. The MLIP is trained using an active-learning workflow that combines ab initio molecular dynamics, Bayesian uncertainty quantification, and kernel ridge regression, enabling efficient exploration of diverse atomic environments. Additionally, we model an Al/Al3Zr grain-boundary system using experimentally observed orientation relationships and calculate the stress-strain behavior. This framework provides a computationally efficient strategy for exploring the phase space of Al-based alloys and guiding the design of materials with optimized mechanical properties.

MM 7.2 Mon 16:00 SCH/A215

Atomistic modelling of Ni-based superalloys at real chemical complexity — •Aditya Vishwakarma, Sarath Menon, Thomas Hammerschmidt, and Ralf Drautz — Interdisciplinary Centre for Advanced Materials Simulation, Ruhr University Bochum, Germany

Ni-based superalloys are critical high-temperature high-load materials for jet-engine turbine blades. While *ab-initio* computation has been essential for fundamental understanding (e.g., in binary NiAl), simulating the full chemical complexity of commercial superalloys has remained computationally infeasible. In this work, we demonstrate how Graph Atomic Cluster Expansion (GRACE) foundational models overcome this limitation to investigate the complex phase stability of the γ and γ' phases in industrially relevant Ni-based superalloys. We compute the binary NiAl phase diagram, successfully reproducing the critical γ-γ' phase coexistence. We then extend these phase stability calculations to a CMSX-4 type multi-component composition using hybrid Molecular Dynamics/Monte Carlo simulations. Our results reveal the short-range order (SRO) in the γ phase and quantify long-range order (LRO) in the γ' phase. We specifically find that refractory alloying elements (Ta, W, Ti) exhibit strong LRO alongside Al across the operational temperature range. These findings validate that foundational machine learning interatomic potentials are now capable of calculating complex phase diagrams and capturing subtle ordering and clustering phenomena in multi-component alloys. This capability marks a crucial step toward realizing faster, computationally-driven design of next-generation, single-crystal Ni-based superalloys.

MM 7.3 Mon 16:15 SCH/A215

A machine-learning approach to investigate deformation mechanisms in Mo-Si-based alloys — •Julie Hammoud and Karsten Albe — Technische Universität Darmstadt, Darmstadt, Germany

Mo-Si-X alloys have gained significant attention for high-temperature applications such as turbine blades, due to their outstanding creep resistance, thermal stability and corrosion resistance. In general, Mo-Si-X alloys include three phases: two intermetallic phases (Mo_3Si and Mo_5SiX_2) and a Mo solid solution phase Mo_{ss}. Despite its limited oxidation resistance, the solid solution phase enhances the room temperature fracture toughness of the system. However, the Mo solid solution also incorporates Si-rich subphases with a complex microstructure that leads to an unconventional and still insufficiently understood solid solution strengthening behaviour. Previous studies indicate that small additions of Si (0.1 wt.%) soften Mo, motivating a closer examination of this effect. In this study, we employ a machine-learning interatomic potential (MLIP) based on the Atomic Cluster Expansion (ACE) formalism for the Mo-Si binary system. MLIPs have demonstrated their capability to combine first principles calculations accuracy with the scalability characteristic of empirical potentials. To investigate how Si affects the mechanical response of Mo, we examine two aspects: (i) the concentration dependence of Si on the elastic moduli, analyzed within the framework of the Fleischer model, and (ii) the influence of Si on the behaviour of screw dislocations activity under external loading.

MM 7.4 Mon 16:30 SCH/A215

Jog-Pair Formation and Climb Mechanisms of Dissociated Dislocations in FCC Metals — •Erik Bitzek[1], Sergei Starikov[2], and Daria Smirnova[1,2] — [1]Max Planck Institute for Sustainable Materials, Düsseldorf, Germany — [2]ICAMS, Ruhr-Universität Bochum, Germany

Jogs on dislocations are preferred sites for vacancy segregation and thus play a critical role in dislocation climb. Under conditions of high point-defect supersaturation – such as after quenching or irradiation – the availability of jogs along the dislocation line can become the rate-limiting factor for climb. Understanding jog-pair nucleation is therefore essential for modeling the kinetics of dislocation creep. Jog pair formation on split edge dislocations in fcc metals was first investigated by Thomson and Balluffi [J. Appl. Phys. 1962] and atomistic simulations [Sarkar et al., PRB 2012] confirmed the suggested mechanism. However, both studies assumed a certain vacancy configuration at the dislocation as the initial nucleus.

Using high-temperature molecular dynamics simulations of dislocations in vacancy supersaturated nickel, we identify an alternative pathway that takes place without predefined nuclei. We demonstrate the role of ⟨110⟩-oriented vacancy tubes in the climb of edge and 60° dislocations and propose a new climb mechanism for 30° dislocations involving double cross-slip of the screw partial dislocation. These findings highlight how atomistic simulations can inform mesoscale models of creep and annealing.

MM 7.5 Mon 16:45 SCH/A215

Seeking descriptors for predicting mechanical properties of transition-metal light-element compounds — •Rui Zhang[1,2], Xinlei Gu[1], Kan Zhang[1], Chang Liu[3], and David Holec[2] — [1]Department of Materials Science, Jilin University, Changchun 130012, China — [2]Department of Materials Science, Montanuniversity Leoben, Franz Josef-Straße 18, 8700 Leoben, Austria — [3]College of Physics, Jilin University, Changchun 130012, China

Mechanical strength and durability are key properties that dictate service life. To meet requirements of modern technological and industrial applications, it is essential to screen, sort and predict targeted mechanical properties via finding descriptors that can effectively identify materials with specific application needs. Transition-metal light-element (TMLE) compounds show superb mechanical, chemical and thermal properties. We focus on the analysis of the intrinsic physical/chemical parameters of the component elements and structure factors to identify the key factors affecting the mechanical properties of TMLE. In this presentation, we will introduce two research works: (1) Core electron count as a versatile and accurate new descriptor for sorting mechanical properties of diverse transition metal compounds; and (2) Nitrogen vacancy regulated lattice distortion improvement of mechanical properties and wear resistance of (NbMoTaW)Nx thin films. Ultimately, our work yielded a universal descriptor incorporating core electron count and established nitrogen-vacancy-driven lattice distortion as a key structural factor, offering two distinct pathways to guide the design of high-performance materials.

Atomistic-to-Mesoscale Computational and Experimental Analysis of the Interactions between Dislocations, Precipitates, Grain and Phase Boundaries in Complex Alloys — •Liming Xiong — NC State University, Raleigh, NC, USA

In this talk, we will present multiscale computational and experimental analysis on the deformation behavior of complex alloys. In experiments, polycrystalline nickel, alloy 709, and Ni3Al-NiCr (γ/γ') alloys are deformed in a transmission electron microscope (TEM). Microstructure evolution is imaged through in-situ TEM. Local stress build up at the slip-GB/PBs are measured by electron backscattering diffraction (EBSD). Meanwhile, concurrent atomistic-continuum (CAC) simulations are performed to understand how a queue of dislocations interacts with the atomically structured precipitates, coherent twin boundaries (CTBs), GB, and γ/γ' PB. One unique feature of CAC is to accommodate the microscale slip containing a large population of dislocations together with the atomistic structure nearby the precipitates/GB/PBs all within one model. Our several findings are: (i) the sequential dislocation-precipitates differs from the single dislocation-precipitates. It is history dependent and has a mechanism cross-over from Orowan bowing out to cross-slip; (ii) the CTBs don't block dislocations. They can accommodate incoming dislocations by allowing them to migrate and form a pileup on the CTB; (iii) dislocation motion is smooth in γ phase but jerky in γ' phase. Such insight will support the design of high-performance alloys by configuring the precipitates, CTBs, GBs, and PBs in them appropriately.

MM 7.7 Mon 17:30 SCH/A215

The Effect of Rhenium on Irradiation Induced Defects in Tungsten-Rhenium Alloys Studied by Positron Annihilation Spectroscopy — •Lisa-Marie Krug[1], Danny R. Russell[1], Maximilian Suhr[1], Leon Chryssos[1], Lucian Mathes[1], Mikhail Zibrov[2], Thomas Schwarz-Selinger[2], and Christoph Hugenschmidt[1] — [1]Heinz Maier-Leibnitz Zentrum (MLZ), Technical University of Munich, Garching, Germany — [2]Max Planck Institute for Plasma Physics, Garching, Germany

The plasma-facing components in a nuclear fusion reactor have to withstand irradiation by 14 MeV neutrons. Tungsten is considered to be the most suitable plasma-facing material, due to its high melting point, high thermal conductivity and low erosion under fusion reactor operating conditions. In addition to radiation damage, neutron irradiation of tungsten induces nuclear transmutation reactions, resulting in the formation of rhenium. We investigated the effect of Re on the defects produced during the irradiation of W. We provide bench-marking data at extremely high damage doses using ion-irradiation. Transmutation to Re is substituted by Re-ion irradiation or the use of W-Re alloys. Positrons provide a non-destructive, atomic scale resolution of defect analysis of the irradiation damage. Positron Annihilation Spectroscopy (PAS) is a suitable method to determine the defect type, concentration and chemical surrounding. We observe a positive effect of Re on the radiation damage after irradiation at both room temperature and 1350 K. We have found evidence that fewer vacancy clusters are present after irradiation of W-3%Re alloys.

MM 7.8 Mon 17:45 SCH/A215

Understanding the influence of residual elements on the toughness of martensitic steels towards recycled steels — •Eloho Okotete, Subin Lee, and Christoph Kirchlechner — Karlsruhe Institute of Technology, Karlsruhe, Germany

Martensitic steels are critical for many load-bearing applications due to their inherent microstructure, giving rise to unique mechanical properties. However, traditional steelmaking routes produce high greenhouse gas emissions, posing a long-term threat to our environment. Cleaner steel production alternatives aim to use recycled iron scrap as input to electric arc furnaces used in steelmaking. A significant concern for key stakeholders in the steel industry and academia is the presence of residual elements, including Cu, Sn, Sb, As, and P, in iron scrap. Hence, an in-depth analysis of the role of the residual elements on the local and global mechanical properties of martensitic steel would provide relevant insights for the development of environmentally friendly steelmaking alternatives. Small-

scale mechanics using indentation-based techniques can help locally probe how the critical microstructural features of lath martensite, such as prior austenite grain boundaries, packets, blocks, and laths, are affected by residual elements.

In this talk, we use nanoindentation, micro-pillar compression, and micro-cantilever bending experiments to identify the residual element that has the most detrimental effect on the microstructure and properties of our lath martensite. Then, proceed to determine the most impacted microstructural feature of our microstructure as well as the predominant damage mechanism in the steel samples.

MM 7.9 Mon 18:00 SCH/A215

Martensitic phase transformation and anomalous hardening of CrMnFeCoNi high-entropy alloy deformed by high pressure torsion — Robert Chulist[1], Aurimas Pukenas[2], Anton Hohenwarter[3], Reinhard Pippan[3], and •Werner Skrotzki[2] — [1]AGH University of Science and Technology, Krakow, Poland — [2]Technische Universität, Dresden, Germany — [3]Montanuniversität, Leoben, Austria

Under hydrostatic pressure, the CrMnFeCoNi high-entropy alloy (HEA) undergoes a phase transformation from face-centered cubic to hexagonal close-packed. The onset pressure is strongly reduced by high pressure torsion (HPT): shear stress promotes partial dislocation slip. HPT of the low stacking fault energy HEA leads to a nanocrystalline microstructure. The hardness anomaly is due to the extreme nanostructuring, with grain boundary/interphase boundary sliding acting as predominant deformation mechanism: inverse Hall-Petch regime, in which hardness increases with increasing grain size. In submicrocrystalline materials, conventional Hall-Petch hardening dominates, i.e., hardness decreases with increasing grain size.

MM 7.10 Mon 18:15 SCH/A215

Insights into loading condition and microstructural evolution under tribological load — •Antje Dollmann, Robin Freville, Patric Gruber, Christoph Kirchlechner, and Christian Greiner — IAM, KIT, Karlsruhe, Germany

Tribological loading changes the microstructure of materials in contact, e.g. in coarse-grained metals, grain refinement occurs, followed by cracks formation and wear particles removal leading to component failure. This requires an adequate description of the stress field to understand the ongoing microstructural evolution. Due to the complexity of tribological loading, two approaches were explored, both on single-crystalline face-centred cubic metallic materials:

(1) The experiments on CoCrFeMnNi were designed in such a fashion that in some crystal orientations deformation twins were formed. These served as probes to validate various stress field models. General trends regarding the influence of different materials parameters can be identified. The most significant mismatch is between the experimentally observed deformation layer depth and the calculated depth by the stress field. (2) In copper, one deformation layer was analysed by *Laue. Based on its higher sensibility towards small deformations, the deformation layer thickness was greater than what had been detected previously. The combination of those approaches gives deep insight into the so far hidden stress field, which will support future efforts in designing materials to withstand tribological loading.

MM 8: Materials for the Storage and Conversion of Energy II

Time: Monday 15:45–18:30 Location: SCH/A216

MM 8.1 Mon 15:45 SCH/A216

Self-Consistent Hubbard Corrections for Accurate Modelling of Li- and Na-Ion Cathodes — •Valentina Sanella[1,2], Stefan Schären[1,3], Cristiano Malica[4], Livia Giordano[5], Nicola Marzari[1,3,4], Claude Ederer[2], and Iurii Timrov[1] — [1]PSI, Switzerland — [2]ETHZ, Switzerland — [3]EPFL, Switzerland — [4]U Bremen, Germany — [5]UniMiB, Italy

Accurate first-principles modelling of layered transition-metal oxides is essential for understanding and optimizing cathode materials for Li- and Na-ion batteries.

In this work, we investigate two widely studied systems: $LiCoO_2$ and P2-Na_xMnO_2, using density-functional theory (DFT) with self-consistent Hubbard corrections (DFT+U+V). We apply onsite U parameters to both transition-metal 3d orbitals and oxygen 2p states, together with intersite V derived from density-functional perturbation theory (DFPT), enabling a consistent treatment of electron localization and metal-oxygen hybridization.

For $LiCoO_2$, we show that including a U correction on oxygen significantly improves predictions of the intercalation voltages, resolving known inaccuracies associated with standard DFT approaches. In Na_xMnO_2, the extended Hubbard formalism provides a more realistic description across varying sodium concentrations, leading to reliable predictions of structural stability and electrochemical trends.

Our results demonstrate that self-consistent U and V parameters provide significant improvements over empirical or fixed values, enabling reliable predictions of structural and electronic properties.

MM 8.2 Mon 16:00 SCH/A216

Voltage Profile Predictions for Na-Ion Cathodes: A Hybrid MLIP / PBEsol+U+V approach — •Stefan Schären[1,2], Valentina Sanella[1,3], Manuel Dillenz[4], Nicola Marzari[2], and Iurii Timrov[1] — [1]PSI, Villigen, Switzerland — [2]EPFL, Lausanne, Switzerland — [3]ETHZ, Zürich, Switzerland — [4]DTU, Copenhagen, Denmark

Sodium-ion batteries are emerging as a sustainable alternative to lithium-ion batteries, but are limited by the lack of a cathode that offers high voltage, energy density and long-term stability. Here, we present a computational approach that accelerates the prediction of voltage profiles during cathode discharge, using a combination of self-consistent Hubbard-corrected DFT (PBEsol+U+V), and foundational machine-learning interatomic potentials (MLIPs). Using $Na_xV_2(PO_4)_3$ (NVP) as a test case, we show that MLIP-based pre-screening reduces the number of required DFT calculations to a fraction of those needed for a traditional cluster expansion, while retaining comparable accuracy. Furthermore, the self-consistent Hubbard U and V corrections yield electronic occupations that closely match the chemical intuition for oxidation states, enabling a direct analysis of vanadium redox activity and associated volume changes during desodiation. Altogether, the approach delivers a useful and predictive toolkit for identifying high-performance Na-ion cathodes in the future.

MM 8.3 Mon 16:15 SCH/A216

Electronic structure of perovskite oxides calculated with dynamical mean field theory — •Daniel Mutter[1], Jannis Ehrlich[1], Frank Lechermann[2], Daniel F. Urban[1], and Christian Elsässer[1] — [1]Fraunhofer IWM, Freiburg — [2]Institut für Theoretische Physik III, Ruhr-Universität Bochum

Perovskite oxide materials containing first-row transition-metal (TM) elements are regarded as promising alternatives to platinum-based electrodes for high-temperature solid-oxide fuel and electrolyser cells. This is due to the strong electronic correlation effects of the localized 3d electrons of the TM, which directly influence the mechanism and activity of the oxygen reduction reaction. We analyze the electronic structure of perovskite oxides by means of a combined approach of density functional theory and the dynamical mean field theory (DFT+DMFT) to account for the correlation of the electrons in the TM-3d orbitals. We exemplarily demonstrate the influences of static versus dynamic correlation. In addition, we consider correction methods to treat the correlation in the O-2p orbitals, namely the self-interaction correction (SIC) or the DFT-1/2 method. A systematic study of different A- and B-site occupations of the ABO_3 perovskite phases will be presented.

MM 8.4 Mon 16:30 SCH/A216

Unraveling the connection between Jahn-Teller dynamics and charge transport in $LiMn_2O_4$ — •Manuel Dillenz, José Maria Castillo Robles, Mikkel Agerbo Essendrop, Ivano Eligio Castelli, and Juan Maria García Lastra — Department of Energy Storage and Conversion, Technical University of Denmark, Kgs. Lyngby, DK-2800, Denmark

Future energy storage solutions demand batteries that are energy-dense, fast-charging, and based on abundant materials. However, ultrafast dynamics in battery electrodes remain insufficiently characterized despite their crucial role in energy storage performance. Moreover, charge transport in Mn- or Ni-based cathodes is strongly influenced by local structural distortions originating from Jahn-Teller active centers. $LiMn_2O_4$ (LMO) exemplifies this behavior, featuring a ferrodistortive tetragonal ground state that undergoes an order-disorder transition at 290K, where pseudorotations continuously reorient the Jahn-Teller axis. These processes occur on timescales relevant for to polaron and ion transport in the electrode. By combining ab initio molecular dynamics (AIMD) simulations with nudged elastic band (NEB) calculations, we reveal that the interplay of JT and polaron dynamics governs the kinetics of charge transfer in LMO. Our work provides essential mechanistic understanding for enhancing charge transport in Jahn-Teller active electrode materials.

MM 8.5 Mon 16:45 SCH/A216

Defect Landscape of $Ba_2In_2O_5$: The Role of Oxygen Interstitials — •Rachele Sciotto and Karsten Albe — achgebiet Materialmodellierung, Institut für Materialwissenschaft, Technische Universität Darmstadt, Otto-Berndt-Str. 3, D-64287 Darmstadt, Germany

$Ba_2In_2O_5$ (BIO) is a promising n-type mixed ionic and electronic conductor (MIEC) for oxygen permeation membranes and solid oxide fuel cells (SOFCs).

At ambient conditions, BIO adopts an orthorhombic brownmillerite structure with alternating InO_6 octahedral and InO_4 tetrahedral layers that can host interstitial oxygen atoms at sites of structural vacancies. Existing defect thermodynamics models consider only this type of oxygen interstitial; however, oxygen interstitials forming O-O dumbbells, found in oxides like ZnO and In_2O_3, are also possible. In this work, we investigate the potential existence of O-O dumbbells in BIO using density functional theory (DFT). By calculating formation enthalpies as a function of Fermi level and concentrations as a function of oxygen chemical potential, we identify two distinct classes of interstitial configurations. Neutral O-O dumbbells are stabilized over a wide Fermi-level range, while negatively charged interstitials at the structural oxygen vacancy site become favorable under *n*-type conditions. Although the neutral dumbbells do not contribute to charge compensation, they form in high concentrations. They could therefore serve as intermediate positions for oxygen diffusion pathways, thereby influencing the material's ionic and electronic conductivity.

MM 8.6 Mon 17:15 SCH/A216

Interplay of Dynamic Defects and Ultrafast Carrier Dynamics in Lead-Free Double Oxide Perovskites Toward Stable, High- Performance Photovoltaics — •Manasa Gattavadi Basavarajappa, Arijeet Sarangi, and Sudip Chakraborty — Harish-Chandra Research Institute, Chhatnag Road, Jhunsi, Prayagraj - 211019, India

Oxide-based double perovskites are gaining increasing attention as stable and environmentally benign alternatives to halide perovskites in photovoltaic and optoelectronic devices. Their structural versatility and chemical flexibility open pathways for fine-tuning both electronic and lattice properties, yet their carrier dynamics and defect behavior remain less understood. In this work, we investigate these aspects using a combination of first principles calculations and advanced simulation techniques. Non-adiabatic molecular dynamics is employed to capture ultrafast carrier relaxation and to quantify the role of electron*phonon coupling in determining charge transport and recombination lifetimes. The results highlight efficient charge separation and suppressed nonradiative recombination channels, which are essential for high photovoltaic efficiency. To establish the dynamical stability of the materials, we carry out a phonon-based symmetry analysis that confirms the absence of imaginary modes and reveals the interplay between structural distortions and vibrational spectra. In parallel, we explore the formation and dynamic evolution of intrinsic point defects through defect-mediated molecular dynamics simulations.

MM 8.7 Mon 17:30 SCH/A216

Morphological study of $LiNi_{0.5}Mn_{1.5}O_4$ synthesized with alkali molybdates by density functional theory — •Liang-Yin Kuo[1], Tavinder Singh[1], Rio Akbar Yuwono[2], Fu-Ming Wang[2], and Harald Oberhofer[1] — [1]Chair for Theoretical Physics VII and Bavarian Center for Battery Technologies, University of Bayreuth — [2]Graduate Institute of Applied Science and Technology, National Taiwan University of Science and Technology

High-voltage spinel $LiNi_{0.5}Mn_{1.5}O_4$ (LNMO) has emerged as a promising cathode active material for next-generation lithium-ion batteries due to its high operating voltage (~ 4.7 V vs. Li/Li^+), manganese abundance, and potential for high energy density. Single-crystal (SC) LNMO has attracted particular interest because it offers enhanced structural integrity, reduced surface area for electrolyte interaction, and improved cycling stability. Among the synthesis methods, molten-salt synthesis has shown promise for producing SC LNMO. However, the role of the precursor salts remains unclear. In this study, the effects of alkali molybdates, specifically Li_2MoO_4 and Na_2MoO_4, on the SC LNMO formation mechanism are investigated by density functional theory (DFT). Surface energies of various facets are calculated to analyze the resulting Wulff shapes. Our results indicate that LNMO synthesized with Li_2MoO_4 tends to form a truncated octahedron shape, whereas Na_2MoO_4 leads to an octahedron morphology with aggregation into polycrystalline structures. Furthermore, the influence of surface energy on nucleation is discussed, providing insight into morphology control in SC LNMO synthesis.

MM 8.8 Mon 17:45 SCH/A216

Thermodynamic Stability of $MgSc_2Se_4$ Surfaces — •Sebastian Utz[1] and Axel Gross[1,2] — [1]University Ulm, Ulm, Germany — [2]Helmholtz Institute Ulm, Ulm, Germany

$MgSc_2Se_4$ represents a promising candidate for post-lithium battery technologies as a solid-state magnesium ion conductor. With magnesium being significantly more abundant and cheaper than lithium, magnesium-based materials could offer sustainable alternatives for next-generation energy storage systems. While the bulk properties and ion diffusion of $MgSc_2Se_4$ have already been studied extensively, its surface structure and properties remain largely unexplored. However, understanding its surface behaviour is crucial as surfaces and interfaces can behave substantially differently from the bulk. In real applications, like batteries, the properties of surfaces and their interfaces may be limiting factors for stability and mass transfer. This work addresses this gap in the literature by investigating the low-index surfaces of $MgSc_2Se_4$ using grand-canonical density functional theory. Our computational approach enables the characterisation of thermodynamic surface stability and structure under varying chemical potentials. The results provide fundamental insights into surface terminations and their stability in different chemical environments. Combined with experimental validation, these findings could enable detailed atomistic studies of mass transfer at and through $MgSc_2Se_4$ surfaces, supporting the rational assesment of $MgSc_2Se_4$ as a battery material.

MM 8.9 Mon 18:00 SCH/A216

LDH Under Stress: Assessing Degradation Pathways of Ni-Fe-V Catalysts Under Technical Operating Conditions — •Juan Manuel Lombardi, Charles Pare, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institut der MPG, Berlin

The transition to a sustainable energy landscape relies on electrocatalysts that are not only active and affordable but also structurally robust under operating conditions. Ni-based layered double hydroxides (LDHs) doped with Fe and V are among the most promising OER candidates for anion-exchange membrane water electrolyzers (AEMWE), owing to their tunable lattice chemistry and rich redox behavior. However, the mechanistic influence of these dopants and how they reshape catalytic performance and structural stability remains insufficiently understood due to the immense configurational complexity.

In this contribution, we present an integrated strategy tailored to address this complexity directly. Our evolutionary exploration framework EZGA provides a systematic route through the high-dimensional composition-structure landscape, employing chemically informed operators and explicit diversity control to generate physically meaningful structural candidates. Machine-learning interatomic potentials (MLIPs) enable high-throughput sampling of thermally accessible configurations with near first-principles fidelity, revealing how dopants modulate stability and reactivity. Together, these elements deliver a predictive workflow that reveals how dopants reshape the accessible configurational landscape and provides a mechanistic picture of their influence on stability and reactivity.

MM 8.10 Mon 18:15 SCH/A216

Quantum-mechanical study of miscibility of Sn in $LaNi_5$ — •Martin Friák[1], Petr Čípek[2,1], Anna Huňařová[2,1], Kateřina Dočkalová[2,1], Jana Pavlů[2,1], and Ondřej Zobač[1] — [1]Institute of Physics of Materials, v. v. i., Czech Academy of Sciences, Žižkova 22, Brno, 61600, Czech Republic — [2]Institute of Chemistry, Masaryk University in Brno, Kotlářská 2, Brno, 61137, Czech Republic

The $LaNi_5$ compound is a prototypical hydrogen-storage material intended for future energy applications. Some of its properties have not been sufficiently studied so far, and some critically important data are missing. In particular, there are conflicting literature reports related to the substitution of Ni atoms with Sn atoms in $LaNi_5$. We have employed quantum-mechanical calculations implementing the density functional theory (DFT) within the generalised gradient approximation (GGA) to determine the ground-state structural, electronic, thermodynamic, and vibrational properties of several substituted $La(Ni,Sn)_5$ phases. Our computational cell containing 48 atoms allowed for simulating different Sn/Ni ratios as well as different configurations of substituting Sn atoms. Our results indicate that the free energy of formation is concave and there is a miscibility gap and a decomposition into two phases, one with a low and one with a high Sn concentration. Our theoretical study was complemented by experiments which found a similar miscibility gap, too.

MM 9: Topical Session: Physics-driven Artificial Intelligence for Materials II

Topical Talk MM 9.1 Mon 15:45 SCH/A251

Atomistic simulations in the ternary Fe-O-H system: interatomic potential development and applications — •Baptiste Bienvenu[1], Mira Todorova[1], Matous Mrovec[2], Ralf Drautz[2], Dierk Raabe[1], and Jörg Neugebauer[1] — [1]Max Planck Institute for Sustainable Materials, Düsseldorf, Germany — [2]Interdisciplinary Centre for Advanced Materials Simulation, Ruhr Universität Bochum, Germany

Atomistic modeling of iron oxides is challenging, requiring accurate electronic structure calculations and extensive length and time scales to simulate elementary mechanisms such as the extraction of metallic iron from its oxides through hydrogen-based reduction. To enable atomic scale modeling of these and other technologically relevant processes within the ternary Fe-O-H system (e.g., hydrogen embrittlement, water splitting), an accurate yet efficient interatomic potential is needed, something that is currently lacking in the literature. First, we focus on the binary Fe-O system, for which we previously developed a robust and transferable Atomic Cluster Expansion (ACE) machine-learning potential with an explicit account of magnetism, to study bulk diffusion and the structure and stability of various surfaces of iron oxides. We then extend the model to include hydrogen and show that the resulting ACE potential can faithfully reproduce key mechanisms of the Fe-O-H system: (i) surface reactions and microstructure evolution during hydrogen reduction of iron oxides, (ii) surface reactions of iron and its oxides with water and (iii) hydrogen trapping, interaction with extended defects and permeation in metallic iron.

MM 9.2 Mon 16:15 SCH/A251

Learning long-range interactions with equivariant charges — •Marcel F. Langer, Egor Rumiantsev, Tulga-Erdene Sodjargal, Michele Ceriotti, and Philip Loche — Laboratory of Computational Science and Modeling, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

Machine-learning interatomic potentials trained on first-principles data have become key tools across computational physics, chemistry, and biology. Equivariant message-passing neural networks, including transformer variants, now deliver state-of-the-art accuracy, but their cutoff-based graphs restrict the treatment of long-range physics such as electrostatics, dispersion, and electron delocalisation. Existing long-range corrections based on inverse-power laws of distances capture only scalar interactions and cannot convey higher-order geometric information, limiting their applicability. To address this, we propose the use of equivariant (rather than scalar) charges to mediate long-range interactions and build a graph neural-network architecture, LOREM [1], around this equivariant message-passing scheme. The talk will outline the architecture, present results on several benchmark datasets, and discuss our work on universal long-range interatomic potentials.

MM 9.3 Mon 16:30 SCH/A251

Physics-informed Hamiltonian-learning for large-scale electronic-structure calculations — •Martin Schwade, Shaoming Zhang, Frederik Vonhoff, Frederico P. Delgado, and David A. Egger — Physics Department, TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany

Exploring the optoelectronic properties of large-scale materials systems across a wide temperature range using conventional density functional theory (DFT) is often prohibitively computationally expensive. Recent advances in deep neural network approaches offer a promising route to efficiently predict accurate effective Hamiltonians, yet incorporating temperature dependence remains challenging, largely due to the substantial volume of training data typically required. In this work, we introduce HAMSTER [1], a physics-informed Hamiltonian-learning framework that achieves high accuracy with exceptional data efficiency, requiring only a small fraction of the training data demanded by alternative machine-learning models. We demonstrate the capabilities of Hamster on several halide perovskite systems, known for their soft lattices and strong electron-phonon coupling, and show that it reliably reproduces their optoelectronic properties across a broad range of temperatures.

Making equivariant graph neural network prediction of electronic structure properties fast and accurate — •Chen Qian[1], Valdas Vitartas[1], James Kermode[1], and Reinhard J. Maurer[1,2] — [1]University of Warwick, UK — [2]University of Vienna, AT

Machine learning predictions of band structures and equivariant electronic properties, such as real-space density functional theory (DFT) operator matrices and response properties, have the potential to accelerate electronic structure prediction while avoiding expensive ab initio calculations. However, most current models struggle to strike a balance between prediction accuracy and inference speed. Following our previous work on the equivariant graph neural network MACE-H [arXiv:2508.15108], we assess the model's performance on DFT operator matrices and, subsequently, on a property based on electron-phonon response, the electronic friction tensor. We compare its applications across various datasets. Furthermore, we analyze several existing algorithm- and hardware-based acceleration methods for the computationally intensive Clebsch-Gordan tensor product in terms of accuracy and computational efficiency, and discuss their respective suitable application scenarios. To this end, we present the MACE-H2 framework, which features an O(3) equivariant graph neural network with many-body expansion and suitable acceleration approaches and provides separate routines for DFT operator matrices and electron-phonon response prediction. The model achieves high accuracy and inference speed and is suitable for high-throughput band-structure calculations and material discovery.

MM 9.5 Mon 17:15 SCH/A251

Predicting the Thermal Properties of Semiconductor Defects with Equivariant Neural Networks — •Jonas A. Oldenstaedt, Manuel Grumet, Xiangzhou Zhu, Patrick Rinke, and David A. Egger — Physics Department, TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany

Predicting temperature-dependent properties of defects in semiconductors remains computationally challenging, even with density functional theory (DFT), due to the large supercells and long simulation times required for the calculations. In our recent work [1], we developed an active-learning workflow to accelerate defect calculations by combining two equivariant graph neural networks, trained using DFT calculations: MACE for predicting energies and forces needed in molecular dynamics, and DeepH-E3 for predicting electronic Hamiltonians needed for computing electronic properties across many thermally-excited configurations. We discuss the performance of our approach for predicting structural and electronic properties of intrinsic defects in the prototypical semiconductor GaAs, and demonstrate calculation accuracy comparable to DFT at much reduced computational cost. Furthermore, we discuss extensions of our approach to predict the thermal behavior of defects in more complex semiconductors such as halide perovskites.

MM 9.6 Mon 17:30 SCH/A251

Learning exact exchange with symbolic regression — •Noah Hoffmann, Santiago Rigamonti, and Claudia Draxl — Humboldt-Universität zu Berlin, Berlin, Deutschland

Density functional theory (DFT) is the most widely used method for the ab-initio prediction of material properties. It is used for computing structural, vibrational, and electronic properties and more. One important factor influencing the accuracy of the predictions is the choice of the exchange-correlation functional. PBE is the de-facto standard functional because of its good results for ground-state properties at comparatively low computational cost. The most prominent downside of this functional, however, is the underestimation of electronic band gaps. Hybrid functionals like PBE0 compensate this by mixing PBE with the non-local exact-exchange (EXX) energy. This improves band-gaps but comes with a drastic increase in computational cost. We apply symbolic regression (SR), a machine-learning technique, to find inexpensive yet accurate exchange potentials as a surrogate for the EXX potential. This enables computationally efficient DFT calculations with an accuracy close to that of hybrid functionals. To generate the training data for the SR models, we used the optimized effective potential (OEP) method, in which a local approximation to the EXX potential is constructed. The OEP method provides rather accurate electron densities. The SR models are then validated with respect to their numerical stability and their ability to predict band gaps. Compared to PBE, the SR models show improved band gap predictions on OEP band gaps with comparable computational cost.

MM 9.7 Mon 17:45 SCH/A251

Development of a GRACE Machine-Learning Potential for Modeling SiC Epitaxial Growth — •Anders Vesti, Thomas Hammerschmidt, and Ralf Drautz — Ruhr Universtät Bochum, Bochum, Germany

Silicon carbide (SiC) is a highly attractive wide band-gap semiconductor for power electronics due to its high breakdown field and low on-state resistance. However, the widespread adoption of SiC-based devices is hindered by challenges in epitaxial growth, including uncontrolled polytype switching and defect formation, which ultimately increase production costs.

In this work, we present the development and benchmarking of a physics-driven machine-learning interatomic potential for SiC based on the GRACE formalism. Starting from a general-purpose foundational model, we refit the potential using comprehensive C, Si, and SiC datasets to construct a specialized model tailored for simulating SiC epitaxy.

We validate the resulting GRACE potential against density functional theory (DFT) calculations and available experimental data for Si, C, and SiC. The developed model provides a basis for testing proposed growth mechanisms in SiC epitaxy.

MM 9.8 Mon 18:00 SCH/A251

Integrating FlashMD into LAMMPS for Efficient Long-Timestep Molecular Dynamics — •Johannes Spies, Filippo Bigi, and Michele Ceriotti — Laboratory of Computational Science and Modeling, Institut des Matériaux, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

FlashMD [1] is a machine-learning model that predicts future molecular configurations from the current state, reducing the need to call machine-learning interatomic potentials at every timestep and enabling larger effective integration steps.

I present its integration into LAMMPS. The implementation acts as a drop-in replacement for standard integrators and makes FlashMD directly available to the molecular simulation community. The interface is modular and extensible through the metatomic ecosystem, allowing new predictor models to be added with minimal effort.

The contribution outlines the integration strategy and initial performance results, focusing on usability, extensibility, and compatibility with existing MLIP workflows. The approach provides a practical route to accelerating large-scale atomistic simulations by reducing the frequency of expensive potential evaluations while maintaining physical reliability.

Learning to Converge: ML-based Initialization for Fast DFTB Simulations — •Maximilian L. Ach, Karsten Reuter, and Chiara Panosetti — Fritz-Haber-Institut der MPG, Berlin

Density Functional Tight-Binding (DFTB) [1], a class of semiempirical electronic structure methods, captures the electronic structure of a material, unlike conventional machine-learned (ML) interatomic potentials, at a significantly lower computational cost compared to *ab initio* methods. Despite this gain in efficiency, for many processes, DFTB does not scale favorably with the number of atoms, and simulations of realistic material systems often represent a significant challenge due to the associated computational overhead. A large portion of this cost can be attributed to the difficulty of converging these calculations efficiently. To address this, we introduce an ML-enhanced scheme, which significantly accelerates and improves the DFTB self-consistent charge convergence. Our approach leverages state-of-the-art ML methods to provide improved initializations for DFTB calculations, hence reducing the overall cost. We demonstrate the effectiveness of this method on small molecules and a range of materials.

Chemically graded materials for accelerated exploration of the TRIP-TWIP Ti-alloy family — •Lola Lilensten — IRCP - CNRS, Paris, France

Twinning induced plasticity (TWIP) and transformation induced plasticity (TRIP) in β-metastable titanium alloys provide remarkable work hardening, enhancing ductility and strength, opening up new possibilities for titanium alloys. These mechanisms depend on the metastability of the retained β phase and thus on the alloy composition.

However, the development of these alloys is still limited. Current design approaches are mostly empirical, relying on datasets that focus on composition and deformation mechanisms, neglecting factors like processing conditions, grain size, and oxygen content. This leads to inconsistencies and overlooks optimization opportunities through microstructure engineering.

The chemically graded materials approach is proposed to tackle this problem, enabling quick identification of compositional ranges where specific deformation mechanisms occur, and consistent results since all compositions share the same processing. This method accelerates the study and development of TRIP/TWIP Ti-alloys.

MM 11: Structurally and Chemically Complex Alloys

Time: Tuesday 10:15–11:45 Location: SCH/A215

MM 11.1 Tue 10:15 SCH/A215

Quantifying chemical short-range order in Ti–Zr–Nb alloys — Yujun Zhao[1,2], Andrea Fantin[3], Yue Li[1], Tong Li[2], and •Yilun Gong[4] — [1]Max-Planck-Institut für Nachhaltige Materialien, Düsseldorf, Germany — [2]Ruhr Universität Bochum (RUB), Bochum, Germany — [3]Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany — [4]University of Oxford, Oxford, UK

Chemical short-range order (CSRO) is expected to influence phase stability and defect interactions in Ti–Zr–Nb alloys, yet its direct quantification in equiatomic TiZrNb has remained unresolved. Here, we apply X-ray absorption spectroscopy (XAS) and X-ray pair-distribution-function (PDF) analysis to experimentally probe local chemical environments in single-phase bcc TiZrNb. Nanometre-scale compositional fluctuations and elemental pair distributions are further explored using orientation-specified atom-probe tomography (APT). XAS and PDF measurements reveal small but systematic local distortions in element-specific partial coordination shells (from XAS), consistent with emerging CSRO, and ensemble-averaged structural distortions in the atomic network (from PDF). To interpret these findings, we develop density functional theory-trained interatomic potentials and perform on-lattice Monte Carlo simulations to obtain the temperature-dependent equilibrium CSRO pair correlations. Together, these results provide the first quantitative CSRO map for TiZrNb, capturing its temperature and crystallographic dependence. This establishes TiZrNb as a reference system for understanding how CSRO influences phase stability, interstitial accommodation, and mechanical behaviour in refractory alloys.

MM 11.2 Tue 10:30 SCH/A215

Radiation Tolerance in High Entropy Alloys — •Jyoti Verma[1], Paul Chekhonin[2], Andreas Worbs[1], Cornelia Kaden[2], Maciej Oskar Liedke[3], and Gregor Hlawacek[1] — [1]Institute of Ion Beam Physics and Material Research,Helmholtz Zentrum Dresden Rossendorf, Bautzner Landstrasse 400 — [2]Institute of Resource Ecology,Helmholtz Zentrum Dresden Rossendorf, Bautzner Landstrasse 400 — [3]Institute of Radiation Physics,Helmholtz Zentrum Dresden Rossendorf, Bautzner Landstrasse 400

High-entropy alloys (HEAs), or compositionally complex alloys (CCAs), are near-equiatomic multicomponent materials forming single-phase solid solutions with exceptional mechanical strength, thermal stability, and radiation resistance, making them strong candidates for structural use in advanced nuclear systems. In Generation IV fission and future fusion reactors, materials must endure 500*600 $^{\circ}$C, high neutron fluxes, and helium and hydrogen generated by 14 MeV neutrons, which significantly influence irradiation-induced defect evolution. We are investigating the irradiation response of Co-free (CrFeMnNi) CCAs using Fe-ion irradiation at 300°C to 1, 3, and 10 dpa. Transmission electron microscopy revealed typical dislocation loops, while positron annihilation spectroscopy identified vacancy-type defects and vacancy-dislocation complexes, whose concentration decreased with dose, suggesting progressive interaction and annihilation between vacancies and dislocations at higher irradiation levels. These results demonstrate the promising irradiation tolerance of Co-free CCAs for structural use in next-generation reactors.

MM 11.3 Tue 10:45 SCH/A215

Preparation of an impurity-free quinary alloy surface without significant changes in composition — •Yong-He Pan[1], Niklas Osterloh[1], Wun-Chang Pan[1], Natalia Pukhareva[2], Alfred Ludwig[2], and Karina Morgenstern[1] — [1]Physical Chemistry I, Ruhr University Bochum, Universitätsstr. 150, 44780 Bochum, Germany — [2]Centre for Interface-Dominated High-Performance Materials (ZGH), Ruhr University Bochum, Universitätsstr. 150, 44780 Bochum, Germany

Compositionally Complex Solid Solutions (CCSSs) are a promising new pathway to electrochemical catalysts [1,2]. Their complex surface offers multiple adsorption sites for different reaction steps simultaneously [3]. We investigated the composition of the surface elements and impurities using X-ray photoelectron spectroscopy. The quinary alloy sample Ag-Au-Ir-Pd-Pt was prepared in ultra-high vacuum by argon sputtering and annealing. Surface impurities were removed by sputtering, and the alloy composition remained stable even during prolonged thermal treatment. Optimal sputtering and annealing parameters for achieving a clean surface were established. This study clarifies the effects of these processes on the surface composition ratio of Ag-Au-Ir-Pd-Pt alloys.

MM 11.4 Tue 11:00 SCH/A215

Effect of partial occupancy on the properties of FeCr σ-phase — •Mariano Forti[1], Guillaume Laplanche[1], Wenhao Zhang[2], Ralf Drautz[1], and Thomas Hammerschmidt[1] — [1]Ruhr Universität Bochum, Germany — [2]LINK, CNRS-Saint-Gobain- NIMS

The σ-phase forms in Fe-Cr alloys over 870K at about 50 at.% Cr, strongly affecting their performance. Atomistic studies usually assume a sublattice model, but experiments show fractional occupancy of the Whyckoff sites, creating many possible local atomic configurations. This complexity limits direct sampling with DFT and opens questions about the effect of partial occupancy on properties of the σ-phase.

We address the problem using a combination of DFT and MLIPs for a $Fe_{16}Cr_{14}$ σ-phase with experimentally observed site occupancy. We use a GRACE potential to screen all possible configurations of the intermetallic and validate the predictions with DFT calculations of a representative selection of configurations.

This approach enables a direct comparison between the traditional sublattice models and explicit disorder. Our results show that partial occupancy stabilizes the σ-phase, while mechanical properties differ roughly 10% from those predicted by sublattice models.

These findings provide a clearer picture of the local chemical disorder effects on the mechanical response of the σ-phase.

MM 11.5 Tue 11:15 SCH/A215

Accurate temperature-dependent Gibbs free energies of point defects in B2 MoTa — •Xiang Xu[1], Xi Zhang[1], Sergiy V Divinski[2], and Blazej Grabowski[1] — [1]University of Stuttgart, Stuttgart, Germany — [2]Universität Münster, Münster, Germany

Controlling order-disorder motifs is proven to be a key strategy for tuning performance in complex concentrated alloys. To this end, understanding ordered configurations is particularly important, as they represent the theoretical boundary of atomic diffusion, phase stability, and order-disorder phenomena. Since point defects like vacancies and antisites control diffusion and thereby affect ordering and phase evolution, their thermodynamic properties provide critical insight into the fundamental mechanisms behind property tuning. However, difficulties in stabilizing highly ordered refractory phases and the computational complexity of finite-temperature free energy calculations have limited quantitative understanding of their defect thermodynamics. To address this gap, we employ first-principles methods to investigate vacancy thermodynamics in the prototype B2-ordered MoTa alloy systematically. By explicitly accounting for electronic excitations and thermal vibrational contributions, particularly the explicit anharmonicity, we reveal distinct temperature-dependent Gibbs energies for vacancies and antisites in the B2-ordered MoTa. Vibrational pair distribution analysis, performed using an accurate machine-learning potential, demonstrates that the difference in thermal contributions arises from the vibrational phase spaces of the investigated point defects.

MM 11.6 Tue 11:30 SCH/A215

Modelling Bulk and Confined High-entropy Materials — •Chen-Chen Er[1,2], Tom Barnowsky[1,2], and Rico Friedrich[1,2] — [1]TU Dresden — [2]Helmholtz-Zentrum Dresden Rossendorf, Dresden

High-entropy materials (HEMs) are single-phase multi-component disordered systems with unique electronic, mechanical, and thermal properties that are promising for applications in the energy and electronics sectors. HEMs include disordered ceramics such as carbides, nitrides, or oxides with ordered anion sublattices and disorder on the metal cation sites. Generally, five or more cation species are required to maximize configurational entropy.

In our work, efficient modelling of the disordered systems is conducted based on an ensemble of ordered structures as implemented in the partial occupation algorithm (POCC) [1] within the AFLOW framework [2,3]. Predictive descriptors including the entropy forming ability (EFA) [4] and disordered enthalpy-entropy descriptor (DEED) [5] are crucial to assess synthesizability. Here, we present new results for several bulk and confined high-entropy ceramics.

Harmonising Symmetry and Spin: Unveiling Giant Rashba Splitting and Diverse Topological Phases in Composite Quantum Materials — •Arijeet Sarangi, Rajib Sarkar, and Sudip Chakraborty — Harish-Chandra Research Institute, Chhatnag Road, Jhunsi, Prayagraj - 211019, India

We present a systematic theoretical study of ABX-type composite quantum materials crystallizing in non-centrosymmetric hexagonal structures, carried out through high-throughput DFT calculations. Approximately 50 candidate systems were screened to explore the interplay between structural symmetry breaking, strong SOC and emergent electronic properties. Our investigation reveals a striking coexistence of Rashba spin splitting and topologically nontrivial band topology across this materials family, with Rashba coefficients and band inversions strongly dependent on atomic ordering and chemical composition. To complement the band-structure analysis, we perform Berry phase calculations, which confirm the topological character of selected states and identify Berry curvature hotspots near avoided crossings. Building upon this, we evaluate the spin Hall conductivity and orbital Hall conductivity for representative compounds, demonstrating substantial intrinsic values comparable to those in established topological semimetals. These findings point to a strong potential for dissipationless spin and orbital current generation, key ingredients for next-generation spintronic and orbitronic devices. These results establish a promising design space for multifunctional applications, bridging spintronics and topological electronics.

TiO_2 meets water: Band alignment and spectral properties for solar-driven catalysis using Koopmans spectral functionals — •Marija Stojkovic[1], Edward Linscott[2,3], and Nicola Marzari[1,2,3] — [1]Theory and Simulations of Materials (THEOS), École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland — [2]Center for Scientific Computing, Theory and Data, Paul Scherrer Institute, 5232 Villigen PSI, Switzerland — [3]National Centre for Computational Design and Discovery of Novel Materials (MARVEL), Paul Scherrer Institute, 5232 Villigen PSI, Switzerland

Photocatalytic water splitting has drawn considerable attention for renewable energy production. Thanks to its favorable band gap and band-edge positions, titanium dioxide has remained one of the most promising materials since its first reported photocatalytic water splitting. However, conventional computational approaches often struggle to accurately predict band gaps and band alignments. Here, we showcase the capabilities of Koopmans spectral functionals for evaluating photocatalysts* properties, showing how these can accurately predict band structures and level alignments for rutile, anatase, and brookite TiO_2. Furthermore, we investigate the impact of explicit water on band alignment at TiO_2-water interface by combining advanced molecular dynamics methods with electronic-structure Koopmans calculations.

MM 12.3 Tue 10:45 SCH/A216

Theoretical Calculation of Finite-Temperature X-Ray Absorption Fine Structure: Application to Sodium K-Edge in NaCl — Philipp Hönicke[1,2], Yves Kayser[3], and •Pouya Partovi-Azar[4] — [1]Helmholtz-Zentrum Berlin (HZB), Hahn-Meitner-Platz 1, 14109 Berlin, Germany — [2]Physikalisch-Technische Bundesanstalt (PTB), Abbestr. 2-12, 10587 Berlin, Germany — [3]Max Planck Institute for Chemical Energy Conversion, Stiftstr. 34-36, 45470 Mülheim an der Ruhr, Germany — [4]Institute of Chemistry, Martin Luther University Halle-Wittenberg, Von-Danckelmann-Platz 4, 06120 Halle (Saale), Germany

A comprehensive computational framework for calculating the full X-ray absorption fine structure (XAFS) through quantum-chemical simulations is presented. The near-edge region is accurately captured using time-dependent density-functional perturbation theory applied to core excitations, while *ab initio* molecular dynamics provides sampling of core-excitation energies and interatomic distance distributions for interpreting extended X-ray absorption fine structure (EXAFS) features. Owing to the efficiency of the approach, the total spectrum can be decomposed into contributions from bulk, defective, and surface environments, which commonly coexist in experimental systems. The methodology is demonstrated for sodium at the Na K-edge in NaCl, where the predicted spectra show good agreement with experimental measurements on thin film samples. This strategy offers a practical route to generating chemically specific XAFS cross-section data for elements that remain challenging to characterize experimentally.

MM 12.4 Tue 11:00 SCH/A216

Spin-Charge Coupling at Mixed Fe/Cr Nodes Governs Optical Gaps in MIL-100 Photocatalysts — •Sabuhi Badalov[1], Patrick Länger[2], Jürgen Senker[2], and Harald Oberhofer[1] — [1]Chair for Theoretical Physics VII and Bavarian Center for Battery Technologies, University of Bayreuth — [2]Chair for Inorganic Chemistry III and Northern Bavarian NMR Centre, University of Bayreuth

With a view on photocatalytic CO_2 reduction, we investigate how mixed metal Fe/Cr nodes in MIL-100 metal organic frameworks (MOFs) influence the MOFs electronic and optical response. Using hybrid level density functional theory (DFT) on models of Fe_3O, Fe_2CrO, $FeCr_2O$ and Cr_3O, we map the evolution of spin-resolved edge levels and Kohn-Sham holes during the stepwise substitution of Fe with Cr. Time-dependent DFT calculations reveal dense $O(2p)\rightarrow M(3d)$ ligand-metal charge transfer (LMCT) bands, appearing between approximately 3.5 and 4.5 eV. From these we derive composition-dependent optical band gaps and λ_{max} values. The calculated trends, modest red/blue shifts of the first bright excitation and systematic hardening of the LMCT manifold with increasing Cr content, quantitatively agree with the experimentally obtained gaps. Our combined theoretical/experimental approach provides a deep microscopic insight into the influence of the Fe/Cr mixed metal centers on spin topology, band edges, and optical absorption. Ultimately, our work points the way towards a rational design of MIL-100 for maximal CO_2 conversion.

Beyond Ion Dynamics: Efficient Charge Transport Simulations including Electrons at Battery Scales — Matteo Rinaldi, Karsten Reuter, and •Christian Carbogno — Fritz-Haber-Institut der MPG, Berlin

Small polarons, i.e., atomically localized excess charges, are fundamental for charge transport in energy materials. A quantitative modeling of their dynamics is challenging, though, since it typically requires not only long time and length scales, but also an account of electronic degrees of freedom at an *ab initio* level. In this work, we overcome this hurdle via a machine-learning interatomic potential that explicitly accounts for small polarons, which are incorporated as semi-classical degrees of freedom that adiabatically follow the nuclei. Using HSE06 calculations [1] as training data, we validate the approach for $BiVO_4$ and further demonstrate its power for lithium titanium oxide (LTO), a prototypical anode material featuring polarons [2]. By running accelerated sampling and large-scale molecular dynamics simulations, we clarify the mechanisms that drive ionic and polaronic transport as well as their coupling in LTO. This reveals that polarons do not merely serve as spectators, but thermodynamically adapt to the much slower ionic motion. This results in an increase of ionic conductivity, in line with experimental measurements. For the first time, this theoretically corroborates the occurrence of a correlated polaron-ion dynamics with profound implications for the design of energy materials.

Ion Transport in Mixed-Halide Lithium Argyrodites from Machine Learning Potentials — •Yufeng Xu, Takeru Miyagawa, Waldemar Kaiser, and David A. Egger — Physics Department, TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany

Lithium argyrodites Li_6PS_5X (X=Cl, Br, I) are structurally and chemically complex solid electrolytes. Their ionic conductivity is strongly affected by static forms of disorder, including sulfur-halide anti-site defects [1] and compositional disorder introduced through halide mixing [2]. In this study, we use the MACE message-passing architecture [3] together with machine-learning molecular dynamics to examine ion transport mechanisms in both pure and mixed-halide Li_6PS_5X. We analyze how static and dynamic disorder in mixed-halide systems shapes Li ion diffusion, and how these changes in ion conduction are reflected in the vibrational spectra of the argyrodites. Positron Annihilation Studies of Nuclear and Highly Oriented Pyrolytic Graphite — •Jagoda Urban-Klaehn, Arvin Cunningham, and William Windes — Idaho National Laboratory, 1955 Fremont Ave, Idaho Falls, ID 83415 USA

Graphite is a life-limiting component in nuclear reactor design thus its microstructure characterization and the effects of extreme conditions are of great importance.

We examined nuclear graphite materials of different origin, porosity and grain sizes by use of Positron Annihilation Lifetime Spectroscopy (PALS).

We determined that each type of graphite has its specific signature with trapping lifetimes in the range: 360-410 ps, and the most important factor was the grain size. Graphite with the coarse grain showed less positron trapping compared to fine grain which agrees with literature.

Graphite that was heat-treated (2300 C) showed a significant increase in positron trapping thus changes in the microstructure. PALS studies on Highly Oriented Pyrolytic Graphite (HOPG) polycrystalline specimens showed less trapping due to its polycrystalline nature. We are planning to use ELBE slow positron beam at different temperatures to study isotropic graphite defects formation enthalpy as well as crystalline graphite*s depth profiling.

MM 12.8 Tue 12:15 SCH/A216

Positron annihilation spectroscopy for atomic defects in functional materials — •Maciej Oskar Liedke, Eric Hirschmann, Jyoti Verma, Sebastian Klug, and Andreas Wagner — Institute of Radiation Physics, Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328, Germany

Positron annihilation spectroscopy (PAS) is a highly effective method for the characterization of point defects and their agglomerates in functional bulk materials and thin films. The method provides access to defect concentration in the range of 0.01-100 ppm, which is common for most material classes, including metals, semi-, and superconductors. The utilization of the radiation source ELBE at HZDR in Dresden, which delivers a pulsed positron beam, enables depth profiling by varying the kinetic energy of positrons. The integration of PAS techniques with density functional theory calculations facilitates understanding of defect types and local chemistry at the defected crystal sites. In this contribution, we will present few highlights from positron studies and discuss the role of defects in wide-bandgap semiconductors, such as Ga2O3, in addition to superconducting Nb-based coatings, and high-entropy alloys intended for fusion applications. The presentation will emphasize the control over transitions between different polymorphs of Ga2O3 driven by ion irradiation and resulting defect microstructure. Furthermore, we will demonstrate the correlations between deposition parameters and defect landscapes in Nb alloys. We will conclude discussing healing processes in CrFeMnNi subjected to Fe-ion irradiation, which is analogous to neutron radiation in nuclear systems.

MM 12.9 Tue 12:30 SCH/A216

Operando X-ray Absorption Spectroscopy studies of the X-ray exposed active and passive fiber preforms and their recovery properties upon UV-laser light — •Ali KARATUTLU[1,2], Esra KENDIR TEKGÜL[1], Iremnur DURU[1,2], Timuçin Emre TABARU[2], Latif Ullah KHAN[3], Messaoud HARFOUCHE[3], and Bülend ORTAÇ[1] — [1]Bilkent University, Institute of Materials Science Nanotechnology and National Nanotechnology Research Center (UNAM), Ankara, 06800 Turkey — [2]Sivas University of Science and Technology, Department of Engineering Basic Sciences, Sivas, 58100 Turkey — [3]Synchrotron-light for Experimental Science and Applications in the Middle East (SESAME), Allan, 19252, Jordan

In the development of active fiber preforms and active fibers containing rare-earth (RE) ions such as Yb+3 ions for 1-micron laser applications, the determination of the local environment around the Yb+3 ions is of paramount importance for their high optical-optical efficiency. In the long-term operation or when exposed to the gamma or X-ray exposures, the unwanted structural units are usually associated with the defects called color centers. This study demonstrates the formation of photodarkening upon gamma and X-ray exposures and operando X-ray absorption spectroscopy to determine the structural change around Yb+3 ions or Ge+4 ions with different doping levels before and after the irradiation of X-rays.

MM 13.1 Tue 10:15 SCH/A251

Surface reconstruction via automated LEED analysis based on Bayesian optimization — •Xiankang Tang and Hongbin Zhang — Institute of Materials Science, Technische Universitat Darmstadt, 64287 Darmstadt, Germany

Recent advances in machine learning have enabled the automation of many material characterization processes, which are essential for realizing autonomous experimentation for solid-state materials in the near future. Low-energy electron diffraction (LEED) is a fundamental technique in surface science, providing structural reconstruction information encoded in the energy-dependent intensity modulation of diffracted beams. However, the complexity of data analysis and the computational demands have limited the broader adoption of quantitative LEED in routine surface structure determination. In this work, we implement a Bayesian optimization-based approach to automatize the LEED I(V) analysis, where the best matching structures can be obtained for the experimental I(V) curves by minimize the R-factor between the experimental and simulated I(V) data. This approach can bee combined with density functional calculations or atomisitic simulations to further accelerate the recommendation of plausible structures by minimizing total energies.

MM 13.2 Tue 10:30 SCH/A251

Structural relaxations for nonstoichiometric alloys without forces — •Luca Numrich and Hongbin Zhang — Insitute of Materials Science, Technische Univerität Darmstadt, Darmstadt, Germany

Advances in machine learning and first-principles electronic-structure methods are accelerating materials design, focusing on stoichiometric compounds. Coherent potential approximation (CPA) is a standard approach for alloys with chemical disorder but there is no compatible implementation for forces, hindering the investigation of structural relaxations for nonstoichiometric alloys. For example, in many Ni-based Heusler alloys, a high-temperature disordered B2 phase transforms into the fully ordered $L2_1$ structure upon cooling via a second-order B2-$L2_1$ order-disorder transition.

In this work, we integrate Bayesian optimization (BO) with CPA as implemented in the exact muffin-tin orbitals (EMTO) code to identify low-energy crystal structures for nonstoichiometric alloys, as demonstrated for Ni-Mn-Ga-X Heusler alloys. Symmetry analysis is used to reduce the number of independent Wyckoff coordinates, which serve as parameters for BO, while the energy per atom computed via EMTO-CPA defines the objective function to be minimized. Using a Gaussian process surrogate model with a parallel upper confidence bound acquisition function, the framework autonomously proposes candidate structures with progressively lower energies. Thus, instead of a relaxation via interatomic forces, an acquisition function is guiding the relaxation.

MM 13.3 Tue 10:45 SCH/A251

A Python-based workflow for phase identification and mapping via Raman spectroscopy — •Felix Drechsler[1], Mahnaz Mehdizadehlima[2], Cameliu Himcinschi[1], David Rafaja[2], and Jens Kortus[1] — [1]TU Bergakademie Freiberg, Institute of Theoretical Physics, Freiberg, Germany — [2]TU Bergakademie Freiberg, Institute of Materials Science, Freiberg, Germany

Raman spectroscopy is a powerful tool for identifying phases and compounds. It is highly sensitive to both chemical and structural variations and is particularly attractive due to its minimal sample preparation requirements. This makes it well suited for fast phase identification and the determination of spatial phase distributions, complementing established techniques such as X-ray diffraction, element mapping via X-ray spectroscopy, and phase mapping using electron backscatter diffraction. However, phase-resolved analysis of Raman mappings remains challenging, as it involves processing high-dimensional data matrices and robust identification relies on comparing the complete spectrum with references.

In this talk, we present a Python-based workflow developed to address this challenge. The approach employs multivariate analysis methods and integrates mathematical similarity metrics with reference datasets to enable robust and reproducible phase identification. The proposed workflow provides an efficient way to construct Raman phase maps and offers a valuable tool for material characterization.

Automated Prediction of Phase Stability with ab-initio Accuracy — •Prabhath Chilakalapudi, Marvin Poul, Jan Janssen, and Jörg Neugebauer — Computational Materials Design, Max-Planck-Institute for Sustainable Materials, Düsseldorf

Developing sustainable metallic alloys-free of toxic elements and compatible with circular synthesis-requires novel and efficient ways to explore large composition spaces. A key bottleneck is the automated, ab-initio-accurate prediction of temperature-composition phase diagrams, where experimental phase data is limited or difficult to obtain.

We present a reproducible, automated workflow that uses Machine-Learned Interatomic Potentials (MLIPs) such as Atomic Cluster Expansion (ACE)[1] and non-equilibrium thermodynamic integration (Calphy[2]) to compute free energies and phase stabilities. By analysing key approximations including point-defect models, different entropic contributions, and free-energy interpolation schemes, we quantify the reliability of the calculated phase boundaries and provide meaningful "error bars" on the diagram. The workflow is demonstrated for representative binary alloys and is structured for gradual scaling to multicomponent systems. We leverage the pyiron[3] workflow framework for reproducible and efficient automation, to accelerate the discovery of sustainable materials.

Towards Disorder-Aware Materials Discovery - Recognizing and Modeling Crystallographic Disorder — •Konstantin S. Jakob[1], Aron Walsh[2], Karsten Reuter[1], and Johannes T. Margraf[1,3] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Imperial College London — [3]Universität Bayreuth

Recent computational materials discovery efforts have led to an enormous number of predictions of previously unknown, potentially stable inorganic, crystalline materials. However, these efforts are currently limited to predicting perfectly crystalline materials. As a consequence, many of these predictions cannot be verified in experiments, where kinetic effects, defects, and crystallographic disorder can be crucial. Here, we discuss disorder as a current frontier in materials discovery. To this end, we show that machine learning classification models can reliably recognize disordered materials and demonstrate that a significant fraction of computationally predicted materials are likely disordered [1]. On the example of compositionally complex transition metal ferrite spinels, we then demonstrate how machine learning interatomic potentials and Monte Carlo sampling can be used to tackle such disordered systems efficiently.

Efficient Exploration of the Unknown: Distance-Based Active Learning with SISSO Descriptors and Mendeleev Similarities for Materials Discovery — •Sreejani Karmakar[1], Akhil S. Nair[1,2], Lucas Foppa[1], and Matthias Scheffler[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Freie Universität Berlin, Berlin, Germany

The performance of AI models depends strongly on the distribution of their training data, which ideally should be independent and identically distributed. Materials-science datasets often violate this condition, containing redundancy and bias that hinder the discovery of statistically rare high-performance materials. Active learning (AL) helps by building concise, diverse training sets, introducing underrepresented materials classes. Commonly, AL relies on uncertainty estimates derived from the variance of model ensembles[1], but these are frequently overconfident and limit AL efficiency. We introduce an alternative strategy that selects candidate materials based on their distance from the existing training set in a low-dimensional descriptor space[2]. These descriptors, derived via SISSO (sure independence screening and sparsifying operator) symbolic regression approach. This distance-guided approach outperforms ensemble-based uncertainty AL, successfully identifying perovskites with exceptional properties. Adding the Mendeleev similarity metric further improves dataset diversity and supports efficient navigation of unexplored material space.

Where Are Large Language Models Actually Useful for Materials Design? — •Hedda Oschinski, Maximilian L. Ach, David Greten, Konstantin S. Jakob, Christian Carbogno, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin

The rapid development of large language models (LLMs) and LLM-based agents has opened new possibilities for accelerating materials discovery and design. In this work, we explore their potential in the context of solar cell materials, a class of systems requiring complex, multi-property optimization across chemistry and materials science. By systematically evaluating a range of tasks for a well-known test set of Elpasolites - from context preparation and descriptor prioritization to design hypothesis generation and autonomous validation within an agent framework - we identify where current LLMs provide genuine utility and where critical limitations remain. Our findings offer a grounded perspective on how these tools can be integrated into materials discovery workflows, and what developments are needed to expand their impact in the future.

MM 13.8 Tue 12:15 SCH/A251

Predictive and interpretable machine learning models for thermodynamics tuning of metal hydrides for hydrogen storage — •Sinan S. Faouri[1], Kai Sellschopp[2,3], Claudio Pistidda[3], and Paul Jerabek[3] — [1]Mechanical and Industrial Engineering Department, Applied Science Private University, Amman, Jordan — [2]Department of Chemical and Process Engineering, University of Canterbury, Christchurch, New Zealand — [3]Institute of Hydrogen Technology, Helmholtz-Centre Hereon, Geesthacht, Germany

Metal hydrides remain among the most promising materials for solid-state hydrogen storage due to their tunable thermodynamic behavior. However, predicting key properties such as equilibrium pressure and hydrogenation enthalpy remains challenging, especially across diverse alloy systems. In this work, we explore feature-based machine learning strategies to model these thermodynamic quantities from elemental descriptors and derived structural features. The study combines experimental and computational data to identify the most relevant predictors governing hydrogen absorption thermodynamics. Particular attention is given to the relationship between atomic-scale size parameters, electronic features, and their collective influence on pressure-enthalpy correlations. The results demonstrate that data-driven approaches can reveal non-obvious structure-property relationships and guide the search for alloys with optimized storage performance. The presented framework offers a step toward integrating machine learning with physical insights for accelerated discovery of functional hydrides.

MM 13.9 Tue 12:30 SCH/A251

Score-based diffusion models for accurate crystal structure inpainting and reconstruction of hydrogen positions — •Timo Reents[1], Arianna Cantarella[2], Marnik Bercx[1], Pietro Bonfà[2,3], and Giovanni Pizzi[1] — [1]PSI Center for Scientific Computing, Theory and Data, CH-5232 Villigen PSI, Switzerland — [2]Department of Physics and Earth Sciences, University of Parma, IT-43124 Parma, Italy — [3]Dipartimento di Scienze Fisiche, Informatiche e Matematiche, University of Modena and Reggio Emilia, IT-41125 Modena, Italy

Generative AI methods are rapidly evolving to speed up and improve materials discovery. Diffusion based models can not only be adopted to generate new materials with desired properties but also to reconstruct crystal structures for which structural information is only partially available. In this work, we use Microsoft's mattergen [1], a diffusion based model originally designed to generate new stable crystal structures, and extend it to reconstruct missing hydrogen sites in crystal structures reported in experimental databases. This is particularly useful as the experimental measurement of hydrogen sites with standard XRD is typically challenging due to weak scattering of hydrogen. We show how to leverage image inpainting approaches known from computer vision, combined with universal machine learning interatomic potentials, to improve the success rate of correctly identifying the missing sites or finding lower energy configurations while significantly lowering the computational cost with respect to a direct DFT approach.

Shining Light on Gold-in-Gallium: DFT Insights into Photocatalytic Benzyl Alcohol Oxidation — •Oliver Conquest[1], Chung Nguyen[2], Sarina Sarina[2], and Catherine Stampfl[1] — [1]School of Physics, The University of Sydney, Sydney, Australia — [2]School of Chemical and Biomolecular Engineering, The University of Sydney, Sydney, Australia

Recent experimental results have shown that pure liquid Ga with an oxide later does not perform well as a photocatalyst for Benzyl alcohol conversion to Benzaldehyde. When Au nanoparticles (Au NP) are introduced into the system, it emerges as an excellent Benzyl alcohol conversion photocatalyst. The Au NP develop an ultra-thin amorphous-GaO_x (a-GaO_x) skin when placed in liquid Ga, the a-GaO_x in the presence of Au is expected to play an important role in the photoreaction. Therefore, understanding the reaction mechanism requires atomic level investigation into the a-GaO_x/Au(111), and Au(111)/a-GaO_x/Ga interfaces. We perform molecular dynamics and density functional theory (DFT) calculations to provide insight into the charge and photoexcited properties of the Au(111)/a-GaO_x/Ga heterostructures with a careful emphasis on the a-GaO_x layer. The DFT calculations of the a-GaO_x/Au(111) interface demonstrate the charge transfer characteristics between the Au(111), a-GaO_x Ga-liq layers and provide a new detailed understanding of the photocatalytic mechanisms at play.

MM 14.2 Tue 11:45 SCH/A315

Reactive Edges and Inevitable Adsorption in Carbon Nanomembranes — •Levin Mihlan[1], Filip Vuković[2], Andrei Postnikov[3], Verena Müller[4], and Jürgen Schnack[1] — [1]Universität Bielefeld, Germany — [2]TU Wien, Austria — [3]Université de Lorraine, France — [4]Friedrich-Schiller-Universität, Germany

Carbon nanomembranes (CNMs) are nanometer-thin materials synthesized via electron-induced crosslinking of aromatic self-assembled monolayers. These membranes can be functionalized for various applications, initially serving as molecular filters. In addition to their internal structure, the precise elemental composition is not yet fully understood [1]. Therefore a first-order prediction for ultraviolet photoelectron spectroscopy (UPS) was developed based on DFT-calculated densities of state. Combined with theoretical carbon-only CNM model structures and an analysis of the near-zero binding-energy region, this approach enables statements regarding the saturation of different regions as well as the presence of reactive edges and dangling bonds. Since these regions are highly unstable under ambient conditions, physisorption and chemisorption of elements such as hydrogen and oxygen are to be expected. In this work, various CNM model structures are systematically investigated using this methodology, ultimately supporting the presence of such depositions, provided that other observations are valid.

Volume increase of silica glass due to water intercalation and silanol group formation — Manuel Enns[1], Wolfgang Körner[1], Christian Elsässer[1,2], and •Daniel F. Urban[1,2] — [1]Fraunhofer Institut für Werkstoffmechanik IWM, Freiburg, Germany — [2]Freiburger Materialforschungszentrum FMF, Albert-Ludwigs-Universität Freiburg, Germany

We present a theoretical study on the change of volume of silica glass due to the intercalation of molecular water and the formation of silanol groups. By a statistical representative set of density functional theory calculations, we obtained a volume increase per mole of molecular water in amorphous SiO_2 of 2.5 cm^3/mol. In comparison, for the reaction of water to silanol groups we found on average a 3.5 times larger volume increase of 8.7 cm^3/mol. Our results show that the exothermic dissolution of H_2O into silanol pairs is not restricted to small rings of size three and four. We find an equal distribution of reaction energies over all ring sizes which we explain by the structural relaxation and the related energy gain of the entire amorphous neighbourhood. Statistically, most exothermic dissolution of H_2O may happen at five-membered rings since they outnumber the three- and four-membered rings in amorphous SiO_2. Our findings shed new light on the underlying mechanisms and the size of the volume change of the water intercalation in silica glass and we discuss our findings with respect to previous experimental and theoretical work.

MM 14.4 Tue 12:15 SCH/A315

Insights into the interplay of relaxation and crystallization of Vit106a glass — •Lukas Musiol[1], Merlin Kempf[2], Lukas Musiol[1], Remi Daudin[2], and Gerhard Wilde[1] — [1]Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany — [2]Université de Grenoble Alpes, CNRS, Grenoble INP, Laboratoire SIMaP, Grenoble, France

Metallic glasses are metastable systems that show relaxation behavior towards a local energy minimum and crystallize when heated sufficiently above their glass transition temperature (Tg). Different modes of relaxation can be accessed by varying the combination of relaxation time and temperature. At temperatures significantly lower than Tg only β-relaxation is expected, corresponding to local rearrangements of few atoms. For temperatures close to Tg and for long times only α-relaxation is observed which corresponds to collective rearrangements in the glass. While these two relaxations are often considered independent, a growing body of evidence shows that they are linked [J. Phys. Chem. Lett., 3 (2012), 735; Intermetallics, 93 (2018), 101]. Additionally few attempts have been made to understand how structural changes during relaxation influence crystallization behavior.

Vit106a as a model system of bulk metallic glasses has been investigated concerning the relaxation dynamics and changes in crystallization behavior using conventional scanning calorimetry correlated to strutural analyses using transmission electron microscopy-based methods.

MM 14.5 Tue 12:30 SCH/A315

Unraveling the Correlation Between Populated Site Energies, Activation Barriers and Saddle Point Energies in Solid Ion Conductors — •Martin Schäfer[1], Mohammad A. Badragheh[2], Michael Vogel[2], and Karl-Michael Weitzel[1] — [1]Universität Marburg, Marburg, Germany — [2]T.U. Darmstadt, Darmstadt, Germany

Transport phenomena in disordered materials are governed by a complex potential energy landscape that includes a distribution of local energy minima (sites),

saddle point energies and local energy barriers. An understanding of the connection of these properties is essential to unravel the transition between local hops and long-range transport.

In this work, the populated site energy distribution (PSED) is experimentally determined by the Charge Attachment Induced Transport (CAIT) technique that yields concentration dependent diffusion coefficients and activation energies by comparison of measured concentration depth profiles to calculated profiles gained by Nernst-Planck-Poisson modeling [1]. The distribution of local barriers is probed through Nuclear Magnetic Resonance (NMR) measurements [2]. For Li3B7O12, the FWHM of the PSED is determined to be 250 meV while the activation energies show a FWHM of about 440 meV suggesting that the apparent energy distribution of saddle points must be significantly broader than the distribution of site energies.

Quantum Geometric Injection and Shift Optical Forces Drive Coherent Phonons — •Luke Pimlott and Habib Rostami — University of Bath, Bath, United Kingdom

We identify injection and shift rectified Raman forces, which are phononic counterparts of the photogalvanic effect, that drive lattice vibrations and trigger transient emergent properties. These forces are governed by the quantum geometric tensor, a phononic shift vector, and interband asymmetries in the electron-phonon coupling. As a response to pulsed light, the injection force induces displacive atomic motion, while, unlike conventional impulsive mechanisms, the shift force produces impulsive atomic displacement in the resonant interband absorbing regime when time-reversal symmetry is broken. Using the bilayer Haldane model, we quantify the injection and shift forces acting on interlayer shear phonons through both analytical and numerical methods. Strikingly, we reveal strong tunability, both in magnitude and direction, of the rectified forces by varying the driving frequency and magnetic flux, uncovering a distinct quantum geometric mechanism for ultrafast and coherent manipulation of quantum materials.

MM 15.2 Tue 14:15 SCH/A215

Charge Density Wave Transition in $ZrTe_3$ from First Principles — •Josu Diego López and Matteo Calandra Buonaura — University of Trento, Trento, Italy

$ZrTe_3$ is a quasi-one-dimensional compound that undergoes a charge density wave (CDW) transition at 63 K with a propagation vector of $\mathbf{q}_{\mathrm{CDW}}$ =(0.07, 0, 0.33) in reciprocal-lattice units and characterized by a very sharp Kohn anomaly in reciprocal space. Although Fermi surface nesting between the quasi-1D bands has been widely invoked to explain this instability, a complete first-principles characterization of the lattice dynamics is still lacking. In particular, the phonon modes at the CDW wavevector have never been computed, even within the harmonic approximation, leaving open fundamental questions regarding the role of the electron-phonon interaction in this material.

In this work, we analyze from first principles the electronic and vibrational properties of the high-temperature phase of $ZrTe_3$. We show that only the correct characterization of the Fermi surface yields an imaginary harmonic phonon mode consistent with the observed CDW. Having access to the harmonic phonons at the critical wavevector also enables the calculation of the electron-phonon interaction at $\mathbf{q}_{\mathrm{CDW}}$, providing a framework to directly compare the electron-phonon mechanism with the nesting scenario in driving the CDW formation.

Coupled phase transition and valence fluctuations in Fe-doped $BaTiO_3$: a combined DFT and DMFT study — •Zhiyuan Li, Ruiwen Xie, and Hongbin Zhang — Institute of Materials Science, TU Darmstadt, 64287 Darmstadt Germany

Rational control of structural phase transitions in perovskites is a key challenge in materials design. In Fe-doped $BaTiO_3$(BTO), experiments observe a tetragonal-to-hexagonal transition, yet the governing microscopic mechanisms remain unclear. A critical control parameter is the Goldschmidt tolerance factor, which relies intimately on the dopant ionic radius and, consequently, the valence state. However, the valence of Fe in BTO remains a long-standing open question, with conflicting reports necessitating a treatment beyond standard DFT. Here, we employ Density Functional Theory (DFT) combined with Dynamical Mean-Field Theory (DMFT) to investigate this interplay. DMFT reveals that the Fe dopant exhibits strong valence and spin fluctuations, which are significantly suppressed by oxygen vacancies to stabilize a high-spin state. Integrating these electronic insights, our total-energy calculations identify three cooperative mechanisms driving the phase transition: tolerance factor variations, Jahn-Teller distortions, and oxygen vacancy formation. Then a systematic quantitative analysis was performed on these three factors. These findings provide a unified microscopic understanding of defect-mediated phase control.

MM 15.4 Tue 14:45 SCH/A215

Interface structure and migration in phase transformations between Fe_3O_4 and Fe_2O_3 — •Martina Ruffino[1], Baptiste Bienvenu[1], Xuyang Zhou[2], Guangyi Guo[1], Barak Ratzker[1], Dierk Raabe[1], and Yan Ma[3] — [1]Max Planck Institute for Sustainable Materials, Düsseldorf, Germany — [2]Xi'an Jiaotong University, Xi'an, China — [3]TU Delft, The Netherlands

Although redox phase transformations between hematite (Fe_2O_3) and magnetite (Fe_3O_4) entail long-range diffusion, they are known to occur on well-defined $(111)_{\mathrm{mag}}||(0001)_{\mathrm{hem}}$ habit planes, and to maintain the oxygen sublattice fixed up to a change in stacking sequence (fcc and hcp arrangement for Fe_3O_4 and Fe_2O_3, respectively). Moreover, hematite formations during magnetite oxidation, as well as magnetite formations in hematite during reduction, are often observed to be of lenticular shape. In this study, we propose interfacial disconnections (i. e. steps with dislocation character) suitable for the accomplishment of these phase transformations. Using atomistic simulations with an atomic cluster expansion (ACE) potential developed for iron and its oxides, we calculate the equilibrium structures of the disconnections and we study their motion as a means to transform magnetite into hematite and vice-versa. We then validate theoretical calculations experimentally by investigating i) partially oxidised magnetite and ii) partially reduced polycrystalline hematite. Using transmission electron microscopy, we analyse the hematite/magnetite interfaces, characterising them as faceted interfaces containing steps; we observe good agreement with the simulated disconnection structures.

MM 15.5 Tue 15:00 SCH/A215

Grain boundary thermodynamics away from idealized boundaries: How line defects affect stability — •Tobias Brink[1], Swetha Pemma[1,2], Lena Langenohl[1], Saba Saood[1], Yoonji Choi[1], Rebecca Janisch[2], Christian H. Liebscher[2], and Gerhard Dehm[1] — [1]MPI for Sustainable Materials, Düsseldorf, Germany — [2]Ruhr-Universität Bochum, Germany

The concept of grain boundary (GB) phases (or "complexions") was developed to describe how the atomic structure and/or chemistry of GBs depend on external conditions, such as temperature or chemical potential. Analogous to bulk phases, GB phases also affect material properties. Even in the case of pure metals, structural GB transformations impact diffusivity and GB mobility. Simulation studies often concentrate on special, symmetric boundaries, which are easy to describe. It is unlikely, however, that their behavior can be generalized to the variety of imperfect GBs in a real polycrystal.

Here, we use atomistic simulations with empirical potentials to investigate thermodynamics of asymmetric GBs in Cu. Symmetric ⟨111⟩ tilt boundaries exhibit two GB phases. These also exist in asymmetric GBs, but contain multiple line defects (disconnections) that enable the deviation from the symmetric GB plane. We found the same defects in thin film samples using scanning electron transmission microscopy. Most importantly, their presence alters the thermodynamic stability of the two GB phases, even for very small deviations from the symmetric GB. We conclude that defects of defects have to be considered in interface thermodynamics.

MM 15.6 Tue 15:15 SCH/A215

Size effects on phase change: solid-state wetting vs. coherency stress — •Yong Li[1] and Jörg Weissmüller[2,1] — [1]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany — [2]Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg, Germany

Coherent phase transformations in interstitial solid solutions or intercalation compounds with miscibility gaps are crucial to the behavior of energy storage materials, particularly metal hydride and lithium-ion compounds nanoparticles. Prior studies often attribute size-dependent phase transformation behavior either to solid-state critical-point wetting at particle surfaces or to coherent stresses from solute-saturated surface layers. We introduce a hybrid numerical approach that couples atomistic grand canonical Monte Carlo simulations with continuum mechanics analysis of coherency-stress, allowing wetting and mechanical constraints to be simulated simultaneously or independently, thereby decoupling their respective contributions. For material parameters representative of realis-

tic interstitial solutions, we find that solid-state wetting has only a minor influence, whereas coherency stress dominates the size dependence. Mechanical interactions reduce phase-transformation hysteresis at small sizes and increase solute binding in the solid, thereby lowering the chemical potential 'plateau' at the phase coexistence.

MM 15.7 Tue 15:30 SCH/A215

Critical-point wetting at crystal surfaces: Cahn-Hilliard residuum and occurence of first-order wetting transition — •Marine Bossert[1], Yong Li[2], and Jörg Weissmüller[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg, Germany — [2]Institute of Hydrogen Technology, Helmholtz Center Hereon, Geesthacht, Germany

Since its publication in 1958, the work by J.W. Cahn and J.E. Hilliard on the free energy of non-uniform systems [1] has been the basis for numerous studies, such as phase-field simulation of microstructure evolution or solute segregation to lattice defects. Cahn and Hilliard found that the second derivative (Laplacian) of the composition field governs the excess energy of systems with conserved networks of sites - such as crystals. A partial integration of the excess energy gives the gradient-square representation, which has been used in all follow-up works in an approximate form that neglects the partial integration residuum. Inspecting critical-point wetting at the surface of an Ising-type FCC crystal with a miscibility gap, this study shows that the solutions obtained with the (exact) second derivative or with the (approximate) gradient-square expressions for the free energy are in fact qualitatively different: the first-order wetting transition predicted by the gradient-square approach is not confirmed by the second-derivative one. Moreover, atomistic Monte-Carlo simulations confirm the absence of a first-order transition. [1] Cahn, J. W., & Hilliard, J. E. (1958).The Journal of Chemical Physics, 28(2), 258-267.

Low and High Dose Gamma Radiation Effect on Germanium-Doped Optical Fibers: Investigation of Color Centers — •Esra Kendir Tekgül — Bilkent University UNAM, Institute of Materials Science and Nanotechnology, Ankara, 06800, TURKEY

Ge-doped optical fibers are widely used in sensing, data transmission, and space technologies, making their radiation resistance crucial. Gamma irradiation creates radiation-induced defects that form color centers, degrading optical transmission. In this study, five Ge-doped fibers and one quartz fiber were exposed to gamma rays of 0.5-50 kGy. RIA values at 550, 600, 680, and 755 nm were measured before and after irradiation, and color centers were identified from the RIA spectra. GeX, Ge-NBOHC, and GeY defects were attributed to Ge contributions, whereas ODC(II), STH1, and STH2 were attributed to the SiO2 matrix. NA and FTIR results showed radiation-induced changes in refractive index and a decrease in NA. Overall, the findings highlight the potential of Ge-doped fibers for radiation-hard applications and dosimetric sensing.

MM 16.2 Tue 14:15 SCH/A216

Switching applications in optical circuits using the electrochromic properties of LiMn2O4 — •Vinit Kumar Agarwalla[1], Yug Joshi[2], Guido Schmitz[1], and Mayank Kedia[3] — [1]Institut für Materialwissenschaft, Universität Stuttgart, Stuttgart Germany — [2]Max Planck Institute for Sustainable Materials, Dusseldorf, Stuttgart — [3]Institut für Photovoltaik, Universität Stuttgart, Stuttgart Germany

Optical communication depends on the accuracy with which the path of light is controlled to minimize signal loss in waveguides. The current method of optimizing the path of light is to maintain the waveguide's refractive index using the thermooptic effect. The waveguide consists of a core in which light travels, surrounded by cladding material to ensure total internal reflection, and a third protective outer layer. Here, I propose using electrochromic lithium manganese oxide(LiMn*O*, LMO) as a waveguide cladding. The primary wave from the core extends into the cladding known as evanescent waves, so changing the cladding*s refractive index changes the evanescent waves' path and thus the entire path of the light. Previous work has shown a change in refractive index in the visible region. Building on that, we measured IR reflectance spectra showing continuous visible-to-IR transitions, 100% reflectance, and resonance shifts with lithiation. Calculations show that a 38 μm waveguide can induce a π phase shift at 1550 nm. We also propose various delithiation methods to alter optical properties without degrading the optical structure.

MM 16.3 Tue 14:30 SCH/A216

In-Situ Activation of a Monolithic SrTiO3 Single Crystal for Room Temperature Hydrogen Sensing — •Karl-Michael Weitzel, Timo Kassubek, and Kevin Rein — Department of Chemistry, Philipps-Universität Marburg, Marburg, Germany

The development of reliable, fast, and cost-effective hydrogen sensors is of increasing importance for the safe implementation of a hydrogen-based economy. This work presents a novel and simple single-step method to convert an insulating strontium titanate (SrTiO3) single crystal into a highly sensitive, monolithic hydrogen sensor that operates at room temperature. The activation is achieved by applying a moderate DC electric field (100 V/cm) across a symmetric Pt/SrTiO3/Pt capacitor structure at 180 ˚C in a pure hydrogen atmosphere (200 mbar). This process causes a drastic and stable reduction in the material's resistance by several orders of magnitude. We propose a model of "field-induced chemical doping" to explain this transformation. The resulting activated crystal exhibits excellent hydrogen sensing properties at room temperature, detecting molecular hydrogen (H2) over an exceptionally wide partial pressure range from 0.0001 mbar to 1000 mbar with an accuracy of a few percent. The sensing mechanism is based on the reaction of hydrogen with the activated SrTiO3 sample, involving the release of electrons back into the conduction band and lowering the device's resistance. This monolithic approach opens a new pathway for designing robust and easy-to-fabricate chemical sensors from wide-bandgap oxides.

MM 16.4 Tue 14:45 SCH/A216

The laser-induced synthesis of Co-MOFs, the investigation of optic, gase sorption, DFT and sensor properties — Saliha MUTLU[1,2], Bülend ORTAÇ[2], Ali KARATUTLU[2,3], Taylan GÖRKAN[2], Engin DURGUN[2], Dilek SÖYLER[4], Saniye SÖYLEMEZ[4], Jelena LILLEPÄG[5], Volkan FILIZ[5], Nergis ARSU[6], and •Sevil SAVAŞKAN YILMAZ[1] — [1]Karadeniz Technical University Chemistry Department, Trabzon, Türkiye — [2]Bilkent University, Institute of Materials Science Nanotechnology and National Nanotechnology Research Center (UNAM), Ankara, 06800 Turkey — [3]Sivas University of Science and Technology, Department of Engineering Basic Sciences, Sivas, 58100 Turkey — [4]Department of Biomedical Engineering, Necmettin Erbakan University, Konya, 42090 Turkey — [5]Helmholtz-Zentrum Geesthacht, Institute of Polymer Research, Max-Planck-Str. 1, 21502 Geesthacht, Germany — [6]Yildiz Technical University, Department of Chemistry, Davutpasa Campus, Istanbul, 34220 Turkey

High-power rapid laser-induced synthesis of MOFs has drawn significant attention due to the rapid and effective preparation conditions for Zn- and Ni-MOFs. In this study, the Co-MOF microcrystals yield visible light photoluminescence with relaxation times on the order of ns, showing controllable properties, including low-temperature paramagnetic state transition, supported by magnetic measurements and DFT calculations. Outstanding performance in gas sorption and electrochemical sensing has been demonstrated with low separation costs and ultra-low LODs for dopamine, respectively.

MM 16.5 Tue 15:00 SCH/A216

First-Principles Study of Electronic and Optical Properties of Mo-Doped $CsPbBr_3$ Perovskites — Said Al Azar[1], Anas Al-Reyahi[2], •Saleh Bashaish[3], and Marwan Mousa[4] — [1]Zarqa University, Zarqa, Jordan — [2]Hashemite University, Zarqa, Jordan — [3]Al-Ahliyya Amman University, Amman, Jordan — [4]Jadara University, Irbid, Jordan

$CsPbBr_3$ perovskites, particularly when doped, show great promise for tandem solar cells and advanced optoelectronics. This study employs density functional theory (DFT) and semi-classical Boltzmann transport theory to comprehensively investigate the structural, electronic, magnetic, thermoelectric, and optical properties of Mo-doped $CsPb_{(1-x)}Mo_xBr_3$ (x = 0, 0.25, 0.5, 0.75). Our calculations confirm the structural stability of all compositions and reveal a transformative electronic behavior: Mo-doping induces a ferromagnetic half-metallic state. Notably, the x = 0.5 composition exhibits an ideal band gap for solar applications (1.872 eV via mBJ) and a high spin-up figure of merit (zT) approaching unity at room temperature. Additionally, enhanced absorption in the infrared region suggests potential for IR photodetectors. These findings establish Mo-doped $CsPbBr_3$ as a compelling multifunctional material for spintronic and high-efficiency optoelectronic devices.

MM 16.6 Tue 15:15 SCH/A216

Optimizing NiTi Interatomic Potentials Through Atomic Cluster Expansion — •Petr Šesták[1,2], Petr Jaroš[1], Miroslav Černý[2], and Petr Sedlák[1] — [1]Institute of Thermomechanics Czech Academy of Sciences, Prague, Czechia — [2]CEITEC, Brno University of Technology, Brno, Czechia

In this work, we present an interatomic potential for NiTi based on the Atomic Cluster Expansion, developed using the Pacemaker software package. We validate this potential by comparing it against the results of simulations using other

interatomic potentials, quantum-mechanical calculations, as well as our own experimental data. Our quantum-mechanical calculations utilize density functional theory (DFT) within the generalized gradient approximation (GGA) to determine the ground-state structural, electronic, thermodynamic, and elastic properties of NiTi in low-temperature (martensitic) phase. The target properties include elastic constants, phonon spectra calculations, and vacancy formation energy. Specifically, the stress-strain method was employed to compute the full tensor of the second-order elastic constants and assess the mechanical stability of the studied phases, ensuring that the results are consistent with those obtained using other established potentials.

MM 16.7 Tue 15:30 SCH/A216

Response of NiTi martensite to mechanical loading — •Miroslav Černý and Petr Šesták — Central European Institute of Technology, CEITEC, Brno University of Technology, Purkyňova 123, Brno, Czechia

Shape-memory alloys are unique materials capable of undergoing large reversible strains and exhibiting the shape-memory effect, which is driven by external changes of temperature. These remarkable properties are based on a martensitic transformation between austenite (high-temperature phase) and martensite (low-temperature phase). The NiTi shape memory alloy has become the most widely used shape memory material in industrial, high-tech, and medical applications due to its unique thermal and mechanical properties.

In this work we aim at fundamental understanding of the behavior of twins in the martensite structure under mechanical loading. For this purpose, we constructed computational supercells representing both the perfect and twinned martensite and studied their responses to shear and tensile loading. Such calculations are computationally very demanding when using ab initio approaches. Therefore, we employed machine learning to develop a new interatomic potential, tailored specifically for the martensite struc-ture. Computationally accessible predictions based on the potential were benchmarked from first principles.

Modelling Diffusion Kinetics in Refractory High Entropy Alloys Using Graph Neural Network Database Models — •Klemens Lechner[1], Jiyao Zhang[1], Peter Wagatha[2], Wolfram Knabl[2], Helmut Clemens[1], and David Holec[1] — [1]Department of Materials Science, Montanuniversitaet Leoben — [2]Plansee SE

Refractory high-entropy alloys (RHEAs) offer exceptional mechanical and thermal properties, such as high-temperature strength, and may exhibit high-temperature oxidation and corrosion resistance. However, their stability at high temperatures has yet to be confirmed. Nonetheless, even thermodynamically unstable solid solutions can have useful applications if the decomposition is slow. This is inherently connected with the (self-)diffusion kinetics. In this study, we present a workflow for the systematic investigation of diffusion kinetics in RHEAs. The necessary diffusion barriers are predicted using a graph neural network (GNN). We train the GNN using an active learning cycle involving molecular statics simulations with a universal machine-learning interatomic potential (uMLIP). The training data of migration barriers are calculated using the Nudged Elastic Band method. By varying the amount of training data, the GNN can be trained to an accuracy that, in theory, can fully mimic that of the uMLIP but with a more efficient computation. This is crucial for larger-scale modeling applications, e.g., the kinetics of decomposition, ordering or clustering of specific elements. We demonstrate the usage and performance of the GNN to quantify self-diffusion in Mo-Nb-Ta-W alloys using the Kinetic Monte Carlo method.

MM 17.2 Tue 14:15 SCH/A251

Broken neural scaling laws in machine learning for optical properties of metals — •Max Grossmann, Marc Thieme, Malte Grunert, and Erich Runge — Institute of Physics and Institute of Micro- and Nanotechnologies, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Neural scaling laws guide the development of machine-learning models and their training datasets. Here, we investigate them in the context of materials science, where data are inherently costly and scarce, using dielectric functions of metals as an example. We compute dielectric functions for 205,224 intermetallic compounds using high-throughput *ab initio* calculations and train two multi-objective graph neural networks, OptiMetal2B and OptiMetal3B—the latter incorporating three-body interactions—to predict the complex interband dielectric function and the Drude frequency. Systematic variations in the number of training data and model parameters reveal so called "broken" neural scaling laws. Data scaling follows a smoothly broken power law, with steeper slopes occurring above 20,000 materials. In contrast, parameter scaling follows a conventional power law but saturates at around ten million parameters. Including three-body interactions improves accuracy by about 12% but leaves scaling slopes essentially unchanged. These findings suggest that, in the context of spectroscopy, expanding high-quality datasets is a more effective way to improve machine-learning models than optimizing network architectures, increasing body order, or merely increasing network size.

MM 17.3 Tue 14:30 SCH/A251

Simultaneous Learning of Static and Dynamic Charges — Philipp Stärk[1], •Philip Loche[2], Marcel Langer[1], Henrik Stooss[1,3], Michele Ceriotti[2], and Alexander Schlaich[1,3] — [1]Stuttgart Center for Simulation Science, University of Stuttgart, Germany — [2]Laboratory of Computational Science and Modeling, École Polytechnique Fédérale de Lausanne, Switzerland — [3]Institute for Physics of Functional Materials, Hamburg University of Technology, Germany

Long-range interactions and electric response are essential for accurate modeling of condensed-phase systems, yet remain challenging for atomistic machine learning. Static charges modulate Coulomb interactions, while dynamic charges such as atomic polar tensors describe the response to external electric fields. We compare strategies for learning both types of charges: independent models; coupled learning with or without an isotropic dielectric correction; and coupled learning with an environment-dependent screening. While screening corrections are crucial in the coupled case, assuming homogeneous, isotropic screening fails in heterogeneous systems such as water clusters. Learning a local screening restores accuracy for dynamic charges but offers negligible improvement over independent models while increasing computational cost.

MM 17.4 Tue 14:45 SCH/A251

A high-throughput study of heterostructures with polar discontinuities — •Maria Andolfatto[1,2,3], Junfeng Qiao[2,1], Davide Campi[3], and Nicola Marzari[1,2] — [1]PSI - Switzerland — [2]EPFL - Switzerland — [3]Unimib - Italy

Heterostructures composed of two bulk insulating materials with different polarizations can exhibit localized conductive states at the interfaces and could lead to a wide range of technological applications. Currently, most studies focus on perovskite-based materials to engineer such heterostructures, whose number and performance is limited. This project aims to identify new candidate heterostructures exhibiting interface-localized conductive states by leveraging high-throughput computational screening. Starting from thousands of bulk materials, we compute the polarization and we systematically identify thousands of possible interface combinations. Finally, we analyze the resulting localized density of states of thirty-one heterostructures to assess the formation of two-dimensional electron gases (2DEGs).

MM 17.5 Tue 15:00 SCH/A251

Leveraging Koopmans band structure for exciton characterization in materials — •Miki Bonacci[1], Nicola Colonna[1], Edward Linscott[1], and Nicola Marzari[1,2] — [1]PSI Center for Scientific Computing, Theory and Data, 5232 Villigen PSI, Switzerland — [2]Theory and Simulation of Materials (THEOS), Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland

Exciton characterization is crucial for several materials applications, ranging from energy transport and storage technologies to photocatalysis, plasmonic, sensing. The ab initio state-of-the-art approach is many-body perturbation theory (MBPT), in particular the Bethe-Salpeter equation (BSE) [1]. This is usually built on top of computationally demanding G0W0 quasiparticle (QP) band structures (BSE@G0W0 approach). In this work, we demonstrate how it is possible to construct the BSE Hamiltonian starting from Koopmans functionals [2] eigenvalues as the main ingredient for the BSE Hamiltonian (BSE@KI), obtaining optical spectra with comparable accuracy with respect to the BSE@G0W0, at reduced computational cost. Automated workflows to compute BSE@KI are provided within the AiiDA workflow engine [3].

MM 17.6 Tue 15:15 SCH/A251

Many-body perturbation theory vs. density functional theory: A systematic benchmark for band gaps of solids — •Marc Thieme[1,2], Max Grossmann[1], Malte Grunert[1], and Erich Runge[1] — [1]Institute of Physics and Institute of Micro- and Nanotechnologies, Technische Universität Ilmenau, 98693 Ilmenau, Germany — [2]Institute of Applied Physics, Friedrich Schiller Universität, 07743 Jena, Germany

The band gap is one of the most important material properties for optoelectronic applications. However, predicting band gaps remains a challenging task in materials science. Here, we benchmark many-body perturbation theory against density functional theory, the workhorse of computational materials

science, for predicting the band gaps of solids. We systematically compared four GW variants—G_0W_0 using the plasmon-pole approximation (G_0W_0-PPA), full-frequency quasiparticle G_0W_0 (QPG_0W_0), full-frequency quasiparticle self-consistent GW (QSGW), and QSGW augmented with vertex corrections in W (QS$G\hat{W}$)—against the currently best-performing and popular density functionals. Our results show that the QS$G\hat{W}$ produces band gaps so accurate that they can even flag questionable experimental measurements, albeit at an extremely high computational cost. To balance accuracy and efficiency, we identify lower-cost alternatives, such as the QPG_0W_0 and a rescaled version of the QSGW, which achieve nearly the same accuracy as the QS$G\hat{W}$ while being significantly more efficient, making them promising candidates for generating high-fidelity datasets in machine-learning-driven materials discovery.

MM 17.7 Tue 15:30 SCH/A251

Learning G_0W_0 Self-Energies in Real Space with Equivariant Neural Networks — •Elisabeth Keller, Karsten W. Jacobsen, and Kristian S. Thygesen — CAMD, DTU Physics, Kongens Lyngby, Denmark

Many-body G_0W_0 calculations provide highly accurate quasiparticle energies for semiconductors and insulators beyond standard density-functional theory, but at a much higher computational cost.

To overcome this limitation, we use equivariant neural networks to replace the explicit G_0W_0 self-energy evaluation. The networks are trained on G_0W_0 self-energies from GPAW projected onto an atom-centered LCAO basis. Using this representation, we investigate how the real-space localization of the self-energy enables learning from atomic configurations.

MM 18: Liquid and Amorphous Materials II

Time: Tuesday 14:00–15:30 Location: SCH/A315

Influence of Phosphorus Content on the Symmetry and Correlation Length of the Medium-Range Order in Pd-Ni-P Bulk Metallic Glasses — •Hongshuai Li, Harald Rösner, and Gerhard Wilde — Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Pd-Ni-P metallic glass is known as an excellent glass former, which enables systematic investigation of how variations in phosphorus (P) content affect its structural characteristics. In this study, we investigate the influence of P concentration on the dominant correlation length and the local symmetries of motifs within Pd-Ni-P metallic glass using fluctuation electron microscopy (FEM) and angular correlation microscopy. In FEM, the relationship between normalized variance and probe size can be used to examine the medium-range order (MRO) in amorphous materials. Our experimental results reveal that, as the composition deviates from the eutectoid composition Pd40Ni40P20, the correlation lengths associated with the dominating motifs undergo significant changes. Moreover, the volume fraction of the medium-range order increases as the P content diverges from the eutectoid composition. Regarding the symmetry analysis, the P content exerts a strong impact on the four-, five-, and six-fold symmetries. Specifically, as the P content moves away from the eutectoid composition, five-fold symmetry becomes prominent relative to the four- and six-fold symmetries.

MM 18.2 Tue 14:15 SCH/A315

Decoupling Structural and Mechanical Behavior in CuZr Metallic Glasses — •Askar Kvaratskheliya[1], Jürgen Eckert[1,2], and Daniel Şopu[1,3] — [1]Erich Schmid Institute of Materials Science, Leoben, Austria — [2]Technical University of Leoben, Leoben, Austria — [3]Technical University of Darmstadt, Darmstadt, Germany

Although lacking of long range order symmetry, metallic glasses (MG) possess a high degree of short- and medium-range order that governs their macroscopic properties. Particularly, in case of CuZr MG, network of five fold symmetry clusters defines the degree of local order. These motifs resist shear, stabilize energy minima, and inhibit strain localization. In this study, we systematically decouple the contributions of distinct motif perturbations by simulating irradiation-induced structural states through targeted atomic dilution. Specifically, we construct post-irradiation analogs of $Cu_{64}Zr_{36}$ MG by systematically removing atoms according to their local motifs. This approach enables decoupling of the influence of local topology from the overall degree of rejuvenation. We investigated how perturbation of specific motifs alters relaxation, stress distribution, and mechanical strength. Recent advances in high-performance computing have enabled a clear shift toward large-scale, high-throughput molecular dynamics workflows. Leveraging this paradigm, we performed an extensive parameter sweep consisting of hundreds of independent molecular dynamics simulations, systematically varying temperature and structural perturbation protocols.

MM 18.3 Tue 14:30 SCH/A315

Influence of Xe swift heavy ions irradiation on the mechanical properties of PdNiP bulk metallic glasses — •Maren Jeromin[1], Marilena Tomut[1,2], and Gerhard Wilde[1] — [1]Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str.10, 48149 Münster — [2]GSI Helmholtzzentrum für Schwerionenforschung, 64291 Darmstadt

Pd40Ni40P20 bulk metallic glass samples that had been subjected to different relaxation states were investigated by nanoindentation and laser scanning microscopy (LSM) for irradiation effects induced by swift heavy ions. The samples were irradiated with 630 MeV Xe-ions at the UNILAC accelerator at GSI in Darmstadt. During irradiation, the samples were partially covered with honeycomb- patterned masks to enable direct comparison between irradiated and non-irradiated areas. LSM revealed a distinct swelling step at the mask boundary, whose height increased with ion fluence and varied systematically with the relaxation state of the material. The observed swelling is attributed to ion track formation, where localized melting and rapid re-solidification generates excess volume due to cooling rates exceeding the initial quenching rate. Nanoindentation measurements demonstrated a fluence-dependent decrease in hardness; however, the hardness of irradiated regions consistently remained higher than that of pristine samples. These findings offer new insight into the structure modification of bulk metallic glasses under medium-mass swift ion irradiation, where elastic collision effects increasingly compete with ion track formation governed by electronic energy-loss processes.

MM 18.4 Tue 14:45 SCH/A315

A ReaxFF study of the covalency-driven cracking-to-shearing transition in metal-metalloid glasses — •Shansi Liao[1], Jürgen Eckert[1,2], and Daniel Şopu[1,3] — [1]Erich Schmid Institute of Materials Science, Leoben, Austria — [2]Technical University of Leoben,Leoben, Austria — [3]Technical University of Darmstadt, Darmstadt, Germany

Revealing the atomistic origins of failure in amorphous solids remains challenging. In metal-metalloid glasses, mechanical response is strongly governed by the breaking and reformation of covalent bonds which cannot be adequately captured by non-reactive interatomic potentials. Here, large-scale reactive molecular dynamics simulations using a ReaxFF potential that includes angular constraints for covalent bonding reveal a composition-dependent transition from cleavage cracking to shear banding in model CuSi glasses. During loading, a highly connected, rigid Si-rich network suppresses strain delocalization, generating mechanically unstable regions characterized by shear-induced reductions in coordination number and severe distortions of Si-Si-Si bond angles. These unstable regions serve as energetically favorable pathways along which the crack advances. As Cu content increases, reduced angular rigidity promotes widespread shear transformation and shear-band-mediated plasticity. In contrast, the modified embedded-atom method potential, which intrinsically overestimates the angular flexibility of the Si-rich networks, fails to reproduce this transition. Our results show that angular rigidity of the interatomic potential is a key descriptor of plasticity in metal-metalloid glasses.

MM 18.5 Tue 15:00 SCH/A315

Macroscopic response of $Pd_{40}Ni_{40}P_{20}$ Bulk Metallic Glasses to GeV ^{238}U Ion irradiation — •Richard von Destinon, Maren Jeromin, Marilena Tomut, and Gerhard Wilde — Institut für Materialphysik, Universität Münster, Münster, Germany

Ion tracks formed by localized heating due to intense electronic excitations of the target atoms offer new pathways to tailor the mechanical properties of bulk metallic glasses. In this work, we investigate the effects of swift heavy ion irradiation on macroscopic behavior such as the hardness, swelling and strain-rate sensitivity on the well-characterized bulk metallic glass $Pd_{40}Ni_{40}P_{20}$. The samples were thermally relaxed at $0.94T_g$ and subsequently irradiated with 1.14 GeV U ions at the UNILAC accelerator at GSI Helmholtzzentrum für Schwerionenforschung, Darmstadt. By using aluminum degraders of different thicknesses, the energy loss of the ions at the sample surface and their corresponding penetration depths were systematically varied. Characterization was carried out using Laser Scanning Microscopy (LSM) as well as nanoindentation with displacement depths up to 0.3 μm. The results show a pronounced increase of swelling as well as a decrease in hardness with increasing irradiation fluences. The strain-rate-sensitivity increases at higher fluences, suggesting that the increased structural heterogeneity within the irradiated metallic glass alters the local stress distribution, affecting the shear band propagation.

MM 18.6 Tue 15:15 SCH/A315

Compositional and Surface Variations in Sasanian Early Islamic Glasses from Gorgan, Ray, and Istakhr — •Farahnaz Bayat Nejad[1], Mohammadamin Emami[2], Rémy Chapoulie[3], and Farzaneh Bayat Nejad[4] — [1]Islamic Azad University, Central Tehran Branch, Tehran, Iran — [2]Art University of Isfahan, Isfahan, Iran — [3]Archéosciences Bordeaux, UMR 6034 CNRS, Université Bordeaux Montaigne, Pessac, France — [4]Islamic Azad University, Central Tehran Branch, Tehran, Iran

This study investigates the compositional and microstructural characteristics of Sasanian*Early Islamic glasses from Gorgan, Ray, and Istakhr. Laser-Induced Breakdown Spectroscopy (LIBS), Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM-EDX), and Hyperspectral Imaging (HSI) were used to assess elemental composition, surface morphology, and colorant phases. Distinct variations in Ca/K/Na ratios reflect differences in raw materials and production recipes across the three sites. SEM-EDX reveals heterogeneous corrosion layers and localized devitrification, especially in Istakhr samples with silica-rich alteration crusts. HSI spectra identified absorption features of Fe**, Mn, and Cu** chromophores associated with glass coloration. These results provide insight into technological choices and raw material exchange networks in Late Antique Iran, demonstrating the power of non-destructive, multi-analytical methods in archaeometric glass research.

MM 19: Poster Session

Time: Tuesday 18:00–20:00 Location: P5

MM 19.1 Tue 18:00 P5

RuNNer 2.0: A Fast Software Environment forHigh-Dimensional Neural Network Potentials — •Moritz R. Schäfer[1,2], Alexander L. M. Knoll[1,2], J. Richard Springborn[1,2], Henry Wang[1,2], K. Nikolas Lausch[1,2], Moritz Gubler[3], Jonas A. Finkler[4], Gunnar Schmitz[1,2], Alea Miako Tokita[1,2], Emir Kocer[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany — [3]Paul Scherrer Institute PSI, Villigen, Switzerland — [4]Department of Chemistry and Bioscience, Aalborg University, Denmark

Machine learning potentials (MLPs) have emerged as a widely used approach for large-scale atomistic simulations in chemistry and materials science. They offer computationally efficient access to highly accurate potential energy surfaces (PES) derived from ab initio reference data. As techniques in this area continue to grow in complexity and reach greater maturity, the need for robust, efficient, and user-friendly tools becomes increasingly significant. Here, we introduce the second major release of RuNNer, an open-source, stand-alone software package designed for constructing and evaluating second-, third-, and fourth-generation high-dimensional neural network potentials (HDNNPs). RuNNer 2.0 integrates the complete workflow into a fully MPI-parallelized program – from generating atomistic descriptors and training machine learning models to deploying them in molecular dynamics simulations.

MM 19.2 Tue 18:00 P5

Coordination Corrected Enthalpies for the Thermodynamics of Ionic Materials — •Balaram Thakur[1,2] and Rico Friedrich[1,2] — [1]Technische Universität Dresden, 01062 Dresden. — [2]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden.

Accurate formation enthalpies are essential for data-driven materials discovery. Density functional theory (DFT) predictions are accurate for compounds chemically similar to their elemental references (metallic systems like alloys). However, for ionic materials, it shows large deviations from the experimental values (≥ 100 meV/atom), leading to incorrect stability predictions. The coordination-corrected enthalpies (CCE)[1] method addresses this issue by applying corrections based on oxidation state and cation coordination number. This reduces errors to about 25 meV/atom and resolves inconsistencies among polymorphs.

Here, we extend CCE beyond oxides to halides, focusing on fluorides and chlorides, chosen for their diverse bonding environments and technological relevance in the energy sector, electronics, and optics. Using AFLOW [2,3], these corrections broaden the applicability of CCE and improve thermodynamic predictions for halogen-based ionic compounds, thus enabling more reliable design and screening of functional materials.

MM 19.3 Tue 18:00 P5

Experimentally supported machine-learning interaction potential for Pd-Si — •Przemyslaw Dziegielewski[1], Jerzy Antonowicz[1], Zuzanna Kostera[1], Oleksii Liubchenko[2], and Ryszard Sobierajski[2] — [1]Faculty of Physics, Warsaw University of Technology, Warsaw, Poland — [2]Institute of Physics Polish Academy of Sciences, Warsaw, Poland

Classical Molecular Dynamics (MD) simulations were utilised to reproduce the X-ray Free-Electron Laser (XFEL) experiment. Using the pump-probe technique, a Pd-Si alloy with various Si contents was melted and subsequently solidified with a high cooling rate. The EAM (Embedded Atom Method) potentials available for Classical MD allowed us to obtain simulation results showing high consistency with the experiment for pure Pd and the good glass-forming Pd83Si17 alloy.

However, at low Si contents, they become unreliable, generating a structure that is a combination of the hcp and fcc phases, whereas the experimental data clearly indicate the occurrence of the fcc phase only. The two phases differ only slightly in energy, and the occurrence of the hcp phase for alloys with nearly 100% Pd content takes place, for example, under high-pressure conditions. In our presentation, we introduce an alternative approach to simulating metallic alloys using a Machine Learning (ML)-generated potential within the VASP code. Our proposed procedure may constitute a universal approach for the effective and rapid creation of interaction potentials for the purpose of analysing experimental data.

MM 19.4 Tue 18:00 P5

Unveiling Anharmonicity in High-temperature Diffusion Through Transition State Thermodynamic Integration — •Wenchuan Liu[1], Xi Zhang[1], Xu Xiang[1], Sergiy Divinski[2], and Blazej Grabowski[1] — [1]Institute for Materials Science, University of Stuttgart, D-70569 Stuttgart, Germany — [2]Institute of Materials Physics, University of Münster, 48149 Münster, Germany

Accurate modeling of high-temperature atomic diffusion requires a full treatment of thermal effects, particularly anharmonic lattice vibrations, which are often oversimplified in density functional theory (DFT)-based descriptions. We introduce a novel ab initio method, transition state thermodynamic integration (TSTI), that explicitly incorporates anharmonic contributions to vacancy migration Gibbs energies. TSTI combines DFT, molecular dynamics, and machine-learning interatomic potentials within a unified ab initio framework. Applied first to BCC tungsten, the method quantitatively captures non-Arrhenius diffusivities arising from anharmonicity. We further demonstrate its general applicability to metastable HCP aluminum, enabling high-fidelity input for CALPHAD-type mobility modeling. TSTI provides a general route to computing high-temperature diffusivities with DFT accuracy.

MM 19.5 Tue 18:00 P5

Every configuration counts: An Exact Approach to Doping Effects in AlN — •Oliver Heymer and Jens Kortus — Institute of Theoretical Physics, Freiberg, Germany

We present a new method to study doping effects within Kohn Sham density functional theory. Unlike Zungers Special quasirandom structures [1], our approach generates a complete and irreducible set of crystal structures, capturing all possible atomic configurations and making the description exact. Because we preserve full structural information, we can evaluate configurational entropies and identify the temperatures at which disordered doped AlN structures become energetically favored over the undoped material. Finally, we highlight how doping modifies the band structure and the density of states at the Fermi level.

[1] Zunger A, Wei S, Ferreira LG, Bernard JE. Special quasirandom structures. Phys Rev Lett. 1990 Jul 16;65(3):353-356. doi: 10.1103/PhysRevLett.65.353.

MM 19.6 Tue 18:00 P5

OpenCPMD: Plane-wave-based ab initio molecular dynamics code for large-scale HPC facilities — Tobias Klöffel[1,2], Christian L. Ritterhoff[1], Sagarmoy Mandal[1,2,3], Ritama Kar[3], Nisanth N. Nair[3], and •Bernd Meyer[1,2] — [1]ICMM/CCC, FAU Erlangen-Nürnberg — [2]National High Performance Computing Center, FAU Erlangen-Nürnberg — [3]Department of Chemistry, Indian Institute of Technology Kanpur (IITK), India

We present our recent advances in enabling fast and scalable *ab initio* molecular dynamics simulations on massively parallel HPC architectures with OpenCPMD (www.cpmd.org), an open source, plane-wave-based DFT code [1]. Code changes include new algorithms for hybrid functionals (localization of the orbitals, factorization of the Fock operator, multiple time-stepping [2]), revision of data distribution and communication patterns to reduce inter-node communication, introduction of overlapping computation and communication, partitioning the workload by auto-tuning algorithms, and porting to GPUs. The enhanced performance and scalability of the code is demonstrated on simulations of liquid water with up to 2048 molecules in the unit cell. We show that simulations with many hundred of water molecules for several 100 ps can be done now rou-

tinely within a few days, allowing systematic free energy calculations of chemical processes in liquids.

MM 19.7 Tue 18:00 P5

A Hartree-Fock Analysis of the Finite Jellium Model — •Michael Píro and Jaroslav Hamrle — Czech Technical University, Prague, Czech Republic

A Hartree-Fock analysis of the ground-state electronic structure of the finite spherical jellium model is carried out for systems containing up to 520 electrons in a positive background field with densities ranging from 10^{-3} to 1. The study focuses on resolving the energy-level ordering, accurately characterizing the total energy contributions, and evaluating the performance of local exchange and kinetic-energy approximations. All calculations are performed on a high-resolution real-space grid. Significant discrepancies are observed between the exchange energy obtained from the Hartree-Fock approximation and that predicted by the local density approximation (LDA) evaluated at the computed electron densities, both in the inner region and near the surface of the system. To reconcile these differences, a refined expression for the local one-electron exchange energy density is proposed. In addition, the breakdown of the Thomas-Fermi kinetic-energy model near the surface is addressed by introducing an improved expression for the one-electron kinetic-energy density.

MM 19.8 Tue 18:00 P5

Benchmarking Local Geometry Optimization Algorithms for Realistic Potential Energy Surfaces of Solids — •David Greten[1], Konstantin Jakob[1], Karsten Reuter[1], and Johannes T. Margraf[1,2] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Universität Bayreuth

Efficient and robust local structure relaxations are central to computational materials discovery. We benchmark several widely used local optimizers (based on the BFGS, FIRE and conjugate gradient approaches) for relaxing inorganic crystal structures on complex many-body potential energy surfaces obtained from a universal machine-learned interatomic potential. From relaxations of over 170,000 trial structures generated via element substitution, we quantify convergence rates, relaxation efficiency, and the stability and diversity of obtained minima. Some algorithms (e.g. BFGS with line-search and SciPy's conjugate gradient) show substantially higher convergence rates and consistently yield low energy minima. Meanwhile, the computational effort of the tested algorithms is broadly comparable. Based on these insights we discuss how to optimally combine algorithms to obtain a good trade-off between robustness and diversity of explored minima.

MM 19.9 Tue 18:00 P5

Acquisition strategies in multi-objective Bayesian optimization — •Tatu Linnala[1,2], Matthias Stosiek[1], Joakim Löfgren[2], and Patrick Rinke[1,2] — [1]Department of Physics, Technical University of Munich, Garching, Germany — [2]Department of Applied Physics, Aalto University, Espoo, Finland

Bayesian optimization (BO) is a machine learning technique for optimizing expensive black-box functions, and it is increasingly used in computational and experimental materials optimization. Many BO applications involve multiple competing objectives, requiring multi-objective BO (MOBO) to approximate the Pareto front. We extended the Bayesian Optimization Structure Search (BOSS) code to support advanced MOBO methods, focusing on acquisition strategies. Specifically, we implemented three variants of the expected hypervolume improvement acquisition function: an exact form for bi-objective problems and Monte Carlo approximations for higher dimensions. Additionally, we included scalarization-based methods for greater computational efficiency. These methods were benchmarked on six test cases, including synthetic functions and a real-world lignin extraction problem. Results show that hypervolume-based methods yield the most accurate predictions at high computational cost, although scalarization methods may sometimes be sufficient. This highlights the trade-off between accuracy and computational cost, and the application specificity of the optimal strategy. We provide guidelines for selecting appropriate MOBO settings, and the extended BOSS code provides a flexible toolkit for multi-objective optimization.

MM 19.10 Tue 18:00 P5

Transfer Learning Pipeline for GRACE Foundation Models for Complex Materials — •Christian L. Ritterhoff[1], Yury Lysogorskiy[2], Anton Bochkarev[2], Bernd Meyer[1], and Ralf Drautz[2] — [1]Interdisciplinary Center for Molecular Materials (ICMM) and Computer Chemistry Center (CCC), FAU Erlangen-Nürnberg — [2]Interdisciplinary Centre for Advanced Materials Simulation (ICAMS), Ruhr-Universität Bochum (RUB)

Foundation models of machine-learned interatomic potentials (MLIPs) offer overall good accuracy for a wide range of configurational and chemical spaces. However, achieving high fidelity and high efficiency for dedicated applications often requires further refinement of the model. This is commonly achieved by fine-tuning the foundation model on minimal specialized training data followed by distillation of the acquired knowledge into smaller models. We benchmark different strategies for the example of carbon with its demanding diverse chemistry and structure by fine-tuning the GRACE-1L-OMAT foundation model using the dataset by Qamar *et al.* [1]. Data efficiency is analyzed by training only on randomly chosen subsets of the complete dataset. Advantages of fine-tuning are demonstrated by comparing the obtained models against their randomly initialized counterparts. Finally, the resulting high-fidelity GRACE potential is used for knowledge distillation into a fast, local ACE model. This work validates the transfer learning and distillation paradigm as a robust and efficient pathway for creating deployable potentials for complex materials.

MM 19.11 Tue 18:00 P5

LLZO grain boundaries with doped amorphous domains by adaptively fine-tuned machine-learning interatomic potentials — •yuandong wang, yute chan, karsten reuter, and christoph scheurer — Fritz-Haber-Institut der MPG, Berlin, Germany

Garnet $Li_7La_3Zr_2O_{12}$ (LLZO) is a highly promising solid-state electrolyte (SSE) for lithium batteries. However, its application faces challenges, primarily arising from Li dendrite formation, the impact of grain boundaries (GBs) on Li transport and stability. Introducing amorphous intergranular domains can mitigate dendrite propagation while enhancing Li-ion mobility in GBs. Moreover, aliovalent cation doping (e.g., Al^{3+}, Ga^{3+}, Nb^{5+}, Ta^{5+}) in both cubic and amorphous LLZO offers additional levers to further enhance key properties. Rationally engineering the morphology of amorphous GBs offers an intriguing approach for tuning electrolyte performance.

In this study, we investigate strategies for generating structural motifs covering Li diffusion, GBs, and amorphous LLZO, which are diversified to include ion hopping transition states, large defects, amorphous motifs, etc. An adaptively fine-tuned MACE machine-learning interatomic potential (MLIP) is trained to accurately model large-scale and realistic nanoscale structures of LLZO with doped amorphous GBs. With the fine-tuned MLIP, the morphology, dopant effects and crystalline-amorphous interactions governing Li-ion diffusion pathways and activation barriers in LLZO can be studied in detail.

MM 19.12 Tue 18:00 P5

SEI-ntific Discoveries: A DFTB Journey with Constant Potential — •Anton Beiersdorfer[1], Tobias Melson[2], Felix Riccius[1], Chiara Panosetti[1], Christoph Scheurer[1], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Max Planck Computing and Data Facility, Garching

Lithium-ion batteries excel in short-term power grid balancing, yet their performance and longevity are strongly impacted by the solid electrolyte interphase (SEI) formed at the anode-electrolyte interface. Accurate SEI-formation modeling demands a simulation framework that can explore timescales inaccessible to *ab initio* molecular dynamics (MD) and is simultaneously capable of accounting for explicit electron transfer – a capability lacking in standard machine-learning interatomic potentials.

To this end, we introduce a novel approach that combines the thermopotentiostat [1] simulation scheme with density functional tight binding (DFTB) electronic structure calculations. This enables MD simulations of the anode-electrolyte interface at constant potential and up to the timescale of initial decomposition reactions on the anode surface. We assess the capabilities and limitations of this approach in providing valuable insights into SEI formation and its impact on battery performance and degradation.

MM 19.13 Tue 18:00 P5

Separating light and heat effects in the electrochemical performance ofilluminated V_2O_5 lithium-ion battery cells — •Pavel Rozov[1], Tom Wickenhäuser[1], Luca Bischof[1], Ewa Mijowska[2], and Rüdiger Klingeler[1] — [1]Kirchhoff Institute for Physics, Heidelberg University, Germany — [2]Faculty of Chemical Technology and Engineering, West Pomeranian University of Technology, Szczecin, Poland

Recent studies have demonstrated that lithium-ion batteries can exhibit enhanced electrochemical performance under optical light illumination. However, light exposure also may cause local heating, making it challenging to separate bare photonic and photo-thermal effects. Here, the effects of light illumination on V_2O_5-based electrodes as photoactive cathode material are studied in lithium metal half-cells in which photo-thermal effects are monitored by means of an in-situ Pt1000 thermometer. Our studies allow us to disentangle photonic and temperature effects. We find slightly enhanced Li+ diffusion under illumination but do not confirm significant light-induced enhancement of the battery performance beyond temperature effects which is reported in the literature.

MM 19.14 Tue 18:00 P5

Shining a Light on Stored Charges: Linking Excitation Spectra to Polaron Dynamics in Solar Battery Materials — •Leon Müller, Matthias Kick, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin

Solar battery materials integrate light harvesting and charge storage within a single component, offering a pathway toward simplified systems that could serve as

key elements in future nanoscale energy devices. First experimental findings suggest that charge storage involves the formation of long-lived polaronic states. However, the underlying processes of exciton generation, subsequent charge separation and trapping that enable stable charge storage remain elusive.

Experimentally, charging is accompanied by a reversible color change from white or yellow to blue, indicating a potentially more dynamic process in which charges can jump between multiple trapping sites. This photochromism has been observed in many of the solar battery materials discovered so far, hinting at a mechanism that may be universal to this class of systems.

To explore the processes of charge generation and trapping, we study $LiNbWO_6$ using time-dependent density-functional theory to model the optical response of polaronic states. By connecting the excitation spectra to the underlying dynamics of the stored charges, we aim to clarify the mechanisms that govern charge localization and stability, thereby establishing a microscopic framework for charge storage in solar battery materials.

MM 19.15 Tue 18:00 P5

Anisotropic Thermoelectric Energy Converters Based on Bi Microwires and Films. — •Leonid Konopko[1], Albina Nikolaeva[1], Tito Huber[2], and Denis Shiversky[1] — [1]Technical University of Moldova, Chisinau, Moldova — [2]Howard University, Washington, DC, USA

We demonstrate an innovative method for thermoelectric energy conversion utilizing a single-element device made from an anisotropic material. In such materials, heat flow generates a transverse thermoelectric electric field perpendicular to the direction of the heat transfer. For our experiments, we produced a sample using a 10-meter-long, glass-insulated, single-crystal tin-doped bismuth microwire (outer diameter - 20 μm; core diameter - 4 μm). A crucial aspect of this process was the successful growth of the microwire as a single crystal, achieved through laser-assisted recrystallization under a strong electric field. The microwire was coiled into a flat spiral and mounted onto a thin copper disk. This sample demonstrated high sensitivity to heat flow, reaching up to 10^{-2} V/W, with a time constant of approximately 0.2 seconds. Bismuth films with thicknesses ranging from 2 to 5 μm were deposited onto mica substrates. Experimental samples of heat flux sensors were then fabricated by recrystallizing these films under laser heating in a strong electric field. The observed voltage dynamics at the output of all sensors, in response to modulated heat fluxes, align well with theoretical predictions for anisotropic thermoelectric elements.

The study was supported by the State Project "ReBRAIN" #25.80013.5007. 07RE, 2025-2026.

MM 19.16 Tue 18:00 P5

Structure and transport properties of Li-Zr-Cl-O oxychloride solid electrolytes — •Ziyan Zhang[1,2], Shuai Chen[3], Peter Müller-Buschbaum[1], and Anatoliy Senyshyn[2] — [1]TUM School of Natural Sciences, Chair for Functional Materials, Garching, Germany — [2]MLZ, TUM, Garching, Germany — [3]TUM School of Natural Sciences, Chair for Physics of Energy Conversion and Storage, Garching, Germany

All-solid-state batteries using halide-based electrolytes have attracted attention due to their promising combination of room-temperature ionic transport, formability, and interfacial compatibility. Within this class, oxychloride compositions offer an additional degree of freedom via anion chemistry while retaining the beneficial processing of chlorides. The current study systematically characterizes mechanochemically prepared Li-Zr-Cl-O oxychlorides. A targeted Li2+yZrCl6-yOy series was established under standardized processing conditions. Laboratory powder X-ray diffraction was used to quantify the structural response to changes in oxygen content and processing conditions, using Rietveld analysis to determine lattice parameters. Electrochemical impedance spectroscopy yielded ionic conductivities and activation energies at ambient temperature. The resulting dataset provides a detailed composition-processing-structure- transport map for Li-Zr-Cl-O and delineates a practical recipe window for maximizing room-temperature conductivity under a purely mechanochemical synthesis route, thereby laying a robust laboratory baseline for subsequent interfacial and operando investigations.

MM 19.17 Tue 18:00 P5

Segregation of H in planar defects of BCC Fe — •Rohan Kumar, Mariano Forti, Rebecca Janisch, Thomas Hammerschmidt, and Ralf Drautz — Ruhr university Bochum, Universitatstr 150, 44801, Bochum Germany

The transition to a hydrogen-based economy in Europe is well underway, but challenges remain in the development of suitable infrastructure, as well as in migrating the existing facilities. Among other dificulties hydrogen embrittlement of steels hinders the applicability of known and new materials for hydrogen technologies.

This study focuses on the atomistic simulation assessment of hydrogen embrittlement in body-centered cubic (BCC) Fe using advanced computational methods. Density Functional Theory (DFT) is a standard tool for studying segregation phenomena, providing high accuracy but limited to small systems and short time ranges. In the other hand, the recent emergence of universal machine learning interatomic potentials (MLIPs) pose them as a powerful tool to study atomistic systems at larger scales with DFT precision.

In this work, we utilize GRACE MLIP to study tilt and twist grain boundaries (GBs) in ferritic Fe, finding GB energies in agreement with DFT results. The GBs were analyzed using DBSCAN and Voronoi analysis to identify hydrogen segregation sites. We study H segregating of in both tilt and twist GBs and analyze site preference trends.

MM 19.18 Tue 18:00 P5

Experimental Determination of Site Energy Spectrum of Hydrogen in Metal Thin Films — •Magdalena Seiler, Stefan Wagner, and Astrid Pundt — Karlsruhe Institute of Technology (KIT), Institute of Applied Materials (IAM-WK), Engelbert- Arnold-Straße 4, 76131 Karlsruhe, Germany

Metal-hydrogen interactions affect the mechanical properties of structural materials and the performance of solid-state hydrogen storage. Hydrogen occupies the metal lattices interstitial sites or different defects, whose site energy distribution characterizes the metal-hydrogen interaction. The site energy can be affected by the stress state, as suggested by theoretical calculations [1]. In this presentation, the constraints of a thin film adhered to a rigid substrate serve as a model 2D stress state. We experimentally determine the chemical potential of hydrogen in respective metal thin films during electrochemical hydrogen loading, and simultaneously measure the stress resulting in the hydrogen-absorbing, 1D expanding thin film. The result is compared to a Distribution of Site Energies (DOSE) model [2], in which Fermi-Dirac statistics are used to describe the hydrogen occupancy of the density of sites. Thereby, we obtain a site energy spectrum and quantify defect fractions.

MM 19.19 Tue 18:00 P5

In-Situ Electrochemical Micromechanics of Hydrogen-Charged Palladium — •Hou Zhang[1], Henry Ovri[1], and Shan Shi[1,2] — [1]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany — [2]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, Hamburg, Germany

The substantial lattice parameter mismatch between the hydrogen-diluted and hydrogen-rich phase, coupled with the embrittlement effect in metal hydrides, are critical factors limiting the long-term structural integrity and performance reliability of hydrogen-related functional materials used in actuation, sensing, transportation, and energy storage. Palladium, due to its high hydrogen solubility, rapid hydrogen diffusion at room temperature, and its ability to reversibly absorb and desorb hydrogen through electrochemical control, serves as a model material for studying the underlying chemo-mechanical coupling. However, the local mechanical response and microstructural evolution of Pd during electrochemical hydrogen absorption are not yet fully understood. In this study, we employ an in-situ electrochemical nanoindentation setup to conduct compression tests on Pd micropillars subjected to varying hydrogen concentrations. Electron backscatter diffraction (EBSD) analysis will be used to characterize grain orientation, enabling us to further investigate the influence of crystallographic orientation. The insights gained from this study will deepen the understanding of chemo-mechanical coupling in metal-hydrogen systems and contribute to the advancement of hydrogen-related technologies.

MM 19.20 Tue 18:00 P5

In-depth Study of Hydrogen Permeation through Zinc Coated Steel — •Tatjana Ott[1,2], Elahe Akbari[1], Christoph Cobet[2], Jiri Duchoslav[2], Heiko Groiss[2], Andreas Muhr[3], Reza Sharif[3], Thomas Steck[3], Laura Mears[1], and Markus Valtiner[1] — [1]Institute of Applied Physics, Vienna University of Technology, 1040 Vienna, Austria — [2]Johannes Kepler University Linz, Altenberger Straße 69, 4040 Linz, Austria — [3]voestalpine Stahl GmbH, 4020 Linz, Austria

Objectives: Hydrogen permeation measurements are used to obtain information such as diffusion coefficients and trap sites, as well as to investigate corrosion processes. Studying the hydrogen permeation through zinc coated steel sheets provides insights into the mechanisms of cathodic hydrogen generation and the protective capabilities of different zinc coatings. Utilizing samples prepared with an optimized sample preparation protocol, hydrogen permeation through zinc coated ultra-high-strength steel (UHSS) was investigated.

Results and Conclusions: The electrochemical process for the palladium deposition on steel was optimized, resulting in an increased sensitivity for hydrogen permeation. Different zinc coatings were compared to determine the protective abilities of the coating as well as different types of entry side reactions. Results showed that the zinc coatings provided significant protection against hydrogen permeation. Overall, hydrogen permeation measurements provided valuable insights regarding both the reactions taking place at different coating types and their protective abilities.

MM 19.21 Tue 18:00 P5

Hydrogen-induced resistance response in nanoporous Pd-Cu thin film — •Yushen Huang[1] and Shan Shi[2,1] — [1]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany — [2]Research Group of Integrated Metallic Nanomaterials Systems, Hamburg University of Technology, Hamburg, Germany

The large-scale utilization of hydrogen energy requires high-performance sensing technologies for real-time hydrogen monitoring and leakage prevention. Pd-based hydrogen sensors are considered among the most promising candidates and are widely used in commercial devices due to palladium's strong affinity for hydrogen. However, during cyclic hydrogen absorption and desorption, Pd undergoes repeated phase transition, which can lead to accumulation of local misfit strains and defects. This results in signal hysteresis, prolonged response times, and poor reproducibility particularly in dense Pd films. Inspired by the excellent microstructural stability and actuation performance durability observed in nanoporous Pd bulk samples after over 1500 cycles of phase transition, this work investigates the potential of nanoporous Pd-Cu thin films for hydrogen sensing. In this work, a nanoporous Pd-Cu thin film (~100 nm thick) was prepared via electrochemical dealloying, and its electrical resistance response during electrochemical hydrogen charging was measured using a four-point probe method. Additionally, the pore size of nanoporous Pd-Cu will be tuned by adjusting the preparation conditions and post thermal treatment, enabling the sensors with enhanced stability, long-term reliability, and high-precision hydrogen monitoring.

MM 19.22 Tue 18:00 P5

Crystallization kinetics of supercooled liquid palladium — •Zuzanna Kostera[1], Przemyslaw Dziegielewski[1], Ryszard Sobierajski[2], and Jerzy Antonowicz[1] — [1]Warsaw University of Technology, Faculty of Physics, Warsaw, Poland — [2]Polish Academy of Science, Institute of Physics, Warsaw, Poland

In this work we use large-scale molecular dynamics to study crystallization kinetics of supercooled liquid palladium over 0.3-0.6 T_m (T_m = 1828K). The crystallization temperature strongly affects the final polycrystalline morphology, reflecting temperature-dependent nucleation and growth kinetics. From the evolving grain structure we extract homogeneous nucleation and growth rates and construct a time*temperature*transformation (TTT) diagram. The TTT diagram yields a critical cooling rate of 10^{13} K/s, consistent with Pd's poor glass-forming ability. Homogeneous nucleation peaks at 10^{35} $m^{-3}s^{-1}$ near 0.5 T_m and its temperature dependence agrees with classical nucleation theory.

MM 19.23 Tue 18:00 P5

DFT study of the optical and electronic properties of N-Acyl-N'-Aryl thiourea derivatives — •amani zaghdoudi — University of Carthage, Faculty of Sciences of Bizerte, Laboratory of Materials Physics: Structure and Properties (LR01ES15), Physics of Nanometric Components and Devices Group, Jarzouna 7021, Bizerte, Tunisia

We report a DFT-based theoretical study of novel N-acyl-N'-aryl thiourea derivatives as potential selective fluoride sensors. Molecular structures were optimized at the B3LYP/LANL2DZ level with GAUSSIAN 09.

IR, Raman, and UV-Vis spectra were simulated to probe their vibrational and electronic responses. UV-Vis analysis reveals π-π^* and n-π^* transitions influenced by aryl substituents and fluoride binding. IR and Raman results show characteristic C=O and C=S stretches, with frequency shifts upon complexation, indicating interaction at the thiourea core.

Mulliken and NBO analyses reveal charge redistribution and donor*acceptor interactions. Frontier molecular orbital analysis indicates a reduced HOMO-LUMO gap upon fluoride binding, suggesting enhanced reactivity. These findings support the application of these compounds as promising molecular fluoride sensors.

MM 19.24 Tue 18:00 P5

Electronic properties of Carbon nanoscrolls — •Tzu-Ching Hsu[1], Jhih-Shih You[1], Hsiu-Chuan Hsu[2], and Ion Cosma Fulga[3] — [1]Department of Physics, National Taiwan Normal University, Taipei, Taiwan, — [2]Graduate Institute of Applied Physics, National Chengchi University, Taipei, Taiwan — [3]Institute for Theoretical Solid State Physics, IFW Dresden, Dresden, Germany

Carbon nanoscrolls (CNS), rolled-up structures formed from single-layer graphene, have recently attracted significant attention owing to their distinctive geometry. In this work, we theoretically investigate the topological properties of a series of ABC-stacked CNS with various chiral vectors that break mirror symmetry, within the small-curvature approximation. As the chiral vector is varied, we find that the Dirac cones in the fictitious Brillouin zone shift away from half of the magnetic flux quantum. Furthermore, we show that the combined C_2T symmetry, the composition of a 180° rotation and spinless time-reversal symmetry, protects the Dirac cones even when chiral symmetry is broken. Our results provide a foundation for further studies of the fundamental physics and potential applications of CNS and other two-dimensional materials with similar geometries.

MM 19.25 Tue 18:00 P5

Correlating Atomic Structure and Grain Boundary Energy in the 5D Space of Degrees of Freedom — •Mahkam Madadi[1], Timo Schmalofski[1], Martin Kroll[2], Holger Dette[3], and Rebecca Janisch[1] — [1]ICAMS, Ruhr-University Bochum, Germany — [2]Chair of Stochastics and Machine Learning, University of Bayreuth, Germany — [3]Chair of Stochastics, Ruhr-University Bochum, Germany

In materials design, it is essential to develop grain boundary (GB) models that effectively relate the atomic structure to the macroscopic properties of grain boundaries. Grain boundaries are categorized by five degrees of freedom (DOF), which include grain boundary plane orientation, rotation axis, and the misorientation angles between adjacent grains. On the other hand, the energy associated with these boundaries is governed by microscopic state, including atomic positions and structural units . This study seeks to investigate the correlation between the microscopic structure and the energy of grain boundaries. Previous studies often explored only a subset of these DOFs, typically by varying one or two while keeping the others fixed. In contrast, this study employs molecular statics in combination with a statistical approach [1] to assess the complete 5D space of DOFs and to model and analyze the microstructure-energy relationship.

MM 19.26 Tue 18:00 P5

Machine-learned interatomic potentials for hydrogen-affected fracture in silica minerals — •Valentína Berecová[1,2], Martin Friák[1], and Jana Pavlů[2] — [1]Inst. Phys. Mater., Czech Acad. Sci., Brno, Czech Republic — [2]Dept. Chem., Masaryk Uni., Brno, Czech Republic

Flint, a cryptocrystalline form of silica, is known for its ability to fracture into curved surfaces through conchoidal flaking. Although this behaviour has been used for millennia to produce cutting tools, the atomistic mechanisms that enable such edges remain poorly understood. To clarify these processes, we develop a machine-learned Si-O-H interatomic potential trained on high-accuracy quantum-mechanical data, providing near ab initio resolution at computational costs suitable for simulations. Particular attention is given to hydrogen-related interactions: natural flint contains hydration and hydroxylation that can influence fracture pathways and crack propagation. The training dataset includes hydrogen-containing species, surface terminations, strained configurations, amorphous structures and defect environments. The resulting potential is applied to atomistic simulations of fracture in defect-rich silica, offering new insight into conchoidal fracture at the atomic scale and supporting the design of brittle materials with controlled failure behaviour. Financial support from the Czech Academy of Sciences (Praemium Academiae of M.F. and the Strategy AV21 project "The power of objects: Materiality between past and future") is gratefully acknowledged. Computational resources were provided by e-INFRA CZ and IT4Innovations National Supercomputing Center.

MM 19.27 Tue 18:00 P5

Silica-Supported Nano Metal Complexes Derived from a Schiff Base Ligand: Structural, Theoretical, and Catalytic Investigations — •Tarek El-Dabea — Chemistry Department, Faculty of Science, King Salman International University, Ras Sudr, Sinai 46612, Egypt

Silica-based nanomaterials were prepared from natural silica sand and used as supports for nano metal complexes containing Ru(III), Fe(III), VO(II), and Ag(I) ions. The SiO2 support, obtained via a grinding and paste-based technique, provided a stable high-surface matrix for immobilization. Complexes derived from a bidentate Schiff base ligand were characterized by spectroscopic and analytical methods, confirming their geometry and stoichiometry. Solution studies showed stable metal-ligand coordination, while DFT and TD-DFT analyses gave insights into the optimized structures and electronic transitions consistent with experiment. Among the investigated systems, the Ru(III)/SiO2 composite exhibited distinctive electronic and catalytic properties, efficiently promoting multicomponent reactions under microwave irradiation. Optimized eco-friendly conditions (H2O/EtOH) gave high yields, and the catalyst

MM 19.28 Tue 18:00 P5

synchrotron XAFS Study of Fe3O4/Au core–shell nanoparticles for magnetic–plasmonic applications — •Mai El-Masry[1], Giuliana Aquilanti[2], Messaoud Harfouche[3], Neama Imam[4], and Jan Ingo FLEGE[4] — [1]Thebes Higher Engineering Institute, Cairo, Egypt — [2]Elettra Sincrotrone Trieste, Italy — [3]SESAME Synchrotron, Aman, Jordan — [4]Brandenburg University of Technology Cottbus-Senftenberg, Germany

Magneto-plasmonic nanostructures enable multifunctional biomedical applications, including imaging, sensing, and targeted diagnostics. We synthesized Fe3O4/Au core–shell nanoparticles via a seed-mediated method and characterized them using synchrotron X-ray Absorption Fine Structure (XAFS) at the Fe K and Au L3 edges. XAFS analysis provided element-specific information on oxidation state, coordination, and local structure, confirming core–shell in-

tegrity and strong interfacial coupling. XRD and high-resolution TEM verified a crystalline Fe3O4 core and FCC Au shell, while VSM measurements demonstrated superparamagnetic behavior with high saturation magnetization. EXAFS and XANES results revealed metallic Au and Fe–O coordination consistent with magnetite, confirming successful shell formation. These results establish the structure-property relationship in magnetic–plasmonic nanostructures and demonstrate the importance of SESAME synchrotron techniques for advancing nanomaterials for sensing, imaging, and biomedical technologies.

MM 19.29 Tue 18:00 P5

Relaxation and crystallization behavior of the metallic glass former PdNiP near the glass transition temperature — •Noah Colell — Universität Münster, Institut für Materialphysik, Wihelm-Klemm Str. 10, 48149 Münster

Analysis of $Pd_{40}Ni_{40}P_{20}$ metallic glass is conducted with Flash DSC measurements, realizing high heating and cooling rates. Relaxation is realized through systematically varying temperatures and durations of annealing by cycling to investigate the effects on glass transition and crystallization. Different relaxation modes (α and β) are targeted and their response to the heat treatment is analyzed. Due to the high rates available in Chip calorimetry, the range of temperatures available for relaxation experiments avoiding crystallization can be extended. As one results, it is observed that the relaxation enthalpy does not show a linear trend even with logarithmic scaling. This might be due to the combining effects of α and β relaxation. Through different annealing times different relaxation modes seem to be activated. The so-called shadow glass transition (β) can be seen with smaller duration and converges into a stronger enthalpy recovery with larger ones. This indicates a connection between the two relaxation modes.

MM 19.30 Tue 18:00 P5

Molecular micro-heterogeneity: Structure formation and phase behavior in aqueous alkylamine mixtures — •Lena Friedrich[1], Martina Požar[2], Aurélien Perera[3], Michael Paulus[1], Nicola Thiering[1], Jaqueline Savelkouls[1], Eric Schneider[1], Bernada Lovrinčević[2], Dirk Lützenkirchen-Hecht[4], and Christian Sternemann[1] — [1]Fakultät Physik / DELTA, Technische Universität Dortmund, 44221 Dortmund, Germany — [2]University of Split, Faculty of Science, 21000 Split, Croatia — [3]Sorbonne Université, Laboratoire de Physique Théorique de la Matière Condensée, F75252 Paris, France — [4]Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, 42097 Wuppertal, Germany

Aqueous alkylamines exhibit an unusual phase behavior [1] and an intruiging form of self-assembly [2]. X-ray diffraction experiments at BL8 and BL9 (DELTA, TU Dortmund) reveal intense structur factor pre-peaks that vary with composition and chain length, indicating peculiar micro-heterogeneity. Diffraction intensities calculated from MD simulations resemble the measured intensities and show bilayer-like arrangements in which amine headgroups saturate and stabilize water domains, forming transient clusters that prevent macroscopic phase separation, explaining the remarkable miscibility of aqueous amines compared to other associating liquids such as alcohols [3]. Supported by BMBF via DAAD in PROCOPE (57704875 & 50951YA). [1] J. Glinski et al., J. Colloid. Interface Sci. 162, 129-134 (1994); [2] L. Almasy et al., PCCP 21, 9317 (2019); [3] A. Perera et al., arXiv:2510.02146

MM 19.31 Tue 18:00 P5

Effects of physical properties on the solidification kinetics of undercooled Zr-Cu-Ni alloy under reduced gravity — •Chu Yu, Yindong Fang, and Stephanie Lippmann — IAP, FSU Jena, Albert-Einstein-Straße 15, 07745, Jena, Germany

In our previous work, we investigated the solidification kinetics of glass forming alloy Zr50Cu35Ni15 using electromagnetic levitation facilities (EML) under different gravity conditions to compare with the electrostatic levitation facility (ESL). Using both methods, crystal growth velocities increased with increasing undercooling below 260 K. Within the undercooling range 260-320K, velocities plateaued. Compared to ESL, EML on the ground generated stronger convective flow in the undercooled melt. Slight differences in velocities were observed within the undercooling range 50-175K. However, the primary phase is not changed by the magnetic convection. To investigate the differences in the low undercooling region and the physical properties of the melt, we measured the conductivity and viscosity of the melt under reduced gravity during parabolic flight campaign 2023 and 2025. The relationship between viscosity and crystal growth velocities at the low undercooling region is discussed.

MM 19.32 Tue 18:00 P5

Exploring Molecular Fragmentation and Structure in PVP Thin Films via Atom Probe Tomography — •Parisha Diwan — University of stuttgart

In this work, spin coating was used to create thin films of polyvinylpyrrolidone (PVP), which were then analysed using atom probe tomography (APT). APT measurements were performed to investigate the polymer at the nanoscale after lift-outs were created and shaped into sharp edges. The mass spectrum identified the primary molecular fragments generated during analysis, and the 3D reconstruction demonstrated the arrangement of various PVP molecule components in the film. These findings show that APT can help us better understand the structure of polymer thin films by providing specific chemical information. This study supports the future application of APT in polymer research and thin-film characterisation by highlighting its potential as a helpful tool for organic material analysis.

MM 19.33 Tue 18:00 P5

Electronic property analysis of structure and bonding at oxidized aluminium surfaces — •Lütfi Çağlar Ege[1], Nebahat Bulut[1], Zhengqing Wei[1], Inna Plyushchay[2], and Sibylle Gemming[1] — [1]Institute of Physics, TU Chemnitz, Germany — [2]Institute of Physics, National Taras Shevchenko University of Kyiv, Ukraine

The crystal structure has a large influence on material properties that are important for many applications, especially in the case of aluminium oxide (AlO_x), which forms a protective layer on aluminium. Understanding the structure and bonding during the oxidation mechanism of the low-energy aluminium surfaces Al(001), Al(110), and Al(111) is the main interest of this study, which highlights the surface reactivity. We attempted to analyse the interaction of the electronic states and forces of the oxygen and aluminum atoms to observe the relaxed bonding positions. First principles calculations were employed as the theoretical approach to investigate the electronic properties with respect to the position of oxygen within the irreducible wedge of the surfaces.

MM 19.34 Tue 18:00 P5

The vacancy effect to the mechanical properties of high entropy borides — •Nebahat Bulut[1], Inna Plyushchay[2], Anna Pliushchai[1], and Sibylle Gemming[1] — [1]Institute of Physics, TU Chemnitz — [2]Institute of Physics, National Taras Shevchenko University of Kyiv, Ukraine

High entropy transition metal diborides ($HETMB_2$) present complex lattice distortions that strongly influence their mechanical properties. These distortions are the result of atomic mismatch, metal-boron site vacancies, and strong covalent/ionic bonding. The randomly disordered structures of $HETMB_2$ are constructed with equimolar metal atom ratios to obtain the elastic stiffness tensors. Small strains are applied to the equilibrium unit cell to calculate the elastic response by performing first principles calculations using Quantum Espresso. Understanding the influence of lattice distortion on mechanical properties, we introduce distortion parameters which show the vacancy effect of different transition metal atoms. The distortion parameters were quantified based on the interatomic distances of nearest neighbor bond lengths. Mechanical stability and elastic anisotropy of $HETMB_2$ were analyzed as function of configurational disorder. It is discussed how the lattice distortions modify the Peierls barrier for dislocation motion.

MM 19.35 Tue 18:00 P5

Band geometric transverse current driven by inhomogeneous AC electric field — •M Maneesh Kumar, Sanjay Sarkar, and Amit Agarwal — Indian Institute of Technology Kanpur, Kanpur, India

We develop a semiclassical theory for electron wavepacket dynamics in the presence of an inhomogeneous AC electric field. While static electric-field gradients are known to generate charge transport governed by the quantum metric, we show that AC field gradients induce an additional geometric current that vanishes in the DC limit. This response originates from a novel band-geometric quantity, the higher-order connection (HOC) tensor, constructed from cubic products of interband Berry connections. We derive explicit expressions for the AC field-limit and identify the symmetry conditions under which it arises. Remarkably, inhomogeneous AC fields can generate an anomalous Hall-like response even in nonmagnetic systems. Applying the theory to Bernal-stacked bilayer graphene, we demonstrate that the HOC-induced response produces a measurable Hall current peaking at band edges. These results establish inhomogeneous AC fields as a powerful probe of higher-order band geometric quantities beyond Berry curvature and the quantum metric.

MM 19.36 Tue 18:00 P5

Modelling heat transport in BTBT and its derivatives using non-equilibrium molecular dynamics (NEMD) simulations — •Simon Jamnik, Florian Lindner, Florian Unterkofler, and Egbert Zojer — Graz University of Technology

Benzothieno[3,2-b]benzothiophene (BTBT) is a high-performance organic semiconductor whose derivatives C8-BTBT (with an octyl side chain) and Ph-BTBT (with a phenyl side chain) are widely used in OFETs due to their high mobilities, environmental stability and solution processability. Side-chain engineering strongly influences their physicochemical and thermal properties: experiments show that alkyl chains improve solubility while suppressing heat transport, whereas phenyl chains enhance along-chain conductivity and reduce interchain transport.

To analyse these effects, we employ non-equilibrium molecular dynamics (NEMD), which provides a complementary real-space perspective through spatially resolved temperature profiles and enables the direct identification of thermal-transport bottlenecks. Accurate forces for large-scale NEMD were ob-

tained using moment tensor potentials (MTPs) trained on ab initio data generated via VASPs on-the-fly machine-learning force-field (MLFF) framework, allowing near first-principles accuracy at greatly reduced computational cost.

MM 19.37 Tue 18:00 P5

Neural Network Potentials for Molecular Dynamics Simulations of NASICON Solid Electrolytes — •Insa F. de Vries and Nikos L. Doltsinis — Institute of Solid State Theory, University of Münster, Wilhelm-Klemm-Straße 10,48149 Münster

Solid-state electrolytes are by now well-established components for the development of safe and efficient batteries. Among them, the sodium superionic conductor (NASICON) family offers an appealing degree of tunability. Their open framework allows for the substitution of lattice sites and the adjustment of diffusing ion concentration, making them an attractive choice for material design. Accurately modeling and predicting ion and thermal transport properties in these systems by *ab initio* molecular dynamics (AIMD) simulations poses a challenge due to the large supercells and time scales required. In this study, we therefore train neural network (NN) potentials for various members of the $Na_{1+x}Zr_2Si_xP_{3-x}O_{12}$ (x = 0, 1, 2, 3) family using training data obtained by accelerated AIMD [1]. The NN potentials are then employed to calculate the sodium ion diffusion coefficient – a key transport property. The performance and results obtained with the NN potential are validated against those obtained from *ab initio* trajectories. In addition, both the NN potential and the *ab initio* results are then compared to corresponding data generated with a previously developed force field [2].

MM 19.38 Tue 18:00 P5

An extended two-temperature model for copper — •Simon Kümmel and Johannes Roth — FMQ, University of Stuttgart, Germany

The two-temperature model (TTM) describes a set of coupled heat conduction equations of an electronic and lattice subsystem that allows the study of materials under strong electronic excitation following laser irradiation.

Here, we present recent advances in the development of an implementation coupled to a molecular dynamics code. In particular, this implementation allows the study of effects that emerge from the change of the bond strength at high degrees of excitation. For that, we recently developed an electron temperature-dependent interaction potential for copper [1] that is capable of reproducing bond-hardening at high degrees of excitation. We discuss the importance of energy conservation when using such interactions and propose an implementation strategy.

Furthermore, we discuss the importance of taking ballistic electron motion into account before the establishment of an electron temperature within such TTM simulations. We compare two approaches and discuss the differences.

Ballistic transport effects on the thermal conduction in nanowires — Ralf Meyer[1], Graham W. Gibson[2], and •Alexander N. Robillard[1] — [1]Laurentian University, Sudbury, Ontario, Canada — [2]University of Alberta, Edmonton, Alberta, Canada

The effect of ballistic transport on the thermal conduction in nanowires is studied with molecular dynamics and phonon Monte Carlo simulations. Simulations of nanowires between a heat source and a heat sink show — in agreement with previous results by other groups — the occurrence of a non-linear temperature profile with steep temperature gradients near the source and the sink combined with a reduced temperature gradient in the middle of the wire. The reduced gradients in the centre are then compared to a simple radiator model. This model predicts linear temperature profiles with a reduced gradient and discreet jumps at the wire ends. The comparison shows that if the wires are longer than the typical mean free path of the phonons, the radiator model is able to describe the reduction of the temperature gradient in the middle of the wires as well as their thermal resistances. The steep gradients at the wire ends can then be seen as the realization of the radiator model's discreet jumps in the more complex computer simulations.

MM 19.40 Tue 18:00 P5

Many-body localization for fermions and bosons - similarities and differences — •Krystian Jablonowski — University of Warsaw, Poland

In this talk, I will present a study that employs energy-level statistics as a robust diagnostic of localization phenomena across different quantum statistics. Using energy-level statistics, I analyze how Hubbard-type interactions shape the transition between localized and delocalized regimes in disordered many-body systems. Particular attention is given to how the strength of interactions influences spectral properties and dynamical behavior. A central theme of the talk is the contrast between fermionic and bosonic systems. By examining how particle statistics modify level-spacing distributions and the stability of localized phases, the study highlights both shared mechanisms and fundamental differences in their localization dynamics. Beyond mapping out the transition, I discuss how disorder and interaction-induced correlations jointly determine the structure of the many-body spectrum, offering insight into when and why localization persists or breaks down. Overall, the talk aims to provide a unified yet discriminating perspective on how fermions and bosons experience many-body localization, clarifying the similarities and distinctions that arise from their quantum statistical nature.

MM 19.41 Tue 18:00 P5

Perturbation theory for light-induced frequency shifts of thin quartz acoustic resonators — •Marinus Lehmann, Marek Bekir, and Carsten Henkel — Universität Potsdam, Institut für Physik und Astronomie, Germany

Quartz microbalance devices (QCM) are widely used for high precision mass measurements and the characterisation of liquid overlayers. In addition, QCMs are sensitive to various environmental changes like heating due to light irradiation. A light-induced shift of the acoustic resonance frequency has been shown by various groups [1,2]. Its explanation requires a combination of acoustic theory [3] with calculations for heat conduction [4] to model the cross-coupling between static thermal strain and the acoustic resonance. We try to clarify the mechanism by focussing on the time constants of the frequency shift transients.

MM 19.42 Tue 18:00 P5

Anomalous resistance behavior of NiTi alloys at high temperatures — •Tianyi Xu[1], Leo Pies[1], Oluwaseyi Oluwabi[2], Sven Graus[1], Andreas Kreyssig[1], Jan Frenzel[2], and Anna E. Böhmer[1] — [1]Experimental Physics IV, Ruhr-University Bochum, Bochum, Germany — [2]Institute for Materials, Ruhr-University Bochum, Bochum, Germany

NiTi-based shape-memory alloys, widely used in actuators, biomedical devices, and high-precision components, are well known for their thermally driven phase transformations and associated functional properties. While their structural behavior has been extensively characterized, the electrical transport properties—particularly at elevated temperatures—remain comparatively unexplored, despite their relevance for high-temperature functional applications. In this work, the electrical resistance of $Ni_{1+x}Ti_{1-x}$ was determined up to temperatures of more than 700 °C. The resistive signature of the established martensite-austenite transition was clearly detected. Remarkably, the resistance exhibits a reproducible exponential increase as the temperature exceeds 500 °C.

This high-temperature behavior has not been reported previously and suggests that additional mechanisms—beyond the known phase transitions—govern charge transport in NiTi at elevated temperatures. These findings highlight the need for deeper investigation of high-temperature electronic behavior in shape-memory alloys. We will discuss the possible mechanisms resulting in this behavior, including the formation of precipitate phases.

MM 19.43 Tue 18:00 P5

Correlated-electron metallic systems at extremely high temperature — •Zuzanna Helena Filipiak[1,2] and Andrew P. Mackenzie[1,2] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]School of Physics and Astronomy, University of St Andrews, Scotland, UK

Although the low-temperature regime is the most established experimental phase space to study correlated-electron systems, a unique physical insight can be won from study at much higher temperatures as well. In particular, the unresolved mystery of the Planckian dissipation - with its linear-in-temperature electrical resistivity sometimes persisting over a few orders of magnitude in temperature with an unchanged slope - is worth studying across wide ranges of temperature. We have developed two setups in which resistivity of a metallic sample is measured as a function of temperature (ranging from 2 to 1000 K), magnetic field (up to 14 T) and the chemical reactivity of the exchange gas (oxygen, argon, vacuum). In this contribution we report on our current understanding of the observed presence and lack of resistivity saturation in different compounds from the groups of the weakly-interacting delafossites ($PdCrO_2$ and $PdCoO_2$) and the more strongly-interacting ruthenates (Sr_2RuO_4, $Sr_3Ru_2O_7$ and $Ca_3Ru_2O_7$).

MM 19.44 Tue 18:00 P5

Thermal Conductivity Measurements Using Laser Flash Analysis in $Mg_3(Sb,Bi)_2$ and Related Compounds — •Thomas Terörde[1], Benjamin Bornmann[1], Christian Hess[1], Ran He[2], Vishak Sivasubramaniyan Sudandiradevi[2], and Kornelius Nielsch[2] — [1]Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, Wuppertal, Germany — [2]Leibniz-Institut für Festkörper- und Werkstoffforschung (IFW) Dresden, D-01171 Dresden, Germany

This work presents temperature-dependent thermal conductivity measurements of $Mg_3(Sb,Bi)_2$-based thermoelectric compounds obtained using laser flash analysis down to 150 K. Maximizing thermoelectric performance requires high electrical conductivity while simultaneously minimizing thermal conductivity,

which is achieved by reducing the lattice contribution and thereby weakening the Wiedemann-Franz relation. The Sb/Bi ratio of $Sb_{0.6}Bi_{1.4}$ yield favorable band convergence and minimal lattice thermal conductivity. Modification of the transport behavior is sought through additional codoping with Te and Nb. Our systematic measurements as a function of Mg, Te, and Nb contents yield intrinsically reduced thermal conductivity, where an increase in the Te and Nb contents leads to a rise in the thermal conductivity at elevated temperatures, consistent with previous reports.

MM 19.45 Tue 18:00 P5

Li transport in V2O5 quantified by optical microscopy — •Vidula Angane-Ambure, Monica Mead, and Guido Schmitz — Institute of Materials Science, University of Stuttgart, Heisenbergstraße 3, 70569 Stuttgart, Germany

Vanadium pentoxide (V2O5) is an interesting cathode material due to its layered structure and high theoretical capacity; however, its electrochemical performance is strongly limited by lithium-ion transport and the evolution of phase boundaries during (de)intercalation. To measure lithium-ion transport in V2O5 and clarify transport mechanisms we apply a novel method that uses the optical response upon ion intercalation in in-situ optical microscopy. In this setup a clear diffusion geometry is established and therefore weaknesses of conventional electrochemical methods for quantification of diffusion in battery electrode materials can be circumvented. By evaluating the measured RGB values, the diffusion front is determined. Diffusional transport can then be separated from linear transport across a kinetic interface (such as phase boundaries) and the temperature dependence of the ion transport is quantified, yielding an activation energy for transport in V2O5. Additionally, the concentration-dependence of Li transport in V2O5 is studied in lithiation and delithiation experiments, showing faster delithiation than lithiation.

MM 19.46 Tue 18:00 P5

Beyond arsenopyrite's monoclinic model: new insights on triclinic symmetry and local, chemically driven disorder in $FeAs_{1-x}S_{1+x}$ — •Esteban Zuñiga-Puelles[1,2], Ayberk Özden[2], Nebahat Bulut[2], Raul Cardoso-Gil[3], Christoph Hennig[4,5], Gerhard Heide[2], Cameliu Himcinschi[2], Jens Kortus[2], and Roman Gumeniuk[2] — [1]Leibniz Institute for Solid State and Materials Research Dresden, Germany — [2]TU Bergakademie Freiberg, Germany — [3]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [4]Helmholtz-Zentrum Dresden-Rossendorf, Germany — [5]European Synchrotron Radiation Facility, Grenoble, France

In this work, we revisit the structural description of different natural $FeAs_{1-x}S_{1+x}$ specimens. High-resolution synchrotron PXRD reveals additional reflections incompatible with the commonly assumed monoclinic $P2_1/c$ model but fairly consistent with triclinic $P\bar{1}$ symmetry. Raman spectroscopy displays vibrational features deviating from monoclinic simulations, while Mössbauer spectra show multiple inequivalent Fe-sites linked to distinct local crystal electric fields. All samples show weak paramagnetism, and the magnetic moments decrease with increasing As-content, indicating that only a small portion of Fe-atoms resides in environments sufficiently distorted to cause deviations from the expected diamagnetism of low-spin Fe^{2+}. Altogether, the structural, vibrational, and magnetic responses support a revised view of arsenopyrite as a complex Fe-based semiconductor, where local As/S symmetry disruptions and chemically driven disorder govern its physical properties.

MM 19.47 Tue 18:00 P5

Heat-treatment dependent hydrogen embrittlement behaviour of additively manufactured 316L — •Kai Lagemann, Gabriele Palazzo, Stefan Wagner, and Astrid Pundt — Institute for Applied Materials, Karlsruhe Institute of Technology, Karlsruhe, Germany

This study investigates the mechanical behaviour of additively manufactured austenitic stainless steel 316L (AM316L) for different post-processing heat treatments and its susceptibility to hydrogen embrittlement. Specimens were produced in the as-built (AB) condition and after heat treatments at 400 °C, 650 °C, 900 °C, and 1050 °C. Comprehensive microstructural characterization and tensile testing were performed to evaluate the correlation between heat-treatment-induced microstructural changes and mechanical properties. Particular this study focuses on assessing the influence of hydrogen on the fracture behaviour and embrittlement sensitivity of the differently heat-treated AM316L conditions. The findings provide an improved understanding of the interplay between additive manufacturing, microstructural evolution during heat treatment, and diffusion-based hydrogen-induced degradation mechanisms in AM316L [1]. [1] Kai Stefan Lagemann, Gabriele Palazzo, Tim Lucas Haag, Svetlana Korneychuk, Stefan Wagner, Christian Kübel and Astrid Pundt. Influence of Microstructure and Heat Treatment on Hydrogen Diffusion in Additively Manufactured 316L Stainless Steel. manuscript submitted, 2026.

MM 19.48 Tue 18:00 P5

In Situ Investigation of Phase Evolution During Oxidation and Reduction of Powder Bed Fusion Copper Powders — •Eric Schneider[1], Lena Friedrich[1], Jaqueline Savelkouls[1], Fabienne Hellwig[2], Milli Suchita Kujur[2], Nick Hantke[3], Arne Röttger[2], Jan T. Sehrt[3], and Christian Sternemann[1] — [1]Technische Universität Dortmund, Maria-Goeppert-Mayer-Str. 2, D-44227 Dortmund — [2]Bergische Universität Wuppertal, Bahnhofstraße 15, D-42651Solingen — [3]Ruhr-Universität Bochum, Universitätsstraße 150, D-44801 Bochum

The additive manufacturing (AM) process of laser-based powder bed fusion of metals (PBF-LB/M) enables the efficient production of complex components with internal cavities. Fabricating dense structures from pure copper remains challenging due to copper's high thermal conductivity and its low absorption of infrared laser radiation. Targeted surface modification, such as oxidation or nickel coating, can enhance the processability and reusability of copper powders. This study examines the oxidation behavior of copper powder in air and its controlled reduction in an $Ar/2\%H_2$ atmosphere at temperatures up to 350 °C. X-ray diffraction measurements were conducted at the BL9 beamline of the DELTA synchrotron radiation source. The findings provide key insights into the evolution of copper powder surfaces under PBF-LB/M-relevant atmospheres and offer practical guidance for industrial copper powder processing. This research is funded by the DFG through projects 508745195, RO 4523/9-1, SE 2935/6-1, and STE 1079/9-1.

MM 19.49 Tue 18:00 P5

Transferable Hamiltonian-learning model for large-scale finite temperature electronic-structure calculations — •Kaiwen Chen, Martin Schwade, and David Egger — Physics Department, TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany

Exploring the optoelectronic properties of large-scale systems across various temperatures and structures using conventional density functional theory (DFT) often encounters significant computational challenges. Recent advancements in machine learning (ML) Hamiltonians and the wide availability of DFT-databases have made it possible to train models, capable of predicting accurate Hamiltonians and electronic structure across the chemical space. However, creating a model that can determine temperature-dependent electronic structure with such transferability remains a difficult task. Building on our earlier work involving a physics-informed temperature-transferable Hamiltonian-learning model [1], we introduce an extension of this method that enables it to be trained on a wider field of compositions and thus be able to predict accurate effective Hamiltonians for different chemical compositions.

Neural Network Atomistic Modeling of Dislocation Plasticity in Ceramics — •Shigenobu Ogata and Shihao Zhang — The University of Osaka, Osaka, Japan

Dislocations in ceramics are increasingly recognized as levers for toughening intrinsically brittle materials and for tailoring functional responses. Yet atomistic simulation of their plasticity remains difficult because ceramic bonding combines ionic and covalent character, dislocation cores are often nonstoichiometric and charged, and core structures can be highly extended in complex lattices - features that exceed the fidelity of empirical interatomic potentials. Here, we develop neural network potentials (NNPs) for dislocation plasticity in three representative functional ceramics - ZnO, GaN, and SrTiO3. The NNPs accurately reproduce charged and nonstoichiometric core structures, slip barriers, and the long-range electrostatic interactions between charged dislocations. Leveraging these models, we examine plasticity via nano-pillar compression and nano-indentation, finding excellent agreement with experimental observations. The results establish a practical workflow for constructing NNPs that enable detailed, large-scale atomistic modeling of dislocation behavior in ceramics and open new avenues for predictive exploration of plastic deformation and property tuning in functional ceramic systems.

MM 21: Phase Transformations II

Time: Wednesday 10:15–13:00 Location: SCH/A215

MM 21.1 Wed 10:15 SCH/A215

On the nature of solutal melting in Cu-Pd — •Nagarjuna Remalli[1], Huai Zhang[1,2], Nisha Singh[1], Nuria Navarrete[1], Julien Zollinger[3], and Florian Kargl[1,4] — [1]Institute for Frontier Materials on Earth and in Space, German Aerospace Center (DLR), 51147 Cologne, Germany — [2]Department of Mechanical Engineering, University of Alberta, AB T6G 2G8 Alberta, Canada — [3]Université de Lorraine, Institut Jean Lamour, 54000 Nancy, France — [4]Foundry Institute, Fundamentals of Solidification, RWTH Aachen University, 52072 Aachen, Germany

We report on the kinetics of the solid-liquid (s-l) interface during solutal melting of isomorphous Cu-Pd melting couples. Using X-ray radiography (XRR) with sub-second time resolution the solutal melting dynamics along with the evolution of solute concentration fields was investigated. To this end circular melting couples of different thicknesses (220 μm and 460 μm) were in-situ monitored in an isothermal field at 1090°C slightly above the melting point of copper (1085°C) and well below the one of palladium (1555°C).

Sample thickness dependent differences in dissolution speed were observed which are suggested to be related with buoyancy-driven convective flow. By comparing SEM analysis results of the re-solidified Cu-Pd alloys with the in-situ results good agreement was found. Persistent non-equilibrium conditions were found at the s-l interface at the end of melting, independent of sample thickness or melting mechanism.

MM 21.2 Wed 10:30 SCH/A215

Chemoelastic effects, phase equilibria, and uphill diffusion in Cu-Pd nanoparticles — •Idan Klein, Feitao Li, and Eugen Rabkin — Department of Materials Science and Engineering, Technion - Israel Institute of Technology, Haifa 3200003, Israel

We fabricated nanoparticles (NPs) of Cu-40 at.% Pd alloy via solid state dewetting and subsequent slow-cooling of Cu-Pd bilayers deposited on a sapphire substrate. We observed that some nanoparticles which experienced partial transformation from a disordered A1 FCC phase to the ordered B2 β-CuPd exhibited compositional discontinuity, with the ordered phase being richer in Pd. This compositional discontinuity was associated with fully or partially coherent interphase boundary. At the same time the FCC particles that did not experience any transformation, the fully transformed β-CuPd particles, and partially transformed particles with incoherent interphase boundary exhibited homogeneous distribution of the components. We developed a thermodynamic model which demonstrated that misfit-strain from the coherent interface influences the thermodynamics of the system, depressing the transformation temperature. Redistribution of the components causes changes to the lattice parameter of each of the phases, mitigating the misfit between them, reducing free energy and encouraging the phase transformation.

MM 21.3 Wed 10:45 SCH/A215

Mechanism of structure formation during electrochemical dealloying — •Gideon Henkelmann[1] and Jörg Weissmüller[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Germany — [2]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany

During electrochemical dealloying of a solid solution, atoms of the more noble species rearrange by surface diffusion to form a connected nanoporous structure with a characteristic length scale. Details of the underlying nanoscale self-organization process, specifically the criteria that select this characteristic length scale, remain to be understood. Here, we study this issue by kinetic Monte Carlo simulations. While previous studies started out with corroding a planar single-crystal surface, our approach starts by forming an internal cavity and follows the evolution of the surface of the growing void. This allows us to focus on passivation or bifurcation of the corrosion front in a realistic scenario with curved and rough surfaces. We find that passivation is governed by simple geometric criteria related to the enrichment of the more noble species on the pore surface. Furthermore, the variation of the resulting structure size with the overpotential may be rationalized by a Gibbs-Thomson-type scaling law.

MM 21.4 Wed 11:00 SCH/A215

ab-initio investigation of short-range order in Fe-Si-Al alloys — •Daniil Khodachenko[1], Franco Moitzi[1,2], Andrei Ruban[2], Oleg Peil[2], and Vsevolod Razumovskiy[1,2] — [1]Christian Doppler Laboratory for digital materials design guidelines for mitigation of alloy embrittlement, Leoben Austria — [2]Materials Center Leoben Forschung GmbH, Leoben Austria

Unique electromagnetic properties of steels with silicon and aluminum make them an excellent choice for the production of transformers and electric motors. These so-called electrical steels have enhanced energy efficiency due to reduced core losses and enhanced magnetic permeability. However, increasing the concentration of silicon and aluminum beyond a critical amount leads to significantly reduced ductility, which makes production very challenging.

The theoretical origin of these embrittlement effects is still not fully understood, as ab initio modeling based on Density Functional Theory (DFT) is rather challenging, due to requiring large supercells and complex magnetic interactions. Such first-principles simulations frequently use approximations that assume a fully random distribution of the alloying elements. However, real systems are not perfectly random, due to atomic interactions, which result in short-range ordering (SRO) of the atomic sites. We investigate atomic SRO phenomena using accurate DFT- and Green's function-based methods to study effective cluster interactions and their magnetic state dependence. Finally, we perform Monte-Carlo simulations to investigate phase transitions and the effect of SRO in these materials.

MM 21.5 Wed 11:15 SCH/A215

Ordering in Mo-Cr-Ti-Al refractory high-entropy alloys via machine learned interatomic potential — •Jiyao Zhang[1], Klemens Lechner[1], Markus Masswohl[2], Petra Spörk-Erdely[2], and David Holec[1] — [1]Department of Materials Science, Montanuniversität Leoben, Franz-Josef-Strasse 18, 8700 Leoben, Austria — [2]Institute of Materials Science, Joining and Forming, Graz University of Technology, Kopernikusgasse 24/I, 8010 Graz, Austria

Refractory high-entropy alloys (RHEAs) offer exceptional mechanical and thermal properties, such as excellent high-temperature strength, making them favorable competitors to nickel-based superalloys. Origin of the superior high-temperature performance of the Mo-Cr-Ti-Al RHEA can be tracked to its two-phase microstructure of disordered BCC and ordered B2 phases. Modeling RHEAs poses significant challenges, as accurate density functional theory (DFT) calculations are extremely time-consuming, a difficulty worsened by the alloys' complex compositions. Universal machine learning interatomic potentials (UMLIPs) have recently emerged as a promising solution. Trained on vast DFT datasets, UMLIPs enable near-DFT accuracy for large-scale simulations of thousands of atoms. In this work, we utilize UMLIPs in mixed Monte Carlo/Molecular Dynamics simulations to evaluate the thermal stability of ordered versus disordered states in Mo-Cr-Ti-Al system as a function of the Al contents. Furthermore, we analyze the impact of composition on order/disorder transition temperature and elastic properties. We validate our findings against experimental data.

MM 21.6 Wed 11:45 SCH/A215

Shear-stress dependent formation of Si-polymorphs during saw dicing analyzed by raman spectroscopy — •Zainab Zainab[1,2], Jörg Debus[2], and Hannes Kurtze[1] — [1]Bernburger street 55, 06366 Köthen (Anhalt) — [2]August-Schmidt-Str. 4, 44227 Dortmund

Raman spectroscopic analysis of diced silicon wafers reveals that the saw cutting process generates considerable amounts of metastable silicon polymorphs (BC8/R8) along with the original diamond-cubic structure (DC-Si). We demonstrate that the formation of these phases exhibits a distinct spatial distribution that correlates with the shear stress profile imposed by the rotating blade. The DC-Si signal is strongest near the bottom of the cut (wafer tape side), while BC8 and R8 phases are most concentrated near the top surface at the blade entry point. This gradient arises from differences in the mechanical stress state: at the top, the steeper blade angle generates substantial shear stress in addition to normal compressive stress, facilitating shear-induced phase transformation at locally applied pressures. At the bottom, the nearly parallel blade trajectory produces predominantly normal stress with minimal shear, suppressing the formation of metastable phases. Additionally, we find that specific feed rates enhance phase transformations and intensify the spatial gradient. These findings confirm that shear stress is the critical enabling factor for polymorph formation during mechanical processing of silicon, consistent with recent studies showing dramatic reduction in transformation pressures under non-hydrostatic conditions.

MM 21.7 Wed 12:00 SCH/A215

Investigating the temperature-driven structural phase transition in α-In2Se3: A Raman study — •Saswata Talukdar, Mitanshi Gupta, Devesh Negi, Suvodeep Paul, Shalini Badola, Shivani Tripathi, Ravi Shankar Singh, and Surajit Saha — Indian Institute of Science Education and Research Bhopal, Bhopal, 462066, India

In recent years, the complex characteristics and polymorphic nature of indium selenide (In2Se3) have distinguished it as a prominent candidate among 2D semiconductors for memory and nano-electronic applications. Despite comprehensive research on its thermal, electrical, and optical properties, the structural dynamics, especially the phase transitions over temperature, remain elusive. In this work, temperature-dependent Raman spectroscopy of bulk α-In2Se3 reveals well-defined spectral signatures corresponding to its multiple polymor-

phic phases, providing direct evidence of its structural transitions. Our results also show that the phase transition is governed not solely by temperature, but it is further influenced by the local strain, which forms wrinkles on the surface of the material, playing a crucial role in directing the transition pathway. Moreover, comparative Raman measurements on exfoliated flakes highlight a pronounced thickness-dependent modulation of the transition behavior, underscoring the critical role of dimensionality in governing phase stability and evolution. Altogether, this work presents a comprehensive picture of the phase transitions in In2Se3, offering valuable insights for its integration into future high-performance phase-change memory applications.

MM 21.8 Wed 12:15 SCH/A215

Transforming martensite in Ni-Mn-Ga within picoseconds — •Klara Lünser[1,2], Yuru Ge[3,4], Fabian Ganss[3], Daniel Schmidt[5,6], Daniel Hensel[5], Mike J. Bruckhoff[7], Bruno Neumann[3,4], Mariana Brede[5], Sakshath Sadashivaiah[8,9], Markus E. Gruner[7], Peter Gaal[5,6], and Sebastian Fähler[3] — [1]University Duisburg-Essen — [2]RCFEMS, Bochum — [3]HZDR, Dresden — [4]TU Dresden — [5]Leibniz IKZ, Berlin — [6]TXproducts, Hamburg — [7]CENIDE, University of Duisburg-Essen — [8]Helmholtz-Institut Jena — [9]GSI Darmstadt

Martensitic transformations are driving a wide range of emerging applications, including high-stroke actuation, mechanocaloric refrigeration, and thermoelastic energy harvesting. However, systematic investigations of the fast dynamics and fundamental speed limits of martensitic transformations are scarce. In this study, we employed a synchrotron-based time-resolved diffraction technique to investigate the martensitic transformation induced by 200 fs laser pulses. Our results show that the transformation from martensite to austenite occurs within 100 ps, limited by the synchrotron probe pulse duration. We also demonstrated that an appropriate laser fluence and undercooling can complete a full transformation cycle within 5 ns, the fastest value reported for martensitic transformation. Our study highlights the importance of analyzing the lattice temperature during martensitic transformations and discusses the need for and limits of this approach. Furthermore, we found that stress must be considered as a competing influence on the martensitic transformation, in addition to temperature.

MM 21.9 Wed 12:30 SCH/A215

In-situ view on contact and solutal melting of Al-Cu — •Florian Kargl[1,2], Matthias Kolbe[1], and Nagarjuna Remalli[1] — [1]Institute for Frontier Materials on Earth and in Space, German Aerospace Center, Cologne, Germany — [2]Foundry Institute, Fundamentals of Solidification, RWTH Aachen University, Aachen, Germany

Melting plays an important role in many technical processes such as casting, additive manufacturing, etc. but is far less understood than solidification. We report on the kinetics of the solid-liquid interface during contact and solutal melting of Al-Cu melting couples. Al-Cu melting couples consisting of an Al-annulus and a Cu-disc in close contact were processed in an isothermal temperature field. The melting process was in-situ monitored with X-radiography with a sub-second time resolution determining interface kinetics and liquid composition changes. For contact melting a temperature below the melting points of Al and Cu but above the eutectic temperature was chosen. For solutal melting the sample was processed above the melting point of Al. We observed contact melting to be initiated along Cu-grain boundaries with intermetallic layers representing the entire phase diagram forming between the liquid and the still solid Cu. The layer structure has been verified post-mortem by optical imaging and quantified by SEM-EDX. Solutal melting was found to be dependent on sample thickness with buoyancy convection increasing the reaction speed in thicker samples. Further, asymmetric reaction patterns were observed to arise due to Al2O3-layer build-up and/or initial Al2O3-presence at the Al-Cu interface and/or partial Al-detachment during melting.

MM 21.10 Wed 12:45 SCH/A215

Forming bicontinuous microstructures by distributed internal melting at the Ni3Sn4 peritectic — •Zhongyang Li[1], Lukas Lührs[1], and Jörg Weissmüller[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg — [2]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany

A recent study on peritectic melting of TiAg suggests that a bicontinuous structure can be obtained through liquid film migration (LFM) during annealing. Without the requirement of mass exchange with the environment, peritectic melting is free of the restrictions on sample size. To date, application of this method is limited to TiAg. In this work, the intermetallic compound Ni3Sn4 is selected as the new parent system for peritectic melting. After annealing and quenching, spherical clusters are obtained, consisting of crystallographically aligned Ni3Sn2 ligaments and interpenetrating Sn phase. The phase decomposition proceeds via the LFM mechanism, i.e. complete melting of Ni3Sn4 and growth of Ni3Sn2 across the melt layer. Constitutional supercooling, induced by a composition gradient within the melt, promotes cellular growth of Ni3Sn2 nuclei, resulting in a ligament structure. Based on previous studies on peritectic and partial melting, we propose the concept of distributed internal melting, which utilizes the internal pre-melting sites (vacancies, dislocations and grain boundaries) to initiate LFM and generates bicontinuous structures through heat treatment.

Hashing It Out: Overcoming the Duplicate Structure Filtering Bottleneck for Large Data Sets — •Julian Holland, Juan Manuel Lombardi, Chiara Panosetti, and Karsten Reuter — Fritz Haber Institute, Berlin, Germany

With the increasingly data-rich landscape of computational chemistry research, new bottlenecks to material property elucidation have emerged stemming from data processing. Duplicate detection is often an essential data processing step for active learning, global optimization, and general PES exploration algorithms to ensure efficiency and functionality. Such duplication checks typically scale unfavorably with the number of structures, potentially taking longer to perform than the data generation. Hashing-based methods, which have decoupled scaling with dataset size, circumvent this but are conventionally too rigid to reliably find duplicates. In this talk, we present a democratic hashing duplicate detection algorithm that is flexible enough to detect duplicate structures with arbitrarily similar, but distinct, global descriptors nearly instantly. The uniqueness of the structure can be determined by an ensemble of hash functions associated with a set of randomly perturbed global descriptors. We compare the performance of our duplicate detection algorithm against conventional distance-matrix-based methods and introduce a standardized suite of duplicate detection benchmarks. Our algorithm is not only faster but often significantly more robust at detecting known duplicates.

MM 22.2 Wed 10:30 SCH/A216

MC3D: The Materials Cloud FAIR and full-provenance materials database — •Michail Minotakis — PSI Center for Scientific Computing, Theory and Data, 5232 Villigen PSI, Switzerland

Carefully curated databases of materials and their properties have become invaluable resources for a range of applications, from property prediction using machine learning techniques to materials discovery. Here, we introduce MC3D, the Materials Cloud three-dimensional database, in which more than 95% of the available materials are, to date, classified as experimentally known. This database is derived from structures sourced from three major databases: the Pauling File, the Inorganic Crystal Structure Database, and the Crystallography Open Database. After careful curation, the final collection of 72,609 unique stoichiometric compounds is refined using density-functional theory calculations at the PBEsol level, executed in Quantum ESPRESSO and leveraging the SIRIUS library for optimized GPU performance. The AiiDA materials informatics infrastructure (http://aiida.net) manages each workflow stage, ensuring full traceability and preserving simulation provenance. The results are freely accessible in the MC3D section of Materials Cloud (https://mc3d.materialscloud.org) and are already being used as a starting point for materials discovery projects, such as novel thermoelectrics, electrides, superconductors, or materials displaying a large nonlinear Hall effect.

MM 22.3 Wed 10:45 SCH/A216

Building a FAIR Community around Parsing — •Nathan Daelman[1], Alvin N. Ladines[1], Esma Boydas[1], Martin Kuban[1], Bernadette Mohr[1], Sascha Klawohn[1], Rubel Mozumber[1], Christina Ertural[2], Silvana Botti[3], Joseph F. Rudzinski[1], Lauri Himanen[1], and FAIRmat Team[1] — [1]Inst. für Physik, Humboldt-Universität zu Berlin — [2]Department of Materials Chemistry, Federal Institute for Materials Research and Testing, Berlin — [3]RC-FEMS and Faculty of Physics, Ruhr University Bochum

NOMAD [nomad-lab.eu][1, 2] is an open-source data infrastructure for materials science data. One of its most praised features is how NOMAD allows for direct ingestion of various software output formats. This gives data producers access with minimal effort to the whole toolkit infrastructure system regardless of their choice of simulation code. As the NOMAD community extends into related scientific disciplines, parsing procedures should grow alongside and empower casual users to contribute too. To this end, I will be presenting two new parsing frameworks: (i) Mapping Annotation which connects code-specific formats to the NOMAD interoperable schema, while gracefully handling syntatic concerns; (ii) an agentic LLM interface for hooking up third-party parsers via the

Model Context Protocol (MCP). Finally, I will highlight how both approaches fit into NOMAD Plugins and NOMAD Actions.

Uncertainty Propagation in Machine-learned Interatomic Potentials — •Haitham Gaafer, Jan Janssen, and Jörg Neugebauer — Computational Materials Design, Max-Planck-Institute for Sustainable Materials, Düsseldorf

Accurate multiscale materials modeling requires that uncertainties be quantified and propagated consistently from the electronic-structure level to macroscopic property predictions. Machine-learned interatomic potentials (MLIPs), trained on density-functional theory (DFT) reference data, now routinely reach near-DFT accuracy at dramatically reduced computational cost. Yet the connection between fitting errors in an MLIP and uncertainties in derived physical properties, such as bulk moduli or phase stabilities, remains insufficiently understood. We present a data-driven pyiron workflow designed to analyze how uncertainties originating in MLIP training propagate into thermomechanical property predictions. As a case study, we construct diverse DFT training sets for Cu, Ag, and Au using the Automated Small SYmmetric Structure Training (ASSYST) workflow, and fit computationally efficient atomic cluster expansion (ACE) potentials employing a minimal basis optimized to reach a target root-mean-square error. These potentials are subsequently used to determine equations of state and to quantify uncertainties in key properties, including the equilibrium lattice constant, bulk modulus, and its pressure derivative. Our results provide a transparent link between MLIP fitting quality and property reliability, offering a systematic route for uncertainty-aware atomistic modeling.

MM 22.5 Wed 11:15 SCH/A216

Accurately predicting thermal conductivity using non-equilibrium molecular dynamics simulations and machine-learned force fields — •Florian Unterkofler[1], Lukas Legenstein[1], Sandro Wieser[2], and Egbert Zojer[1] — [1]Graz University of Technology, Austria — [2]TU Wien, Austria

With the rise of machine-learned interatomic potentials, simulations have become an even more crucial tool for predicting material properties. We previously achieved accurate predictions of experimentally observed thermal conductivity of acenes, using system-specific, machine-learned Moment Tensor Potentials (MTPs) within a lattice dynamics approach.[1] To obtain a complementary real-space perspective, we now investigate whether comparable accuracy can be achieved using non-equilibrium molecular dynamics (NEMD).

Here, we present the workflow required to obtain accurate and reliable predictions when applying MTPs in NEMD simulations. We show that, due to the inherently stochastic nature of both MD and MTP training, a thorough statistical analysis of multiple simulations with different initial conditions and different realizations of the MTP is necessary. Furthermore, we highlight the importance of selecting appropriate training data to generate robust MTPs. When these considerations are taken into account, we achieve an excellent agreement between experiments, lattice-dynamics, and NEMD results, with NEMD simulations providing tools to investigate heat-transport bottlenecks in real space.

MM 22.6 Wed 11:45 SCH/A216

Data-efficient training of interatomic potentials using finite-temperature DFT structures — •Martin Schlipf[1], Sudarshan Vijay[1,2], and Georg Kresse[1,3] — [1]VASP Software GmbH, Berggasse 21/14, 1090 Vienna, Austria — [2]Department of Chemical Engineering, Indian Institute of Technology Bombay, Powai, Mumbai, Maharashtra 400076 India — [3]Faculty of Physics and Center for Computational Materials Science, University of Vienna, Kolingasse 14-16, A-1090 Vienna, Austria

We successfully generated a database of 150,000 unique finite-temperature structures using VASP and a "one-shot" DFT method to systematically sample atomic environments across the periodic table. Despite the small size of our training set compared to the millions typically used for foundation models, our resulting interatomic potentials achieve a force prediction error of 72 meV/Å. This performance is of the same magnitude as current state-of-the-art foundation models when tested against the same high-quality dataset. This result demonstrates that focusing on data quality and chemical diversity at finite temperatures is as impactful as massive data quantity. Furthermore, we showcase the computational infrastructure that made it possible to integrate interatomic potentials into an ab-initio software and discuss necessary enhancements to electronic optimization methods to compute magnetic materials more reliably.

MM 22.7 Wed 12:00 SCH/A216

MACE-based Machine Learning Interatomic Potentials for Iron-Nickel Alloys: Validation Across Composition and Pressure Ranges — •Kushal Ramakrishna[1], Mani Lokamani[1], and Attila Cangi[1,2] — [1]Helmholtz-Zentrum Dresden-Rossendorf (HZDR), D-01328 Dresden, Germany — [2]Center for Advanced Systems Understanding (CASUS), D-02826 Görlitz, Germany

Machine-learned interatomic potentials have emerged as powerful tools bridging quantum-level accuracy with mesoscale simulations in computational materials science. We present a comprehensive evaluation of MACE models for iron-nickel alloys across a wide range of compositions and pressures, with direct relevance to Earth's core modeling and industrial applications. We construct special quasirandom structures (SQS) to simulate random iron-nickel alloy configurations and train MACE models on density functional theory datasets combined with experimental validation data. Extensive short-range order analysis confirms improved chemical randomness for larger supercells, critical for faithful property sampling. Multiple MACE flavors are systematically compared against experimental measurements for structural and elastic properties in both body-centered cubic and face-centered cubic phases. Our results demonstrate that fine-tuned MACE models achieve remarkable predictive accuracy for equation-of-state behavior and elastic properties across all compositions. This approach successfully bridges computational predictions with experimental observations, enabling accelerated materials discovery for technologically relevant transition metal alloys.

MM 22.8 Wed 12:15 SCH/A216

Benchmarking the MACE Foundation Model for Solid-State Ion Conductors — •Takeru Miyagawa, Yufeng Xu, Levon Satzger, Waldemar Kaiser, and David A. Egger — Physics Department, TUM School of Natural Sciences, Technical University of Munich, 85748 Garching, Germany

Recent progress in foundation model machine learning potentials (MLPs) has demonstrated promising transferability and accuracy across diverse material classes [1, 2]. Instead of being trained from scratch for each new system, these large pretrained models aim to provide broadly accurate force and energy predictions that can be refined for new chemistries with comparatively small datasets. This offers a complementary route to traditional system-specific MLPs and may reduce the cost of studying complex ionic materials.

Here, we benchmark the MACE foundation model [2] on representative solid-state ion conductors (SSICs) through direct comparison with first-principles calculations. We assess its accuracy for phonons and vibrational properties, characterize temperature-driven structural and phase transitions, and analyze ion transport across different phases. We then explore data-efficient DFT-based fine-tuning strategies to improve the foundation model's accuracy for SSICs and clarify the limits and strengths of pretrained representations in the context of ionic transport. MACE-μ-α: A Foundation Model for Molecular Dipole Moments and Polarizabilities — •Nils Gönnheimer[1,2], Venkat Kapil[3], Karsten Reuter[2], and Johannes T. Margraf[1,2] — [1]Universität Bayreuth — [2]Fritz-Haber-Institut der MPG — [3]University College London

Machine-learning interatomic potentials (MLIPs) have had a strong impact on computational chemistry, physics, and materials science in recent years by filling the accuracy gap between first-principles methods and classical force fields, at a fraction of the computational cost of the former. MLIPs are so far typically limited to predicting energies and forces, however, while other properties traditionally obtained from first-principles calculations have remained less accessible. Here, equivariant neural network architectures have led to enormous progress, as they allow the prediction of vectorial and tensorial properties on the same footing as energies and forces.

Here, we present the MACE-μ-α architecture for predicting dielectric properties based on the MACE MLIP framework. Trained on over 1.6 million organic systems, the corresponding foundation model allows the accurate prediction of molecular dipole moments and polarizabilities, as well as Raman and IR spectra (when combined with an MLIP). Notably, despite being trained on gas-phase molecules and clusters, the model also shows transferability to condensed systems such as molecular crystals.

MM 23: Topical Session: Dislocations in Functional Materials I (joint session MM/FM)

Mechanical seeding of dislocations for room-temperature plasticity in ceramics — •Wenjun Lu[1], Jiawen Zhang[1], and Xufei Fang[2] — [1]Department of Mechanical and Energy Engineering, Southern University of Science and Technology, Shenzhen, 518055, China — [2]Institute for Applied Materials, Karlsruhe Institute of Technology, Karlsruhe,76131, Germany

The pursuit of room-temperature ductile ceramics has long been hindered by their inherent brittleness. Here, we demonstrate a simple strategy to seed mobile dislocations at room temperature with densities up to 1014 m-2, enabling ceramics to sustain plastic compressive strains exceeding 30%. These dislocations multiply through cross-slip and motion, effectively suppressing brittle fracture without high-temperature processing. Using in situ nano-/micromechanical deformation and ex situ bulk tests, we bridge the length scales of plasticity and reveal a strong dependence of yield strength and flow behavior on dislocation density. Specifically, SrTiO3 micropillars transition from brittle fracture (dislocation-free) to plastic yield when mechanically seeded dislocations are present. Yield strength first decreases then rises with increasing dislocation density, reflecting complex structural evolution observed via transmission electron microscopy. These findings highlight dislocation engineering as a viable pathway toward ductile ceramics and open avenues for tuning their mechanical and functional properties through room-temperature dislocation plasticity.

Contribution: Wenjun Lu is the Speaker.

MM 23.2 Wed 10:30 SCH/A251

Impact of mechanically seeded dislocations on the mechanical properties of perovskite ceramics — •Jiawen Zhang[1], Xufei Fang[2], and Wenjun Lu[1] — [1]Southern University of Science and Technology, Shenzhen, China — [2]Karlsruhe Institute of Technology, Karlsruhe, Germany

The inherent brittleness of functional ceramics severely hinders their engineering application. The strong ionic and covalent bonds in ceramics make dislocation nucleation, motion, and multiplication difficult at room temperature. Recent research challenges the conventional perception of ceramics as inherently brittle materials, with dislocations emerging as a promising avenue for enhancing their mechanical properties. By using a Brinell ball indenter to perform surface scratching, crack-free plastic deformation zones with tunable dislocation density can be generated on the ceramic surface. The dislocation generation mechanism and dislocation-dominated plastic deformation mechanism were investigated by introducing dislocations into perovskite SrTiO3 and KTaO3. Room temperature micropillar compression tests then revealed that as the mechanical seeded dislocation density increased,SrTiO3 exhibited a *brittle* to *ductile* transition as the dislocation density increased from ~1010 m-2 to ~1014 m-2. However, the (001) KTaO3 single crystal exhibits a *brittle* to *ductile* then to *brittle* transition as the dislocation density increased from ~1010 m-2 to ~1015 m-2. Additionally, the yield strength displayed a complex trend, initially decreasing and then increasing in these two perovskite oxide ceramics.

MM 23.3 Wed 10:45 SCH/A251

Dislocation interaction with a tilt low angle grain boundary in bi-crystal SrTiO3 — •Kuan Ding[1,2], Atsutomo Nakamura[3], Patrick Cordier[4,5], and Xufei Fang[3,6] — [1]Department of Materials and Earth Sciences, Technical University of Darmstadt, 64287 Darmstadt, Germany — [2]Max Planck Institute for Sustainable Materials, Max-Planck-Straße 1, 40237 Düsseldorf, Germany — [3]Department of Mechanical Science and Bioengineering, Osaka University, 1-3 Machikaneyama-chou, Toyonaka, Osaka, 560-8531, Japan — [4]Unité Matériaux et Transformations, Université de Lille, 59655 Villeneuve d'Ascq Cedex, France — [5]Institut universitaire de France (IUF), 75005 Paris, France — [6]Institute for Applied Materials, Karlsruhe Institute of Technology, Kaiserstr. 12, 76131 Karlsruhe, Germany

For applications of ceramics with dislocation-tuned mechanical and functional properties, it is pertinent to achieve dislocation engineering in polycrystalline ceramics. However, grain boundaries (GBs) are effective barriers for dislocation glide at room temperature. It is critical to understand the fundamental processes for dislocation-GB interaction. We investigated a bi-crystal SrTiO3 with a 4° tilt GB. Brinell indentation was used to generate a plastic zone at the mesoscale without cracking, allowing for direct assessment of GB-dislocation interaction. Together with dislocation etch pits imaging and transmission electron microscopy analysis, we observe dislocation pileup, storage, and transmission across the LAGB. Our observations reveal new insights into dislocation-GB interaction at room temperature at mesoscale.

MM 23.4 Wed 11:00 SCH/A251

Dislocation-Mediated Extraordinary Room-Temperature Plasticity in Inorganic Semiconductors — •Xiaocui Li[1] and Yang Lu[2] — [1]Department of Materials Science and Engineering, City University of Hong Kong, Kowloon, Hong Kong SAR, China — [2]Department of Mechanical Engineering, The University of Hong Kong, Pokfulam, Hong Kong SAR, China

Inorganic semiconductors, with their ionic or covalent bonds, are typically brittle at room temperature, restricting their use in flexible electronics. Our recent study reveals that all-inorganic perovskite (CsPbX3, X=Cl, Br, I) single-crystal micropillars can achieve extraordinary room-temperature plasticity with average plastic strain of ~64% (Nat. Mater. 2023, 22, 1175). They can be morphed into distinct geometries without cracks or cleavage. The deformation is mediated by partial dislocations on {011}<0-11> slip system, featuring four equivalent variants that address the lack of deformation pathways in ionic crystals. Sequential activation of variants prevents strain hardening and crack formation caused by dislocation reactions. First-principles calculations attribute this plasticity to low slip barriers enabling sustained deformability and strong Pb-X bonds preserving crystal integrity. Leveraging this deformability, we developed shape-customizable optoelectronic devices that maintain stable functional properties and bandgap energies post-deformation. This discovery overturns the notion of brittleness in inorganic semiconductors, and provides a foundation for advanced applications in flexible electronics and deformable sensors.

MM 23.5 Wed 11:15 SCH/A251

Dislocations as Key Enablers on the Road to Functional and Resilient Oxide Ceramics — •Oliver Preuss[1], Enrico Bruder[2], Zhangtao Li[3], Yinan Cui[3], Jinxue Ding[1], Philippe Carrez[4], and Xufei Fang[1] — [1]Institute for Applied Materials, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Division Physical Metallurgy, Department of Materials and Earth Sciences, Technical University of Darmstadt, Darmstadt, Germany — [3]Department of Engineering Mechanics, Tsinghua University, PR China — [4]Materials and Transformations Unit, Université Lille, Lille, France

Designing oxide ceramics that unite high mechanical resilience with strong functional performance is challenging. We show that introducing ultra-high dislocation densities ($\approx 10^{15}$ m^{-2}) into materials such as MgO and $SrTiO_3$ provides a direct route to enhance both damage tolerance and functional properties. Cyclic Brinell ball scratching at room temperature generates near-surface, dislocation-rich zones of arbitrary size and shape. These regions markedly alter fracture behaviour, arresting propagating cracks and suppressing crack initiation, as demonstrated by Vickers indentation and quasi-in situ DCDC tests. Crystal-plasticity phase-field simulations reproduce the observed toughening mechanism. The dislocation networks also improve transport properties, increasing electrical conductivity while reducing thermal conductivity by nearly half: an advantageous combination for thermoelectric performance. This work establishes a practical strategy for dislocation engineering to achieve oxide ceramics with combined mechanical robustness and enhanced functionality.

MM 24: Invited Talk: Andrea Bachmaier

Time: Wednesday 15:00–15:30 Location: SCH/A251

Invited Talk MM 24.1 Wed 15:00 SCH/A251

Recent advances in processing of rare-earth free MnBi magnets by severe plastic deformation — •Andrea Bachmaier[1], Lukas Weissitsch-Reiner[1], Martin Kraus[1], Michael Meindlhumer[2], and Stefan Wurster[1] — [1]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences — [2]Department of Materials Science, Montanuniversität Leoben

Magnetic materials are key materials needed for Green energy technologies. The research on rare-earth free magnetic materials has increased significantly in recent years, driven by supply chain issues, environmental and social concerns.

Severe plastic deformation processing of magnetic materials and its influence on the magnetic properties have attracted increasing research interest in the last years.

In this contribution, the use of high-pressure torsion deformation to synthesize the rare-earth free α-MnBi phase is in focus. Our recent experimental results of the process-structure-property relationships that link chemistry, synthesis and processing parameters with microstructure evolution and magnetic properties are discussed. An emphasis is put on detailed characterization of the microstructure by backscattered electron imaging, electron backscattered diffraction as well as x-ray diffraction utilizing high energy synchrotron radiation since it strongly influences the magnetic properties.

MM 25: Interface Controlled Properties, Nanomaterials, and Microstructure Design I

Time: Wednesday 15:45–17:00 Location: SCH/A215

MM 25.1 Wed 15:45 SCH/A215

Confined but Active: Atomic-Scale Dynamics of Gallium and Silver Intercalation in Graphene/SiC — •Nadire Nayir[1], Qian Mao[2], Malgorzota Kowalik[2], and Adri van Duin[2] — [1]Paul-Drude-Institut für Festkörperelektronik, Leibniz Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, 10117 Berlin, Germany — [2]The Department of Mechanical Engineering, The Pennsylvania State University, PA, US

Metal intercalation at the interface of epitaxial graphene and SiC offers a powerful approach for stabilizing covalently bonded materials in two dimensional form [1-2]. This talk focuses on the atomic-level modeling of 2D metals (i.e. Ga and Ag) grown via confinement heteroepitaxy [2]. The intercalation mechanisms differ notably between metals. Combined photoemission electron microscopy and multiphysics simulatiosn reveal that while metal de-intercalation emerge in all cases, their re-intercalation dynamics vary markedly. For Ag, reversible de- and re-intercalation occurs through defects. In contrast, Ga exhibits irreversible de-intercalation characterized by faster kinetics. Multiphysics simulations integrating ReaxFF and Density functional theory simulations uncover the origin of these distinct behaviors, showing that Ga atoms bind more strongly to graphene than Ag atoms consistent with the faster, irreversible diffusion kinetics observed experimentally. Overall, the findings highlight that both the thermophysical properties of the intercalated metal and its interactions with defective graphene critically determine the intercalation behavior. [1] Nature materials 19 (6), 637-643(2020) [2] Small 20 (11), 2306554(2024)

MM 25.2 Wed 16:00 SCH/A215

Accelerating grain boundary segregation studies in ferritic steels with machine learned interatomic potentials — •Han Lin Mai[1], Tilmann Hickel[2], and Jörg Neugebauer[1] — [1]Max Planck Institute for Sustainable Materials GmbH, Dusseldorf, Germany — [2]BAM Federal Institute for Materials Research and Testing, Berlin, Germany

The segregation of solute and impurities to grain boundaries (GBs) can critically alter the mechanical properties of steels. To predict segregation phenomena, ab-initio methods such as density functional theory (DFT) are frequently used, but their computational expense limits the size of the model GBs viable for computation. This limitation has rendered access to segregation statistics out of reach and therefore has hindered our understanding of segregation phenomena. Here, we present a machine learned interatomic potential (MLIP) for multiple Fe-X binary alloys that predict segregation energies approaching ab-initio accuracy with automated dataset generation techniques. We use these potentials to conduct high-throughput segregation studies to generate segregation energy spectra and compare these to those commonly found in GBs accessible to DFT studies. Commonly purported relationships between GB quantities such as excess volume, site volume and GB energies and the strength of segregation binding of solutes and impurities are re-examined and revised.

MM 25.3 Wed 16:15 SCH/A215

Defect Phase Diagrams for Exploring Chemo-Structural Coupling in Ni Grain Boundaries — •Prince Mathews[1], Ali Tehranchi[1], Jörg Neugebauer[2], and Tilmann Hickel[1,2] — [1]Federal Institute for Materials Research and Testing (BAM), Berlin, Germany — [2]Max Planck Institute for Sustainable Materials, Düsseldorf, Germany

The knowledge-driven framework of defect phase diagrams (DPDs) offers an effective and systematic approach to design materials with tailored properties. Unifying bulk and defect thermodynamics along with the consideration of structural and chemical complexities around defects, DPDs advance the fundamental understanding of defects and can also provide a pathway for guided microstructure design. In this work, we apply the framework of DPDs using ab-initio calculations to evaluate the stability of defect phases and investigate defect phase transformations in Ni grain boundaries. In competition with the nearest intermetallic phase, Nb containing defect phases are stable in Σ5 [001]/(310) whereas Nb containing defect phases are not stable in Σ3 [110]/(111) grain boundaries. Moreover, our findings indicate the preference of solutes to segregate at sites around defects with partial column occupations. Furthermore, with the application of a sub-lattice based model, we present the insights on grain boundary site column coverages as a function of temperature. In addition, we discuss a new approach for determining a characteristic defect width using the solute distribution probability across the defect which facilitates the integration of defects into the CALPHAD methodology.

MM 25.4 Wed 16:30 SCH/A215

Non-Hermitian physics and exceptional points at Z2 Weyl semimetal*ferromagnet junctions — •Tong Wang[1], Robert Amelung[2], and Flore Kunst[1,2] — [1]Max Planck Institute for the Science of Light, Staudtstraße 2, 91058 Erlangen, Germany — [2]Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Non-Hermitian systems extend beyond the framework of Hermitian quantum mechanics and allow for the description of open systems with loss and gain. The study of non-Hermitian physics leads to an enrichment of topological phases of matter and practical applications in photonics and sensing. Here we study the junction between a metallic ferromagnet and a Z2 Weyl semimetal [1], where a combined time-reversal symmetry and reflection symmetry leads to degenerate helical Fermi arcs on certain surfaces. The couplings at the material interface give arise to a complex self-energy in the Green's function [2], rendering the effective Hamiltonian of the Fermi arc surface states non-Hermitian. We show that non-Hermiticity can break a degenerate Fermi arc into pairs of exceptional point, and the resulting exceptional phase persists for a wide parameter range regarding the magnetization of the ferromagnet and topological mass term of the semimetal. We also discuss the how the exceptional points may influence physical properties of the Z2 Weyl semimetal. [1] T. Morimoto and A. Furusaki, Phys. Rev. B 89 235127 (2014). [2] E. J. Bergholtz and J. C. Budich, Phys. Rev. Res 1 012003(R) (2019).

MM 25.5 Wed 16:45 SCH/A215

Theory Unravels Electro-Ionic Metal-Support Interactions at Supported Electrocatalyst Nanoparticles — •Yufan Zhang, Tobias Binninger, Jun Huang, and Michael Eikerling — Theory and Computation of Energy Materials, Institute of Energy Technologies, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany

Electrochemical energy conversion requires electrocatalysts to accelerate reactions. Most theoretical studies used idealized planar electrodes, whereas real catalysts typically consist of supported nanoparticles (NPs) with heterogeneous compositions and structures that lead to unique electronic and ionic properties.

In this talk, I will present results from our recently published paper [1]. Using density-potential functional theory, we calculate the contact electrification of a Ag NP and a Au support. While traditional view believes that electron redistribution is confined to the NP-support contact interface, we reveal that it also occurs at the NP's external surface, directly influencing the catalytically active sites. The electron redistribution generates an electric field in electrolyte surrounding the supported NP, which further leads to ion separation. The support-induced charge perturbations at the NP's external surface can be no longer described by the classical concept of the potential of zero charge for planar electrode. To address this, we define a global and two local characteristic potentials. It is demonstrated that the electronic and ionic effects are strongly coupled at supported NPs, and are therefore best described as electro-ionic metal-support interactions (EIMSI).

Theoretical investigation of the conductivity of the $LiMnPO_4$ Battery Material — •Franz Winkler and Harald Oberhofer — Chair for Theoretical Physics VII and Bavarian Center for Battery Technologies, University of Bayreuth

Developing better batteries and thus battery materials is a crucial step in humanity's urgent energy transition. Thereby, theory can play an important role in characterizing and understanding the properties of the involved materials. In this contribution we present our work on olivine $LiMnPO_4$ which exhibits some desirable properties such as a high energy density and a high potential and thus operating voltage. However, its adoption is hampered by a bad conductivity. In order to understand the barriers to conductivity and suggest potential remedies we compute electronic and ionic transport properties and how they could be influenced by defects.

The electron and hole band transport mobilities are calculated using Hubbard-corrected electronic density functional theory (DFT+U), both for antiferromagnetic and paramagnetic $LiMnPO_4$ as well as materials derived by substitution. For ionic conductivity we determine the minimal energy path of the Li ions via

the nudged elastic band (NEB) method. To reduce calculational cost and enable larger systems, we use machine learned force fields and refine these models via DFT to transition states. Li ions are transported in $LiMnPO_4$'s 1D channels. However these diffusion paths can be blocked by antisite defects. As those very strongly limit ionic transport we investigate their stability with first-principle DFT, phonon and thermodynamics calculations.

MM 26.2 Wed 16:00 SCH/A216

Multiscale modeling of cooperative defect dynamics in MoS_2 — •Aaron Flötotto[1,2], Erich Runge[1,2], and Christian Dressler[1,2] — [1]Technische Universität Ilmenau, Institut für Physik, Ilmenau, Germany — [2]Technische Universität Ilmenau, Institut für Mikro- und Nanotechnologien, Ilmenau, Germany

Chalcogen vacancies strongly influence the electrical and memristive properties of transition metal dichalcogenides including MoS_2. However, capturing their dynamics at device-relevant time and length scales is challenging due to the high energy barriers associated with individual atomic jumps [1]. We have developed a multiscale framework for MoS_2 that uses *ab-initio* molecular dynamics to generate training data for machine-learning force fields. This step reveals the motifs of cooperative sulfur-vacancy migration and cluster formation [2]: (i) Vacancy migration almost exclusively occurs by vacancy-assisted hopping, implying nonlinearities and suggesting memristive behavior; (ii) An energy barrier comparable to lab temperatures protects long vacancy lines against splitting into smaller vacancy clusters.

These insights are incorporated into a Monte-Carlo model that reproduces several key experimental observations and enables the prediction of device level quantities, such as the vacancy-density-dependence of the diffusion coefficient of sulfur vacancies in MoS_2.

Coupled Spin–Orbital–Lattice Interactions in FeO: A DFT+U and Heisenberg Analysis — •Hao Chen, Christoph Freysoldt, Mira Todorova, and Jörg Neugebauer — Max-Planck-Institut für Nachhaltige Materialien GmbH, Düsseldorf, Germany

Wüstite (FeO) is a prototypical correlated oxide where spin, orbital, and lattice degrees of freedom are intricately coupled. In addition, significant deviations from stoichiometry can occur via oxygen vacancies and Fe^{2+}/Fe^{3+} mixed valency. Local lattice distortions and orbital reorientations around such defects can modify magnetic exchange pathways and thus the defect formation energies. Using DFT+U, we investigate how the orbital orientation in Fe^{2+} correlates with structural strain and magnetic interactions. Our results reveal a well-defined correlation between the minority-spin t_{2g} occupation and the rhombohedral distortion parameter, giving rise to four distinct symmetry-broken orbital states. By mapping total-energy differences between these orbital configurations onto an effective Heisenberg model, we show that the exchange constants are sensitive to orbital orientation, evidencing strong superexchange–orbital coupling. This framework provides quantitative insight into the competition between Jahn–Teller-like lattice distortions and anisotropic magnetic exchange arising from orbital orientation. Building on this, the study provides a unified DFT+U-based picture of spin–orbital–lattice coupling in FeO and establishes a consistent energetic framework for incorporating spin and orbital effects into defect calculations.

MM 26.4 Wed 16:30 SCH/A216

Quantum interference in higher pseudospin fermions — •Gargee Sharma and Arpan Gupta — Indian Institute of Technology Delhi, Hauz Khas, New Delhi 110016 India

We construct a unified theory of quantum-interference corrections in disordered pseudospin-s fermions described by $k\cdot\mathbf{S}$ Hamiltonians. Employing the rotation-group structure of SU(2), we derive closed-form wavefunctions, scattering and vertex corrections, and Cooperon kernels valid for arbitrary pseudospin s in two and three dimensions. A universal "parity rule" emerges: integer s (orthogonal symmetry, $T^2 = +1$) yields weak localization, half-integer s (symplectic, $T^2 = -1$) yields weak antilocalization, while interband and intervalley scattering renormalize the prefactor via a finite Cooperon-mass matrix. Explicit results for $s = \frac{1}{2}$ and $s = 1$ reproduce graphene and spin-1 Weyl limits and verify the general scaling laws. Our approach resolves the long-standing ambiguity in interband scattering, providing an analytic route for arbitrary s and concrete predictions for multifold-fermion materials.

MM 26.5 Wed 16:45 SCH/A216

Effects of strong electron-electron interactions on the conductivity of free-standing graphene — •Maksim Ulybyshev[1], Adrien Reingruber[1], and Kitinan Pongsangangan[2] — [1]Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Würzburg, Germany — [2]Department of Physics, Faculty of Science, Mahidol University, Bangkok, Thailand

Transport in strongly correlated systems is often described using the Boltzmann equation, where correlation effects enter through the collision integral. In practice, the collision integral is usually evaluated with a number of approximations, such as computing scattering amplitudes only up to tree-level diagrams. These approximations become unreliable when interactions are sufficiently strong.

Free-standing graphene provides a representative example, as the effective coupling constant of its low-energy effective field theory exceeds unity. Using unbiased Quantum Monte Carlo (QMC) simulations on lattices with up to 102x102 unit cells and long-range Coulomb interactions, we investigate both the DC and optical conductivity of free-standing graphene. We find that the optical conductivity remains essentially unaffected by interactions, whereas the DC conductivity exhibits a strong dependence on both temperature and interaction strength. We then compare these results with kinetic-theory calculations based on the Boltzmann equation, highlighting how the QMC data can guide improvements in the accuracy of the collision integral.

MM 27: Topical Session: Dislocations in Functional Materials II (joint session MM/FM)

Topical Talk MM 27.1 Wed 15:45 SCH/A251

Dislocations in perovskite oxides: similarities and differences — •Pierre Hirel — Univ. Lille, CNRS, INRAE, Centrale Lille, UMR 8207 - UMET - Unité Matériaux et Transformations, F-59000 Lille, France

The experimental discovery of room-temperature ductility in strontium titanate $SrTiO_3$ in 2001, has revealed the surprising mobility of dislocations in ⟨110⟩{110} slip systems. Atomic-scale simulations have contributed to resolving the core structure of these dislocations, and their role in the ductile-brittle transition. Since then, similar ductile behaviour was found in related perovskite oxides $KNbO_3$ and $KTaO_3$. However, other perovskites like $BaTiO_3$ or $CaSiO_3$ remain essentially brittle at room temperature, despite having the same crystal lattice and similar chemical compositions as ductile perovskites.

MM 27.2 Wed 16:15 SCH/A251

Probing the Known Unknown of the Dislocation Dynamics in Oxides and Semiconductors — •Liming Xiong — NC State University, Raleigh, NC, USA

Dislocation dynamics in oxides and semiconductors are widely aware, but its exact nature and impact on the properties and functionality of these materials are not fully understood yet. One reason is that the well-established knowledge for dislocation dynamics in metals often can't fully explain or even fail when used for oxides and semiconductors. To fill this knowledge gap, here we will present a concurrent atomistic-continuum computational tool for probing the dislocation dynamics in oxides and semiconductors. This tool has a unique feature to accommodate the motion/multiplication of μm-long dislocations together with the atomic-scale core structure evolution along the dislocation within all within one single model. Taking dislocation-seeded SrTiO3 and ZnS as sample materials, we will: (i) map the core structure/stress along a dislocation line to its local charge states and motion mechanism; (ii) measure the dislocation mobility and its dependence on stress, temperature, dopant concentration, charge states, electrical field, light illumination, and dislocation line lengths ranging from nanometers to micrometers; (iii) predict how local internal stress builds up when a mesoscale dislocation slip interacts with an atomically structured grain boundaries, and how such a high local stress may initiate a crack in turn. A consolidation of such simulation data into constitutive rules needed by higher-scale models for interpreting experimental observations will be also discussed.

MM 27.3 Wed 16:30 SCH/A251

Electric Field Effects on Dislocation Motion in SrTiO3 via Mesoscale Indentation — •Alexander Frisch[1], Daniel Isaia[2], Oliver Preuss[2], and Xufei Fang[1] — [1]Institute for Applied Materials, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Department of Materials and Earth Sciences, Technical University of Darmstadt, Darmstadt, Germany

Dislocations in perovskite oxides have the potential of tuning functional properties of electroceramics, however their behavior and stability under externally applied electric fields remain elusive. Therefore, we investigated the effect of high densities of dislocations onto the dielectric breakdown behavior of SrTiO3, a model perovskite material. Lower dielectric breakdown strengths were found in the high-dislocation-density samples, engineered through the Brinell scratching method. Further, the effect of a 2 kV/mm electric field on the introduction and mobility of dislocations in SrTiO3 was investigated. While no changes to the

dislocation plastic zone size, depth, or dislocation distribution were observed, the results suggest the stability of pre-engineered dislocation structures in perovskite oxides under applied electric fields. These results will be interpreted in the context of the dislocation charge state, associated electric field forces, and defect-modified electrical/thermal conductivity.

MM 27.4 Wed 16:45 SCH/A251

Generating a "ferroelectric metal" by preferential reduction of dislocations in $BaTiO_3$ — •Christian Rodenbücher[1], Gustav Bihlmayer[2], Carsten Korte[1], and Kristof Szot[3] — [1]Forschungszentrum Jülich GmbH, Institute of Energy Technologies (IET-4), 52425 Jülich, Germany — [2]Forschungszentrum Jülich GmbH, Peter Grünberg Institut (PGI-1), 52425 Jülich, Germany — [3]University of Silesia, Institute of Physics, 41-500 Chorzów, Poland

Redox processes in transition metal oxides are of high relevance for sensors, information technology, superconductivity, and energy conversion. Perovskites with mixed ionic-electronic conductivity, such as $BaTiO_3$, are of particular interest because oxygen nonstoichiometry controls electronic charge carriers and thus conductivity. Surprisingly, thermal reduction in vacuum can induce metallic behaviour with conductivities far exceeding predictions from point-defect chemistry. To clarify the origin of this metallic state, we investigate the electronic transport, electronic structure, and chemical composition of $BaTiO_3$ single crystals during annealing and cooling under ultrahigh vacuum. Surface-sensitive techniques such as XPS and LC-AFM allow us to correlate electronic structure changes with the insulator-to-metal transition. We find that surface-layer dislocations act as preferential reduction sites, forming conducting filaments that yield macroscopic metallic behaviour despite minimal overall oxygen loss. Metallic behaviour persists into the ferroelectric phase. Nanoscale mapping shows that metallic filaments and piezoelectrically active regions coexist thus explaining how a "ferroelectric metal" can exist.

MM 27.5 Wed 17:00 SCH/A251

Dislocation dynamics in Ni-based superalloys: atomistic simulations and uncertainty quantification — •Geraldine Anis, Thomas Hudson, and Peter Brommer — University of Warwick, Coventry CV4 7AL, UK

Ni-based superalloys exhibit extraordinary strength at high temperatures. This strengthening effect is largely attributed to precipitation strengthening, where dislocations are hindered by precipitates present in their microstructure. In our work, we model dislocation trajectories obtained from Molecular Dynamics (MD) simulations of Ni-Ni_3Al. A reduced model was developed to describe dislocation-interface interactions within this system, which captures important features of the MD dislocation trajectories. The developed model was tested on a representative system and was shown to capture a range of qualitatively different dislocation behaviour. The model parameter distributions were then determined using Differential Evolution Monte Carlo (DE-MC) sampling and a Gaussian process surrogate model. The present approach offers a means of identifying atomistic-scale parameters, which can be used to inform larger length scale simulations of dislocations. Determining parameter distributions using DE-MC means that parameter uncertainties can be propagated through a hierarchy of multiscale models. We illustrate how such uncertainty propagation can be achieved by considering a dislocation mobility law with quantified uncertainties in pure Ni. This work is part of a wider study aiming to model the deformation behaviour of Ni-based superalloys with a focus on quantifying and propagating uncertainties.

MM 28: Members' Assembly

Welcome to this general meeting of the DPG-SKM division MM! All of you, presenters of MM talks or posters and other interested participants of this conference, are cordially invited to this meeting. We will come together in a relaxed atmosphere, supported by drinks and pretzels (at least) for personal exchange. We will award the poster prizes, discuss the current conference, and ask for your suggestions for future Topical Sessions in MM, Symposia, and invited speakers. Take this opportunity to share your ideas regarding our MM program for our next DPG spring meeting.

Time: Wednesday 17:15–18:45 Location: SCH/A251

All members of the Metal and Material Physics Division are invited to participate.

MM 29: Invited Talk: Philipp Pelz

Time: Thursday 9:30–10:00 Location: SCH/A251

Invited Talk MM 29.1 Thu 9:30 SCH/A251

Three dimensional sub-Ångström resolution imaging from 4D-STEM experiments — •Philipp Pelz — Friedrich Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

Electron ptychography is rapidly emerging as a way to turn scattered high-energy electron waves into precise three-dimensional atomic maps, effectively solving a challenging inverse problem that links measurement, modeling, and reconstruction. By combining multi-slice physics, joint optimization, and automated data collection, we can now recover sub-Ångström 3D structures even when the experiment violates classical limits in electron microscopy such as depth of focus and tomographic completeness. These methods dramatically expand the range of materials and volumes that can be imaged at true atomic resolution, opening the door to data that is richer, more robust, and more compatible with theory and simulation. I will present several results that bridge experiment and computational modeling through a unified, physics-based reconstruction framework, show applications to nanomaterials and outline our ambitions to scale the method to larger volumes.

MM 30: Interface Controlled Properties, Nanomaterials, and Microstructure Design II

MM 30.1 Thu 10:15 SCH/A215

Statistics of Shear-Coupled Grain Growth in Polycrystals — •Marco Salvalaglio[1], Caihao Qiu[2], Jian Han[2], and David J. Srolovitz[3] — [1]Institute of Scientific Computing, TU Dresden, 01062 Dresden, Germany — [2]Department of Materials Science and Engineering, City University of Hong Kong, Hong Kong SAR — [3]Department of Mechanical Engineering, The University of Hong Kong, Pokfulam, Hong Kong SAR

Grain growth in polycrystals, the coarsening of crystalline domains with different orientations, is traditionally viewed as a capillarity-driven process governed by interfacial energy minimization. However, grain-boundary migration can also induce, and in turn couple to, shear deformation, making microstructure evolution sensitive to externally applied stress. At the microscopic level, this behavior arises from the motion of disconnections, steps with dislocation character constrained at grain boundaries. Using a multi-phase-field (PF) framework that incorporates disconnection flow through coarse-graining, we demonstrate that accounting for shear coupling enables realistic grain-growth behavior in single-component polycrystals. Simulations reproduce recent experimental observations of weak correlations between grain boundary velocity and curvature. We then use PF simulations to analyze key aspects of microstructure evolution, including grain-size distributions, grain-shape evolution, and statistical characterization of the evolving network.

MM 30.2 Thu 10:30 SCH/A215

Revealing nanovoids in growth-resistant regions of nanocrystalline Pd–Au using atom probe tomography — •Johannes Wild[1], Fabian Andorfer[4], Svetlana Korneychuk[2,3], Jules M. Dake[4], Dorothée Vinga Szabó[1,2,3], Stefan Wagner[1], Carl E. Krill III[4], and Astrid Pundt[1,2] — [1]Institute for Applied Materials, Karlsruhe Institute of Technology — [2]Institute of Nan-

otechnology, Karlsruhe Institute of Technology — [3]Karlsruhe Nano Micro Facility (KNMFi), Karlsruhe Institute of Technology — [4]Institute of Functional Nanosystems, University of Ulm

Nanocrystalline Pd–Au produced by inert gas condensation (IGC) shows extreme abnormal grain growth (AGG) upon heat treatment. In some cases, narrow regions of residual nanocrystalline material resist coarsening entirely, persisting between abnormally grown grains exceeding 100 μm. We investigate these growth-stagnant regions using site-specific SEM/FIB lift-outs, atom probe tomography (APT) and TEM. FIB cross-sections reveal that these nanocrystalline regions are significantly more porous than the surrounding matrix, and APT reconstructions from them exhibit a strongly elevated density of OH-containing clusters, which are largely absent elsewhere. By analysing local ion-density variations during field evaporation into voids, we show that these OH clusters correspond to nanovoids in the material. Correlating porosity with grain morphology, we find that the most porous regions exhibit the strongest resistance to grain growth, indicating that nanoscale porosity is a key factor in stabilizing the nanocrystalline grain structure in IGC Pd–Au (manuscript submitted).

MM 30.3 Thu 10:45 SCH/A215

Vacancy-mediated extreme abnormal grain growth in inert gas-condensed nanocrystalline Pd–Au: when what's missing runs the show! — Fabian Andorfer[1], Johannes Wild[2], Jürgen Markmann[3,4], Markus Ziehmer[1], Jules M. Dake[1], Torben Boll[2], Dorothée Vinga Szabó[2,5,6], Stefan Wagner[2], Astrid Pundt[2,5], and •Carl E. Krill III[1] — [1]Inst. of Functional Nanosystems, Ulm University — [2]Inst. for Applied Materials, KIT — [3]Inst. of Hydrogen Technology, Helmholtz-Zentrum Hereon — [4]Inst. of Materials Physics and Technology, TUHH — [5]Inst. of Nanotechnology, KIT — [6]Karlsruhe Nano Micro Facility (KNMFi), KIT.

Inert gas-condensed Pd–Au exhibits extreme abnormal grain growth (AGG), marked by a small number of grains growing dendritically through a matrix of nanocrystallites, eventually reaching sizes of 100 μm or more. The triggers for rapid growth of abnormal grains (emergence) and for maintaining this growth advantage (persistence) remain unclear. Annealing under hydrogen accelerates emergence without altering grain morphology, suggesting that the ~ 5 vol% porosity inherent to inert gas condensation not only pins matrix/matrix grain boundaries (GBs) but also governs where and when abnormal grains emerge. In nano-Pd–Au, pores can coarsen by vacancy diffusion along GBs, with larger pores growing at the expense of smaller ones. Small-angle x-ray scattering measurements support such an evolution in pore-size distribution. Vacancy transport, rather than variations in boundary mobility, appears to establish the spatiotemporal conditions for AGG in this system.

MM 30.4 Thu 11:00 SCH/A215

Small-angle x-ray scattering of nanoporous gold - a discussion of the structure factor and its implications for local order — •Celina Passig[1,2], Jürgen Markmann[2,1], and Jörg Weissmüller[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, Germany — [2]Department Hybrid Materials Systems, Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, Geesthacht, Germany

Nanoporous gold (NPG) made by dealloying is a popular model system for studies of size and interface effects as well as microstructure evolution in nanomaterials. Here, we investigate to what extent information on the microstructural geometry may be obtained by Small-Angle X-Ray Scattering (SAXS). It is well established that NPG exhibits a sharp interference peak, indicative of a characteristic wavelength underlying its leveled-wave-like microstructure and, hence, of an exceptional degree of order. Remarkably, our measurements even reveal a secondary peak at larger wave number. We compare the experimental data to simulations for small-angle scattering of NPG generated (1) by kinetic Monte Carlo (KMC) studies of dealloying or (2) as leveled-wave structures. On that basis, we discuss in how far the secondary interference peak is intrinsic to the microstructure of idealized, uniform NPG and what information it provides on the geometry of that microstructure. Since the feature vanishes during coarsening, we inspect how this process affects the order of the ligament network.

MM 30.5 Thu 11:15 SCH/A215

Enhanced Field Emission Current Density in Chemically Engineered Multiwall Carbon Nanotube - Neodymium Oxide Heterostructures — •Anima Mahajan[1], Menaka Jha[2], and Santanu Ghosh[1] — [1]Department of Physics, Indian Institute of Technology, Hauz Khas, New Delhi -110016, India. — [2]Institute of Nano Science & Technology, Knowledge City, Sector-81, Mohali, Punjab- 160062, India.

The MWCNT, neodymium oxide (Nd*O*), and MWCNT-Nd*O* heterostructure were successfully fabricated through a facile three-step synthesis process: the synthesis of MWCNT rods by the chemical vapor deposition technique, the synthesis of the Nd*O* nanoparticles by using the micellar-assisted solid-state route, and the fabrication of the MWCNT-Nd*O* heterostructure. Moreover, the MWCNT-Nd*O* heterostructure exhibits enhanced field emission properties, with a lower turn-on field of 2.4 V/*m compared to pure MWCNT and Nd*O*, which have turn-on fields of 3.6 and 3.8 V/*m, respectively. The emission current stability at a preset value of 6 V/*m over an 8-hour duration is found to be fairly good, characterized by current fluctuations within * 3% of the average value. The enhanced field emission (FE) performance of the MWCNT-Nd*O* heterostructure is attributed to its high enhancement factor (β) of ~3.3*10*.

MM 30.6 Thu 11:30 SCH/A215

Exploring Superconductivity in Misfit Nanodevices — •Sushmita Chandra and Claudia Felser — Nöthnitzer Str. 40, 01187 Dresden

Recently, MISFIT layered compounds (MLCs) have attracted considerable attention in the field of 2D materials due to their unique structure, crystallographic diversity, and chemical tunability. Typically, MLCs can be represented by the general formula [(MX)(1+δ)]m[(TX2)n] with m, n = 1, 2, 3, where M = Sn, Sb, Pb, Bi, rare-earth elements; T = Ta, Nb, Mo, etc., and X = S, Se, Te. The lattice mismatch between the distorted rock salt MX layers and hexagonal TX2 counterparts creates a strained interface in the MLCs which allows a charge transfer from one layer to another, leading to a wealth of fascinating physical phenomena and modulations in the electronic structure. Although MLCs have been extensively studied for their potential applications in thermoelectrics, the fabrication of nanodevices with single- or multilayer MISFIT crystals is a challenging task and has not been explored at all. In this talk, I will present the fabrication of nanodevices based on high-quality MISFIT single crystals. I will also correlate how the misfit strain is associated with the superconducting transition and affects the electronic transport in these natural van der Waals heterostructures.

MM 31: Transport in Materials: Diffusion, Charge, or Heat Conduction II

Thermal Transport through Benzene-1,3,5-Trisamide Fibers — •Eberhard Lukas Flöter and Fabian Pauly — Universität Augsburg, Augsburg, Germany

Benzene-1,3,5-trisamides (BTAs) are a group of chiral and polar molecules which consist of a benzene ring, three amide groups and various side groups. Hydrogen bonding between the amide groups lets the BTAs assemble to columns. These columns pack into hexagonal structures, forming fibers. Since BTAs are chiral and polar, there are multiple configurations that these structures can take. We use nonequilibrium molecular dynamics (NEMD) methods and force fields to model thermal transport through BTA fibers in various configurations. In the presentation we discuss how thermal transport depends on side groups, molecular stacking and defects.

MM 31.2 Thu 10:30 SCH/A216

Phonon Interference in Single-Molecule Junctions — Sai C. Yelishala[1], Yunxuan Zhu[1], •Pablo M. Martinez[2,3], Hongxuan Chen[4], Mohammad Habibi[1], Giacomo Prampolini[5], Juan Carlos Cuevas[3,6], Wei Zhang[4], Guilherme Vilhena[2], and Longji Cui[1,7] — [1]Paul M. Rady Department of Mechanical Engineering, University of Colorado Boulder, USA — [2]Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), Spain. — [3]Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Spain. — [4]Department of Chemistry, University of Colorado Boulder, USA — [5]Istituto di Chimica dei Composti Organo Metallici (ICCOM-CNR), Italy. — [6]Condensed Matter Physics Center (IFIMAC), Spain — [7]Materials Science and Engineering Program and Center for Experiments on Quantum Materials, University of Colorado Boulder, USA.

Wave interference opens a new route to control transport properties and has been widely studied in electronic and photonic materials. However, interference of phonons, which govern thermal transport in insulators, has been poorly characterized due to experimental challenges. We report the observation of phonon interference at room temperature in molecular-scale junctions. This is enabled by custom-developed scanning thermal probes which can track heat flowing through a single molecular junction at a time. Using isomers of oligo(phenylene ethynylene)3 with either para- or meta-connected centre rings, we reveal a 40% reduction in thermal conductance for the latter. Quantum-mechanically accurate simulations show this difference arises from the destructive interference of phonons through the molecular backbone.

MM 31.3 Thu 10:45 SCH/A216

Phunky.jl - A Multithreaded Phonon Spectral Function Calculator In Julia — •William L. Wenig and Nakib H. Protik — Humboldt-Universität zu Berlin, Berlin, Germany

The ability to compute the phonon properties of materials is crucial for the understanding of physical phenomena such as transport and spectroscopy. At present, several code packages exist that allow ab initio access to phonon computations. These codes are mostly written in traditional languages such as Python, Fortran, or C++. In this talk we present Phunky.jl, a new tool for computing the harmonic and anharmonic phonon properties of materials. The tool is written in Julia, a language that has been designed specifically for scientific computation. It allows researchers to write software at a high level of abstraction, while generating code that runs at speeds faster or comparable to that of more traditional languages in this domain. Phunky.jl is written in an extensible manner so that one can easily expand and interface it with phonon transport solvers. We will highlight the capabilities of Phunky.jl by calculating the phonon spectral quantities for a selection of materials.

MM 31.4 Thu 11:00 SCH/A216

Understanding How Pressure Enhances Heat Transport in Organic Semiconductors — •Lukas Legenstein[1,2], Sandro Wieser[1,3], Michele Simoncelli[4], and Egbert Zojer[1] — [1]Graz University of Technology, Austria — [2]Montanuniversität Leoben, Austria — [3]TU Vienna, Austria — [4]Columbia University, USA

Understanding how lattice thermal conductivity changes under pressure is increasingly important in materials science, yet difficult to predict because materials exhibit a variety of behaviors, ranging from monotonic increases or decreases to anomalous trends. Molecular crystals, including organic semiconductors, stand out for exhibiting unusually large pressure-induced increases relative to their (ultra-)low thermal conductivities.

Our test system, naphthalene, crystallizes in a herringbone stack, a packing motif common in most π-conjugated organic semiconductors. Measurements up to 2 GPa from previous literature show an isotropic thermal conductivity that is up to four times higher than at ambient conditions. By combining highly accurate machine-learned potentials with the Wigner transport equation, we not only reproduce these findings but also elucidate how compression affects naphthalene's anisotropic thermal conductivity and how phonon tunneling becomes less relevant with increasing pressure. Finally, we trace the pressure-induced enhancement to frequency upshifts and the associated modifications in phonon scattering.

MM 31.5 Thu 11:15 SCH/A216

Building Trust in Ab Initio Machine-Learning Potentials for Extreme Materials – Applications to Strongly Anharmonic Ceramics and Thermal Insulators — •Shuo Zhao[1], Kisung Kang[1,2], and Matthias Scheffler[1] — [1]The NOMAD Laboratory at FHI, Max Planck Society — [2]School of Materials Science and Engineering, Chonnam National University

Thermal insulating ceramics and semiconductors often exhibit significant anharmonicity, particularly associated with rare events such as Frenkel defect creation and rattling phonon modes. These phenomena not only disrupt the phonon picture and the conventional perturbative methods for heat transport, but also pose challenges for the effective and trustful training of machine-learned interatomic potentials (MLIPs). Our contribution describes the implementation of a framework that combines the non-perturbative Green-Kubo formalism with a sequential, uncertainty guided active learning scheme using `AlmoMD`[1] with equivariant neural networks `NequIP`[2] and `So3krates`[3]. The approach is demonstrated by application to possibly ultra-low thermal conductivity materials[4]. Our results not only substantiate reliable predictions of thermal conductivity for strongly anharmonic systems but also pave the way for the accelerated exploration and design of novel thermal insulators.

MM 31.6 Thu 11:45 SCH/A216

Probing Lattice Anharmonicity and Thermal Transport in Ultralow-κ Materials Using Machine Learning Interatomic Potentials — •Soham Mandal[1], Ashutosh Srivastava[2], Tanmoy Das[1], Abhishek Singh[2], and Prabal Maiti[1] — [1]Centre for Condensed Matter Theory, Department of Physics, Indian Institute of Science, Bangalore 560012, India — [2]Materials Research Centre, Indian Institute of Science, Bangalore 560012, India

Crystalline solids with ultralow lattice thermal conductivity (κ) are promising candidates for thermoelectric and thermal-barrier applications, yet understanding heat transport in such strongly anharmonic systems remains challenging. Perturbative frameworks such as the Boltzmann transport equation (BTE) are unreliable when anharmonicity is large and higher-order phonon scattering cannot feasibly be computed. Here, we develop machine-learning interatomic potentials (MLIPs) to study heat transport in TlAgSe and $Cs_2PbI_2Cl_2$ and compare three transport formalisms: Green-Kubo (GK), BTE, and the Wigner transport equation (WTE). BTE underestimates κ, while WTE improves agreement but slightly overpredicts due to neglected higher-order scattering. The non-perturbative GK framework captures full anharmonicity and closely matches the experimental κ value. Phonon scattering rates exceeding the Ioffe-Regel limit and the degree of anharmonicity $\sigma^A > 0.5$ confirm the strongly anharmonic nature of both materials. This MLIP-integrated framework advances predictive understanding of ultralow-κ heat transport and supports future materials design.

MM 31.7 Thu 12:00 SCH/A216

Current-voltage curves of transformer oils: Analytical and numerical results — •Markus Bier — Technische Hochschule Würzburg-Schweinfurt, Schweinfurt, Germany

High-voltage transformers contain oil, which should allow for convective heat transport while sustaining electrical insulation. These oils are complex fluids composed of various molecular and colloidal species which, over time, give rise to the formation of charged entities due to numerous, by now not entirely known and fully understood mechanisms. A widely used technique to diagnose transformer oils are current-voltage curves, which can exhibit remarkable and non-trivial transient features upon polarisation of a relaxed oil or repolarisation of an electrically stressed oil. Theoretical modelling provides a bottom-up approach to link current-voltage curves to the underlying charge transport processes. The present contribution reports on analytical and numerical results obtained within theoretical investigations of reaction-drift-diffusion models based on Poisson-Nernst-Planck (PNP) theory. After presenting an analytical solution of the PNP equations for a semi-infinite system in the non-equilibrium steady state as well as analytical cross-over boundaries between different repolarisation regimes, the main features of numerical transient current-voltage curves for polarisation and repolarisation are discussed.

Interband effects in the matrix Boltzmann transport equation — •Elena Trukhan and Nakib H. Protik — Department of Physics and CSMB, Humboldt University of Berlin

The current state-of-the-art ab initio method for computing electronic transport properties relies on the Boltzmann transport equation (BTE). However, the BTE fails to capture certain quantum effects, most notably interband coherence. To address this limitation for phonon transport, Simoncelli et al [1]. developed an approach based on the Wigner transport equation, which incorporates these effects by including the off-diagonal terms of the density matrix. This framework was later adapted to electrons by Cepellotti and Kozinsky [2]. Their method, however, involves several critical simplifications; for instance, it ignores kinetic corrections and treats the collision integral within a relaxation time approximation (RTA). Also, modern derivations rely on the assumption of a band-diagonal form of the interaction self-energies, which might not hold generally. In this work, we derive a more general electronic transport equation from a Green's function formalism. Using a modified Kadanoff-Baym Ansatz, we carefully track the terms that survive various standard approximations in the Dyson equations in the band representation, explicitly include electron-impurity and electron-phonon interactions, keeping self-energy in non-diagonal form and present a framework that captures interband coherence while moving beyond the RTA.

Stoichiometric Locking in the High State of Charge in Solid Ion Conductors: A Kinetic Monte Carlo Study — •Roya Ebrahimi Viand, Chiara Panosetti, Christoph Scheurer, Karsten Reuter, and Sebastian Matera — Fritz-Haber-Institut der MPG, Berlin

The advancement of solid-state batteries critically relies on a deep understanding of ion transport in crystalline electrolytes and electrode active materials. We present a kinetic Monte Carlo (kMC) approach with fast update rules for transition propensities that enables efficient simulation of systems with long-range Coulomb interactions. Our study systematically probes the effects of state of

charge (SOC), temperature, and applied external electric field on ionic mobility. We observe a pronounced mobility minimum near 100% SOC, where ions freeze in a low-energy Coulomb superlattice configuration that persists even under applied electric fields. Deviations from stoichiometry dramatically enhance transport by introducing defect pathways, with nearly symmetric behavior for ion and vacancy diffusion. By decomposing the state of charge into a reference and an excess carrier concentration (ΔSOC), we find that the intrinsic mobility per excess carrier remains approximately constant across different SOC values, revealing that transport is fundamentally mediated by the ΔSOC disrupting the reference structure. Analysis of effective activation energies across different SOC values reveals behavior consistent with percolation-controlled transport, where the availability of defect-mediated pathways strongly influences the energy landscape for ion diffusion.

MM 32: Topical Session: Advanced Nanomechanics – Accelerating Materials Physics from the Bottom I

Time: Thursday 10:15–12:45 Location: SCH/A251

Topical Talk MM 32.1 Thu 10:15 SCH/A251

High-Throughput Nanomechanics and Data-Driven Workflows for Mapping Composition-Microstructure-Property Landscapes — •Ruth Schwaiger — Forschungszentrum Juelich, Institute of Energy Materials and Devices, IMD-1: Structure and Function of Materials, Juelich, Germany

Combinatorial and high-throughput (CHT) methods are enabling nanoscale mechanical studies that span broad compositional and microstructural spaces with unprecedented efficiency. This talk presents an integrated perspective on how automated nanoindentation, combinatorial thin-film libraries, and machine-learning analysis jointly accelerate the discovery of composition-microstructure-property relationships.

Combinatorial thin-film libraries provide dense, continuous coverage across multicomponent compositions, enabling systematic mapping of phase formation, defect structures, and mechanical response. For example, CHT workflows applied to Ni-Al coatings captured structural transitions and hardness trends across the phase diagram, enabling development of a mechanistic hardness model that integrates grain-size, solid-solution, and phase-fraction strengthening. To extract intrinsic material properties from such heterogeneous datasets, data-driven analysis methods, ranging from physics-informed regression to unsupervised clustering, allow the identification of mechanically distinct regions, quantification of data sufficiency, and robust separation of compositional, microstructural, and defect-driven effects.

MM 32.2 Thu 10:45 SCH/A251

Reliability of Interatomic Potentials for Surface- and Size-Dependent Mechanical Behavior — •Sriram Anand, Jan Janssen, Jörg Neugebauer, and Erik Bitzek — Computational Materials Design, Max-Planck-Institute for Sustainable Materials, Düsseldorf

Material properties at the nanoscale differ markedly from the bulk, largely due to the increased surface-to-volume ratio. Surface stresses in particular are thought to modify the elastic response and contribute to the anomalous mechanical behavior of nanoobjects. These effects are typically investigated using atomistic simulations; however, the interatomic potentials used in such studies are generally not fitted to surface stresses. As a consequence, both the quantitative values (e.g., Young's modulus) and, to a lesser extent, the deformation mechanism of nanoobjects obtained from simulations may deviate from physical reality.

Here, we present a systematic study of surface stresses, nonlinear elasticity, and stacking-fault energies in FCC metals as predicted by a broad set of classical and machine-learning interatomic potentials. Using first-principles data as reference, we compile a benchmark database of these key quantities and demonstrate - through tensile deformation of nanowires - how the choice of potential can markedly influence simulated mechanical properties and deformation behavior. Our benchmark of surface stresses, higher-order elastic constants, and fault energies provides a robust foundation for the accurate design of reliable next-generation nanoelectromechanical devices.

Topical Talk MM 32.3 Thu 11:00 SCH/A251

Expanding nanoindentation capabilities: Data-driven and novel experimental approaches — •Michael Wurmshuber[1], Matthias Glosemeyer[1], Pouya Hassanzadeh Sarhangi[1], Verena Maier-Kiener[2], Heinz Werner Höppel[1], and Matthias Göken[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Montanuniversität Leoben, Leoben, Austria

As material discovery and manufacturing accelerate through artificial intelligence and additive manufacturing, high-throughput materials characterization is essential to ensure fast-paced material development. Here, nanoindentation with its capability to measure small material volumes and individual microstructural constituents in a quick manner, has the edge over classical slow-paced mechanical testing. Since Oliver and Pharr's groundbreaking work, nanoindentation has developed to extract not only hardness and modulus but numerous other mechanical properties through specialized indentation protocols. This talk presents two approaches to further extend the information space we receive from nanoindentation. First, we introduce a novel spherical indentation technique enabling local mapping of inelastic backstrain via loading-unloading-reloading experiments, allowing for the mapping of underlying geometrically necessary dislocation networks. Second, we demonstrate how artificial neural networks and ensemble methods can accelerate flow curve characterization from standard Berkovich nanoindentation. Together, these advances demonstrate how data-driven and experimental innovations can significantly expand the information accessible from nanoindentation measurements.

Topical Talk MM 32.4 Thu 11:45 SCH/A251

Additive Manufacturing and Nanomechancics - where is the Link? — •Ralph Spolenak — Laboratory for Nanometallurgy, Department of Materials, ETH Zurich, Switzerland

While size effects in mechanical properties of metals created by whisker growth and thin films had been known since the 1950s, the introduction of micro- and nanoscale subtractive manufacturing (also known as focused ion beam milling) became a game changer as it allowed to study size effects practically independent of the material and its microstructure. The contribution will focus on additive micro- and nanoscale manufacturing with voxel sizes down to 30 nm and how both the manufacturing process (with regards to microstructure control and chemistry) as well as the dimension influences mechanical properties. Comparison will be made to sputter deposited materials including self-organized microstructure, such as nanoporosity by dealloying or local pore formation by Kirkendall voiding, as well as nanostructured reactive multilayers. Finally, the potential combination of subtractive and additive processes will be discussed.

MM 32.5 Thu 12:15 SCH/A251

Mechanical Behaviour of Nafion Membranes — •Mateja Jovanović[1,2,3], Matthias Baldofski[2], Nicolas Bernhard[2], Marcin Rybicki[2,4], Miljan Dašić[3], and Igor Stanković[3,5] — [1]Institute of Technical Sciences of the SASA, K. Mihailova 35/IV, 11000 Belgrade, Serbia — [2]Freudenberg Technology Innovation SE&Co. KG, Hoehnerweg 2-4, 69469 Weinheim, Germany — [3]Institute of Physics, University of Belgrade, Pregrevica 118, 11080 Zemun, Serbia — [4]Freudenberg e-Power Systems GmbH, Bayerwaldstrasse 3, 81737 München, Germany — [5]Departamento de Ingeneria Mecanica, Universidad Tecnica Federico Santa Maria, Av. Espana 1680, Valparaiso, Chile

Proton Exchange Membrane Fuel Cells (PEMFCs) utilise polymer membranes like Nafion, valued for their proton conductivity and mechanical integrity. In this work, we examine the stress-strain response of Nafion membranes, focusing on how hydration, crystallinity, and temperature modulate mechanical behavior, using molecular dynamics simulations. Here, we demonstrate that membrane hydration level and structural ordering fundamentally influence mechanical properties under applied stress. Water distribution and polymer chain dynamics are closely connected to the stress-strain response, suggesting that structural organization at the nanoscale is crucial in governing overall mechanical performance across different conditions. By integrating clustering algorithms, structural descriptors, and stress-strain analyses, this study provides a comprehensive view of how membrane architecture and environmental factors govern mechanical performance.

MM 32.6 Thu 12:30 SCH/A251

The Fracture toughness of thin films — •Mathias Göken[1], Benoit Merle[2], and Jun Lou[3] — [1]Department of Materials Science & Engineering I, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Materials Science and Engineering, Universität Kassel, Germany — [3]Department of Materials Science and NanoEngineering, Rice University, Houston, Texas, USA

The mechanical properties of thin films play a pivotal role for applications either as freestanding films or as coatings. So far, the understanding of the fracture toughness of very thin films and especially of their thickness dependence is limited. Bulge testing is a very reliable technique for characterizing the mechanical properties of thin films, where a freestanding film is subjected to a controlled pressure from underneath and the deflection of the film is recorded. Bulge tests

have shown that the fracture toughness of ductile and soft Au drops down to extremely low values of only 2 MPam1/2 if the film thickness is reduced to 100 nm. On the other hand, single layer graphene has shown a fracture toughness of around 4 MPam1/2. In this paper the thickness dependence of the fracture toughness is discussed based on an old and simple basic fracture mechanics concept derived by Bluhm and Knott in the 1960th. It is shown, that based on this model it is easy to predict the fracture toughness of thin films and their thickness dependence. The results agree surprisingly well with the experimental data on graphene and Au thin films.

MM 33: Invited Talk: Stefan Nolte

Time: Thursday 15:00–15:30 Location: SCH/A251

Invited Talk MM 33.1 Thu 15:00 SCH/A251

LPBF with Ultrashort Laser Pulses - Additive Manufacturing Beyond Current Limits — •Stefan Nolte[1,2], Hagen P. Kohl[1], Lisa Matthäus[1], Tobias Ullsperger[1], Dongmei Liu[1], and Stephanie Lippmann[1] — [1]Friedrich Schiller University Jena, Institute of Applied Physics, Jena, Germany — [2]Fraunhofer Institute for Applied Optics and Precision Engineering IOF, Jena, Germany

Ultrashort-pulse lasers introduce additional degrees of freedom to powder bed fusion through the choice of pulse duration, repetition rate, and pulse energy. The short interaction times enable extremely high local temperatures and highly confined melt pools, with heat accumulation tunable through the pulse repetition rate. This allows precise control over melt dynamics, thermal gradients and cooling rates, which remain largely fixed in continuous-wave systems. A key outcome is accelerated solidification and pronounced grain refinement. The confined melt geometry and reduced heat accumulation suppress segregation, cracking, and vaporization-driven compositional shifts, enabling alloys and microstructures that are difficult to achieve with conventional laser melting. These processing characteristics contribute to improved mechanical uniformity, enhanced phase distribution, and greater design flexibility in alloy development. We will introduce the governing mechanisms of ultrashort-pulse interaction in metal additive manufacturing and highlight their impact through material case studies. Demonstrated benefits include grain refinement in Al-Si, dense and crack-free structures in refractory metals, and reduced vaporization with improved composition control in hypereutectic Al-Li.

MM 34: Hydrogen in Materials I

Time: Thursday 15:45–17:30 Location: SCH/A215

MM 34.1 Thu 15:45 SCH/A215

In-situ mechanical characterization of 316Ti hollow specimens in hydrogen environments - from ambient down to 20 K — •Elvina Gaisina, Simeon Eckerle, Camelia Schulz, Zahra Abbasi, Astrid Pundt, and Klaus-Peter Weiss — Karlsruhe Institute of Technology, Germany

The Application of Liquid Hydrogen (AppLHy) project explores the feasibility of a hybrid pipeline system transporting liquid hydrogen while simultaneously using the cold enables superconducting electrical energy transmission. Developing such a system requires a reliable understanding of material behavior under cryogenic conditions and exposure to hydrogen environments. However, conventional test setups that simulate these conditions are often large, complex, and require extensive safety measures to prevent hydrogen leakage. To provide a safer and more efficient testing method, this study presents an in-situ mechanical testing approach using hollow cylindrical specimens pressurized with gas. Austenitic stainless steel 316Ti, a widely applied cryogenic compatible material, was selected for testing. The hollow specimens were filled with hydrogen or helium at pressures up to 200 bar and subjected to tensile loading at temperatures ranging from ambient down to 20 K. The results show that some hydrogen-induced effects become noticeable primarily after substantial plastic deformation. Significant changes in mechanical properties and fracture behavior are observed only at 200 K.

MM 34.2 Thu 16:00 SCH/A215

In situ Micromechanical Investigation of Hydrogen Embrittlement Mechanisms in Fe3%Si — •Maral Sarebanzadeh[1], Svetlana Korneychuk[1,2], Rolf Rolli[1], Hans-Christian Schneider[1], Astrid Punt[1], Xufei Fang[1], and Christoph kirchlechner[1] — [1]Institute for Applied Materials, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Insitute of Nanotechnology, Karlsruhe Institute Technology, Karlsruhe, Germany

Hydrogen embrittlement (HE) remains a critical limitation for the reliable use of hydrogen in structural applications. Among the proposed micromechanisms, hydrogen-enhanced localized plasticity (HELP) is widely discussed, suggesting that hydrogen facilitates dislocation motion and localizes deformation. However, its microstructural manifestation remains insufficiently understood and rarely observed directly. To address this, we investigate HE in Fe3%Si using in-situ micropillar compression combined with tritium charging, leveraging the advantage of probing a few dislocations in a well-defined geometry. Micropillar tests conducted before and after charging with a protium/tritium gas mixture show a strong increase in yield strength, indicating pronounced dislocation blocking rather than enhanced glide. We demonstrate that dislocations can lose mobility, with the activating stress increasing by a factor of 2-3. Transmission electron microscopy (TEM) and electron energy loss spectroscopy (EELS) investigations are being performed to identify hydrogen-containing features around dislocations and to clarify how hydrogen governs dislocation mobility in bcc materials such as Fe3%Si.

MM 34.3 Thu 16:15 SCH/A215

Theoretical study of temperature dependencies in HELP- and HEDE-based damage models on the fatigue behavior of ferritic steel by hydrogen — Alexandra Stark[1,2], Petra Sonnweber-Ribic[1], and •Christian Elsässer[2,3] — [1]Robert Bosch GmbH, CR, 71272 Renningen — [2]Fraunhofer IWM, 79108 Freiburg — [3]University of Freiburg, FMF, 79104 Freiburg

In this theoretical study, the influence of temperature dependencies in hydrogen embrittlement (HE) models on the fatigue damage of ferritic steel is investigated by using a coupled hydrogen-diffusion and crystal-plasticity finite-element simulation framework. We focus on the characteristic "bell-shaped" dependence of HE on temperature and examine its effects by means of HE models based on Hydrogen Enhanced Local Plasticity (HELP) and Hydrogen Enhanced Decohesion (HEDE) mechanisms. Hydrogen-induced fatigue damage is monitored by a fatigue indicator parameter (FIP): maximized damage occurs within a narrow temperature range consistent with experimental results reported in literature. Our results arise from an interplay of plastic strain localization and hydrogen trapping, combined with a sufficiently efficient supply of hydrogen. The findings of this study highlight how the interplay of hydrogen diffusivity, trap filling kinetics, and available diffusible hydrogen plays a critical role for the temperature dependence of HE. In addition, the influence of varying trap binding energies is explored, which has a substantial effect on both temperature behavior and induced fatigue damage.

MM 34.4 Thu 16:30 SCH/A215

Atomistically Informed Grain-Boundary Thermodynamics for Phase-Field Modelling of Hydrogen-Driven Microstructural Evolution in Aluminium — •Bharathi Ganesh Ganesan Sekar[1], Ali Tehranchi[1], Tilmann Hickel[1], and Nils Warnken[2] — [1]Bundesanstalt für Materialforschung und -prüfung, Berlin, Germany — [2]University of Birmingham, Birmingham, United Kingdom

Hydrogen-driven microstructural evolution in polycrystalline aluminium (Al) is strongly influenced by grain-boundary (GB) structure and hydrogen (H) segregation. We aim to develop an atomistically informed phase-field framework to describe these effects, with relevance to hydride formation. Molecular-statics simulations were performed for representative FCC Al symmetric-tilt boundaries $\Sigma5(310)$, $\Sigma5(210)$, and $\Sigma3(111)$ to assess whether H segregation can initiate hydride formation. Instead, H induces defect-mediated structural transitions and shows distinct relaxation pathways during ingress and discharge. At high H content, the GB cleaves and free surfaces form. To generalise these insights, a library of 250 microstates was generated for each GB plane normal within the $\Sigma5$ family by sampling rigid-body translations and boundary-plane atomic fractions. This enables construction of GB energies as a function of plane normal, with temperature dependence introduced through Boltzmann weighting. H effects are included by evaluating segregation energies for the minimum-energy microstate of each plane normal, yielding H-chemical-potential-dependent GB energies. These results provide essential GB energetics for phase-field modelling of H-driven microstructural evolution in Al.

MM 34.5 Thu 16:45 SCH/A215

Understanding of hydrogenation induced planar defects in a proton-based battery material — •Yujun Zhao, Stefan Zaefferer, Yug Joshi, and Dierk Raabe — Max-Planck-Institut für Nachhaltige Materialien, Max-Planck-Straße 1, 40237 Düsseldorf, Deutschland

Research on nickel-metal hydride batteries provides valuable insights for advancing hydrogen storage systems. However, the battery cycle stability is limited by crystalline defects generated during hydrogenation. Therefore, an in-depth understanding of these defects is critical for improving the long-term cyclic performance of electrode materials. In this work, electrochemically charged hydrogen induces the formation of planar defects and dislocation bands in LaNi5 intermetallic compound. The correlations among crystallographic orientations, defect characteristics, and local hydrogen concentration were explored by multiscale characterization techniques, including electron backscattered diffraction (EBSD), electron channeling contrast imaging (ECCI), transmission electron microscopy (TEM), and atom probe tomography (APT). In particular, the atom probe evaporation behavior of LaNi5 along different orientations are revealed, clarifying the local magnification effect and the loss of spatial resolution. The influences of the planar defects on the evaporation behaviors of metallic elements and hydrogen atoms are also discussed.

MM 34.6 Thu 17:00 SCH/A215

Hydrogen Solution Energies at Microstructural Defects in Ferritic Steels — •Onur Can Şen[1,2,3], Santiago Benito[2], Sebastian Weber[2], and Rebecca Janisch[3] — [1]Max Planck Institute for Sustainable Materials, Germany — [2]Institute for Materials, Chair of Materials Technology, Ruhr-University Bochum, Germany — [3]ICAMS, Ruhr-University Bochum, Germany

Hydrogen is essential for sustainable industries but can also cause severe degradation through hydrogen embrittlement (HE). Trapping H at microstructural defects helps mitigate HE, though its efficiency depends on how each defect affects H solution energy.

This study combines experiments and DFT calculations to examine how microstructural defects in ferritic steels influence H trapping, focusing on different grain boundary (GB) types with and without segregants.

DFT was used to calculate solution energies at several special GBs in ferrite, both clean and with alloying elements (Cr, Cu, Ti) or vacancies, and these energies were linked to structural and electronic GB parameters.

Ferritic model alloys with varied compositions were produced and characterised. By optimizing processing, we increased the fraction of special GBs in the microstructure (Şen et al., JMRT (2025)).

The calculated solution energies serve as input for Oriani's model to predict thermal desorption spectra of these alloys.

Overall, this work shows how combining simulations and experiments clarifies the role of microstructural heterogeneities in HE.

MM 34.7 Thu 17:15 SCH/A215

Investigation of phase stability and defects in FeTi for H2 storage application — •Shankha Nag[1], Ali Tehranchi[1], Ruben Bueno Villoro[2], Christian Liebscher[2], Yuanyuan Shang[3], Claudio Pistidda[3], and Tilmann Hickel[1] — [1]Bundesanstalt für Materialforschung und -Prüfung, Berlin, Germany — [2]Fakultät für Physik und Astronomie, Ruhr Universität Bochum, Bochum, Germany — [3]Helmholtz-Zentrum Hereon, Geesthacht, Germany

Safe, durable, and efficient storage remains a central hurdle in hydrogen economy, where metal hydrides offer a promising route, particularly for stationary applications. Among these materials, FeTi stands out as a cost-effective system capable of reversible hydrogen uptake and release under near-ambient conditions. As part of BMBF-funded collaborative project GreenH2Metals, we performed atomistic simulations aimed at elucidating experimentally observed microstructural transformations such as formation of secondary phases and hydrides. We analyzed the thermodynamic stability of competing phases using ab initio calculations and examined chemical segregation as well as heterogeneous precipitation at dislocations and planar defects. Defect phase diagrams, along with the roles of vacancies and antisite defects in bulk diffusion, are explored in detail. The impact of various tramp elements on these processes is assessed through high-throughput calculations enabled by workflow frameworks such as pyiron. Together, these computational insights support a data-driven alloy design strategy for optimizing FeTi-based materials for sustainable hydrogen storage.

MM 35: Additive Manufacturing / Transport in Materials III

Time: Thursday 15:45–17:30 Location: SCH/A216

MM 35.1 Thu 15:45 SCH/A216

Tailoring Microstructure and Mechanical Properties of LPBF Ti-5553 Alloy by STA Heat Treatment — •Yang Lei[1,2], Parthiban Ramasamy[2], and Jürgen Eckert[1,2] — [1]Department of Materials Science, Chair of Materials Physics, Montanuniversität Leoben, Jahnstraße 12, A-8700 Leoben, Austria — [2]Erich Schmid Institute of Materials Science, Austrian Academy of Sciences, Jahnstraße 12, A-8700 Leoben, Austria

Ti-5553 is a metastable β titanium alloy widely used in aerospace gears due to its exceptional strength, toughness, and hardenability. However, Laser Powder Bed Fusion (LPBF) fabrication introduces significant limitations, particularly strong anisotropy and persistent columnar grains.

Solution Treatment and Aging (STA) offers a critical pathway to tailor these properties. This study investigates the microstructural evolution during STA, revealing a competition between nucleation driving force and diffusion kinetics that dictates the initial α-phase morphology. Notably, the columnar β grain size was restricted after heat treatment due to Zener pinning effect exerted by α precipitates, which impedes boundary migration and suppresses recrystallization.

Consequently, the specific microstructural features formed during solution treatment significantly influence subsequent aging behavior. Since β-grain refinement is inhibited, the enhancement in tensile strength is attributed primarily to Orowan strengthening via dispersed precipitates rather than Hall-Petch strengthening.

MM 35.2 Thu 16:00 SCH/A216

Electron Microscopy Investigation of AM316L before and after Heat Treatment: Implications for Hydrogen Diffusion — •Gabriele Palazzo[1,2,3], Kai Stefan Lagemann[1], Svetlana Korneychuk[1,2,3], Stefan Wagner[1], Christian Kübel[2,3], and Astrid Pundt[1] — [1]Institute for Applied Materials, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Institute of Nanotechnology, Karlsruhe Institute of Technology, Karlsruhe, Germany — [3]Karlsruhe Nano Micro Facility, Karlsruhe, Germany

As hydrogen technologies evolve, understanding local hydrogen-metal interactions in structural alloys becomes critical. High-pressure hydrogen storage requires materials resistant to hydrogen embrittlement (HE). Austenitic stainless steels are promising, and selective laser melting (SLM) enables attractive properties but can reduce resistance to hydrogen environmental embrittlement (HEE). We investigate additively manufactured 316L (AM316L) steel and its interaction with dissolved hydrogen, focusing on microstructure evolution under directed heat treatments. SEM and (S)TEM with STEM-EELS/EDX map elemental distributions, while EBSD and STEM-ACOM resolve grain structure and sub-grain dislocation cells (SDC). Comparing as-built and heat-treated states by ex-situ TEM and hydrogen diffusion measurements, we show that heat treatment alters the microstructure, reduces hydrogen diffusivity, and lowers HEE susceptibility [1]. [1] Kai Stefan Lagemann, Gabriele Palazzo, Tim Lucas Haag, Svetlana Korneychuk, Stefan Wagner, Christian Kübel, and Astrid Pundt. Manuscript submitted. 2026.

MM 35.3 Thu 16:15 SCH/A216

Diffusion processes in magnetron sputtered copper-gold thin films: layer design, argon pressure tuning and Kirkendall effect — •Oliver Wipf and Ralph Spolenak — Departement of Materials, ETH Zürich, Vladimir-Prelog-Weg 1-5/10, 8093 Zürich, Switzerland

Controlled Kirkendall voiding is a promising diffusion process to fabricate hollow nano- and micro-structures. This work extends the understanding and use of the Kirkendall effect as a route to fabricate voids in magnetron sputtered copper-gold thin films, a process with a high degree of control over the deposited thin films and a pathway to scalable, novel applications of diffusion self-organized thin film technology.

To study the diffusion in the thin films, double and triple layered samples were fabricated using low and high argon gas pressures during the deposition. Annealing of the samples resulted in large voids located at the wafer to film interface and in the center of the film, depending on the layer structure. Using a comprehensive diffusion study, we demonstrate that diffusion in copper-gold thin film diffusion couples is dominated by vacancies moving, which leads to the growth of Kirkendall voids.

MM 35.4 Thu 16:30 SCH/A216

Visualizing lithium dynamics in battery electrodes by operando optical microscopy — •Monica Mead[1], Shihao Wei[1], Vidula Ambure[1], Nadine Kerner[1], Roham Talei[1], Yug Joshi[2], and Guido Schmitz[1] — [1]Max Planck-Institut für nachhaltige Materialien GmbH, Max-Planck-Straße 1, 40237 Düsseldorf — [2]Universität Stuttgart, Heisenbergstraße 3, 70569 Stuttgart

Typically, chemical diffusion coefficients of Li-ions in battery electrodes are measured by purely electrochemical methods such as potentiostatic or galvanostatic intermittent titration technique (GITT/PITT), cyclic voltammetry (CV) or electrochemical impedance spectroscopy (EIS). Surprisingly, the correspondingly

determined diffusion coefficients vary within up to ten orders of magnitude. This cannot be explained solely by the influence of concentration dependence and microstructure. To clarify the origin and thereby understand which additional factors influence the ion transport, alternative methods have to be developed and applied. Therefore, we apply a method based on optical microscopy and the optical response upon Li intercalation in different Li-ion battery electrodes, such as lithium manganese oxide, lithium titanate, vanadium oxide and silicon. With this method, the transport along several hundreds of micrometres can be measured, which allows differentiation between different transport mechanisms (diffusion/transport across a kinetic barrier). We find that abovementioned electrochemical methods tend to underestimate the diffusion coefficient. We discuss the origin with respect to the transport mechanism.

MM 35.5 Thu 16:45 SCH/A216

Kinetic analysis of lithium transport in silicon anode using operando optical microscopy — •Shihao Wei[1], Monica Mead[1], Yug Joshi[2], and Guido Schmitz[1] — [1]Heisenbergstraße 3, 70569, Stuttgart, Germany — [2]Max-Planck-Straße 1, 40237, Düsseldorf, Germany

Understanding lithium diffusion and phase transformation in silicon(Si) anodes is essential for the advancement of high-capacity lithium(Li)-ion batteries. In this work, Li transport behavior and phase evolution are investigated using an in-situ optical method, which enables direct visualization of phase movement and measure Li migration across phase boundaries, advantages not offered by conventional techniques, such as EIS, SIMS, and NMR. First, it is observed that the lithiation process on a semi-infinite plane is predominantly governed by diffusion-controlled parabolic growth, with minimal evidence of interface-controlled linear growth. The temperature dependence of transport is explored, quantified with an Arrhenius-like model, revealing the activation energy of diffusion and interfacial reaction. In contrast, delithiation exhibits markedly sluggish kinetics and behaves fundamentally differently. To investigate this behavior, smaller circular geometries with limited diffusion depth creating a 2D transport scenario are examined. In these confined structures, lithiation is demonstrated by a Deal-Grove-type model. Remarkably, during delithiation, instead of a distinct moving interface, the lithiated phase gradually fades as lithium ions leave. Such a difference implies that lithiation and delithiation follow distinct reaction pathways.

MM 35.6 Thu 17:00 SCH/A216

W diffusion in Mo-Ta alloys: temperature dependence and vacancy energetics — •Aditya Burla[1], Xiang Xu[2], Felix Kipke[1], Hartmut Bracht[1], Xi Zhang[2], Blazej Grabowski[2], Gerhard Wilde[1], and Sergiy V Divinski[1] — [1]Institut für Materialphysik, Universität Münster, 48149 Münster, Germany — [2]Institut für Materialwissenschaft, Universität Stuttgart, 70569 Stuttgart, Germany

Refractory metals and their alloys have gained renewed attention with the emergence of high-entropy alloy concepts, driven by their exceptional properties at elevated temperatures. However, despite their technological significance, diffusion data for refractory binary systems remain sparse, limiting predictive understanding of defect-mediated transport at high temperatures. This study addresses this gap by investigating tungsten diffusion in the binary Mo-Ta system. Diffusion profiles were measured using secondary ion mass spectrometry after annealing in the temperature range of 1373K to 2273K. A key focus is on correlating the diffusion behavior with the vacancy formation energies. Complementary computational analysis provides atomistic insights, revealing composition-dependent variations in vacancy energetics within the Mo-Ta system. Its influence on W diffusivity and activation energies is discussed. This combined approach provides a comprehensive framework for understanding W diffusion and vacancy-controlled transport in Mo-Ta alloys, offering valuable guidance for the design of advanced refractory materials.

MM 35.7 Thu 17:15 SCH/A216

Hydrogen Diffusion in ß-MoO_3 Thin Films Governed by Structural Changes — •Tim K. Hecker, Martin Becker, and Peter J. Klar — Institute of Experimental Physics I and Center for Materials Research, Justus Liebig University Giessen, Giessen, Germany

Hydrogen incorporation strongly alters the electronic, optical and structural properties of transition-metal oxides. In MoO_3, hydrogen intercalation forms H_xMoO_3 bronzes that exhibit reversible color changes, lattice distortions and notably higher hydrogen diffusion coefficients. Although these effects are central to electrochromic, catalytic, sensing and energy storage applications, the mechanisms of hydrogen transport remain poorly understood, especially in the metastable ß-phase. To address this, we performed electrochemical hydrogen insertion into ß-MoO_3 thin films covered by a PMMA layer, only allowing incorporation in a small, well-defined uncovered stripe. Hydrogen only enters through this gap and then diffuses laterally beneath the PMMA in a semi-infinite space. Using the electrochromic response of MoO_3 in combination with the Beer-Lambert law, we monitored the hydrogen concentration in-situ. These diffusion profiles were then analyzed with a deep-learning algorithm to extract concentration dependent diffusion coefficients. We identify two distinct increases in the diffusion coefficient as hydrogen concentration rises. Complementary Raman measurements during intercalation and deintercalation link these changes to partial structural transformations, each increasing the hydrogen diffusion coefficient by nearly one order of magnitude.

MM 36: Topical Session: Advanced Nanomechanics – Accelerating Materials Physics from the Bottom II

Time: Thursday 15:45–17:15 Location: SCH/A251

Topical Talk MM 36.1 Thu 15:45 SCH/A251

High-temperature micropillar compression for understanding dislocation-precipitates interactions in Ni-Based superalloys — •Subin Lee[1], Sangwon Lee[2], Pyuck-Pa Choi[2], and Christoph Kirchlechner[1] — [1]Institute for Applied Materials, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Department of Materials Science and Engineering, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, South Korea

The mechanical role of plate-like μ phases, topologically close-packed (TCP) precipitates, in Ni-based single-crystal superalloys was investigated using bulk and in situ SEM micropillar compression, supported by electron microscopy and APT. The μ phase showed strong temperature-dependent behavior: it remained rigid at room temperature, enforcing single-slip deformation, but became more compliant at 500 °C through bending and non-basal shearing.

Although acting as local obstacles to slip, μ phases consistently lowered the CRSS of micropillars. This softening resulted from deformation within the μ phase and from microstructural changes in the surrounding γ/γ' matrix. APT revealed Ta enrichment at the μ/γ' interface, enhancing γ' strengthening, while elastic mismatch shifted slip traces away from the interface by tens of nanometers.

Overall, these results highlight the dual role of μ phases. This integrated understanding of μ-phase deformation, interfacial chemistry, and matrix softening provides a fundamental mechanistic understanding for how TCP precipitation shapes the high-temperature mechanical behavior of Ni-based superalloys.

MM 36.2 Thu 16:15 SCH/A251

Nanomechanics of Silicon: Linking Phase Transitions to High-Temperature Plasticity — •Verena Maier-Kiener and Gerald Schaffar — Montanuniversität Leoben, Department materials Science, Leoben, Austria

This presentation focuses on phase transformations in silicon revealed through high-resolution nanoindentation techniques and their interplay with high-temperature deformation behavior. Using a novel unloading contact pressure approach with continuous stiffness measurement (CSM), pressure-induced phase transitions during indentation are investigated with improved precision. The method enables direct calculation of mean contact pressure during unloading and reveals the influence of load-holding segments on transformation onset, aligning well with high-pressure literature data, and was confirmed by Raman spectroscopy. To contextualize these findings, complementary high-temperature nanoindentation studies are discussed. In monocrystalline (100) silicon, a transition from phase transformation to dislocation-controlled plasticity occurs between 300 °C and 400 °C, with further changes above 800 °C. Additionally, spherical nanoindentation on a 1.2μm silicon film at 500 °C and 700 °C extracts stress-strain behavior, confirming thermally activated dislocation glide. Together, these results provide a comprehensive view of silicon's mechanical response, bridging nanoscale phase transformation analysis with bulk high-temperature deformation mechanisms.

MM 36.3 Thu 16:30 SCH/A251

In situ TEM nanomechanics of neutron-irradiated nanocrystalline carbides and the role of amorphous shells in local mechanical response — •Elchin Huseynov — Institute of Radiation Problems of Ministry of Science and Education, 9 B.Vahabzade, Baku AZ 1143, Azerbaijan

Predicting the mechanical reliability of neutron-exposed ceramics remains challenging because classical micromechanical tests average over complex, irradiation-induced defect structures at the nanoscale. In particular, nanocrystalline carbides develop near-surface amorphous layers and defect-rich shells whose role in governing deformation and failure is still poorly quantified. This work introduces an in situ TEM-based nanomechanical workflow for neutron-irradiated nanocrystalline 3C-SiC. Reactor-irradiated nanoparticles at graded fluences serve as a model for plasma-facing and core structural ceramics. Ex situ HRTEM/SAED reveals pronounced agglomeration and a continuous amorphous shell up to 5 nm thick encasing a crystalline core. Building on this microstructural baseline, in situ TEM traction and gentle indentation experiments on nanoparticle films and micro-sized volumes are used to track shell stability and defect evolution under load via ring broadening, lattice-fringe de-coherence and defect coalescence at the shell/core interface. The results reveal a critical amorphous-shell thickness above which deformation concentrates in the disordered layer and promotes early crack initiation, whereas thinner or discontinuous shells favour more homogeneous load transfer across the crystalline core.

MM 36.4 Thu 16:45 SCH/A251

Mechanical Properties of Irradiated Zircaloy Cladding and Their Impact on Structural Integrity During Dry Interim Storage — •Tzu Yen Lin[1], Michel Herm[1], Volker Metz[1], Maria Vrellou[2], and Christoph Kirchlechner[2] — [1]Karlsruhe Institute of Technology, Institute for Nuclear Waste Disposal, P. O. Box 3640, 76021 Karlsruhe, Germany — [2]Karlsruhe Institute of Technology, Institute for Applied Materials, P. O. Box 3640, 76021 Karlsruhe, Germany

In Germany, spent nuclear fuel is planned for disposal in a deep geological repository after 2050. The SNF assemblies are stored in dual-purpose casks, while delays in repository commissioning may extend storage beyond licensed periods. Evaluating the safety of Zircaloy-4 cladding during extended dry storage requires assessing the effects of irradiation damage, hydride formation, and microstructural evolution. This work aims to establish a reliable micromechanical testing methodology for irradiated Zircaloy-4. As a precursor to irradiated samples, Electron Backscatter Diffraction (EBSD) and nanoindentation were performed on non-irradiated cladding in hydrogenated and non-hydrogenated states. EBSD revealed variations in grain size, texture, anisotropy, and dislocation density from manufacturing processes, with further increases from hydrides. Nanoindentation showed higher hardness and reduced modulus in hydride regions compared with the α-Zr matrix. Occasional pop-ins in load-displacement curves indicate dislocations or microstructural discontinuities, consistent with misorientation patterns observed in EBSD.

MM 36.5 Thu 17:00 SCH/A251

Experimental evidence and first-principles verification of deformation of basal twist grain boundaries in Ti — •Biaobiao Yang[1,2], Samuel Hémery[3], Wei Shao[1,2], Victoria Tucker[1,4], Michael S. Titus[1,4], Miguel A. Monclús[1], and Javier LLorca[1,2] — [1]IMDEA Materials Institute, C/Eric Kandel 2, Getafe, 28906 - Madrid, Spain — [2]Department of Materials Science, Polytechnic University of Madrid / Universidad Politécnica de Madrid, E.T.S. de Ingenieros de Caminos, 28040 - Madrid, Spain — [3]Institut Pprime, ISAE-ENSMA, Université de Poitiers, CNRS UPR 3346, Téléport 2, 1 avenue Clément Ader, BP 40109, Futuroscope-Chasseneuil Cedex, 86961, France — [4]School of Materials Engineering, Purdue University, 701 West Stadium Ave., West Lafayette, IN 47907, USA

Recent studies show that Basal Twist Grain Boundaries (BTGBs) are important fatigue-crack nucleation sites in Ti alloys. Micropillar compression combined with high-resolution microscopy revealed extremely easy interfacial shear: one basal grain slides over the other at very low critical resolved shear stresses (45-205 MPa), far below those required for common <a> basal slip. To explain this behavior, first-principles calculations were used to determine the grain boundary energies of BTGBs with different twist angles. The results show that variations in twist angle or in-plane translation produce only negligible changes in grain boundary energy, indicating intrinsically low shear resistance. Together, these experimental and computational findings clarify why BTGBs serve as potent crack-nucleation sites in Ti alloys.

MM 37: Development of Calculation Methods I

MM 37.1 Thu 15:45 SCH/A315

The two-particle Green's function in the particle-particle channel: A survey of approximations — •Caja Annweiler[1], Lucia Reining[2], and Claudia Draxl[1] — [1]Humboldt Universität Berlin, Berlin, Germany — [2]École Polytechnique, Palaiseau, France

While in general setting up and solving the Bethe-Salpeter equation (BSE) is out of reach for realistic systems, it provides an ideal starting point for constructing approximations. In the particle-hole channel, this has lead to established approaches such as the GW-level approximation to capture excitonic effects. This framework can be extended to the BSE in the particle-particle channel (pp-BSE), obtained by choosing a different time-ordering in the two-particle Green's function. The result is an equation describing the propagation of two particles (either electrons or holes). While formally similar to the ph-BSE, it is a promising alternative for the calculation of the exchange-correlation energy and yields important information for topics such as pair correlations in superconductors. Despite growing interest in the pp-BSE, systematic investigations of approximations remain scarce.

In the present work we consider a variety of approximations to the pp-BSE. For this purpose, exactly solvable model systems of interacting electrons provide valuable insights into the minimal ingredients needed to capture the key physics. We present approximations from many-body perturbation theory (HF, GW, etc.) at the level of the self-energy Σ and interaction vertex Ξ on small Hubbard models, with the aim of advancing our understanding of approximations in the pp-channel.

MM 37.2 Thu 16:00 SCH/A315

Reliable Super-Resolution for Real-Time Electronic Structure Theory — •Alexander Gorfer, Karsten Reuter, and Matthias Kick — Fritz-Haber-Institut der MPG, Berlin

Calculating excited state spectra of large systems is often prohibitively expensive with standard frequency-domain methods such as the Casida equations, the Bethe-Salpeter Equation (BSE), or Equation-of-Motion Coupled Cluster (EOM-CC). Real-time methods provide an alternative, as all modes are excited simultaneously. However, long simulation times are required to resolve narrow spectral features with traditional Fourier signal analysis, significantly limiting system size. Super-resolution methods such as Compressed Sensing promise high-resolution spectra from much shorter signals but assume the spectrum to be sparse, an assumption which breaks down in larger systems where sharp features are embedded in a quasi-continuum of smaller nearby peaks. To overcome this, we combine newly designed highly noise-tolerant super-resolution techniques with physically motivated filtering. Using approximate frequency information, we identify the brightest transitions and extract only these important modes from the time propagation. By doing so, we effectively precondition the problem for super-resolution, reducing the number of required time steps for signal reconstruction to a minimum. We demonstrate our approach on systems containing several hundred heavy atoms, achieving up to 20-fold speedups while maintaining spectral accuracy even for signals dominated by large continua.

MM 37.3 Thu 16:15 SCH/A315

Electron thermalization in TDDFT and Ehrenfest molecular dynamics — •Tobias Zier, Uday Panta, and David A. Strubbe — University of California, Merced, USA

A non-equilibrium electronic state will in general thermalize toward an equilibrium state due to electron-electron interactions as well as interactions with ions. The description of such processes has remained unclear and controversial in time-dependent density functional theory (TDDFT), given that the occupation numbers remain fixed over time and that adiabatic functionals do not include explicit dissipation. Nevertheless in the literature signs of thermalization to a Fermi-Dirac distribution have been found in effective occupations constructed by projection of the time-dependent wavefunctions onto the ground state. Key issues include whether this process is physical or an artefact, connection to the Eigenstate Thermalization Hypothesis, and the dependence on the density of states, external fields, and xc functionals. To shed light on these phenomena, we study explicit time propagation of graphene after ultrafast laser pulses, with the Octopus real-space code, with and without ionic motion in Ehrenfest molecular dynamics. We study oscillations and the approach to an effective Fermi-Dirac distribution as well as decay of off-diagonal density matrix elements. This work has implications for treatment of statistical mechanics in a TDDFT framework and the nature of time-dependence in xc functionals, as well as for practical calculations of light-matter interactions especially for strong fields as in laser fusion experiments leading to warm dense matter and plasmas

MM 37.4 Thu 16:30 SCH/A315

Bulk plasmons in elemental metals — •Claudia Cardoso[1], Dario Leon[2], and Kristian Berland[2] — [1]S3 Centre, Istituto Nanoscienze, CNR, 41125 Modena, Italy — [2]Department of Mechanical Engineering and Technology Management, Norwegian University of Life Sciences, NO-1432 Ås, Norway

We have developed an effective analytical representation of the main collective excitations of the dielectric response of 26 elemental metals, starting from first principles calculations. Spectral band structures are then constructed , by ex-

tending our earlier model based on multipole-Padé approximants (MPA) [1,2] to incorporate both momentum and frequency dependence (MPA(q)). With this representation, we are able to identify plasmonic quasiparticle dispersions exhibiting complex features, including non-parabolic energy and intensity dispersions, discontinuities due to anisotropy, and overlapping effects that lead to band crossings and anti-crossings. We find good agreement with available experimental data. The results for elemental metals and their effective MPA(q) representation establish a reference point that can guide both fundamental studies and practical applications in plasmonics and spectroscopy.

Probing the influence of core-hole and atomic multiplets in the final states on L2,3 edges for high-throughput studies — •Prathibha Chandrashekhar, Felix Sorgenfrei, Patrik Thunström, Olle Eriksson, and Heike C. Herper — Department of Physics and Astronomy, Uppsala University

Core level spectroscopy like X-ray absorption spectroscopy and the corresponding X-ray magnetic circular dichroic signals are powerful tools to study a wide variety of element specific properties in materials. In this work, we use ab initio density functional theory (as implemented in RSPt[1]) with multiplet ligand field theory to simulate the spectra by constructing and solving the single impurity Anderson model. We simulate the $L_{2,3}$ edges of transition metals in Heusler alloys, aiming to explore the suitability of the method for future high throughput studies, we look at $CoFeMnSi$ and Ni_2MnGa as our initial test cases. These alloys have been extensively studied for their fascinating tunable electronic and magnetic properties which find applications in spin resolved conductance devices, magnetocalorics and spintronics. We test the influence of Slater-Condon parameters on the spectra. We show that the final state effects are crucial in observing the fine structure and the branching ratio between the edges. This work is funded by Horizon Europe MSCA Doctoral Network grant n.101073486, EU-SpecLab, funded by European Union. [1] RSPt, Relativistic Spin Polarized Toolkit (2017).

Alloy design and deformation behaviour of Mo-based silicide materials — •Manja Krueger — Otto-von-Guericke University Magdeburg

Multi-phase refractory metal-based silicide alloys are attractive candidates for high temperature structural applications. The mechanical behaviour and the oxidation response of this type of materials is significantly affected by the microstructural design, i.e. the chemical composition of the solid solution phase, the volume fraction and homogeneous distribution of the solid solution phase and the silicide phases, the grain size and orientation as well as the concentration of dissolved detrimental impurities and impurity phases. Balancing the ambient and high temperature properties requires to tailor the microstructures, which can be realized by the optimization of the chemical composition using additional alloying elements and the modification of alloying concepts with respect to the manufacturing method. However, processing of refractory metals and alloys is quite challenging due to the ultra-high melting point above 2000°C and their strong tendency to oxidize at intermediate temperatures. This presentation will show the successful processing and tailoring of multi-phase Mo-Si-B alloys by powder metallurgical (PM) routes, directional solidification (DS) processes and laser-based additive manufacturing (AM) techniques. It will be shown that the AM materials are crack-free and the constituents are homogeneously distributed. The microstructure is very fine as can be compared to powder metallurgically processed Mo-Si-B.

Coulometric and (Magneto-)Optical Methods for Studying Hydrogen Absorption into Metals — •Felix Engelhardt, Karin Leistner, and Markus Gössler — Chemnitz University of Technology, 09107 Chemnitz, Germany

Hydrogen absorption into metals like palladium is a widely studied process with applications in hydrogen sensors, hydrogen storage systems, and recently magneto-ionics[1,2]. A major challenge in this field is to accurately quantify the hydrogen concentration within the metal. Traditionally, complex techniques such as nuclear reaction analysis or neutron scattering are used for this purpose. Alternatively, coulometric and (magneto-)optical methods are possible and offer the advantages of a simpler setup and operation under ambient conditions. We revisit the coulometric quantification of electrochemically absorbed hydrogen in metals and metallic multilayers, as well as the analysis of hydrogen absorption kinetics. Potential- and time-dependent coulometry was performed in a liquid-electrolyte flow cell designed to avoid side reactions. Complementary measurements of (magneto-)optical reflectivity of the metals upon hydrogen absorption were carried out to support findings from electrochemical methods. This presentation highlights common pitfalls in hydrogen absorption analysis and shows that, when these errors are minimized, the coulometry method yields accurate average hydrogen concentrations and reliable kinetic data. These results encourage the use of electrochemical methods in catalysis and hydrogen research. [1]M. Bischoff et al., Adv. Funct. Mater. 2024, 34, 2405323 [2]Huang, M. et al., Nat. Nanotechnol. 2021, 16, 981

Interfacial kinetics of hydrogen absorption in nanoporous palladium — •Seoyun Sohn[1,2], Nora Brunkhorst[2], Jürgen Markmann[2,1], and Jörg Weissmüller[1,2] — [1]Institute of Materials Physics and Technology, Hamburg University of Technology, 21073 Hamburg, Germany — [2]Institute of Hydrogen Technology, Helmholtz-Zentrum Hereon, 21502 Geesthacht, Germany

Sorption of hydrogen at metal surfaces is a key process controlling energy-conversion reactions, electrocatalysis, and battery operation. To focus on the interfacial sorption step and minimize bulk-transport contributions, we explore nanoporous (np) Pd as a model system, following the charging/discharging kinetics during electrochemical charging or exposure to H_2 gas at controlled partial pressure. Our observations point towards thermally activated transition across an internal barrier–between adsorbed and absorbed H–as the rate limiting step, and they exhibit anomalous kinetics, where absorption or desorption rates do not monotonously decrease with time. The command critiques the applicability of the Butler-Volmer equation–as a classic approach to the kinetics–and we advertise an alternative kinetic rate law that resolves the problematic issues of the classic approach. We show that the new rate law explains important features of the observations, specifically when admitting for a coherent initiation of the phase change.

MM 39.3 Fri 10:45 SCH/A215

Local hydrogenation of polycrystalline Pd nanodisks studied with in-situ TEM — •Svetlana Korneychuk[1,2], Carl Andersson[3], Stefan Wagner[1], Christoph Langhammer[3], and Astrid Pundt[1] — [1]IAM-WK, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]KNMFi, Karlsruhe Institute of Technology, Karlsruhe, Germany — [3]Chalmers University of Technology, Göteborg, Sweden

Hydrogen distribution and concentration in metals is of central importance for many areas of hydrogen technology, such as hydrogen storage, detection, and hydrogen embrittlement. In particular, arrays of Pd nanodisks can serve as optical hydrogen sensors [1] at room temperature owning to fast kinetics of hydrogen absorption and desorption of Pd. Here we demonstrate hydrogen distribution and concentration in polycrystalline Pd nanodisks with the lateral resolution down to 4 nm extending our previous study on the local measurement of hydrogen concentration in Pd nanoparticles with in-situ TEM [2]. By measuring the shift of the Pd bulk plasmon peak with scanning transmission electron microscopy combined with energy electron loss spectroscopy during in-situ hydrogen gas loading and unloading, local detection of the hydrogen concentration is achieved in TEM. The method offers a way to observe hydrogen concentration at different sites: grain boundaries, surface and grains starting from early stages of hydrogenation to compete hydride formation identifying the pathways of hydrogenation of polycrystalline metals. [1] C. Wadell, et al., ACS Nano 2014 8 (12), 11925-11940 [2] S. Korneychuk, et al., Small 2025, 21, 2407092.

MM 39.4 Fri 11:00 SCH/A215

A comparative density functional theory study of hydrogen adsorption in metal organic frameworks — •Ikutaro Hamada — Department of Precision Engineering, Graduate School of Engineering, The University of Osaka , Suita, Osaka 565-0871, Japan

Metal-organic frameworks (MOFs) and covalent organic frameworks (COFs) have attracted considerable attention due to their design and synthesis flexibility, enabling applications in catalysis, gas adsorption, and separation. Among these, hydrogen storage is one of the most extensively studied properties of MOFs. However, their hydrogen storage capacity remains low, particularly at room temperature, which limits industrial and commercial applications. To design MOFs with enhanced hydrogen storage capability, it is essential to understand the microscopic details of hydrogen adsorption and absorption within these frameworks. In this work, we assess the accuracy of dispersion-inclusive exchange-correlation functionals against the coupled cluster method using hydrogen-benzene complexes, and we investigate hydrogen adsorption in UiO-66, UiO-67, and UiO-68 as prototypical MOFs. We will present details of our systematic exploration of the geometric and electronic structures of hydrogen molecules and their stability within UiO-66, UiO-67, and UiO-68.

MM 39.5 Fri 11:15 SCH/A215

Machine Learning Potential Approach to Complex Hydrogen-Surface Interactions: GRACE Applied to the H/Sn/Ru System — •Manuel Enns and Daniel F. Urban — Fraunhofer IWM, Wöhlerstraße 11, 79108 Freiburg, Germany

Understanding hydrogen interactions with contaminated metal surfaces remains a challenging problem in computational materials science, requiring methods that balance accuracy with computational efficiency to capture complex multi-component dynamics. We demonstrate the application of a GRACE machine learning interatomic potential to study hydrogen behavior on tin-contaminated ruthenium surfaces - a system that exemplifies the challenges of modeling reactive adsorbates on multi-element surfaces. Data from density functional theory calculations on hydrogen penetration mechanisms through ruthenium surfaces with varying tin coverages was used to fine-tune the GRACE potential, enabling computationally efficient molecular dynamics (MD) simulations. The resulting MD simulations successfully capture key dynamic processes including hydrogen diffusion and jump mechanisms, tin growth kinetics at a prior hydrogen coverage, and low-energy hydrogen deposition. This case study demonstrates GRACE's capability to handle complex multi-component systems involving reactive species, providing atomic-level insights into how surface contamination affects hydrogen penetration pathways and adsorbate interactions.

MM 39.6 Fri 11:45 SCH/A215

Diffusion of hydrogen in platinum during HER catalysis — Aparna Saksena[1], Bingxin Li[1], Yujun Zhao[1], J. Manoj Prabhakar[1], Mira Todorova[1], Jörg Neugebauer[1], Dierk Raabe[1], Baptiste Gault[1,2], and •Yug Joshi[1] — [1]Max Planck Institute for Sustainable Materials (MPI-SusMat), Max Max-Planck-Straße 1, 40237 Düsseldorf — [2]Univ Rouen Normandie, CNRS, INSA Rouen Normandie, Groupe de Physique des Matériaux, UMR 6634, F-76000 Rouen, France

Platinum remains the most common electrocatalyst used for hydrogen evolution reaction (HER) in acidic conditions. It is generally believed to act as a proton-blocking catalyst with adsorption of reaction intermediates limited to its surface. In this study, we thoroughly examine how Pt interacts with hydrogen and deuterium (H/D) within the bulk by monitoring the mass change of a Pt electrode in real-time during galvanostatic heavy/water splitting, using an electrochemical quartz crystal microbalance. Surprisingly, we observe an irreversible mass increase over time along with changes in the overpotential for both HER and DER. Atom probe tomography of the Pt electrode after DER confirms that D diffuses into the bulk. The results are supported by density functional theory, showing the formation of an interstitial solid solution of H in Pt. These results challenge the conventional belief that Pt-proton interactions are only surface-limited. They suggest a need to revisit catalyst design strategies, which currently focus on surface-adsorbed species and the rate-limiting Volmer step, by also considering the bulk diffusion of H/D within the Pt matrix.

MM 39.7 Fri 12:00 SCH/A215

Hydrogen induced small polarons in iron oxides using occupation-matrix control DFT+U calculations — Ahmed Abdelkawy, •Mira Todorova, and Jörg Neugebauer — Max Planck Institute for Sustainable Materials, Max-Planck-Str.1, 40470 Düsseldorf

Over 6% of global CO_2 emissions come from using carbon-based reducing agents in iron production. Replacing these agents with hydrogen would result in water as the sole byproduct, thereby reducing harmful emissions. To understand H-based reduction of iron oxides, we focus on hydrogen interactions with bulk hematite (Fe_2O_3). Modeling transition metal oxides is challenging because conventional DFT-GGA has self-interaction errors and inadequately treats the Coulomb repulsion in partially filled d-orbitals. Corrections such as DFT+U or exchange-correlation functionals, which incorporate a fraction of the exact exchange, further complicate matters because they generate a multitude of metastable configurations that DFT cannot predict. In this study, we use DFT+U with occupation matrix control to map the energy landscape of the small electron polaron generated by H interstitials. We construct the three-dimensional potential energy surface of H interstitials using the resulting ground-state configurations. This enables us to gain detailed insight into hydrogen kinetics and rate-limiting steps.

MM 39.8 Fri 12:15 SCH/A215

An atomic-scale master-equation model study of the mobility of a dislocation core interacting with interstitial hydrogen in a metal — •Daniel Pfalzgraf[1], Daniel F. Urban[1,2], and Christian Elsässer[1,2] — [1]Fraunhofer IWM, Wöhlerstraße 11, 79108 Freiburg, Germany — [2]Freiburg Materials Research Center (FMF), University of Freiburg, Stefan-Meier-Str. 21, 79104 Freiburg, Germany

We examine the influence of interstitial hydrogen in a metal on the motion of a dislocation by means of a master equation model. This model takes as input atomic-scale information, such as material-specific defect-migration energy barriers and interatomic interaction energies, to produce the drift velocity of a mechanically driven dislocation core segment as a function of the local hydrogen concentration around it. Our approach can take detailed correlation effects into account, for example, that the dislocation core acts as a mobile hydrogen trap, resulting in an inhomogeneous distribution of hydrogen around it. The results can be used to estimate in which ranges of temperature or interaction strength the presence of hydrogen increases or decreases the mobility of the dislocation core, which is of interest in the context of hydrogen embrittlement mechanisms.

MM 39.9 Fri 12:30 SCH/A215

Hydrogen induced strain instability in Aluminum — •Ali Tehranchi[1,2], Bharathi Ganesh Ganesan Sekar[1], and Tilmann Hickel[1,2] — [1]Bundesanstalt für Materialforschung und -prüfung (BAM), D-12489, Berlin, Germany — [2]Max Planck Institute for Sustainable Materials, D-40237 Düsseldorf, Germany

Hydrogen embrittlement is a persistent form of metal degradation that arises from the complex interactions between hydrogen atoms and defects within metallic lattices. Environmental nanoindentation has become a standard experimental technique for probing these interactions, particularly the mechanisms underlying hydrogen-assisted deformation. In this work, we employ comprehensive large-scale molecular statics simulations in aluminum, complemented by ab initio calculations, to investigate the influence of hydrogen on homogeneous dislocation nucleation –the primary mechanism responsible for pop-in events observed under low-radius indenters. Our defect phase diagram analysis shows that, at hydrogen chemical potentials relevant to nanoindentation experiments, vacancy formation is significantly enhanced, leading to a substantial increase in the concentration of vacancy–hydrogen complexes. These complexes produce large local misfit strains, which in turn reduce the critical shear stress required for material instability and the onset of homogeneous dislocation nucleation.

MM 40: Transport in Materials: Diffusion, Charge, or Heat Conduction IV

MM 40.1 Fri 10:15 SCH/A216

Quantum oscillation and tunable charge density wave of kagome metal ScV6Sn6 — •Changjiang Yi, Xiaolong Feng, Chandra Shekhar, and Claudia Felser — Max Planck Institute for Chemcial Physics of Solids

Compounds with kagome lattice structure are known to exhibit Dirac cones, flat-bands, and van Hove singularities, which host versatile quantum phenomena. We investigate the magnetoelectric transports along with the theoretical calculations of, a nonmagnetic charge-density wave (CDW) metal. ScV6Sn6 exhibits Shubnikov de Haas quantum oscillations, which help to shape the Fermi-surface (FS). The Dirac band is demonstrated along with a nonzero Berry phase. In addition, the compound also shows the anomalous Hall-like behavior up to the CDW phase transition. Under Cr substitution and hydrostatic pressure, the CDW is largely suppressed. The suppression of CDW phase under pressure can be well captured by our first-principles calculations, evidenced by the lift of imaginary phonon bands. The MR and Hall resistance behave differently under Cr substi-

tution and pressure. Our study reveals that the anomalous Hall-like behavior arises from the kagome lattice and persists as long as the lattice is maintained.

MM 40.2 Fri 10:30 SCH/A216

Investigating UAHE in layered delafossite by high-energy electron irradiation. — •Elina Zhakina[1,2], Philippa McGuinness[2], Romain Grasset[3], Seunghyun Khim[2], Marcin Konczykowski[3], and Andrew Mackenzie[2,4] — [1]Department of Applied Physics and Quantum-Phase Electronics Center (QPEC), The University of Tokyo, Bunkyo, Tokyo, Japan — [2]Max Planck Institute for Chemical Physics of Solids — [3]Laboratoire des Solides Irradis, CEA/DRF/IRAMIS, Ecole Polytechnique, CNRS, Institut Polytechnique de Paris, Palaiseau, France — [4]Scottish Universities PhysicsAlliance, School of Physics & Astronomy, University of St. Andrews, St. Andrews, United Kingdom

PdCrO2 belongs to the delafossite family of extremely pure triangular lattice metals. While its Pd layers are metallic, the CrO2 layers are Mott insulating and order antiferromagnetically below 37 K. PdCrO2 [1]. It exhibits an unconventional anomalous Hall effect (UAHE), the origin of which has been the focus of substantial critical discussion. To investigate the origin of UAHE, we conducted a systematic study of the influence of point defects on the Hall effect of PdCrO2, the results of which are reported here. We introduced point-like defects into focused ion beam-sculpted microstructures of PdCrO2 by irradiating them with high-energy electrons. Comparing the results of UAHE as a function of disorder, we demonstrate UAHE behaviour attributed to its extrinsic origin.

MM 40.3 Fri 10:45 SCH/A216

Anisotropic anomalous Hall effect in distorted kagome GdTi3Bi4 — •Avdhesh Kumar Sharma[1], Bo Tai[1], Subhajit Roychowdhury[2], Premakumar Yanda[1], Ulrich Burkhardt[1], Xiaolong Feng[1], Claudia Felser[1], and Chandra Shekhar[1] — [1]Max Plank Institute for chemical physics of solids, Dresden, Germany — [2]Indian institute of science education and research, Bhopal, India

GdTi3Bi4 crystallizes in layered Ti-based kagome nets intertwined with zigzag Gd chains along the a-axis and orders antiferromagnetically below 15 K. Here, we present the temperature and field-dependent electrical transport of GdTi3Bi4 in different directions. The material exhibits anomalous Hall conductivity of 410 Ω-1 cm-1 at 2 K for B || c and it is completely absent for B || a, despite the similar magnetization observed in both orientations. This behavior is quite contradictory, as anomalous Hall effect (AHE) typically scales with the magnetization. Through first principles calculations, it is demonstrated that in the presence of time reversal symmetry broken by the Gd 4f sublattice and spin orbit coupling, the magnetization direction controls the orbital mixing in the Ti t_2g bands, relocating Berry curvature hot spots and producing the observed orientation selective anomalous Hall conductivity (AHC). The results establish GdTi3Bi4 as platform for investigating new avenues of AHE, such as directional AHE, and thus shed new light on the intricate coupling between magnetic and electronic structures, paving the way for exploring novel quantum phenomena.

MM 40.4 Fri 11:00 SCH/A216

Nernst effect in superconducting Weyl semimetal t-PtBi2 — Federico Caglieris[3], •Michele Ceccardi[1], Dmitriy Efremov[1], Grigory Shipunov[1], Iryna Kovalchuk[1,4], Saicharan Aswartham[1], Arthur Veyrat[1,5], Joseph Dufouleur[1,7], Daniele Marré[2,3], Bernd Büchner[1,7], and Christian Hess[1,6,7] — [1]IFW Dresden — [2]University of Genoa — [3]CNR SPIN — [4]Kyiv Academic University — [5]LPS Orsay — [6]Wüppertal University — [7]TU Dresden

Topological materials are among the most promising areas of research in Condensed Matter Physics, offering breakthroughs in dissipationless electronics or in error-free quantum computing. The combination of non-trivial topology and superconductivity opens to novel quantum devices. The discovery of intrinsic materials where such properties appear together represent a frontier in modern condensed matter physics. Trigonal PtBi2 has recently emerged as a possible candidate, being the first example of superconducting type-I Weyl semimetal. However, several aspects of this promising compound still need to be unveiled, concerning its complicated band structure, the actual role of Weyl points in determining its electronic properties and the nature of the superconducting transition. In the work, we experimentally investigated t-PtBi2 single crystals and exfoliated flakes by means of the Nernst effect, which has been demonstrated to be a powerful probe for study the fermiology of complex materials.

MM 40.5 Fri 11:30 SCH/A216

Negative quadratic magnetoresistance generated by spin fluctuations in the metamagnetic bilayer strontium ruthenate Sr3Ru2O7 — •Bastien Michon[1,2], Elisa Auffray[1], Amir Meddas[1], Zhiqiang Mao[3], Freek Massee[1], Pascale Senzier[1], Claude Pasquier[1], and Siham Benhabib[1] — [1]Laboratoire de Physique des Solides - University of Paris-Saclay, Orsay, France — [2]SOLEIL synchrotron, Saint Aubin, France — [3]Eberly College of Science, The Pennsylvania State University, University Park, USA

The bilayer strontium ruthenate Sr3Ru2O7 hosts a metamagnetic transition around 8T and was widely studied for its quantum criticality characterized by its linear-in-temperature resistivity. While most prior work has focused on the magnetic field evolution of the resistivity exponent α, the magnetoresistance (MR) has received less attention. Our low-temperature relative MR measurements on high-purity single crystals reveal two key features absent from the literature:

1. a well-defined negative quadratic MR between 30 and 100K, consistent with enhanced spin fluctuations, and 2. a non-monotonic MR evolution at low temperature within the 1.6-12K range.

The metamagnetic MR peak around 8T reaches nearly 90% at the lowest temperatures, broadens with increasing temperature, shifts to lower fields, and completely disappears between 20-30K. At higher temperature, the MR changes sign and follows a perfect negative H* dependence, with maximum amplitude around 30-40K. These measurements provide the first detailed mapping of the MR in Sr3Ru2O7 across a broad temperature range and up to 14T.

MM 40.6 Fri 11:45 SCH/A216

Quantum Transport in Atomic-Sized Contacts Using Break-Junction Experiments — •Guillem Pellicer and Carlos Sabater — Department of Physics, University of Alicante

The study of atomic-sized metallic contacts is fundamental to understanding the limits of electronic transport at the nanoscale. We present a comparative analysis of electronic transport in atomic-sized contacts, contrasting the behavior of noble metals with that of reactive metals under both ambient conditions and inert atmospheres. We examine how environmental interactions influence the formation and stability of these nanocontacts, employing clustering algorithms to analyze these effects.

MM 40.7 Fri 12:00 SCH/A216

Atomic Transistor-Based Implementation of Logic Gates — •Merlin Schieler[1], Florian Schieren[1], Carlotta Buchner[1], Felix Frank[1], Ida Göbel[1], Katja Marschall[1], Fanqing Xie[1], Florian Wertz[1], and Thomas Schimmel[1,2] — [1]Institute of Applied Physics, Karlsruhe Institute of Technologie (KIT), 76131 Karlsruhe, Germany — [2]Institute of Nanotechnology, Karlsruhe Institute of Technologie (KIT), 76344 Eggenstein-Leopoldshafen, Germany

An atomic-scale quantum conductance switch was demonstrated in our group which allows to open and close an electrical circuit by the controlled and reproducible reconfiguration of individual silver atoms within an atomic-scale junction. The only movable parts of the switch are the contacting atoms. The device is fabricated by electrochemical deposition of silver atoms between the source and the drain electrode. It is entirely controlled by an external voltage of a few millivolts applied to an independent gate electrode. Controlled switching was performed between a quantized, electrically conducting "on-state" exhibiting a conductance of $G_0 = \frac{2e^2}{h} \approx \frac{1}{12.9\,\mathrm{k\Omega}}$ or preselectable multiples of this value and an insulating "off-state". The device, which reproducibly operates at room temperature, represents an atomic transistor or relay, opening intriguing perspectives for the emerging fields of quantum electronics and logics on the atomic scale.

Here, we show a first demonstration of logical operations such as NAND and NOR with electrical circuits consisting of two atomic-scale quantum conductance switches.

MM 40.8 Fri 12:15 SCH/A216

Quantum transport in α-Sn atomic-sized contacts tuned by strain — Francisco Guzmán[1], Wynand Dednam[2], Andres Martinez-garcia[1], Enrico Lombardi[2], Carlos Untiedt[1], and •Carlos Sabater[1] — [1]University of Alicante — [2]University of South Africa

Tin (Sn) transitions from metallic β-Sn (above 286 K) to α-Sn (diamond-cubic, zero-gap semiconductor) below this temperature. α-Sn's electronic properties are theoretically tunable under strain, potentially yielding a Dirac semimetal or topological insulator. We experimentally investigated the quantum electronic transport of α-Sn nanocontacts at 4.2 K using a Scanning Tunneling Microscopy break junction (BJ) setup. Conductance measurements revealed three distinct groups via machine-learning clustering. Supported by Molecular Dynamics (MD) simulations and Density Functional Theory (DFT) calculations with Spin-Orbit Coupling (SOC), our findings demonstrate that atomic contact geometry is crucial for quantum transport in α-Sn, providing insights for spintronics applications.

MM 41: Development of Calculation Methods II

Time: Friday 10:15–12:45 Location: SCH/A251

MM 41.1 Fri 10:15 SCH/A251

Atomistic Framework for Glassy Polymer Viscoelasticity Across 20 Frequency Decades — •Ankit Singh[1], Vinay Vaibhav[1,2], Caterina Czibula[3], Timothy W. Sirk[4], and Alessio Zaccone[1] — [1]Department of Physics "A. Pontremoli", University of Milan, Via Celoria 16, 20133 Milan, Italy — [2]Institut für Theoretische Physik, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — [3]Institute of Bioproducts and Paper Technology, Graz University of Technology, Inffeldgasse 23, 8010 Graz, Austria — [4]US Army DEVCOM Army Research Laboratory, Aberdeen Proving Ground, Maryland 21005, United States

Glassy polymers are central to engineering applications, yet their viscoelastic response over broad frequency and temperature ranges remains difficult to characterize. We extend non-affine deformation theory by incorporating a time-dependent memory kernel within the Generalized Langevin Equation for atomistic non-affine motions, yielding frequency-dependent mechanical response. Applied to poly(methyl methacrylate) (PMMA), the method captures the shear modulus and relaxation spectrum across more than twenty decades in frequency, from hundreds of terahertz down to the millihertz regime, thus bridging polymer mechanics from ordinary to extreme scales. Our predictions show quantitative consistency with independent estimates from oscillatory-shear molecular dynamics, Brillouin scattering, ultrasonic spectroscopy, Split-Hopkinson testing, and dynamic mechanical analysis (DMA), demonstrating a unified theoretical computational route for multiscale characterization of polymer glasses.

MM 41.2 Fri 10:30 SCH/A251

Clarifying the existence of a miscibility gap in platinum-palladium alloys via compositional fluctuations — •Florian Groll, Sebastian Eich, and Guido Schittz — Institute of Materials Science, Stuttgart, Germany

In materials science, the Gibbs free energy is of central importance for calculating phase diagrams. CALPHAD assessments require extensive experimental measurements and data obtained from well-equilibrated samples. For alloy systems with extremely low diffusion coefficients, achieving such equilibrium can be very time-consuming or practically impossible. Because this approach relies only on nanometer-scale equilibration, it provides a significantly more efficient route to the determination of CALPHAD parameters for systems with extremely slow diffusion. The palladium-platinum system is a well-known example for those kind of systems with unknown miscibility gap. In this study, we determine the Pd*Pt phase diagram by extracting the curvature of the Gibbs free energy from local composition fluctuations in the solid state using fluctuation theory. The experimental data needed for applying the local fluctuation theory are obtained from atom probe tomography, and the phase diagram is subsequently calculated.

MM 41.3 Fri 10:45 SCH/A251

Exploring the magnetic phase behaviour of MnAl with a novel sampling method, beginning from first principles — •Georgia A Marchant[1,2], M Nur Hasan[1], Rafael Vieira[1], Julie B Staunton[2], and Heike Herper[1] — [1]Uppsala University, Uppsala, Sweden — [2]University of Warwick, Coventry, United Kingdom

The demand for powerful magnetic materials is ever-increasing, as they dominate our modern technological landscape. Addressing rare earth (RE) criticality is crucial, so the search for viable permanent magnets that are RE-free and RE-lean continues. MnAl, with around 55% Mn content, has been a popular candidate for research in this regard. It transforms from the paramagnetic epsilon phase to the ferromagnetic tau phase when annealed appropriately, but the transition rate enhances under a surprisingly modest magnetic field. To shed light on this, we have computationally predicted the magnetic properties of MnAl across the transition.

The method uses data from first-principles calculations to build efficient atomic models of the phases' magnetic interactions. Thermodynamic properties are then determined with nested sampling (NS). Recently, NS has proven to be a powerful alternative to Markhov chain Monte Carlo sampling (MCMC). While NS has been used extensively in non-magnetic physical chemistry, this work represents its first application to magnetic materials. We present these results to demonstrate the power of NS; compare its effectiveness to MCMC; and unveil previously-unknown magnetic phases of MnAl.

MM 41.4 Fri 11:00 SCH/A251

A Demonstration of the Finite-Temperature Upside-Down Adiabatic Connection with the Asymmetric Hubbard Dimer — •Vincent Martinetto[1,2,3], Juri Grossi[1], and Aurora Pribram-Jones[1] — [1]University of California, Merced, CA 95343, United States — [2]Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — [3]Center for Advanced Systems Understanding, 02826 Görlitz, Germany

The finite-temperature upside-down adiabatic connection is an integral expression for the decorrelation free energy, a quantity of interest when considering finite-temperature strictly correlated electrons. This approach smoothly connects a thermal ensemble of strictly correlated electrons to an ensemble with realistic interaction strength while requiring the density of the system to remain fixed across all interaction strengths. As the strictly correlated limit is the natural opposite of the Kohn-Sham limit, it can provide new insights into the difficult regime of strong correlation in finite-temperature systems. An exact demonstration of the upside-down finite-temperature adiabatic connection will be performed with the asymmetric Hubbard dimer, along with a discussion of strong correlation in finite-temperature systems.

MM 41.5 Fri 11:15 SCH/A251

Towards self-consistent electrostatic corrections for charged defects in periodic boundary conditions — •Ermanno Botti[1,2,3], Davide Campi[3], Nicéphore Bonnet[2], and Nicola Marzari[1,2] — [1]PSI, Switzerland — [2]EPFL, Switzerland — [3]UniMiB, Italy

Charged point defects in semiconductors and insulators play a pivotal role in determining a wide range of physical properties, significantly impacting materials behavior and device performance. First principles calculations have become an essential tool to better characterize defects properties and to speed up technological advancements. However, some key defect properties, such as formation energies in the dilute limit, are highly sensitive to finite size effects in periodic boundary conditions DFT simulations. These issues arise from long range Coulomb interactions between periodic replicas and the neutralizing background needed to prevent the divergence of the electrostatic potential. To reduce these effects, corrections are required to remove these spurious electrostatic interactions. In this work we extend an a-posteriori correction scheme to achieve self-consistency in the open access package Quantum Espresso and test it on simple systems.

15 min. break

MM 41.6 Fri 11:45 SCH/A251

Tessellation-free full charge density method for atom-centered basis sets — •Franco Moitzi[1], Andrei V. Ruban[2,3], Vsevolod I. Razumovskiy[1], and Oleg E. Peil[2] — [1]Christian Doppler Laboratory for Digital material design guidelines for mitigation of alloy embrittlement, Materials Center Leoben Forschung GmbH, Vordernberger Straße 12, A-8700 Leoben, Austria — [2]Materials Center Leoben Forschung GmbH, Vordernberger Straße 12, A-8700 Leoben, Austria — [3]Department of Materials Science and Engineering, Royal Institute of Technology, 10044 Stockholm, Sweden

Accurate Poisson solvers are essential for reliable total energies and forces in Density Functional Theory (DFT) calculations. Atom-centered basis methods, such as Korringa-Kohn-Rostoker methods, often rely on Voronoi tessellations to decompose space, which complicate Poisson solutions in the interstitial region due to the high l-cutoffs required for the nearly flat charge there and the boundary discontinuities, leading to numerical instabilities as atoms move. We introduce a tessellation-free method that avoids these issues by decomposing the charge into non-overlapping atomic spheres and an interstitial region.

Following Andersen *et al.*, the interstitial charge is expanded in screened spherical waves—Helmholtz-equation solutions with special boundary conditions—and smoothly extended from the atomic spheres, allowing the Poisson equation to be solved analytically. Their analytical properties allow accurate evaluation of the Hartree potential, electrostatic, and exchange-correlation energies, enabling precise and efficient DFT calculations with atom-centered basis sets.

MM 41.7 Fri 12:00 SCH/A251

Machine-Learning Augmented Electronic Structure Calculations via Adaptive DFTB Parameters — •Yihua Song, Christoph Scheurer, Karsten Reuter, and Chiara Panosetti — Fritz Haber Institut der MPG

As a semi-empirical DFT approximation, Density Functional Tight Binding (DFTB) combines reduced computational cost with accessible electronic structure, providing a compromise between the full physicality of *ab initio* methods and the speed of machine-learning interatomic potentials. Yet, its accuracy in realistic systems remains limited due to intrinsic approximations and dependence on parametrization quality. To this end, we propose that the precalculated Slater-Koster (SK) electronic interaction tables in DFTB should be adapted to local atomic environments and demonstrate proof-of-principle studies showing the improved electronic structure description. Building on the observed smoothness of SK integrals across chemical and spatial environments, we use machine learning based on atomic descriptors to continuously adapt the parametrization beyond discrete atomic types. As a prototype, we introduce the DFTB Orbital Verity Engine (DOVE), a machine-learning framework that learns subtle discrepancies in electronic parameters across diverse local environments from reference electronic structures. We successfully validate it against complicated

systems with multiple coordination states. This machine-learning framework for environment-adaptive tight-binding parameterization enables scalable electronic structure simulations with enhanced fidelity, efficient speed, and physical interpretability.

MM 41.8 Fri 12:15 SCH/A251

Detecting topologically-protected surface states in doped systems using the coherent potential approximation — •Artem Chmeruk, Dylan Jones, and Liviu Chioncel — University of Augsburg, Augsburg, Germany

The signature of the non-trivial electronic band structure is the existence of gapless conducting states at interfaces where the topological invariant changes. This change signals a topological phase transition, which in real systems can be accomplished through doping. Modeling doping effects can be done by combining density functional theory and coherent potential approximation, which gives the possibility to model a continuous range of concentrations, and provides a sensitive probe to detect the emergent electronic states. Here, we analyse the topologically-protected surface states in $Bi_{2-x}Sb_xSe_3$.

MM 41.9 Fri 12:30 SCH/A251

Defect-induced vibrational modes in graphene — •Iskander Mukatayev, Guillaume Radtke, and Michele Lazzeri — Sorbonne Université, CNRS UMR 7590, MNHN, IMPMC, 4 place Jussieu, 75252 Paris, France

We present a general framework for investigation of the vibrational properties of point defects in graphene, motivated by recent advances in vibrational EELS that enable phonon spectroscopy with atomic resolution. Our approach combines DFT and density-functional perturbation theory with a force-matching procedure [1-2], in which interatomic force constants (IFCs) are computed independently for pristine graphene and defect-containing supercells and then merged to dynamical matrices of very large systems(up to 20000 atoms). This strategy enables the modeling of isolated defects without defect-defect interactions while retaining full ab initio accuracy.

We investigate a wide range of point defects including substitutional dopants (B, N, Si, P), single, double vacancies and Stone-Wales reconstruction. Depending on the details of defect-induced bond reconstruction, different behaviours are observed ranging from quasi-localized (or resonant) states falling in the continuum of the bulk to high-frequency fully localised modes. From these examples we draw conclusions of the conditions of occurrence of both types vibrations.

(Lecture halls HSZ/AUDI, HSZ/0201, HSZ/0204, HSZ/0401, HSZ/0403, TRE/PHYS, TRE/MATH, and WILL/A317; Poster P2)

Invited Talks

O 2.3	Mon	11:00–11:30	HSZ/0201	**Superconducting Fermi arcs.** — •Andrii Kuibarov, Susmita Changdar, Oleksandr Suvorov, Luminita Harnagea, Bernd Büchner, Sergey Borisenko
O 5.1	Mon	10:30–11:00	HSZ/0403	**Can the mineral-water interface save the world? Mineral carbonation, enhanced weathering and negative emissions** — •Philip Pogge von Strandmann
O 5.4	Mon	11:30–12:00	HSZ/0403	**Machine learning exploration of water binding and ice nucleation at silicate and carbon surfaces** — •Mie Andersen
O 7.1	Mon	10:30–11:00	TRE/MATH	**Magnetic Order in 2D Materials Beyond Bulk Constraints** — •Jeison Fischer
O 8.3	Mon	11:00–11:30	WILL/A317	**Controlling nanostructures on surfaces via intermolecular interactions** — •Yunjun Cao
O 14.1	Mon	15:00–15:30	TRE/MATH	**Spin and time-resolved ARPES and the orbital angular momentum of light** — Pierre Nonnon, Romain Géneaux, Karol Hricovini, Christine Richter, David Bresteau, •Mauro Fanciulli
O 15.1	Mon	15:00–15:30	WILL/A317	**Tuning Spin-1/2 Interactions in Graphene: From Long-Range Coupling to Altermagnetic Order** — •Beatriz Viña-Bausá, Manuel A. García-Blázquez, Antonio T. Costa, Joao C. G. Henriques, Roberto Carrasco, Eva Cortés-del Río, Diego Expósito, Pierre Mallet, Jean-Yves Veuillen, Joaquín Fernandez-Rossier, Juan J. Palacios, Iván Brihuega
O 33.1	Tue	10:30–11:00	HSZ/0201	**During-synthesis functionalization of graphene layers** — •Cristina Africh
O 36.1	Tue	10:30–11:00	HSZ/0403	**Acidity in nanoconfinement from ab initio and NNPs simulations** — Anthony Baldo, Muhammad Saleh, Kevin Leung, •Marialore Sulpizi
O 36.4	Tue	11:30–12:00	HSZ/0403	**Living Interfaces: Dissolution and Precipitation Processes at Mineral-Brine Interfaces Revealed by AFM** — •Igor Siretanu, Vincenzo Alagia, Saravana Kumar, Shilpa Mohanakumar, Max Nederstigt, Chinmay Shukla, Michel Duits, Frieder Mugele
O 37.1	Tue	10:30–11:00	TRE/PHYS	**Calculations of excited electronic states by converging on saddle points on the electronic energy surface** — •Hannes Jonsson
O 37.4	Tue	11:30–12:00	TRE/PHYS	**Many-Body Theory meets Electrochemistry: Electronic Structure of Cathode Materials** — •Silke Biermann
O 39.3	Tue	11:00–11:30	WILL/A317	**Electric double layer of platinum electrodes** — •Marc Koper
O 39.6	Tue	12:00–12:30	WILL/A317	**First-principles modelling of electrochemical interfaces** — •Axel Gross
O 51.1	Tue	14:30–15:00	TRE/MATH	**Ultrafast aqueous electric double-layer dynamics** — •Mischa Bonn
O 51.3	Tue	15:15–15:45	TRE/MATH	**Interface-specific nonlinear THz spectroscopy** — •Chuanshan Tian
O 52.1	Tue	14:30–15:00	WILL/A317	**Dynamics of catalytically active, atomically precise clusters on reducible oxide supports under the (fast) scanning tunneling microscope** — •Friedrich Esch
O 55.3	Wed	11:00–11:30	HSZ/0204	**Cationic Mixing in Ultrathin Oxide Films: How substrate and oxygen conditions control nanoalloying.** — •Jacek Goniakowski
O 57.1	Wed	10:30–11:00	HSZ/0403	**From Plasmonic Near-Fields to Electron Dynamics - A Photoemission Perspective** — •Pascal Dreher
O 60.1	Wed	10:30–11:00	WILL/A317	**Disentangling the origins of spin polarization in (inverse) photoemission from solid surfaces** — •Jürgen Henk

O 64.1	Wed	15:00–15:30	HSZ/0403	**Cantilever based Scanning Force Microscopy: Ultimate Sensitivity and Quantitative Imaging of Nanoscale Spin Textures** — •Hans J. Hug
O 64.6	Wed	16:30–17:00	HSZ/0403	**Single-spin sensing: A molecule-on-tip approach** — •Laurent Limot
O 66.1	Wed	15:00–15:30	TRE/MATH	**Ultrafast exciton dynamics in 2D semiconductors and electric field gated devices** — •Jan Philipp Bange
O 67.1	Wed	15:00–15:30	WILL/A317	**New frontiers of one step model of photoemission for quantum materials** — •Jan Minar
O 78.1	Thu	10:30–11:00	HSZ/0401	**The Wendelstein 7-X plasma vessel vacuum system from a scientific perspective** — •Georg Schlisio, Torsten Bräuer, Stylianos Varoutis, Paul McNeely, Dirk Hartmann, Chandra Prakash Dhard, Dirk Naujoks, Victoria Hak, the W7-X team
O 82.1	Thu	10:30–11:00	WILL/A317	**Low-energy inverse photoelectron spectroscopy (LEIPS): probing unoccupied states and conduction band structure in functional materials** — •Hiroyuki Yoshida
O 82.2	Thu	11:00–11:30	WILL/A317	**Enhanced Sensitivity in Low-Energy Inverse Photoemission Spectroscopy with an Off-Axis Parabolic Mirror for Efficient Light Collection** — •Yongsup Park, Jong-Am Hong, Kyu-Myung Lee, Min-Jae Maeng
O 85.1	Thu	15:00–15:30	HSZ/0401	**From light to pressure: Laser-based quantum technologies for the realization of high-precision pressure and vaccum standards** — •Tom Rubin
O 86.1	Thu	15:00–15:30	HSZ/0403	**Ultrafast Dynamics at Surfaces with Machine Learning Surrogates** — •Reinhard Maurer
O 94.1	Fri	9:30–10:00	HSZ/0204	**Surface Chemistry on Copper Oxides** — •Dario Stacchiola
O 97.1	Fri	9:30–10:00	TRE/PHYS	**Questions of Selectivity in Electrocatalysis** — •Vanessa J. Bukas
O 98.1	Fri	9:30–10:00	TRE/MATH	**Electron-phonon interactions in the time domain: from non-equilibrium phonon dynamics to theoretical spectroscopy** — •Fabio Caruso

Invited Talks of the joint Symposium SKM Dissertation Prize 2026 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	9:30–10:00	HSZ/0002	**Stochastic-Calculus Approach to Non-equilibrium Statistical Physics** — •Cai Dieball
SYSD 1.2	Mon	10:00–10:30	HSZ/0002	**Nonuniform magnetic spin textures for sensing, storage and computing applications** — •Sabri Koraltan
SYSD 1.3	Mon	10:30–11:00	HSZ/0002	**Anomalous Quantum Oscillations beyond Onsager's Fermi Surface Paradigm** — •Valentin Leeb
SYSD 1.4	Mon	11:00–11:30	HSZ/0002	**Coherent Control Schemes for Semiconductor Quantum Systems** — •Eva Schöll
SYSD 1.5	Mon	11:30–12:00	HSZ/0002	**On stochastic thermodynamics under incomplete information: Thermodynamic inference from Markovian events** — •Jann van der Meer

Invited Talks of the joint Symposium Designing Quantum Materials with Light: From Floquet to Cavity Engineering (SYFC)

See SYFC for the full program of the symposium.

SYFC 1.1	Mon	9:30–10:00	HSZ/AUDI	**Subcycle videography of strong-field controlled band structures** — •Rupert Huber, Manuel Meierhofer, Ulrich Höfer
SYFC 1.2	Mon	10:00–10:30	HSZ/AUDI	**Engineering Quantum Materials through Structured Cavity Vacuum Fluctuations** — •Angel Rubio
SYFC 1.3	Mon	10:30–11:00	HSZ/AUDI	**Floquet engineering of quantum materials: from semiconductors to semimetals** — •Shuyun Zhou
SYFC 1.4	Mon	11:15–11:45	HSZ/AUDI	**(Quantum) Light Control of Materials** — •Dante Kennes
SYFC 1.5	Mon	11:45–12:15	HSZ/AUDI	**Lightwave-driven electrons in a Floquet topological insulator** — Daniel Lesko, Tobias Weitz, Weizhe Li, Selina Nöcker, Celina Hüttner, Tamara Pröbster, Simon Wittigschlager, Christian Heide, Ofer Neufeld, •Peter Hommelhoff

Invited Talks of the joint Symposium AI and Data Challenges behind Emerging Self-Driving Laboratories (SYAI)

See SYAI for the full program of the symposium.

SYAI 1.1	Thu	9:30–10:00	HSZ/AUDI	**Data and Experimental Foundations for Reliable Self-Driving Laboratories** — •Dr. Marcus Tze-Kiat Ng
SYAI 1.2	Thu	10:00–10:30	HSZ/AUDI	**Digital Catalysis - AI for Experiment Planning and Control** — •Christoph Scheurer
SYAI 1.3	Thu	10:30–11:00	HSZ/AUDI	**Autonomous, Data-Driven Workflows for Materials Acceleration Platforms with pyiron** — •Jan Janssen, Joerg Neugebauer
SYAI 1.4	Thu	11:15–11:45	HSZ/AUDI	**Machine Learning for Autonomous Optimization and Discovery of Materials** — •Pascal Friederich
SYAI 1.5	Thu	11:45–12:15	HSZ/AUDI	**Transforming Our View on Transformers in the Sciences** — •Kevin Maik Jablonka

Sessions

O 1.1–1.1	Mon	9:30–10:15	TRE/PHYS	**Topical Talk Wulfhekel (joint session O/TT)**
O 2.1–2.7	Mon	10:30–12:30	HSZ/0201	**Electronic structure of surfaces: Spectroscopy, surface states I**
O 3.1–3.7	Mon	10:30–12:15	HSZ/0204	**Scanning probe techniques: Method development I**
O 4.1–4.7	Mon	10:30–12:15	HSZ/0401	**Metal & Semiconductor substrates: Adsorption and reaction of small molecules I**
O 5.1–5.6	Mon	10:30–12:30	HSZ/0403	**Focus Session: Mineral-water interfaces I**
O 6.1–6.8	Mon	10:30–12:30	TRE/PHYS	**Organic molecules on inorganic substrates: Adsorption and growth I**
O 7.1–7.7	Mon	10:30–12:30	TRE/MATH	**2D Materials: Electronic structure, excitations, etc. I (joint session O/HL/TT)**
O 8.1–8.7	Mon	10:30–12:30	WILL/A317	**Nanostructures at surfaces:1D, 2D, networks I**
O 9.1–9.12	Mon	15:00–18:00	HSZ/0201	**Organic molecules on inorganic substrates: electronic, optical and other properties I**
O 10.1–10.11	Mon	15:00–17:45	HSZ/0204	**2D Materials beyond graphene: Growth, structure and substrate interaction (joint session O/HL/TT)**
O 11.1–11.8	Mon	15:00–17:00	HSZ/0401	**Metal & Semiconductor substrates: Adsorption and reaction of small molecules II**
O 12.1–12.11	Mon	15:00–17:45	HSZ/0403	**Scanning probe microscopy: light matter interaction at atomic scales**
O 13.1–13.12	Mon	15:00–18:00	TRE/PHYS	**Solid-liquid interfaces: Reactions and electrochemistry I**
O 14.1–14.11	Mon	15:00–18:00	TRE/MATH	**Ultrafast electron dynamics at surface and interfaces I**
O 15.1–15.11	Mon	15:00–18:00	WILL/A317	**Spins on surfaces at the atomic scale I**
O 16.1–16.2	Mon	18:00–20:00	P2	**Focus Session: Structure and Dynamics of Solvent at Electrochemical Interfaces – Poster**
O 17.1–17.12	Mon	18:00–20:00	P2	**Spins on surfaces at the atomic scale – Poster**
O 18.1–18.6	Mon	18:00–20:00	P2	**New methods: Theory – Poster**
O 19.1–19.10	Mon	18:00–20:00	P2	**Vacuum Science & Technology: Theory and Applications – Poster**
O 20.1–20.1	Mon	18:00–20:00	P2	**Electronic structure theory – Poster**
O 21.1–21.2	Mon	18:00–20:00	P2	**Surface magnetism – Poster**
O 22.1–22.6	Mon	18:00–20:00	P2	**Surface dynamics – Poster**
O 23.1–23.10	Mon	18:00–20:00	P2	**Catalysis and surface reactions – Poster**
O 24.1–24.7	Mon	18:00–20:00	P2	**Solid-liquid interfaces: Reactions and electrochemistry – Poster**
O 25.1–25.2	Mon	18:00–20:00	P2	**Solid-liquid interfaces: Structure, spectroscopy – Poster**
O 26.1–26.5	Mon	18:00–20:00	P2	**Plasmonics and nanooptics: Fabrication, characterization and applications – Poster**
O 27.1–27.7	Mon	18:00–20:00	P2	**Plasmonics and nanooptics: Light-matter interaction, spectroscopy – Poster**
O 28.1–28.8	Mon	18:00–20:00	P2	**Oxide and insulator surfaces: Structure, epitaxy and growth – Poster**
O 29.1–29.3	Mon	18:00–20:00	P2	**Oxides and insulators: Adsorption and reaction of small molecules – Poster**
O 30.1–30.4	Mon	18:00–20:00	P2	**Metal & Semiconductor substrates: Structure, epitaxy and growth – Poster**
O 31.1–31.6	Mon	18:00–20:00	P2	**Metal & Semiconductor substrates: Adsorption and reaction of small molecules – Poster**
O 32.1–32.1	Tue	9:30–10:15	TRE/PHYS	**Topical Talk Witte**
O 33.1–33.7	Tue	10:30–12:30	HSZ/0201	**Graphene: Growth, structure and substrate interaction (joint session O/HL)**
O 34.1–34.8	Tue	10:30–12:30	HSZ/0204	**Catalysis and surface reactions I**

O 35.1–35.7	Tue	10:30–12:15	HSZ/0401	**Organic molecules on inorganic substrates: Adsorption and growth II**
O 36.1–36.6	Tue	10:30–12:30	HSZ/0403	**Focus Session: Mineral-water interfaces II**
O 37.1–37.6	Tue	10:30–12:30	TRE/PHYS	**Electronic structure theory I**
O 38.1–38.8	Tue	10:30–12:30	TRE/MATH	**Ultrafast electron dynamics at surface and interfaces II**
O 39.1–39.6	Tue	10:30–12:30	WILL/A317	**Focus Session: Structure and Dynamics of Solvent at Electrochemical Interfaces I**
O 40.1–40.21	Tue	14:00–16:00	P2	**Ultrafast electron dynamics at surface and interfaces – Poster (joint session O/TT)**
O 41.1–41.4	Tue	14:00–16:00	P2	**Topology and symmetry protected materials & Topological insulators – Poster (joint session O/TT)**
O 42.1–42.9	Tue	14:00–16:00	P2	**Electronic structure of surfaces: Spectroscopy, surface states – Poster**
O 43.1–43.17	Tue	14:00–16:00	P2	**Scanning probe microscopy: light matter interaction at atomic scales – Poster**
O 44.1–44.17	Tue	14:00–16:00	P2	**Scanning probe techniques: Method development – Poster**
O 45.1–45.11	Tue	14:00–16:00	P2	**Organic molecules on inorganic substrates: Adsorption and growth – Poster**
O 46.1–46.11	Tue	14:00–16:00	P2	**Organic molecules on inorganic substrates: electronic, optical and other properties – Poster**
O 47.1–47.4	Tue	14:30–15:30	HSZ/0201	**New methods: Theory**

Members' Assembly of the Vacuum Science and Technology Divison (VA)

Thursday 17:15–18:15 HSZ/0401

Members' Assembly of the Surface Science Division

Thursday 18:00–19:00 HSZ/AUDI

Sessions

– Invited, Topical, Contributed Talks, and Posters –

O 1: Topical Talk Wulfhekel (joint session O/TT)

Time: Monday 9:30–10:15 Location: TRE/PHYS

Topical Talk O 1.1 Mon 9:30 TRE/PHYS

Vortices, inter-band coupling and inelastic QPI in two band superconductors — •Wulf Wulfhekel — Physikalisches Institut, Karlsruhe Institute of Technology

The majority of superconductors have more than one Fermi surface, on which the electrons pair below the critical temperature, yet their behavior can be well described by a single-band Bardeen-Cooper-Schrieffer theory. This is mostly due to interband scattering, especially in superconductors in the dirty limit, rigidly linking the pairing amplitude of the bands. We here lift this constrain and study the behavior of the ultra-pure two-band superconductor Pb. We show that at low temperatures, it is neither of type I nor type II and superconducting vortices of arbitrary flux quanta can be formed. We show that on the non-spherical Fermi surfaces, a modified index theory is needed for the description of in gap states in vortices. Further, the two condensates are only weakly coupled and can be individually manipulated. By studying stacking fault tetrahedra, we demonstrate local tuning of interband coupling ranging from weak to strong and the modification of the superconducting order parameters from two well separated gaps to one merged gap around defects. The experiments critically test the theory of multiband superconductors and give a route to access a wide range of predicted quantum effects in these systems. Finally, we demonstrate that quasi particle interference is also possible in the inelastic tunneling channel enabling the imaging of standing phonons with STM.

O 2: Electronic structure of surfaces: Spectroscopy, surface states I

Time: Monday 10:30–12:30 Location: HSZ/0201

O 2.1 Mon 10:30 HSZ/0201

Unveiling the spin texture of the topological surface state in Sb(111) — •Xin Liang Tan[1], Arthur Ernst[2], Anders Christian Mathisen[1], Stefanie Suzanne Brinkman[1], Fabian Göhler[1], Chul Hee Min[1], and Hendrik Bentmann[1] — [1]Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, 7491 Trondheim, Norway — [2]Institut für Theoretische Physik, Johannes Kepler Universität, A 4040 Linz, Austria

Spin-resolved momentum microscopy is a powerful tool for mapping the complete Fermi surface and spin texture of two-dimensional electronic states. Here, we present spin- and momentum-resolved Sb(111) surface state, a benchmark system exhibiting strong spin-orbit coupling and a non-trivial topology. Using a continuous-wave vacuum-ultraviolet laser ($h\nu = 6eV$) for photoexcitation, we achieve efficient k-space mapping of the in-plane spin-polarization components over the full surface Brillouin zone. We will present experimental data obtained for different light polarizations. Our results are compared to first-principles calculations.

O 2.2 Mon 10:45 HSZ/0201

Surface Electronic Structure of Magnetic Kagome Metal GdV_6Sn_6 — •Robin P. Forster[1], Honey Boban[1], Mohammed Qahosh[1], Xiao Hou[1], Yishui Zhou[2], Yixi Su[2], Gustav Bihlmayer[3], Claus M. Schneider[1], and Lukasz Plucinski[1] — [1]PGI-6 Forschungszentrum-Jülich — [2]JCNS Forschungszentrum-Jülich — [3]PGI-1 Forschungszentrum-Jülich

The magnetic Kagome metal GdV_6Sn_6 combines in a single material phenomena such as van Hove Singularities [1,2,3], local moments of the 4f electrons of Gd, and itinerant V 3d electrons [4], providing a platform to study their complex magentic and electronic interactions. We have performed termination-dependent micro-ARPES measurements of paramagnetic GdV_6Sn_6 with 20 μm real-space resolution at 20 K [5]. A series of scans over a photon energy range between 75 eV and 200 eV enabled the distinction between surface and bulk states. We have chosen $h\nu$ of 80 and 130 eV for detailed ARPES scans. In addition, XPS measurements and DFT-GGA slab calculations were performed, which can be used to investigate surface terminations. Preliminary circular-dirchroic ARPES maps exhibit multiple sign inversions that stem from a combination of initial state orbital angular momenta and photoemission final state scattering [6].

Invited Talk O 2.3 Mon 11:00 HSZ/0201

Superconducting Fermi arcs. — •Andrii Kuibarov, Susmita Changdar, Oleksandr Suvorov, Luminita Harnagea, Bernd Büchner, and Sergey Borisenko — Leibnitz Institute for Solid State and Materials Research, Dresden, Germany

$PtBi_2$ is a trigonal non-centrosymmetric material that has recently drawn attention as a natural platform for topological superconductivity, without the need for engineered heterostructures. Recent STM studies have strengthened this claim by showing a superconducting gap with size up to 20 meV and critical temperature around 45 K.

Using angle-resolved photoemission spectroscopy, we demonstrate that both terminations of $PtBi_2$ expose Fermi arc surface states, which become superconducting at approximately 15 K with a gap size up to 3 meV, while the bulk of the material remains metallic, making $PtBi_2$ a surface-only superconductor. Further momentum-resolved gap measurements have shown that the superconducting gap on the Fermi arcs is anisotropic, with the superconducting node located in the center of six Fermi arcs, making it the first *i-wave (l = 6)* superconductor. This anisotropy implies the formation of Majorana surface cones and predicts robust zero-energy flat-band Majorana states at the hinges of the crystal.

O 2.4 Mon 11:30 HSZ/0201

From low- to high-energy photoelectron diffraction: Novel theoretical approaches and Kikuchi diffraction analysis — •Trung-Phuc Vo[1], Olena Tkach[2], Didier Sébilleau[3], Olena Fedchenko[2], Hans-Joachim Elmers[2], Gerd Schönhense[2], and Ján Minár[1] — [1]Univ. of West Bohemia in Pilsen, Czech Republic — [2]Univ. of Mainz, Germany — [3]Univ. of Rennes, France

Time-of-flight momentum microscopy (ToF-MM) enables simultaneous energy- and momentum-resolved mapping of the full photoelectron distribution. Its sensitivity to the strong energy dependence of Kikuchi patterns [1,2] requires advanced theoretical modeling, especially across the broad energy range accessible with modern large-k-field setups [3]. We present a fully relativistic multiple-scattering study of fine diffraction features in core-level photoemission from Ge(100) and Si(100) over kinetic energies from 106 to 4174 eV [4]. Our one-step calculations avoid cluster-size convergence issues and include inelastic scattering to describe pattern broadening. For the first time, we reproduce circular dichroism in the angular distribution of Si(100) 1s with asymmetries up to 31%, and capture both bulk- and surface-sensitive diffraction features. The simulations show good agreement with experimental data obtained using circularly polarized light, demonstrating the robustness of our approach for high-energy photoemission and PED analysis.

O 2.5 Mon 11:45 HSZ/0201

Fermiology and spin polarization of the topological surface states in $PtBi_2$ — •Stefanie Suzanne Brinkman[1], Anders Christian Mathisen[1], Xin Liang Tan[1], Kristian Maeland[2], Øyvind Finnseth[1], Fabian Göhler[1], Chul Hee Min[1], Grisha Shipunov[3], Anna Isaeva[2], Jorge Ismael Facio[4], and Hendrik Bentmann[1] — [1]Center for Quantum Spintronics, Department of Physics, NTNU, Norway — [2]Institute for Theoretical Physics and Astrophysics, University of Würzburg, Germany — [3]Institute of Physics, University of Amsterdam, The Netherlands — [4]Instituto Balseiro, National University of Cuyo, Argentina

Weyl semimetals host topologically protected Weyl nodes in the bulk, that are connected by Fermi arcs on the surface. In $PtBi_2$, recent reports indicate superconductivity in the surface Fermi arcs at elevated temperatures [1]. In this talk, we will present results from spin- and angle-resolved VUV photoemission experiments for both inequivalent surface terminations of $PtBi_2$. Our measurements,

combined with first-principles calculations, establish vastly different low-energy dispersion relations of the Fermi arcs depending on surface termination. Furthermore, we provide evidence for spin polarization of the Fermi arcs. We will discuss the implications of our results for the emergence of unconventional superconductivity on the surface of $PtBi_2$.

O 2.6 Mon 12:00 HSZ/0201

Multi-technique research ecosystem structured around electronic band structure analysis — Takahiro Hashimoto[1], Andreas Janzen[2], •Hrag Karakachian[2], Eleni Anargirou[2], Timo Wätjen[1], and Martin Schmid[1] — [1]Scienta Omicron AB, Danmarksgatan 22, 75323 Uppsala, Sweden — [2]Scienta Omicron GmbH, Limburger Strasse 75, 65232 Taunusstein, Germany

The discovery and control of novel quantum materials are essential to the progress of modern technology. These materials frequently show complex behaviours that demand multiple, complementary techniques to fully understand their properties. For example, the electronic band structure, which is central to understanding emerging quantum materials, is typically investigated using angle-resolved photoemission spectroscopy (ARPES) or momentum microscopy.

Here, we describe how a surface-science research ecosystem centred on ARPES can be established by integrating state-of-the-art capabilities such as molecular beam epitaxy (MBE) for thin-film growth, X-ray photoemission spectroscopy (XPS) for chemical-state analysis, and scanning probe microscopy (SPM) for real-space imaging. Materials innovation is accelerated by combining these complementary techniques, leveraging both laboratory-based and user-facility instrumentation, and developing new tools to extend commercial systems.

We will present several research scenarios focused on electronic band-structure analysis and highlight application examples involving 2D materials and topological materials.

O 2.7 Mon 12:15 HSZ/0201

The TXPES Beamline at SESAME * A New Facility for Advanced Soft X-ray Photoelectron Spectroscopy — •ZEYNEP REYHAN OZTURK — SESAME

The Turkish X-ray Photoelectron Spectroscopy (TXPES) beamline, newly installed at the SESAME synchrotron, is dedicated to advanced soft X-ray photoelectron spectroscopy (XPS/UPS) for surface and interface analysis. Designed for high-resolution measurements across a broad photon energy range, TXPES enables detailed investigation of electronic structure, chemical composition, and oxidation states in complex materials.

The end station features interconnected UHV chambers for sample preparation, analysis, and in situ or near-ambient pressure experiments. Equipped with a hemispherical analyzer, ion gun, LEED, and LEIS, it allows comprehensive surface characterization with variable depth sensitivity.

TXPES provides a powerful platform for studying surface oxidation, adsorption, catalysis, and band alignment under controlled environments, including realistic gas conditions via its high-pressure cell. Currently in commissioning, the beamline will support diverse research on functional oxides, thin films, catalysts, and magnetic materials, highlighting the collaborative effort between Turkish institutions and SESAME toward full user operation.

O 3: Scanning probe techniques: Method development I

Time: Monday 10:30–12:15 Location: HSZ/0204

O 3.1 Mon 10:30 HSZ/0204

Single-Molecule Insights into On-Surface C-C Bond Formation: Radical Control via Sequential Dehalogenation — Qigang Zhong[1], Daniel Kohrs[2], Jannis Jung[3], Daniel Ebeling[1], Doreen Mollenhauer[3], Hermann Wegner[2], and •Andre Schirmeisen[1] — [1]Institute of Applied Physics, Justus-Liebig University Giessen, Giessen, Germany — [2]Institute of Organic Chemistry, Justus Liebig University Giessen, Giessen, Germany — [3]Institute of Physical Chemistry, Justus Liebig University Giessen, Giessen, Germany

On-surface synthesis through dehalogenative coupling provides a powerful route to construct carbon-carbon bonds with atomic precision. Using a combination of scanning tunneling microscopy (STM), atomic force microscopy (AFM), and density functional theory (DFT), we investigated the radical intermediates and coupling pathways of brominated polyaromatic precursors, specifically BBPN and BPIN, on Ag(111). Controlled thermal and tip-induced dehalogenation enabled the selective generation of phenyl and naphthyl radicals, which were subsequently characterized at the single-molecule level. Statistical analysis of tip-induced reactions reveals that cyclization leading to C-C bond formation occurs preferentially when the first dehalogenation takes place at the naphthyl group. Computational modeling demonstrates that radical alignment and flexibility govern the feasibility of C-C coupling. These findings highlight the interplay between precursor structure, radical generation sequence, and surface interactions in steering on-surface coupling chemistry.

O 3.2 Mon 10:45 HSZ/0204

Scanning probe microscopy investigation on cyclocarbons — •Jakob Eckrich[1], Lisanne Sellies[1], Marco Vitek[3], Yueze Gao[2], Fabian Paschke[1], Florian Albrecht[1], Leonard-Alexander Lieske[1], Harry L. Anderson[2], Igor Rončević[3], and Leo Gross[1] — [1]IBM Research Europe - Zurich, Rüschlikon, Switzerland — [2]Oxford University, Oxford, UK — [3]University of Manchester, Manchester, UK

I will discuss our recent investigations of cyclocarbons by means of scanning tunneling microscopy (STM) and atomic force microscopy (AFM). Cyclocarbons, molecular carbon allotropes consisting of a ring of two-fold coordinated carbon atoms, have been synthesized on surface using tip-induced chemistry [1-3], and the formation of larger cyclocarbons by dimerization of precursors was shown [3]. This talk will focus on the generation and investigation of large cyclocarbons.

O 3.3 Mon 11:00 HSZ/0204

Machine Learning Models Tailored for Scanning Probe Microscopy Topographic Data — •Lovis Hardeweg, Johanna Matusche, Johannes Schwenk, Christoph Sürgers, Wolfgang Wernsdorfer, and Philip Willke — Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany

Modern machine learning methods have great potential to automate processes in scanning probe microscopy (SPM). An important step for any automated operation of SPM is the accurate extraction of meaningful information, such as the position and type of adsorbates, from topographic data. Existing frameworks, that localize and identify adsorbates on the surface [1], often rely on large models developed by the traditional computer vision community. Therefore, their application to SPM topographies has certain drawbacks.

Here, we present two machine learning architectures that are adapted specifically for their application to high-resolution low-temperature SPM data. The first model predicts a semantic segmentation on samples with heterogeneous surface material, Ag(001) and MgO/Ag(001) in particular. The second model is trained to identify adatoms, molecules and possible clusters adsorbed on the surface. Both models achieve high accuracy. Additionally, due to their reduced size, they require fewer resources during training and application than models, that have not been purpose-built for their respective tasks.

O 3.4 Mon 11:15 HSZ/0204

Exploring Dissipation in Single-Molecule Manipulation — •Norio Okabayashi[1], Alfred J. Weymouth[2], Sophia Schweiss[2], Thomas Frederiksen[3,4], and Franz J. Giessibl[2] — [1]Kanazawa University, Ishikawa 920-1192, Japan — [2]University of Regensburg, Regensburg D-93053, Germany — [3]Donostia International Physics Center, San Sebastián 20018, Spain — [4]Basque Foundation for Science, Bilbao 48013, Spain

Single-molecule manipulation with scanning probe microscopy (SPM) offers a well-defined platform for studying nanoscale friction. While previous work has focused mainly on the forces driving molecular motion [1], the corresponding dissipation processes remain less explored. Here, we investigate a single CO molecule on Cu(110) using STM, AFM, LFM, and DFT at low temperatures. DFT identifies the preferred adsorption sites and the switching pathway (top-bridge-top), which are confirmed experimentally by IETS and by dissipation signals during AFM and LFM oscillations. In AFM [2], dissipation appears only along specific manipulation paths, whereas in LFM it also arises along trajectories associated with molecular switching. The switching rate is evaluated from STM as a function of lateral tip position, giving the manipulation probability per LFM oscillation cycle. Combining this cycle-resolved rate with the measured dissipation per cycle allows us to quantify the energy dissipated per manipulation event.

O 3.5 Mon 11:30 HSZ/0204

A direct measurement of weak lateral trapping over a C_6 ring — •Alfred John Weymouth[1], Maximilian Titl[1], Shinjae Nam[1], Lukas Hörmann[2], Oliver Hofmann[3], and Franz J. Giessibl[1] — [1]University of Regensburg, Germany — [2]University of Warwick, U.K. — [3]TU Graz, Austria

Six-membered carbon rings (C_6 rings) can be found in a multitude of systems from graphite to organic molecules. Graphitic surfaces are so flat that they have been used to explore superlubricity, where one important aspect of their fric-

tional response is the trapping of a single atom in an individual C_6 ring. This trapping also plays a role in the lateral movement of adsorbates on these surfaces. However, studies investigating trapping on these surfaces often focus only on strongly-bound adsorbates. We experimentally measure the trapping of a weakly-bound single atom asperity using lateral force microscopy with a CO-tip and simulate this system with DFT-based methods. Surprisingly, we observe a uniform lateral spring constant within individual C_6 rings over heights of tens of picometers for a range of systems. To precisely determine the surface trapping, we re-evaluate the lateral spring constant of the CO at the tip apex. With this value, we determined a very weak lateral spring constant of a particle within a C_6 ring.

O 3.6 Mon 11:45 HSZ/0204

Atomic scale energy dissipation as a function of temperature measured with LFM — •Sophia Schweiss[1], Lukas Hörmann[2], Franz Giessibl[1], and Alfred Weymouth[1] — [1]University of Regensburg, Regensburg, Germany — [2]University of Vienna, Vienna, Austria

One method of studying atomically resolved surfaces and adsorbates is small amplitude FM-AFM. With this technique, the conservative (frequency shift, Δf) and non-conservative (dissipated energy, E_{diss}) components of the tip-sample interaction are measured. Lateral force microscopy (LFM) is a related technique in which the tip oscillates laterally. Tip preparation for standard FM-AFM experiments at low temperature often includes the pickup of a CO molecule at the tip apex, which results in an inert tip with enhanced imaging properties. [1] These tip preparation techniques are also available for LFM. Over individual chemical bonds, LFM yields a measurable E_{diss} signal which we interpret as the CO snapping over the bond. [2]

Here, a CO-terminated tip is used to investigate the bonds of PTCDA molecules deposited on a Cu(111) surface with LFM. E_{diss} is measured for different temperatures in the range of 5.3 K to 6.5 K. Certain bonds exhibit a distinct T-dependence, whereas others do not.

[2] Weymouth et al., Phys. Rev. Lett., 124, 196101 (2020)

O 3.7 Mon 12:00 HSZ/0204

Bond-resolved STM with density-based methods — Emiliano Ventura-Macias[1], Jose Martinez-Castro[2], Guillermo Haas[1,3], •Jara Trujillo-Mulero[1], Pablo Pou[1], Markus Ternes[2], Ruslan Temirov[2], Frank Stefan Tautz[2], and Rubén Pérez[1] — [1]Departamento de Física Teórica de la Materia Condensada and Instituto de Física de la Materia Condensada (IFIMAC), Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [2]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425, Jülich, Germany — [3]Grenoble INP-Phelma, 3 Parv. Louis Néel, 38000 Grenoble, France

Bond-resolved STM (BRSTM) combines scanning tunneling microscopy with the intramolecular resolution of CO-functionalized ncAFM. We introduce a simple, broadly applicable method for simulating BRSTM images and apply it to new measurements of PTCDA on Ag(111) acquired with unprecedented tip-sample control (~10 pm). Our approach integrates the Full-Density-Based Model (FDBM) for high-resolution AFM with Chen's derivative approximation, capturing both σ and π tunneling channels while accounting for CO-tip deflection. It accurately reproduces experimental images of PTCDA/Ag(111) and TOAT/Cu(111), including subtle distance-dependent features. We also show that substrate-induced changes in orbital occupation and CO relaxation significantly influence BRSTM contrast.

O 4: Metal & Semiconductor substrates: Adsorption and reaction of small molecules I

Time: Monday 10:30–12:15 Location: HSZ/0401

O 4.1 Mon 10:30 HSZ/0401

Increasingly incoherent: Effects of adatoms on the structure and characterisation of physisorbed aromatic molecules on Cu(111) — •Henry Thake[1], Matthew Stoodley[1,2], Mariia Radova[1], David A. Duncan[2,3], Lukas Hörmann[4], and Reinhard J. Maurer[1,4] — [1]University of Warwick, UK — [2]Diamond Light Source, UK — [3]University of Nottingham, UK — [4]University of Vienna, AT

X-ray standing wave (XSW) is a quantitative structural characterisation technique for hybrid metal-organic interfaces, providing species-dependent adsorption heights at picometer accuracy. Alongside adsorption heights, XSW measurements provide information on the coherence of the signal, directly related to the structural disorder of the overlayer. A series of recent XSW experiments on physisorbed poly-aromatic hydrocarbons (PAHs) revealed surprisingly low coherent fractions that are inconsistent with structural models produced by Density Functional Theory (DFT) calculations. In this talk, we investigate a hypothesis that this apparent increase in disorder may be related to molecular interactions with surface adatoms that are omnipresent at ambient conditions. Using a frozen transfer learned interatomic potential trained on DFT data of PAHs on Cu(111), we probe the influence of adatoms on dynamic adsorption at the interface. Spectroscopic measurements of these systems reveal perturbations in the electronic structure that are consistent with the co-adsorption of PAHs with adatoms. The inclusion of Cu adatoms to Cu(111) consistently increases the disorder for the PAHs, in line with XSW measurements.

O 4.2 Mon 10:45 HSZ/0401

Interfacial Processes in Ionic Liquid-Modified Catalysts — •Laura Ulm, Cynthia C. Fernández, Hans-Peter Steinrück, and Florian Maier — Lehrstuhl für Physikalische Chemie II, Friedrich-Alexander-Universität Erlangen-Nürnberg

Solid catalysts with ionic liquid layers (SCILL) provide a powerful route to tailor the selectivity of catalytic reactions. In this context, we study the elementary reaction steps involved in the hydrogenation of 1,3-butadiene to 1-butene, a reaction in which high selectivity is crucial for hydrocarbon processing. We recently demonstrated that ionic liquids (ILs) selectively modify the adsorption of 1,3-butadiene over 1-butene, that is, the initial step of the hydrogenation of 1,3-butadiene on Pt(111). Herein, we now address the next reaction step, namely, how ultrathin layers of the IL $[C_8C_1Im][PF_6]$ influence olefin displacement from Pt(111). Ultrathin films of IL with thicknesses < 1 nm are prepared in situ by physical vapor deposition. Using temperature-programmed X-ray photoelectron spectroscopy (TPXPS), we track structural and compositional film changes and olefin desorption with increasing temperature. We find that i) IL deposition onto a saturated 1-butene layer enhances the displacement and desorption of 1-butene by a factor of 2.8; ii) 1,3-butadiene remains unaffected by the IL; and iii) IL decomposition on Pt(111) is shifted to higher temperatures by 80 ± 10 K.

O 4.3 Mon 11:00 HSZ/0401

Investigating CO Oxidation on Rh(111)/(332) with High-Repetition-Rate Velocity Resolved Kinetics — •Johannes Diedrich, Arved Dorst, and Tim Schäfer — Georg-August-Universität Göttingen, Institut für Physikalische Chemie, Tammannstr. 6, 37077 Göttingen

Velocity resolved kinetics (VRK) allows measuring the temporal evolution of reaction products from surfaces. A recent development is high repetition rate (HRR)-VRK [1]. By using more ionization pulses per molecular beam pulse, the signal-to-noise ratio is significantly improved and data acquisition accelerated.

An ultra-high-vacuum apparatus used for conventional VRK was modified to HRR-VRK by using a 100 kHz femtosecond laser for multiphoton nonresonant ionization and a TimePix3 event camera. This setup enables measururement of the full time of flight spectrum for every laser pulse.

Preliminary results are presented for the oxidation of CO on Rh(111) and (332) facets. This system allows comparison of conventional and HRR-VRK for a previously investigated reaction [2]. Thermal and hyperthermal CO2 channels are distinguished and deviations from the single-exponential decay are discussed. In future work, the decomposition of hydrazine on Ir will be investigated to gain a deeper understanding of Ir-based monopropellant thruster catalysts.

O 4.4 Mon 11:15 HSZ/0401

First-principles structure search study of multi-component alloys for electrocatalysis — Lei Jia, •Guo-Xu Zhang, and Zhenbo Wang — MIIT Key Laboratory of Critical Materials Technology for New Energy Conversion and Storage, School of Chemistry and Chemical Engineering, Harbin Institute of Technology, Harbin, P. R. China

Multi-component alloys (MCA) have gained increasing attention as electrocatalysts due to their tunability of catalytic properties, while vast composites and diverse active sites make them highly challenging to identify configurations of molecules on surfaces. Here, we combined first-principles calculations with an active machine learning approach, Bayesian Optimization Structure Searching (BOSS), which enables efficient and accurate identification of molecular adsorbate structures on the MCA surfaces. This strategy utilizes smart sampling of adsorption energy surface (AES), constructs a surrogate model to predict the AES landscapes, and continuously refines the models to search global and local minima of adsorption configurations. The performance of first-principles calculations with BOSS was illustrated by benchmark data against single-atom, binary and ternary alloy catalysts. The good predictive power of our method suggests an effective way towards large-scale molecular adsorption for MCA electrocatalysts.

O 4.5 Mon 11:30 HSZ/0401

Surface effects during plasma-activated nitrogen splitting for catalytic ammonia formation — •Sabine Auras and Roland Bliem — ARCNL, Amsterdam, The Netherlands

Plasma-assisted catalysis (PAC) enables the activation of stable molecules, e.g. N_2 or CO_2, by generating reactive species that interact with a catalyst, thereby lowering dissociation barriers and creating new reaction pathways. For ammonia synthesis, PAC is particularly attractive as it can operate under milder conditions than the conventional Haber-Bosch process, potentially improving efficiency while reducing energy input. However, plasma fundamentally alters the reaction environment, which limits the applicability of concepts from thermal catalysis. Therefore, in-situ studies of surface properties and adsorbate evolution are needed to understand the surface chemistry under plasma conditions.

Here, we present the first in situ XPS data of Ru and Rh surfaces during N_2 plasma exposure, as well as mixed N_2/H_2 plasmas. To correlate surface processes and plasma properties, we further characterize the plasma composition by optical emission spectroscopy and monitor gas-phase products using mass spectrometry. The results reveal distinct differences in how activated N_2 species interact with the catalytic surface. This allows us to identify surface intermediates, assess reaction kinetics, and propose a mechanism for NH_3 formation, taking into account the role of different plasma species. Our findings highlight the need for a combined approach to identify the role that plasma and catalytic surfaces play - and thus to understand the interactions driving plasma-assisted catalysis.

O 4.6 Mon 11:45 HSZ/0401

Bonding properties of a CO molecule with metallic adatoms — •Fabian Stilp, Marco Weiss, Mia Fuerst, Maximilian Krueger, Luis Vendolsky, Nicolas Wirth, Hendrik Weinert, and Franz J. Giessibl — Department of Physics, University of Regensburg, Germany

CO terminated AFM tips are often used to investigate molecules on surfaces as they are a powerful tool to make the internal structure of such molecules visible. Their chemical inertness results in high resolution of the single atoms and bonds in such molecule via Pauli repulsion. However, it was shown by Huber et al. [1] that CO terminated tips can form weak bonds to some species of adatoms on a Cu (111) sample such as Fe and Cu. In contrast, Si adatoms only interact via van der Waals attraction and Pauli repulsion.

Can one predict the strength of the bond between the CO molecule and an arbitrary atom just from its electron configuration? To set the rules for this prediction we expand our collection of AFM measurements with various atomic species.

In total the interaction between the CO molecule and the adatom shows up to five different regimes, two attractive and three repulsive. The forces are distinctly pronounced, which allows to group the atoms in four different types.

We analyze the different atomic species for their different barrier before forming the bond, directionality of the bond and electrostatic interactions.

O 4.7 Mon 12:00 HSZ/0401

Online monitoring of the oxygen adsorption on Cu(110) with PEEM and DRS — •Robert Heller, Thorsten Wagner, and Peter Zeppenfeld — Johannes Kepler University, Institute of Experimental Physics, Surface Science Division, 4040 Linz, Austria

We studied the dissociative adsorption of oxygen on the Cu(110) surface using Photoelectron Emission Microscopy (PEEM) and Differential Reflection Spectroscopy (DRS) simultaneously. Unlike many experiments carried out already in the 1970s and 1980s, our approach focusses on real-time monitoring. For oxygen exposures up to ~100L, at temperatures between 350K and 420K, the process saturates at an oxygen coverage of 0.5 with a well-ordered (2×1)O superstructure. At intermediate coverages, a regular pattern of alternating Cu and CuO stripes is formed [1].

We used a PEEM with a xenon lamp (Xe) to study changes in the electron yield (EY) during the exposure. Oxygen adsorption causes a decrease in EY and, hence, an increase in the work function. Since our DRS setup uses the same light source as the PEEM, we can synchronously record the change of the reflectance and reliably compare the two signals. Interestingly, the normalised adsorption curves are not identical, indicating that the PEEM and/or the DRS signals are not directly proportional to the oxygen coverage. This could be related to the effect of the formation of the nanostructured Cu-CuO stripe pattern upon oxygen adsorption [1].

O 5: Focus Session: Mineral-water interfaces I

The Focus Session discusses recent advances in the understanding of mineral-water interfaces. These interfaces are ubiquitous in nature, host of many geological and biological processes, intimately linked to the global carbon cycle, and therefore highly relevant for Earth*s climate. For example, silicate weathering removes carbon dioxide from the atmosphere on geological timescales, acting as a stabilizing feedback mechanism since weathering rates increase with temperature. In the oceans, carbonates dissolve and precipitate in response to changing atmospheric carbon dioxide concentrations, thus far mitigating part of the anthropogenic impact of CO_2 emissions. In addition, numerous industrial and technological processes involve mineral-water interfaces, including seawater desalination, scaling and incrustation prevention, as well as various biochemical applications. However, and despite their importance, many fundamental aspects of mineral-water interfaces remain poorly understood, including water binding and diffusion, structure formation, ice nucleation, growth, or desorption.

This DPG Focus Session will address these aspects at the molecular level, elucidating fundamental processes involving both single water molecules and bulk water in contact with mineral surfaces. The session brings together scientists investigating mineral-water systems under ultrahigh vacuum conditions as well as at mineral-water interfaces in bulk aqueous environments. We aim for a balanced Session with contribution from both renowned experts and young investigators active in the field.

Organized by Philipp Rahe (U Osnabrück), Angelika Kühnle (U Bielefeld), Jan Balajka (TU Vienna), Wolf Gero Schmidt (U Paderborn).

Time: Monday 10:30–12:30 Location: HSZ/0403

Invited Talk O 5.1 Mon 10:30 HSZ/0403

Can the mineral-water interface save the world? Mineral carbonation, enhanced weathering and negative emissions — •Philip Pogge von Strandmann — Johannes Gutenberg University, Mainz

The rising atmospheric CO2 concentrations are clearly having a significant impact on the climate, and will continue to do so. The currently only foreseeable method by which anthropogenic climate change will not be completely catastrophic (i.e. limited to 1.5-2°C warming), is if we implement global "negative emissions" technologies, that is the artificial removal of CO2. Two such technologies directly rely on the mineral-water interface: mineral carbonation and enhanced weathering. Both require the dissolution of silicate minerals in mildly acidic water, and the subsequent precipitation of carbonate secondary minerals, but without too much precipitation of silicate secondary minerals, which hinder the reaction. In fact, the reaction is more complex than that, because numerous reactions occur at the mineral-water interface: dissolution, sorption, exchange, co-precipitation and incorporation into interstitial sites in mineral lattices. Each of these reactions has significant consequences for the efficiency of the reaction and the CO2 drawdown. This presentation will examine these reactions, including the aspects we currently understand and can measure, and those where our knowledge and analytical abilities are still lacking.

O 5.2 Mon 11:00 HSZ/0403

Reconstruction of calcite (10.4) manifests itself in the tip-assisted diffusion of water — •Klausfering Lea, Schneider Florian, Bechstein Ralf, and Kühnle Angelika — Bielefeld University, 33615 Bielefeld, Germany

Calcite is the most common carbonate in the Earth*s crust and plays a fundamental role in environmental and industrial processes. The most stable cleavage plane of calcite is the (10.4) plane. This surface has already been extensively stud-

ied in liquid environments as well as under ultra-high vacuum (UHV) conditions. Under UHV conditions, the surface exhibits a (2 x 1) reconstruction. Due to this reconstruction, there are two energetically different adsorption sites for adsorbates, such as water. Here, we present an atomic force microscopy (AFM) study in which the diffusion of individual water molecules on the calcite (10.4) surface was investigated under UHV conditions at a temperature of 140 K. The positions of individual water molecules could be precisely determined in several consecutive atomically resolved images, allowing the diffusion of the water molecules to be observed. We found that the AFM tip has an influence on the diffusion of the water molecules, but that diffusion only occurs between one type of adsorption positions.

O 5.3 Mon 11:15 HSZ/0403

Nanoscopic insights on ice nucleation on microcline (001) — •Florian Schneider[1], Rasmus Väinö Erik Nilsson[2], Ralf Bechstein[1], Bernhard Reischl[2], Thomas Koop[1], Angelika Kühnle[1], and Tobias Dickbreder[3] — [1]Bielefeld University, Bielefeld, Germany — [2]University of Helsinki, Helsinki, Finland — [3]University of Vienna, Vienna, Austria

Heterogeneous ice nucleation plays a crucial role in various environmental and technological processes. An in-depth understanding of the nucleation at the atomic scale can greatly enhance our capability to create materials with particular ice-nucleating properties and improve our climate models. In the atmosphere, a particularly active ice nucleating particle is dust from the feldspar mineral microcline [1]. However, why microcline outperforms other mineral dust particles in its ice-nucleating ability still remains a puzzle. Here, we present atomic force microscopy images of ice crystals growing from the vapor phase on the (001) surface of microcline at low temperature. In contrast to the prevailing view of active sites such as step edges or cracks being responsible for ice nucleation, we observe ice growth at random positions on the bare terrace. For the closely related feldspar sanidine, in contrast, ice nucleation is prevalent at step edges as expected. This comparison underscores the exceptional ice nucleating ability of microcline as it demonstrates ice nucleation even in the absence of surface defects and raises important questions regarding the different ice nucleation mechanisms on these two feldspar mineral surfaces.

Invited Talk O 5.4 Mon 11:30 HSZ/0403

Machine learning exploration of water binding and ice nucleation at silicate and carbon surfaces — •Mie Andersen — Department of Physics and Astronomy, Aarhus University, Denmark

Mineral-water interfaces play a central role in environments ranging from the interstellar medium to Earth's surface and subsurface. In astrochemistry, the chemical evolution of star-forming regions is controlled by gas-grain interactions on dust grains that may be partially or fully covered by water ice. A key quantity underlying these processes is the binding energy (BE) of adsorbates, which determines desorption and diffusion rates and controls chemical kinetics.

In this contribution, we explore computational strategies to quantify BE distributions at complex, partially ice-covered mineral surfaces. Using graphene and forsterite as model grain substrates, we combine atomistic simulations with machine-learning interatomic potentials to generate realistic surface structures and to efficiently sample BEs. The modelled ice structures range from amorphous structures generated by low-temperature molecular dynamics simulations to highly stable crystalline structures generated by global structure optimization. The resulting BE distributions are analyzed in terms of surface heterogeneity, ice coverage and hydrogen bonding.

While motivated by astrochemical applications, the presented methodology is broadly transferable to mineral-water interfaces under terrestrial conditions. The approach offers a general framework for linking molecular-scale interfacial structure to macroscopic transport and reaction models across disciplines.

O 5.5 Mon 12:00 HSZ/0403

Chiral water structures on dolomite(104) surfaces — •Jonas Heggemann[1], Paul Laubrock[1], Jie Huang[2], Adam S. Foster[2,3], and Philipp Rahe[1] — [1]Institute of Physics, Osnabrück University, Osnabrück, Germany — [2]Department of Applied Physics, Aalto University, Helsinki, Finland — [3]Nano Life Science Institute (WPI NanoLSI), Kanazawa University, Kanazawa, Japan

The formation mechanisms of dolomite ($CaMg(CO_3)_2$), an abundant rock-forming carbonate mineral with rhombohedral structure [1], are still poorly understood in the earth's crust [2]. The lack of replicating mineral growth under geological conditions in the laboratory is a further characteristic of the "dolomite problem" [2]. Consensus could be reached that dolomite formation only occurs in the presence of water [3] and it is further known that (104) is the most stable surface [4].

Here, we unravel a chiral character of dolomite(104) surfaces from non-contact atomic force microscopy data acquired with CO terminated tips. Backed by density functional theory and probe-particle model calculations, the presence of two surface enantiomers is identified. We further investigate water adsorption, with coverage ranging from single molecules to a full monolayer. Preferred water adsorption is found at calcium and magnesium surface sites; yet, the geometries carry a clear chiral property.

Atomically Resolved Imaging of the Gypsum (010) surface — •David Kugler, Andrea Conti, Tun Sinner, Florian Mittendorfer, Michael Schmid, Gareth S. Parkinson, Ulrike Diebold, and Jan Balajka — Institute of Applied Physics, TU Wien, Vienna, Austria

Gypsum ($CaSO_4{\cdot}2H_2O$), the dihydrate of calcium sulfate, is the most abundant sulfate mineral in Earth's crust and it is widely used as a fertilizer and as a construction material. Its bulk crystal structure consists of alternating calcium sulfate bilayers and bilayers of crystal water. While the water in the bulk has been extensively studied, a comprehensive understanding of surface processes is still missing. Water is, however, present on all surfaces in ambient environment and influences surface chemistry. Because the adjacent layers are linked only by hydrogen bonds, gypsum cleaves readily along the (010) plane, exposing large, atomically flat terraces. In this work, noncontact atomic force microscopy (nc-AFM) with a qPlus sensor was used to resolve the atomic structure of the cleaved gypsum (010) surface and to visualize the configuration of adsorbed water. Our results indicate that one of the surface crystal water molecules rotates into a lower energy orientation, forming a hydrogen bond with the second crystal water molecule within the unit cell. Preliminary ab-initio modeling suggests that the first adsorbed water layer preserves the periodicity of the bulk structure by forming hydrogen bonds with the surface crystal water.

O 6: Organic molecules on inorganic substrates: Adsorption and growth I

Time: Monday 10:30–12:30 Location: TRE/PHYS

O 6.1 Mon 10:30 TRE/PHYS

Support-dependent reactivity of Fe-DCA 2D Metal-Organic Frameworks — •Dominik Hrůza[1], Zdeněk Jakub[1], Jakub Planer[1], Tadeáš Lesovský[2], Ayesha Jabeen[1], Pavel Procházka[1], and Jan Čechal[1,2] — [1]CEITEC - Central European Institute of Technology, Brno University of Technology, Purkyňova 123, Brno 61200, Czechia — [2]Institute of Physical Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Technická 2896/2, Brno 61200, Czechia

2D Metal-Organic Frameworks (2D MOFs) are promising materials for applications in catalysis, sensing and spintronics. 2D MOFs based on 9,10-dicyanoanthracene (DCA) linker molecules are particularly intriguing due to their recently demonstrated magnetic and topological properties. Here, we study the reactivity of Fe-DCA supported on two weakly-interacting supports: graphene/Ir(111) and Au(111). Using Scanning Tunneling Microscopy (STM), X-Ray Photoemission Spectroscopy (XPS) and Low-Energy Electron Microscopy/Diffraction (LEEM/LEED), we test how the Fe-DCA reacts with carbon monoxide and molecular oxygen. When the Fe-DCA is supported on graphene, the CO adsorbs on the Fe-sites at temperatures below 200 K, while O2 exposure causes structural collapse of the 2D MOF at room temperature. In contrast, when the Fe-DCA is supported on Au(111), it appears inert to CO adsorption. Overall, our results show how the chemical reactivity of 2D MOFs depends on the supporting surface, providing critical insights for the potential integration of MOFs into functional devices.

O 6.2 Mon 10:45 TRE/PHYS

LT-STM investigation of azulene-based molecular architectures on metal surfaces — •Suchetana Sarkar[1,4], Natasha Khera[1], Kwan Ho Au-Yeung[1,5], Renxiang Liu[1,2,3], Ji Ma[1,2,3], Xinliang Feng[1,2,3], and Francesca Moresco[1] — [1]Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany — [2]Chair of Molecular Functional Materials and Faculty of Chemistry & Food Chemistry, TU Dresden, 01062 Dresden, Germany — [3]Max Planck Institute of Microstructure Physics, Weinberg 2, Halle, Germany — [4]Present address: Department of Chemistry, Philipps-Universität Marburg, 35032 Marburg, Germany — [5]Present address: Physikalisches Institut, Karlsruhe Institute of Technology, Karlsruhe, Germany

Azulene-based molecules offer a unique platform for probing on-surface self-assembly and electronic structure due to their non-benzenoid topology and intrinsic dipole. Presented here are the investigations of two related systems:

a cyclopenta[cd]azulene trimer (CPAT) and a phenyl-functionalized analogue (CPAT-Ph), using low-temperature scanning tunneling microscopy and spectroscopy. CPAT forms well-ordered homochiral domains on Au(111), whereas CPAT-Ph exhibits weak adsorption and high mobility on Au(111) and shows no ordered phases on Cu(110). Spectroscopy reveals clear electronic differences between the molecules and substrate-induced shifts for CPAT-Ph. Finally, the results of thermally induced ring-closing reactions are also shown, discussing routes toward on-surface synthesis of non-benzenoid nanographenes.

O 6.3 Mon 11:00 TRE/PHYS

Surface study of heteromolecular layers for charge injection: deprotonated carboxylic acids mixed with pentacene — •Jakub Planer[1], Veronika Stará[1], Pavel Procházka[1], and Jan Čechal[1,2] — [1]Central European Institute of Technology, Brno University of Technology, Czech Republic — [2]Institute of Physical Engineering, Brno University of Technology, Czech Republic

Heteromolecular organic films represent promising candidates for efficient charge-injection layers in organic optoelectronic devices. Using surface-science experiments together with ab-initio modeling, we investigate the structural and electronic properties of intermixed layers composed of fully deprotonated carboxylic acids and pentacene (PEN) on Ag(100) and Ag(111) substrates. Our work demonstrates that these molecules form blends capable of modulating the electrode work function by up to 0.5 eV, depending on the mixing ratio, while remaining stable during subsequent organic-semiconductor deposition. These findings underline the potential of mixed carboxylate–PEN layers as practical, robust charge-injection modifiers and show that various carboxylic acids can be effectively used in such heteromolecular interfaces [1,2].

O 6.4 Mon 11:15 TRE/PHYS

Orientational Order of Phenyl Rotors on Triangular Platforms on Ag and Au(111) — Richard Berndt[1], Richard Berndt[2], Richard Berndt[2], Richard Berndt[3], and •Richard Berndt[1] — [1]Institut für Experimentelle und Angewandte Physik, CAU Kiel, Germany — [2]Otto-Diels-Institut für Organische Chemie, CAU Kiel, Germany — [3]Centro de Física de Materiales, Donostia-San Sebastián, Spain

We investigated trioxatriangulenium functionalized with phenyl on Ag(111) and Au(111) using low-temperature scanning tunneling microscopy (STM). On Ag, the molecules form hexagonal arrays and the orientations of the phenyl moieties are resolved. Moreover, STM images suggest a dimerization of the molecules. Density functional theory calculations reproduce the experimental data. Van der Waals interaction is the dominant binding mechanism. The apparent dimerization results from an asymmetry of the phenyl wavefunction, which reflects intramolecular hydrogen bonding between the ligand and an oxygen atom of the triangulenium platform. Direct long-range interaction between phenyl moieties across molecules and the intramolecular H bonding are decisive for the orientations of the phenyl moieties. Similar experimental results were obtained on Au(111).

O 6.5 Mon 11:30 TRE/PHYS

Adsorption and Isomerization of Azobenzene Tetramers on Au(111) — •Natasha Khera[1], Ebru Cihan[1], Franz Plate[1], Soyoung Park[2], Ningwei Sun[2], Dmitry A. Ryndyk[1,2], Franziska Lissel[2,3], and Francesca Moresco[1] — [1]Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany — [2]Leibniz Institute of Polymer Research Dresden, Germany — [3]Institute for Applied Polymer Physics, TU Hamburg, 21073 Hamburg, Germany

This work investigates the manipulation and voltage-induced switching of star-shaped azobenzene tetramers [1] on Au(111) using low-temperature ultra-high vacuum scanning tunneling microscopy (LT-UHV STM) to study their adsorption behavior and cis-trans isomerization. On terraces, molecules in the trans state are highly mobile and difficult to image stably, whereas voltage induced switching to the cis state makes them immobile for reliable measurement. The study also utilizes step-edge sites where trans molecules are more stable and can be addressed without prior switching. Voltage pulses with the STM tip produces reproducible switching between high-contrast and low-contrast STM signatures, consistent with the cis-trans isomerization of the azobenzene core. Electric-field-dependent measurements are also performed by retracting the STM tip and recording tip-height vs bias characteristics, providing insight into the electric-field driven response of the molecules.

Steering interfacial molecular self-assembly by substrate-molecule charge transfer — •Benjamin Achatz, Matthias Zeilerbauer, Marco Thaler, and Laerte Patera — Department of Physical Chemistry, University of Innsbruck, Innsbruck, 6020, Austria

Scanning probe microscopy studies of organic molecules on metal substrates have furthered our understanding of substrate-molecule charge transfer processes [1]. On surface self-assembly of the electron acceptor C_{60} is driven by an interplay of short-range attractive Van der Waals forces and long-range repulsive electrostatic interactions [2]. Here we report the formation of an intermixed phase composed of C_{60} and Zn(II)-5,10,15,20-tetrakis(4-aminophenyl)porphyrin (Zn-TAPP) molecules on Ag(111). An approach combining scanning tunneling spectroscopy (STS) and Kelvin probe force microscopy (KPFM) was used to investigate the degree of substrate-molecule charge transfer for C_{60} in close-packed islands and a row-like intermixed structure. Analysis of our tunneling and force spectroscopy measurements revealed that mitigation of the coulomb repulsion drives the formation of the intermixed phase and promotes additional charge transfer to the C_{60} molecules. These results demonstrate that controlling long-range Coulomb interactions can steer the formation of distinct self-assembled structures on metal substrates, offering insights for the design of new charge-optimized molecular nanostructures.

O 6.7 Mon 12:00 TRE/PHYS

Nanostructuring of organic radicals on cobalt surfaces — •Arkaprava Das and M. Benedetta Casu — Institute of Physical and Theoretical Chemistry, University of Tübingen, Tübingen, Germany

Organic radicals are potential candidates for groundbreaking applications like energy storage, quantum computing, and spintronics. To investigate the nature of the adsorption of the radical derivative molecules on cobalt surfaces, we investigate their electronic structure and morphology. The electronic structure at the interface is investigated by using X-ray photoelectron spectroscopy (XPS), and the morphology is studied with scanning electron microscopy. The radical/Co interface interactions have resulted in different nanostructures crucial for device fabrication, whereas changes in line shape of core level spectra confer direct evidence of changed electronic properties at the interface. Considering ecological requirements, we also endeavour to minimize the materials consumption by making the Co substrate reusable, which is in line with the principles of closed-loop circular economy.

O 6.8 Mon 12:15 TRE/PHYS

Competition between dative bonds and aromatic gains — •Jonas Brandhoff[1], Richard Berger[2], Felix Otto[1], Maximilian Schaal[1], Lorenz Brill[1], Oliver T. Hofmann[2], Peter Puschnig[3], Torsten Fritz[1], and Roman Forker[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany — [2]Institute of Solid State Physics, Technical University Graz, Petersgasse 16, 8010 Graz, Austria — [3]Institute of Physics, University of Graz, Universitätsplatz 5, 8010 Graz, Austria

Upon molecular adsorption on a surface, a variety of interactions can occur. Identifying which mechanisms dominate this complex quantum-mechanical landscape is crucial for understanding molecule – surface coupling. One key factor in many π-conjugated systems is aromaticity – a fundamental concept in chemistry describing the energetic stabilization that arises from particular π-electron arrangements. To investigate how aromaticity competes with other adsorption-driven interactions, we study 5,7,12,14-pentacenetetrone (P4O) on different metal surfaces as a model system. P4O is a prototypical molecule expected to undergo aromatic stabilization upon adsorption, where charge transfer from the substrate modifies the topology of the occupied π-system and leads to a more energetically favorable configuration. Using photoemission orbital tomography measurements combined with density functional theory calculations, we show how hybridization with the surface can outweigh a potential aromatic stabilization, *not* necessarily maximizing the latter. We reveal a mechanism in which the unoccupied π-system of the molecule forms dative bonds with the substrate.

O 7: 2D Materials: Electronic structure, excitations, etc. I (joint session O/HL/TT)

Time: Monday 10:30–12:30 Location: TRE/MATH

Invited Talk O 7.1 Mon 10:30 TRE/MATH

Magnetic Order in 2D Materials Beyond Bulk Constraints — •Jeison Fischer — II. Physikalisches Institut, Universität zu Köln

Even though exfoliated microflakes remain widely used in 2D magnetism research, their bulk origin restricts access to many potentially interesting phases, an obstacle that molecular beam epitaxy (MBE) can overcome. MBE enables the controlled synthesis of single-layer materials directly related to, yet often distinct from, their bulk counterparts.

In my talk, I will present structural characterization and discuss the mechanisms behind the formation of such novel 2D materials grown via MBE on graphene. [1-2] The emerging magnetic properties of these new 2D materials will be exemplified with two cases: Cr_2S_3-2D and Fe_2S_2-2D. Cr_2S_3 forms a covalently bonded NiAs-type structure without van der Waals gaps. Using spin-polarized scanning tunneling microscopy (STM) and X-ray magnetic circular dichroism (XMCD), we show that it hosts ferromagnetic coupling within the plane with magnetic moments pointing out-of-plane, combined with A-type antiferromagnetic coupling between different Cr planes. Fe_2S_2 exhibits a unique hexagonal phase, in which Fe atoms occupy tetragonally coordinated sites. Spin-polarized STM reveals that the moments are noncollinear within the plane. We map the in-plane components of two distinct magnetic configurations and find that the moments are confined to the 2D plane, forming a Néel state and a 2Q state.

O 7.2 Mon 11:00 TRE/MATH

Ab initio modeling of magnons and magnon-phonon coupling in 2D magnetic materials — Ali Esquembre-Kucukalic[1], Khoa Le[2], Hsiao-Yi Chen[3], Ivan Maliyov[2], Jin-Jian Zhou[4], Davide Sangalli[5], and •Alejandro Molina-Sánchez[1] — [1]ICMUV, University of Valencia, Valencia, Spain — [2]CALTECH, California, USA — [3]Tohoku University, Japan — [4]Beijing Institute of Technology, Beijing, China — [5]ISM-CNR, Roma, Italy

Understanding spin-wave excitations in two-dimensional magnetic materials is essential for advancing spintronic and quantum information technologies. Chromium trihalides and related 2D magnets provide a platform where the choice of halide influences on the magnetic behavior, yet its impact on magnon properties is not completely understood. We present first-principles calculations of magnon dispersions and wave functions in monolayer Cr trihalides using the Bethe-Salpeter equation (BSE), resolving key features such as the topological gap at the Dirac point. The BSE analysis reveals that magnons originate from electronic transitions spanning a wider energy range than excitons, offering new insight magnon character and enabling the extraction of Heisenberg exchange parameters. Building on this framework, we develop an ab initio description of mag-ph coupling by deriving BSE-based mag-ph interaction matrices and applying them to monolayer CrI3 and hydrogenated graphene. We show that mag-ph and electron-phonon couplings differ markedly, identifying specific phonon modes that dominate magnon scattering.

O 7.3 Mon 11:15 TRE/MATH

Electron-phonon interaction in transition-metal dichalcogenides — •Gerrit Johannes Mann, Thorsten Deilmann, and Michael Rohlfing — Institute of Solid State Theory, University of Münster, Germany

Electron-phonon interaction is a crucial effect in solid state physics, in particular in two-dimensional materials. We developed a generally applicable ab-initio implementation on top of density functional theory using a basis set of localized Gaussian orbitals. It combines finite differences calculations with the perturbative Allen-Heine-Cardona framework in order to calculate the temperature-dependent renormalization of the electronic bandstructure due to electron-phonon interaction. Our implementation circumvents the limiting problems of previous implementations and allows to evaluate Debye-Waller contributions beyond the rigid-ion approximation [1], which are usually neglected.

In addition to the renormalization of the electronic bands, electron-phonon interaction introduces a line broadening due to finite-lifetime effects, which have recently been incorporated into our implementation. In this presentation, we discuss our results, including those with finite-lifetime effects, for two-dimensional transition-metal dichalcogenides, where the renormalization of the electronic bandstructure due to electron-phonon interaction can be as large as several hundreds of meV.

O 7.4 Mon 11:30 TRE/MATH

Surface-state engineering for nonlinear charge and spin photocurrent generation — •Javier Sivianes[1], Peio Garcia-Goiricelaya[2], Daniel Hernangómez-Pérez[3], and Julen Ibañez-Azpiroz[1,4,5] — [1]Centro de Física de Materiales (CSIC-UPV/EHU), Donostia, Spain — [2]University of the Basque Country UPV/EHU, Leioa, Spain — [3]CIC nanoGUNE BRTA, San Sebastián, Spain — [4]IKERBASQUE, Basque Foundation for Science, Bilbao, Spain — [5]Donostia International Physics Center (DIPC), Donostia, Spain

We systematically explore the generation of nonlinear charge and spin photocurrents using spin-orbit-split surface states. This mechanism enables net DC flow along the surface plane even in centrosymmetric bulk environments like the Rashba prototype Au(111), where we characterize the main quadratic contributions by combining model predictions with density functional calculations. We further identify the Tl/Si(111) surface as a prime scenario for experimental verification; with slight doping, it develops metallic surface states featuring remarkable relativistic properties deviating from the Rashba paradigm, while the bulk remains semiconducting. Its nonlinear charge photocurrent reveals a distinct angular signature and a magnitude comparable to bulk ferroelectrics, highlighting the potential of surface-state photocurrents for low-bias optoelectronic applications. Moreover, the non-trivial spin texture of its surface states enables the generation of pure out-of-plane spin-polarized currents, offering a highly versatile nonlinear spin-filtering functionality beyond the conventional spin Hall effect.

O 7.5 Mon 11:45 TRE/MATH

Influence of Vanadium Doping on WSe_2, as seen through ARPES — •Jana Kähler[1,2], Florian K. Diekmann[1,2], Matthias Kalläne[1,2,3], Tim Riedel[1,2], Adina Timm[1,2], Anja Yalim[1,2], Jens Buck[1,2], Meng-Jie Huang[2], Jules M. Knebusch[1,2], Luka Hansen[1,3], Jan Benedikt[1,3], and Kai Rossnagel[1,2,3] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [3]Kiel Nano, Surface and Interface Science KiNSIS, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

Spintronics offers a compelling, energy-efficient alternative to traditional electronics with potential applications in communications, sensing, and information processing. The vanadium-doped layered transition metal dichalcogenide $2H$-WSe_2 is particularly promising as a room-temperature magnetic semiconductor with gate-tunable transport properties. Here, we use a combination of 11 eV laser, 21.2 eV He-lamp, and soft X-ray synchrotron ARPES to highlight the influence of a fairly small vanadium doping on the electronic structure of WSe_2. Both the pristine and doped compounds were grown by chemical vapor transport in our own laboratory.

O 7.6 Mon 12:00 TRE/MATH

Engineering sulfur vacancy dimers in monolayer WS_2 — •Daniel Jansen[1], Guangyao Miao[1], Jan Keienburg[1], Jeison Fischer[1], Thomas Michely[1], Hannu-Pekka Komsa[2], and Wouter Jolie[1] — [1]Institute of Physics II, University of Cologne, Cologne, Germany — [2]Faculty of Information Technology and Electrical Engineering, University of Oulu, Oulu, Finland

Sulfur vacancies [1] and sulfur vacancy dimers in nearest-neighbor distance [2] in monolayer WS_2 have been experimentally proven to yield bright and stable photon emission, thus holding promises for the development of quantum technologies.

Here we investigate dimers of sulfur vacancies in different configurations in monolayer WS_2 created with the tip of a scanning tunneling microscope [3]. Scanning tunneling spectroscopy reveals strong hybridization of the sulfur vacancy electronic in-gap states, validated by density functional theory calculations. For dimers in nearest-neighbor configuration we find that inelastically tunneling electrons can induce sulfur atom migration, resulting in a rotary motion of the dimer. This motion is studied in detail by analyzing the emerging telegraph noise in the junction. Lastly, we elaborate on scenarios to make use of the dimer motion for the design of vacancy structures and lattices.

Alkali-metal doped transition metal chlorides confined in bilayer graphene: Insights from first-principles calculations — •Munawar Ali[1], Arkady V. Krasheninnikov[2], Giovanni Cantele[1], and Mahdi Ghorbani-Asl[2] — [1]Università degli Studi di Napoli "Federico II," Dipartimento di Fisica "Ettore Pancini," Complesso di Monte S. Angelo, via Cinthia, 80126 Napoli, Italy — [2]Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01314 Dresden, Germany

The intercalation of atomic and molecular species into layered materials has emerged as a powerful strategy for synthesizing novel two-dimensional systems with tunable electronic, magnetic, and energy-storage properties. Encapsulating transition-metal halides into bilayer graphene has proven effective for stabilizing 2D magnetic phases that are otherwise thermodynamically unstable. Using density functional theory, we systematically investigate the intercalation of

metal chlorides (TCl_3, T = Fe, Cu, Mo, Al) doped with alkali metals (Li, Na, K, Rb, Cs) across a range of concentrations. Li- and Na-doped $FeCl_3$, $CuCl_3$, and $MoCl_3$ monolayers exhibit the highest thermodynamic stability, whereas $AlCl_3$ remains unstable even under doping. Bader charge analyses reveal substantial charge transfer from the graphene host to the intercalated layers, particularly in the case of $CuCl_3$, which also shows the strongest binding. These findings provide a theoretical framework for understanding the stability of these heterostructures and highlight alkali-metal-intercalated graphene systems as a platform for engineering tunable 2D magnetic materials.

O 8: Nanostructures at surfaces:1D, 2D, networks I

Time: Monday 10:30–12:30 Location: WILL/A317

O 8.1 Mon 10:30 WILL/A317

Quantum confinement of excited states in a two-dimension metal-organic coordinated network — •Lu Lyu[1], Martin Anstett[2], Wei Yao[3], Tobias Eul[1], Martin Aeschlimann[2], and Benjamin Stadtmüller[1] — [1]Experimentalphysik II, Institute of Physics, Augsburg University, Universitätsstraße 2, 86159 Augsburg, Germany — [2]Department of Physics and Research Center OPTIMAS, RPTU Kaiserslautern-Landau, Erwin-Schrödinger-Straße 46, 67663 Kaiserslautern, Germany — [3]Institute of Advanced Light Source Facilities, Shenzhen 518107, China

Quantum confinement effects of surface electrons in two-dimensional metal-organic coordinated networks (2D-MOCNs) provide a highly tunable platform for exploring the laws of quantum mechanics in condensed matter systems. Here, we focus on a porous network formed by coordinating pyridine-functionalized T4PT molecules with Co atoms on Au(111). One-photon photoemission (1PPE) experiments reveal a substantial energy shift of the Shockley surface state (SS) that is indicative of a hybridization with Co centers. This hybridization is responsible for a leaky channel for electrons between adjacent pores, which prevents the quantum confinement of SS electrons. In contrast, excited electrons into the unoccupied image potential states (IPS) reveal clear signatures of a substantial quantum confinement in a two-photon photoemission (2PPE) experiment. These contrasting observations of SS and IPS can be attributed to the 3D nature of the quantum well potential of the 2D-MOCNs and the distinct surface-perpendicular wave function distribution in the SS and the IPS.

O 8.2 Mon 10:45 WILL/A317

On-surface prepared 2D MOFs as models of single-atom catalysts: Fe-N_3 vs. Fe-N_4 — •Zdeněk Jakub[1], Jakub Planer[1], Dominik Hrůza[1], Ayesha Jabeen[1], Tadeáš Lesovský[1], and Jan Čechal[1,2] — [1]CEITEC, Brno University of Technology, Brno, Czechia — [2]Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czechia

What defines the reactivity of the so-called single-atom catalysts? Here, we utilize 2D Metal-Organic Frameworks (MOFs) synthesized on an inert graphene support to address this fundamental question. By temperature-dependent scanning tunneling microscopy and density functional theory, we quantify the CO adsorption strengths on threefold-coordinated (Fe-N_3) and fourfold-coordinated (Fe-N_4) iron sites embedded within Fe-DCA and Fe-TCNQ 2D MOFs. A significant 0.5 eV difference in CO binding strengths is found, despite the fact that the electronic parameters like Fe oxidation state, spin configuration, occupancy of the individual d-orbitals and their positions with respect to Fermi level are almost identical prior to CO adsorption. We trace the origin of the different reactivity to the higher structural flexibility of the Fe-N_3 sites compared to Fe-N_4. These results highlight the key role of local coordination and demonstrate that reactivity cannot be reliably predicted from electronic structure parameters alone.

Invited Talk O 8.3 Mon 11:00 WILL/A317

Controlling nanostructures on surfaces via intermolecular interactions — •Yunjun Cao — Physical Chemistry I, Ruhr-Universität Bochum, D-44801 Bochum, Germany

Synthesizing sophisticated nanostructures on surfaces requires precise control over intermolecular interactions ranging from strong covalent bonds to weak van der Waals interactions. In the first part of the talk, I will present an irreversible, multi-step covalent coupling strategy for reactive molecules. By precisely controlling the reaction sequence, we synthesize highly branched nanostructures on a metal surface [1]. As a complementary approach, I will then introduce a reversible, multi-step self-assembly protocol for sterically crowded molecules, highlighting how intermolecular van der Waals interactions steer the formation of well-separated cyclic nanostructures with an unprecedented high yield [2]. Finally, I will turn to the single-molecule level and discuss how to control via van der Waals interactions the configuration of individual molecules [3] and the potential energy landscape of a dynamic chirality switch [4]. Our studies highlight how tunable intermolecular interaction strengths control the synthesis of tailored nanostructures on surfaces.

O 8.4 Mon 11:30 WILL/A317

Autonomous Nanoworld: Building Nanostructure Without Human Intervention — •Bernhard Ramsauer[1], Qigang Zhong[2], Stefan Pranger[3], Bettina Könghofer[3], and Oliver T. Hofmann[1] — [1]nstitute of Solid State Physics, NAWI Graz, Graz University of Technology, Graz, 8010, Austria — [2]Institute of Functional Nano & Soft Materials, Soochow University, Suzhou, 215006, China — [3]Institute of Applied Information Processing and Communications, Graz University of Technology, Graz, 8010, Austria

In this contribution, we present atomically precise molecular nanostructures fabricated without human intervention. We demonstrate that simultaneous control of molecular position and orientation is attainable - both are prerequisites for constructing covalently bonded nanostructures in the future. We employ deep reinforcement learning agents to learn the complex tip-molecule-surface interactions by determining the optimal manipulation parameters for moving and rotating molecules. Because exhaustive sampling of all possible manipulation parameters is impossible, we generate a simulation based on selected experiments. This simulation allows us to train robust agents that even generalize to unseen adsorption conditions and arbitrary nanostructures. With this strategy, we autonomously assemble molecular building blocks into arbitrary geometries, establishing a reliable platform for automated molecular assembly.

O 8.5 Mon 11:45 WILL/A317

The Tale of a Band Melting in a Low-Dimensional Nanostructure — •Lenart Dudy[1,2], Julian Aulbach[2], Joerg Schaefer[2], Ralph Claessen[2], Victor Rogalev[2,3], and Piotr Chudzinski[4,5] — [1]Synchrotron SOLEIL, France — [2]U Würzburg, Germany — [3]Diamond Light Source, UK — [4]Queen's U Belfast, UK — [5]Polish Academy of Sciences, Poland

We explore the unusual phenomenon of "band melting" in the quasi-one-dimensional nanostructure Si(553)-Au. Using angle-resolved photoemission spectroscopy (ARPES) and scanning tunneling spectroscopy (STM), we observe a striking disappearance of a well-defined electronic band upon increasing temperature, while the atomic structure remains unchanged. Such dramatic temperature-driven changes are rare and typically associated with strongly correlated systems like Kondo or Mott phases.

Our findings point to electronic disorder and suppressed quantum coherence along one dimension. Supported by theoretical insights, we interpret this behavior within a phenomenological framework involving Luttinger-liquid physics and frustrated (pseudo-)spin interactions. This work sheds light on the interplay between dimensionality, correlations, and disorder in low-dimensional materials, opening new perspectives for understanding emergent electronic phases in nanostructures.

O 8.6 Mon 12:00 WILL/A317

Iron-porphyrin coordination network with surface-bound dysprosium adatoms: implications for long-range magnetic ordering — •Pierre Josse[1,2], Massine Kelai[1,2], Caroline Hommel[1,2], Lukas Spree[1,2], and Fabio Donati[1,3] — [1]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Seoul 03760, Republic of Korea — [2]Ewha Womans University, Seoul 03760, Republic of Korea — [3]Department of Physics, Ewha Womans University, Seoul 03760, Republic of Korea

Ordering spins on surfaces offers significant promise for spintronic, magnetic, magnetoelectric, and magneto-optic technologies. One effective approach is to employ spin-active centers embedded within molecular frameworks capable of self-organizing on surfaces. Porphyrins, with their exceptional chemical versatility and tunability, stand out as particularly suitable candidates for this purpose. Various strategies can be used to achieve such spin ordering, including molecular self-assembly, metal-ligand coordination, and on-surface synthesis involving the formation of C-C bonds. In this work, we present the specific strategies we use to organize spins on surfaces and examine how these methods influence long-range magnetic ordering.

O 8.7 Mon 12:15 WILL/A317

On-Surface Synthesis on Oxide — •Sonja Bohl[1], Kassandra Zoltner[1], Leonard Neuhaus[1], Stefan R. Kachel[1], Agustina Heredia[2], Cissie Slopianka[1], Sophie Schäfer[1], Lisa Arnold[1], Doris Grumelli[2], Sabine Wenzel[1], and J. Michael Gottfried[1] — [1]Fachbereich Chemie, Universität Marburg — [2]INIFTA, Universidad Nacional de La Plata

Oxide surfaces offer the advantage of weak molecule-substrate interactions, enabling a more direct and undistorted probing of the properties of adsorbed molecules compared to metal substrates. However, the reduced adsorption energies represent a central challenge for on-surface synthesis, requiring adjusted precursor strategies to prevent premature desorption from the oxide substrates. In this work, we explore approaches to enable on-surface reactions on thin-film oxides and well-defined bulk oxides. While various nano-carbon structures have previously been synthesized on metal surfaces, we investigate whether analogous processes can be realized on oxides. Furthermore, we examine how metal-organic nanostructures interact with bulk oxide surfaces and whether the substrate can induce changes in their coordination environment. Our methodology combines on-surface synthesis with scanning tunneling microscopy (STM), X-ray photoelectron spectroscopy (XPS), and temperature-programmed desorption (TPD).

O 9: Organic molecules on inorganic substrates: electronic, optical and other properties I

Time: Monday 15:00–18:00 Location: HSZ/0201

O 9.1 Mon 15:00 HSZ/0201

Adsorption-induced chirality of an otherwise highly-symmetrical molecule — •Jannis Lessmeister[1], Chetana Badala Viswanatha[1], Andreas Windischbacher[2], Christian S. Kern[2], Lu Lyu[3], Vitaliy Feyer[4], Iulia Cojocariu[4], Daniel Baranowski[4], Martin Aeschlimann[1], Peter Puschnig[2], and Benjamin Stadtmüller[3] — [1]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, 67633 Kaiserslautern, Germany — [2]Institute of Physics, University of Graz, 8010 Graz, Austria — [3]Institute of Physics, University of Augsburg, 86159 Augsburg, Germany — [4]Peter Grünberg Institute (PGI-6), Jülich Research Centre, 52428 Jülich, Germany

Chirality is a fundamental concept with far-reaching implications across chemistry, biology and materials science. In condensed matter, interest has grown around the chiral-induced spin selectivity (CISS) effect, which promises spin-dependent functionality in chiral molecules without magnetic or heavy-metal components. So far, however, the role of the interface for CISS remains unclear.

To illuminate the interactions at chiral metal-molecular interfaces, we explore how the highly-symmetrical molecule pentacene adsorbes on a naturally chiral copper surface. Employing momentum microscopy we identify changes of the emission pattern of the frontier molecular orbitals of pentacene adsorbed on chiral Cu(643) versus achiral Cu(110). In conjunction with density functional theory calculations, we can attribute these observations to a twisting of pentacene and thus to an adsorption-induced chirality of the otherwise symmetric molecule.

O 9.2 Mon 15:15 HSZ/0201

Explaining Principles of Tip-Enhanced Raman Images with Ab Initio Modeling — •Krystof Brezina[1], Yair Litman[2], and Mariana Rossi[1] — [1]Max-Planck-Institut für Struktur und Dynamik der Materie, Hamburg, Germany — [2]Max-Planck-Institut für Polymerforschung, Mainz, Germany

Tip-enhanced Raman spectroscopy (TERS) is an emerging method for imaging vibrational motion and chemically characterizing surface-bound molecular adsorbates. Existing approaches to TERS simulation often build on strong approximations, including a simplification or neglect of the underlying metallic substrate, often leading to discrepancies with experiments. In this work, we present a new, *ab initio* finite-field formulation of a TERS simulation framework [1] that can efficiently address large-scale, realistic systems under periodic boundary conditions [2]. This treatment is essential as it eliminates known artifacts in simulated TERS images stemming from substrate approximations, as shown by our benchmarks on adsorbates and surface defects, and allows for simulations directly comparable to experiments. In this direction, our simulations of Mg(II)-porphine on Ag(100) correctly explain the spatial intensity variation of experimental TERS images and provide an insight into the fundamental principles that define substrate contribution to the scattering cross section in TERS. Our infrastructure is generally applicable to any solid substrate, is computationally efficient and available within the FHI-aims electronic structure code.

O 9.3 Mon 15:30 HSZ/0201

Periodic Potential Engineering of 2D Superlattices for Enhanced Photocatalysis — •Qun Yang — Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle

Atomically thin semiconductors hold great promise for photocatalytic solar energy conversion, yet often face key challenges such as rapid electron-hole recombination, inappropriate band gaps, and misaligned energy levels to redox potentials. We introduce a general design strategy based on symmetry-defined periodic potentials for 2D photocatalyst engineering. These long-range modulations reshape the band structure and induce robust electron-hole separation without altering the material lattice. Applied to a monolayer InSe photocatalyst, we show that experimentally achievable moiré patterns, such as those formed with twisted hBN, enable miniband formation and tunable spatial charge separation. Moreover, the periodic potential modulates local adsorption energetics, providing a new handle to enhance catalytic activity for both photocatalytic hydrogen and oxygen evolution reactions. Our results provide a path toward the realization of high-efficiency solar-to-chemical energy conversion in a broad range of 2D materials.

O 9.4 Mon 15:45 HSZ/0201

Supramolecular organisation of thermolabile $TbPc_2$ derivatives at surfaces — •Patrick Lawes[1], Joachim Reichert[1], Anthoula C. Papageorgiou[1,3], Joe Komeda[4], Svetlana Klyatskaya[4], Andreas Walz[1,2], Annette Huettig[1,2], Hartmut Schlichting[1,2], Rochio Sánchez-de-Armas[6], Nicolas Montenegro-Pohlhammer[6,7], Carmen J. Calzado[6], Jean-Pierre Bucher[5], Johannes V. Barth[1], and Mario Ruben[4,8] — [1]TU Münich, DE — [2]pureions GmbH, Gilching, DE — [3]National and Kapodistrian University of Athens, GR — [4]Karlsruhe Insitute of Technology, DE — [5]IPCMS Université de Strasbourg FR — [6]Universidad de Sevilla, ES — [7]DIC, CIBQA, Universidad Bernardo OHiggins, CL — [8]CESQ, ISIS, Université de Strasbourg, FR

Creation and study of novel materials towards the goal of quantum information processing, involves sophisticated chemistry integrated into useful architectures. The self-organization of single-molecule magnets, is widely studied and reported. Utilizing electrospray ion beam deposition permits the study of thermolabile, functionalised bis(phthalocyaninato) terbium complexes on surfaces. This work aims to tailor the lattices of spin centres. Complex ligand tuned structures were characterised by scanning tunneling microscopy allowing for potential study into quantum criticality and quantum technologies.

O 9.5 Mon 16:00 HSZ/0201

Orbitals of Artificial Atoms in a Gapped Two-Dimensional Vacuum — Mong-Wen Gu[1,2], Aizhan Sabitova[1,2], Taner Esat[1,2], Christian Wagner[1,2], F. Stefan Tautz[1,2,3], Aleksandr Rodin[4,5], and •Ruslan Temirov[1,2,6] — [1]PGI-3, Forschungszentrum Jülich, Germany — [2]JARA, Fundamentals of Future Information Technology, Germany — [3]RWTH Aachen, Germany — [4]NUS, Singapore — [5]Yale-NUS College, Singapore — [6]University of Cologne, Germany

Artificial atoms–engineered nanostructures that confine electronic states–offer a route toward atom-by-atom design of electronic functionality. In this work, we use low-temperature STM and STS to study single-molecule vacancies in a commensurate PTCDA/Ag(111) monolayer, which act as attractive potentials for the two-dimensional interface-state electrons.

Using feature-detection STS [1,2], we directly image the vacancy-induced bound states and identify artificial analogues of *s*- and *p*-orbitals that split from the parabolic band minimum and hybridise when two vacancies are brought into proximity. Beyond these conventional orbital analogues, the periodically corrugated interface-state band hosts partial band gaps that support additional quasi-localised states with no counterparts in natural atoms. Tight-binding simulations reproduce these high-energy states and reveal their origin in the gap regions of the 2D dispersion.

O 9.6 Mon 16:15 HSZ/0201

Thermal and photo-induced one-dimensional switching of azobenzene derivatives on a graphite surface — •Thiruvancheril Gopakumar[1], Hariom Birla[1], Showkat H. Mir[1], Khushboo Yadav[1], Thomas Halbritter[2], Alexander Heckel[2], and Jayant K. Singh[3] — [1]Department of Chemistry, Indian Institute of Technology Kanpur, Kanpur 208016, India — [2]Institute for Organic Chemistry and Chemical Biology, Goethe-University Frankfurt, Max-von-Laue-Str. 9, 60438 Frankfurt, Germany — [3]Department of Chemical Engineering, Indian Institute of Technology Kanpur, Kanpur 208016, India

In this presentation we demonstrate an unusual one-dimensional (1D) cascade effect in the thermal- and photo-induced switching of azobenzene derivatives deposited on graphite surface. Upon thermal- and photo-induction, molecules switch between their geometric states (trans and cis) along a selected lattice within the assembly up to several hundreds of nanometres. Generally, such directionality is observed only for a length scale of few nanometres. It is revealed that the strong intermolecular interaction along one of the lattices compared to the other is at the origin of the 1D cascading effect. Harnessing cooperative switching opens possibilities for engineering the responses of molecular film

to external trigger and provides opportunities to control the directionality of switching/reactions, and novel nanostructures.

O 9.7 Mon 16:30 HSZ/0201

Accessing Energetically Restricted Optical Transitions in a Single Free-Base Porphyrin Molecule — •Eve Ammerman, Nils Krane, and Bruno Schuler — Empa - nanotech@surfaces Laboratory, 8600 Dübendorf, Switzerland

Charge transfer between a single molecule and the electrodes of an STM leads to a series of excitation and relaxation processes, including radiative relaxation from the molecule's optically active excited states. Utilizing the STM tunnel junction in electroluminescence experiments enables optical characterization on sub-molecular length-scales. However, the electroluminescence phenomenon is constrained by the alignment of ionization and optical state energies. Here, we show how positive ion resonance energy of a free-base tetrabenzoporphyrin (H2TBP) can be tuned relative to the optical emission energy through local gating by the STM tunnel junction or by work function engineering. The tuning of the energy level alignment allows us to produce optical emission from H2TBP on Ag(111), where electroluminescence is energetically restricted, or on Ag(110) where the molecule becomes bright.

O 9.8 Mon 16:45 HSZ/0201

Optical characterisation of single chlorophyll molecules at the sub-nanometre scale — Thiago G. L. Brito[1], •Daniel Arribas[1], Myriam Wadsack[1], Claudia Leticia Gómez Flores[1], Victor Feitosa[1], Klaus Kuhnke[1], Klaus Kern[1,2], Kelvin Anggara[1], and Anna Rosławska[1] — [1]Max Planck Institute for Solid State Research, Stuttgart, Germany — [2]École Polytechnique Fédérale de Lausanne, CH-1015 Lausanne, Switzerland

As one of the main biomolecules harvesting light in photosynthetic organisms, chlorophyll plays a crucial role in biological systems, ultimately sustaining life on Earth. Therefore, the fundamental understanding of its optical properties has attracted widespread interest from the scientific community. However, traditional spectroscopic experiments, often probing complexes, only provide an averaged understanding of the rich photophysics of chlorophyll, where the effects of each possible molecular configuration and the local environment are smeared out. In this work, we address this by exploiting the sub-nm resolution of scanning tunnelling microscopy and the highly-localised plasmonic enhancement of the picocavity in the tunnelling junction. We characterise individual chlorophyll molecules, deposited by electrospray ion beam deposition on a Ag(111) surface with NaCl islands as decoupling layer. By analysing the fluorescence emission excited by the tunnelling electrons, we observe the structural dependency of the molecular opto-electronic properties. Our investigation opens new opportunities for the fundamental understanding of light-harvesting during photosynthesis with unprecedented sub-molecular resolution.

O 9.9 Mon 17:00 HSZ/0201

Polaronic transport through a molecular system with scanning probe microscopy — •Laëtitia Farinacci[1,2,3], Gaël Reecht[3], Christian Lotze[3], and Katharina Franke[3] — [1]University of Wuerzburg, Wuerzburg, Germany — [2]Carl-Zeiss-Stiftung Center for Quantum Photonics Jena-Stuttgart-Ulm, Stuttgart, Germany — [3]Freie Universitaet Berlin, Berlin, Germany

Polarons are quasi-particles in which electron excitations couple to distortions of the local ions network surrounding them. Typically, they are studied in metal oxides where they heavily influence charge transport and thereby often are key to understand and characterize the materials' properties. Here, we use scanning tunneling microscopy and atomic force microscopy to study the properties of Fe-porphine-chloride (FeP-Cl) molecules adsorbed on Pb(111). We observe distinct properties in the dI/dV signal that are indicative of polaronic transport.

More precisely, we find that the FeP molecules form islands in which Cl adatoms are trapped between the molecules. This leads to an effective gating of the molecules by local electric fields that stabilize either of two electronic configurations. Some FeP molecules display sharp peaks in their dI/dV reminiscent of vibrational modes. Importantly, the mapping of these peaks in dI/dV reveal the key role of the electric field and the necessity to account for charge transport through the island. These ingredients are the fundaments of polaron formation and will provide complementary understanding of the fundamental phenomena at the origin their formation in organic/inorganic interfaces.

O 9.10 Mon 17:15 HSZ/0201

Debromination and π-radical formation by single-electron injection on an insulator — •Ye Liu[1], Felix Giselbrecht[1], Lucía Gómez-Rodrigo[2], Manuel Vilas-Varela[2], Tzu-Chao Hung[1], Diego Peña[2], and Jascha Repp[1] — [1]University of Regensburg, Germany. — [2]Universidade de Santiago de Compostela, Spain.

The creation of π-radicals in nanostructures offers promising opportunities in spintronics and quantum technologies1,2, yet their controlled formation on an insulator remains challenging3. Here, we investigated the charge-induced reaction of 11-bromo-11H-benzo[b]fluorene on thick NaCl films (> 20 monolayers) using non-contact atomic force microscopy. The injection of only one electron from the microscope's tip induces debromination, which yield an open-shell structure and a bromide anion. In contrast, removal of an electron from the precursor results in a cation without bond cleavage. The voltage threshold for debromination depends on the molecular adsorption geometry, specifically on whether the bromine atom points upward or downward, reflecting opposite orientations of the molecular dipole moment. We present a feasible tip-induced synthesis strategy for generating a π-radical in molecule on an insulator, offering a promising route toward constructing larger open-shell nanostructure with multiple π-radicals on such surfaces.

O 9.11 Mon 17:30 HSZ/0201

Intramolecular cyclization of helicenes towards non-benzenoid nanographenes via formation of radicals — •Daniel Rothhardt[1], Ming-Lun Pan[2], Christian Wäckerlin[3,4], Hans Josef Hug[1], Yao-Ting Wu[2], Karl-Heinz Ernst[1,5,6], and Miloš Baljozović[1] — [1]Empa, Dübendorf, Switzerland — [2]National Cheng Kung University, Tainan, Taiwan — [3]PSI, Villigen PSI, Switzerland — [4]EPFL, Lausanne, Switzerland — [5]The Czech Academy of Sciences, Prague, Czech Republic — [6]University of Zurich, Zurich, Switzerland

On-surface synthesis has recently become a leading tool for controllable C-C bond formation that would otherwise hardly be accessible by conventional solution chemistry. The advancement of on-surface synthesis gave rise to a novel class of magnetic materials, namely open-shell magnetic nanographenes. The magnetism here mostly stems from the formation of unpaired electrons (radicals) due to a sublattice imbalance, topological frustration or aromatic stabilization. Such carbon-based spin systems are often considered promising candidates for spintronics applications due to their weak spin-orbit coupling and hyperfine interaction, allowing for long spin-lifetime and spin diffusion lengths. Here we demonstrate that the radical formation within the non-planar hydrocarbons such as helicenes leads to intramolecular bond formation and reorganization on Au(111) substrate resulting in non-benzenoid nanographenes. The products are identified using ToF-SIMS, STM and nc-AFM, corroborating the proposed radical-induced cyclization mechanism.

O 9.12 Mon 17:45 HSZ/0201

A Molecule with Half-Möbius Topology — Igor Roncevic[1,2], Fabian Paschke[3], Yueze Gao[2], Leonard-Alexander Lieske[3], Lene A. Gödde[2], Jascha Repp[4], Florian Albrecht[3], Harry L. Anderson[2], and •Leo Gross[3] — [1]Department of Chemistry, The University of Manchester, Oxford Road, Manchester, United Kingdom — [2]Department of Chemistry, Oxford University, Chemistry Research Laboratory, Oxford, United Kingdom — [3]IBM Research Europe - Zurich, Rüschlikon, Switzerland — [4]Institute of Experimental and Applied Physics and Halle-Berlin-Regensburg Cluster of Excellence CCE, University of Regensburg, Regensburg, Germany

Stereoisomers of $C_{13}Cl_2$ exhibiting helical orbitals around a ring of carbon atoms were synthesized by atom manipulation on bilayer NaCl on Au(111). We resolved the enantiomeric geometries of the closed-shell singlet states by atomic force microscopy and mapped their helical orbital densities by scanning tunnelling microscopy. A π-orbital basis of the helical, non-planar singlets that twists by 90° in one circulation is consistent with a half-Möbius topology. In such a topology, the π-orbital basis changes sign with respect to two circumnavigations and is periodic with respect to four circumnavigations. This is in contrast to a topologically trivial Hückel basis, which shows no twist, and a Möbius basis, which twist by 180° in one circulation. We demonstrate reversible switching of the topology, between the two singlets of oppositely threaded half-Möbius topology, and the planar, topologically trivial, triplet state.

O 10: 2D Materials beyond graphene: Growth, structure and substrate interaction (joint session O/HL/TT)

Time: Monday 15:00–17:45 Location: HSZ/0204

O 10.1 Mon 15:00 HSZ/0204

A virtual super-moiré: $MnBr_2$ on graphene on Ir(110) — Affan Safeer[1], Oktay Güleryüz[1], Nicolae Atodiresei[2], •Thomas Michely[1], and Jeison Fischer[1] — [1]II. Physikalisches Institut, Universität zu Köln, Germany — [2]Peter Grünberg Institut, Forschungszentrum Jülich, Germany

$MnBr_2$ on Gr/Ir(110) constitutes a three lattice system, giving rise to a super-moiré pattern – a moiré of moirés. The super-moiré of Gr/$MnBr_2$/Ir(110) is unique, as it involves a virtual moiré of $MnBr_2$ with the Ir(110) surface lattice

– two lattices not in contact with each other. Using a careful Fourier analysis of the bias dependence of scanning tunneling microscope topographs, scanning tunneling spectroscopy, the known properties of Gr/Ir(110), and the results of ab initio calculations, the origin of the virtual moiré is uncovered and related to the inhomogeneous binding of Gr to Ir(110). Comparative experiments with $MnBr_2$ on Gr/Ir(111) show similar growth and structure as on Gr/Ir(110), but highlight the unique properties of the $MnBr_2$/Gr/Ir(110) super-moiré.

O 10.2 Mon 15:15 HSZ/0204

Magnetism of monolayers of $FeCl_2$ and $FeBr_2$ Epitaxially Grown on Bi_2Se_3 — •Sebastien E. Hadjadj[1], Weibin Li[2], Pierluigi Gargiani[2], Cinthia Piamonteze[3], Oleksandr Stetsovych[4], Pavel Jelínek[4], Maxim Ilyn[1], and Celia Rogero[1] — [1]Materials Physics Center(MPC - CFM), Donostia, Spain — [2]ALBA Synchrotron Light Source, Barcelona, Spain — [3]Paul Scherrer Institut, Villigen, Switzerland — [4]FZU - Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic

Two-dimensional transition metal dihalides exhibit novel magnetic and electronic properties. By combining 2D magnetic semiconductors with topological insulators (TIs) novel quantum and spintronic phenomena can be investigated. Here, we report the uniform and epitaxial growth of monolayer $FeCl_2$ and $FeBr_2$ on the TI Bi_2Se_3. Structural and electronic characterization via LEED, STM, and STS measurements revealed a material-specific moiré pattern resulting from lattice mismatch, as well as a position-independent bandgap of 4 eV. Synchrotron-radiation-based XAS and XMCD measurements confirm robust ferromagnetic order down to the monolayer limit, with an intrinsic reduction of the effective spin magnetic moment by 40-50%. These magnetic vdW heterostructures provide a platform for investigating magnetic proximity effects and moiré-induced modifications of topological surface states. [1] S. E. Hadjadj et al., Chem. Mater., 35, 23, 9847*9856,(2023) [2] S. Kerschbaumer et al., Adv. Science, e08262,(2025)

O 10.3 Mon 15:30 HSZ/0204

Rise and fall of 1T-TaS_2: Epitaxial growth of monolayer TaS_2 on Au(111) — •Lars Buss[1], Cathy Sulaiman[1], Raquel Sánchez-Barquilla[1], Iulia Cojocariu[2], Marcin Szpytma[3], Tevfik Onur Menteş[2], Andrea Locatelli[2], Jens Falta[4], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Cottbus, Germany — [2]Elettra-Sincrotrone Trieste S.C.p.A, Basovizza, Trieste, Italy — [3]Faculty of Physics and Applied Computer Science, AGH University of Krakow, Poland — [4]Institute of Solid State Physics, University of Bremen, Germany

Two-dimensional TaS_2 has attracted extensive research interest due to its ability to exhibit electron correlation effects, including charge density waves (CDWs). In particular, 1T-TaS_2 is of interest as it shows a CDW at room temperature. However, when grown on metal substrates, only 2H-TaS_2 has been reported. To elucidate the reasons for the apparent lack of 1T-TaS_2 growth in the literature, we have investigated the growth of TaS_2 on Au(111) employing *in situ* low-energy electron microscopy (LEEM) and micro-diffraction (μLEED) as well as X-ray photoemission electron microscopy (XPEEM) [1]. We show that at elevated temperatures TaS_2 nucleates and grows in the metastable 1T-TaS_2 phase, which transforms into the stable 2H-TaS_2 phase via a temperature-activated process and then continues to grow at a considerably lower rate. Furthermore, we observe CDW-like ordering in 1T-TaS_2/Au(111), though it is suppressed in 2H-TaS_2/Au(111).
[1] L. Buß et al. Phys. Rev. Materials **9**, 074006 (2025).

O 10.4 Mon 15:45 HSZ/0204

Band-Like Transport and its Modulation by Nitrogen Doping in Transferable Semi-Conducting 2D-imine Covalent Organic Framework — •Vijay Bahadur Yadav, Diksha Srivastava, Satya Veer Singh, Itu Pandey, Manabendra Chandra, and Thiruvancheril G. Gopakumar — Indian Institute of Technology Kanpur

Two-dimensional (2D) imine-based covalent organic frameworks (COFs) are promising semiconductors for thin-film electronics and sensing due to their extended in-plane π-conjugation, enabling efficient charge transport. Here, we investigate two highly crystalline 2D imine COF films synthesised via quasi-equilibrium Schiff base condensation. By selecting molecular precursors, we tuned the nitrogen content, producing COFs with ten and six nitrogen atoms per unit cell (10N-COF and 6N-COF). The films are chemically stable in organic solvents and water, mechanically robust, and transferable onto various substrates, allowing fabrication over areas of tens of square centimeters. Electrical measurements using silver electrode arrays show linear current*voltage behaviour, indicating band-like transport, with consistent responses across multiple regions. The conductivity of 10N-COF is ~36 times higher than that of 6N-COF. Density functional theory calculations reveal similar band gaps but enhanced band dispersion near the Fermi level in 10N-COF, improving charge carrier mobility. Nitrogen incorporation thus effectively tunes charge transport in 2D COFs.

O 10.5 Mon 16:00 HSZ/0204

Co_2S_2: a new 2D material and its phase transitions — •Abdallah Karaka, Max Wolfertz, Affan Safeer, Guangyao Miao, Wouter Jolie, Thomas Michely, and Jeison Fischer — II. Physikalisches Institut, Universität zu Köln, Zülpicher Str. 77, 50937 Cologne, Germany

Using molecular beam epitaxy under ultra high vacuum conditions, 2D materials can be synthesized under conditions far from equilibrium for which no bulk parent compound exists.

Co_2S_2-2D is such an example. Using scanning tunneling microscopy and low energy electron diffraction we characterize this new single-layer 2D material crystallizing in the CuI structure (space group: $P\bar{3}m1$ trigonal), when grown on graphene on Ir(111) using molecular beam epitaxy. We found it can be synthesized phase pure upon low temperature growth and moderate annealing with a lattice constant of 3.66 ± 0.05 Å and a height of 6.2 Å. Beyond the single-layer limit it transforms into a new hexagonal crystal structure with a distinctly different lattice parameter of 3.52 ± 0.05 Å and a height of 11.7 Å. This transition typically occurs between 650 and 750 K, although the exact temperature depends on the annealing conditions. The phase transition is accompanied by the emergence of a 2x2 superstructure in the high temperature phase.

O 10.6 Mon 16:15 HSZ/0204

Tailored growth of 2D alloy transition metal dichalcogenides with tunable optical and electrical properties using liquid precursors — •Md Tarik Hossain[1], Axel Printschler[1], Nhat Lam Duong[1], Julian Picker[1], Rahul Sharma[1], Christof Neumann[1], Mona Sedighi[2], Johannes Biskupek[2], Muhammad Sufyan Ramzan[1], Caterina Cocchi[1], Ute Kaiser[2], and Andrey Turchanin[1] — [1]Friedrich Schiller University Jena, Jena, Germany — [2]University of Ulm, Ulm, Germany

Doping or alloying of two-dimensional (2D) transition metal dichalcogenides (TMDs) provides a promising route to tune the optical, magnetic, and electronic properties. Here, we present a liquid-precursor-based chemical vapor deposition (CVD) for the controlled growth of large-area monolayer ($V_xW_zMo_{1-x-y}$)S_2 alloys with tunable optical and electrical properties. Comprehensive characterization using atomic force microscopy, transmission electron microscopy, Raman spectroscopy, photoluminescence (PL) spectroscopy, and ab initio calculations confirms the structural and optical quality. Notably, PL shows a noticeable defect exciton peak at room temperature in the V-doped monolayer. Furthermore, by adjusting the composition, we modulate the carrier type of these monolayers from n-type to p-type or even make the monolayers metallic for high vanadium concentrations, which is deduced from electrical transport measurements and density functional theory calculations. This work demonstrates high potential of liquid-precursor CVD as a platform for the tailored growth of complex 2D TMD alloys for next-generation optoelectronic devices.

O 10.7 Mon 16:30 HSZ/0204

CVD growth and characterization of WSe_2 monolayers on Au(111) and their conversion to Janus SeWS — •Julian Picker[1], Jonas Brandhoff[2], Maximilian Schaal[2], Felix Otto[2], Christof Neumann[1], Torsten Fritz[2], and Andrey Turchanin[1] — [1]Institute of Physical Chemistry, Friedrich Schiller University Jena, Germany — [2]Institute of Solid State Physics, Friedrich Schiller University Jena, Germany

Transition metal dichalcogenides (TMDs) exhibit distinctive optical and electronic properties in the two-dimensional monolayer limit. Recently, Janus TMDs have attracted significant attention because their asymmetric chalcogen composition breaks the out-of-plane symmetry and enables properties not attainable in conventional TMDs. In this work, we initially investigate the structural and electronic characteristics of WSe_2 monolayers grown on Au(111) via ambient-pressure chemical vapor deposition (CVD). Surface-sensitive techniques - including scanning tunneling microscopy (STM), low-energy electron diffraction (LEED), X-ray photoelectron spectroscopy (XPS), and angle-resolved photoelectron spectroscopy (ARPES) - were employed to characterize the properties of these monolayers. Subsequently, the WSe_2 monolayers were transformed into Janus SeWS monolayers through selective chalcogen replacement at the WSe_2/Au interface. A comparative analysis reveals the structural and electronic differences between the two systems.

O 10.8 Mon 16:45 HSZ/0204

Controlling polymorphism in the growth of 2D manganese sulfide on graphene via substrate interaction — •Max Wolfertz, Abdallah Karaka, Nicolas Georgopoulos, Oktay Güleryüz, Affan Safeer, Thomas Michely, and Jeison Fischer — II. Physikalisches Institut, Universität zu Köln, Zülpicher Str. 77, 50937 Cologne, Germany

We investigate the epitaxial growth of single-layer manganese sulfide on graphene/Ir substrates grown via molecular beam epitaxy. Morphology, crystal structure and electronic properties are examined using scanning tunneling microscopy and - spectroscopy and low energy electron diffraction. While bulk MnS exists in the three polymorphs, α-(rock-salt structure), β-(zincblende structure), and γ-MnS (wurtzite structure), its structure in a single-layer is unknown, as fabrication using exfoliation methods cannot be applied. We find that

when grown by molecular beam epitaxy on Gr/Ir substrates manganese sulfide grows in two competing phases: manganese sulfide in trigonal CuI-structure (space group P-3m1) and MnS in thin platelets of a cubic rock-salt structure (space group Fm-3m). Their in-plane lattice parameters are 4.16 Å, and 3.63 Å respectively. We show that the substrate exerts a strong influence on the phase selected. While the growth on Gr/Ir(111) results in a large share of cubic MnS, the Gr/Ir(110) substrate favors the formation of single layer trigonal manganese sulfide. Also, the use of seeding methods for avoiding loss of Mn into the bulk Ir crystals is discussed.

O 10.9 Mon 17:00 HSZ/0204

Low Temperature MOCVD Growth of two-dimensional InSe and InSe/WS2 Heterostructures — •Robin Guenkel, Nils Langlotz, Matvei Kislitsyn, Juergen Belz, and Kerstin Volz — mar.quest|Marburg Center for Quantum Materials and Sustainable Technologies, Philipps University Marburg, Germany

Two-dimensional van der Waals heterostructures offer powerful opportunities for engineered optoelectronic functionality, particularly when type-II band alignment enables efficient charge separation and interlayer transitions. InSe and WS* are especially promising in this regard because their band structures allow for the formation of a type-II interface at the Γ point, which avoids momentum mismatch. This is an essential requirement for robust radiative processes in 2D stacks. This talk presents a low-temperature metal-organic chemical vapor deposition (MOCVD) approach for synthesizing high-quality InSe and vertically integrated InSe/WS2 heterostructures. Using DTBSe and TMIn at 350 °C, we synthesize homogeneous, single-phase InSe films on 2-inch sapphire substrates and extend the process to directly grow on monolayer WS2. Atomic force microscopy, Raman spectroscopy, and energy-dispersive X-ray spectroscopy provide insight into the morphology, crystallinity, and composition of the films, offering a detailed understanding of the growth behavior and the influence of the substrate surface chemistry.

O 10.10 Mon 17:15 HSZ/0204

Synthesis of Vertically Stacked 2D-hBN/Borophene Heterostructures on Ir(111) via Intrinsic Segregation — •Marko Kriegel, Karim Omambac, Smruti Mohanty, Birk Finke, Frank-J. Meyer zu Heringdorf, and Michael Horn-von Hoegen — University Duisburg-Essen and Center for Nanointegration Duisburg-Essen (CENIDE), Lotharstr. 1, 47057 Duisburg, Germany

Research efforts on 2D materials increasingly target complex architectures built from high-quality heterostructures. A key challenge remains the reliable and scalable in-situ fabrication of such systems. In this work, we use high-resolution spot-profile analysis LEED (SPA-LEED) and -microscopy (LEEM) to investigate a synthesis route for an hBN/borophene heterostructure on Ir(111) based on *intrinsic segregation*. At elevated temperatures, boron dissolves into the Ir subsurface region during exposure to the borazine precursor $B_3N_3H_6$ in a CVD process [1], thereby creating a boron reservoir. Increasing the precursor pressure drives the chemical balance toward formation of a complete hBN layer across the Ir surface [2]. Upon cooldown, the decreasing boron solubility induces segregation, resulting in the growth of a continuous borophene layer beneath the hBN overlayer. This one-step CVD approach establishes a promising, scalable pathway for the controlled synthesis of high-quality 2D heterostructures. [1] K. Omambac et al., ACS Nano **15** (2021) 7421 [2] K. Omambac et al., ACS Nano **17** (2023) 17946

O 10.11 Mon 17:30 HSZ/0204

MBE growth and characterization of high-quality monolayer MoS2 on stepped Au surface — •Sayan Debnath, Ram Prakash Pandeya, Konstantin Shchukin, Patrik Staudenmayer, and Alexander Grüneis — Optoelektronische Materialien Institut für Festkörperelektronik, TU Wien, 1040 Wien, Austria

In the present work, we investigate the growth of sub-monolayer MoS2 on Au(788) and Au(111), using molecular beam epitaxy. Sample growth quality is characterized using low-energy electron diffraction, X-ray photoemission spectroscopy, and scanning electron microscopy. Furthermore, a comparative study of the electronic properties was performed by studying the band structure using angle-resolved photoemission spectroscopy (ARPES), and the vibrational properties were measured by angle-resolved polarized Raman (ARPR) spectroscopy.

Our study reveals superior crystalline quality, with fewer S deficiencies, and better azimuthal order of MoS2 grown on the stepped Au(788) substrate compared to the Au(111). In the case of ARPES, we observed more resolved band dispersion on MoS2/Au (788), confirmed by probing the spin-orbit splitting at the Brillouin zone boundary (K point). On the other hand, ARPR of the first Raman mode E2g on MoS2/Au (788) deviates from the symmetry of freestanding MoS2, suggesting the effect of the stepped surface on the vibrational properties. We discuss the role of increased catalytic activity at step edges in promoting the growth of high-quality TMDCs, such as MoS2 and WS2, on stepped surfaces.

Ethylene on Si(001) revisited: New insights from XPS, STM, and Monte Carlo Simulations — •Jannick A. Peters, Sophie Göbel, and Michael Dürr — Institut für Angewandte Physik and Zentrum für Materialforschung, Justus-Liebig-Universität Giessen, Germany

The adsorption of ethylene - the smallest organic molecule with a C=C double bond - on Si(001) seems straightforward and is widely used as reference, e.g., for the determination of absolute surface coverage. On the other hand, there is ongoing discussion about adsorption configurations, coverage dependence, and in particular the site-selective adsorption based on strongly reduced reactivity on the partially covered surface, leading to two-step adsorption kinetics. In this study, the adsorption of ethylene on Si(001) was investigated at 300 K by means of XPS and STM with special focus on the coverage dependence, and was further modelled by means of Monte Carlo simulations. We can show that the first step of the two-step adsorption kinetics results in a saturation coverage of 0.7 ML, which is significantly higher than the commonly referenced coverage of 0.5 ML. STM measurements show that this behaviour is caused by a combination of adsorption statistics, nearest-neighbour interactions, and site-selective hindrance. Higher coverage up to 1 ML is then reached with a significantly higher dose due to the reduced reactivity of the remaining surface sites. Monte Carlo simulations taking into account a limited set of reaction channels accurately describe the complete coverage dependence as well as the local order of the adsorbates on the surface.

O 11.2 Mon 15:15 HSZ/0401

The Influence of Doping on Inelastic H Atom Scattering from Silicon — •Malte Opfermann, Kerstin Krüger, Sophia Tödter, and Oliver Bünermann — Institut für physikalische Chemie, Georg- August-Universität Göttingen, Tammannstraße 6, 37077 Göttingen

Inelastic H atom scattering experiments on the semiconducting Ge(111)c(2x8) surface have revealed a bimodal energy-loss distribution consisting of a narrow low energy-loss component and a broad high energy-loss component with an onset equal to the surface band gap. Theoretical calculations attribute the low energy-loss component to an adiabatic scattering mechanism at the adatom. The high energy-loss component is explained by a non-adiabatic scattering mechanism involving electron transfer across the surface band gap from the rest atom to the adatom.

Recently, we extended our studies to scattering experiments from the Si(100)2x1 surface. Although the experimental energy loss distributions resemble the bimodal behavior of Ge(111)c(2x8), the first component is broader, and the second exhibits a visible but less well-defined onset at the surface band gap. To gain further insight, we carried out scattering experiments from n-doped and p-doped surfaces. The first component shifts to lower energy losses for n-type doping and to higher energy losses for p-type doping, whereas the second component remains essentially unaffected. Based on the theoretical results for Ge(111)c(2x8), we propose a scattering mechanism for the Si(100)2x1 surface.

O 11.3 Mon 15:30 HSZ/0401

***Ab initio* insights into the OER activity of pristine and metal-supported Co_3O_4(111)** — •Muhammad Munawar[1,2] and Rossitza Pentcheva[1] — [1]Department of Physics and Center for Nanointegration (CENIDE), Universität Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany — [2]IMPRS SusMet, Max Planck Institute for Sustainable Materials GmbH, Max Planck-Straße 1, 40237, Düsseldorf, Germany

Co_3O_4 is a promising anode material for the oxygen evolution reaction (OER), yet the role of metallic supports on its electronic properties and performance remains elusive. Here, we employ density functional theory with a Hubbard U term (DFT+U) to investigate the structural, electronic, and catalytic properties of pristine Co_3O_4(111) and Co_3O_4(111) grown on Pt(111). Using *ab-initio* thermodynamics, we determine that the Co tetrahedral termination is the most stable Co_3O_4(111) surface across a broad range of oxygen chemical potentials. Our results reveal that a built-in electric field emerges when Co_3O_4(111) is grown on a metallic substrate like Pt(111), that shifts the valence band maximum in the surface layer toward the Fermi level. Moreover, the work function increases monotonically with applied strain. Furthermore, we compare the OER activity of the pristine Co_3O_4(111) and Co_3O_4(111)/Pt(111) surface. These results provide atomic scale insight into structure-property relationships at oxide and oxide/metal interface, offering guidance for the rational design of next generation oxide-based electrocatalysts.

O 11.4 Mon 15:45 HSZ/0401

Through Stronger Hinderance to Higher Reactivity: Influence of the Alkyl Chains on the Activation Energy of Ether Cleavage on Silicon — Timo Glaser[1], Gustav F. Nolte[1], Tamam Bohamud[1], Philip Keller[1], Mathieu G. Silly[2], Hendrik Weiske[3], Ralf Tonner-Zech[3], and •Michael Dürr[1] — [1]Institut für Angewandte Physik und Zentrum für Materialforschung, Justus-Liebig-Universität Giessen, Germany — [2]Synchrotron SOLEIL, Gif sur Yvette, France — [3]Wilhelm-Ostwald-Institut für Physikalische und Theoretische Chemie, Universität Leipzig, Germany

Reactivity in surface chemistry is often discussed in terms of the interaction between surface states and the functional groups of the reacting molecule. Herein we demonstrate that for finite submonolayer coverage, i.e., surface coverage at which the molecular adsorbates cannot be treated as isolated molecules anymore, the seemingly innocent side chains of the adsorbate can also play a decisive role. For the example of ether cleavage on Si(001), which represents the surface analogue of an S_N2-type reaction, we show both experimentally by means of real-time XPS as well as based on ab-initio calculations that steric hindrance by the side chains determines the activation energy for C-O dissociation into the final state. In contrast to a simple expectation, the *stronger* steric hindrance of the butyl group in butyl methyl ether leads to a *lower* activation energy for ether cleavage on Si(001) when compared to diethyl ether. This effect was traced back to different degrees of destabilization of the precursor and the transition state [1].

O 11.5 Mon 16:00 HSZ/0401

Frontier Orbitals Control Adsorbate Bonding to Stepped Transition Metal Surfaces — •Florian Nitz[1], Stefan Hörandl[1], Dmitriy Borodin[2], and Alec Wodtke[1] — [1]Institute for Physical Chemistry, Georg-August University of Goettingen, Tammannstraße 6, 37077 Goettingen, Germany — [2]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Seoul 03760, South Korea

Developing intuitive models of bonding and reactivity lies at the heart of physical chemistry. While such models have been developed for atoms and molecules, we still lack concepts to explain bonding and reactivity in the solid state, including surface chemistry and catalysis. Here, we address this gap and present a model of covalent bonding between molecular orbitals of an adsorbate and symmetry-specific bands on a metal surface atom, analogous to frontier orbital theory in molecular chemistry. We apply the model to the adsorption of three molecules–CO, NO, and NH_3–on stepped platinum surfaces of varying step density and compare its predictions to experimental adsorption energies. The experiment reveals that the adsorption energies vary systematically with step density, an unexpected phenomenon that can only be explained by the frontier orbital model. Correlations of the adsorbate bond strength with the mean energy of the metal d-electrons or with surface strain fail to describe the experimental observations. This highlights frontier orbitals as a powerful concept to rationalize bonding and reactivity in condensed-phase systems.

O 11.6 Mon 16:15 HSZ/0401

Memory friction and zero-point motion in hydrogen surface diffusion — •George Trenins and Mariana Rossi — MPI for the Structure and Dynamics of Matter, Hamburg, Germany

By virtue of their small mass, hydrogen atoms readily manifest quantum dynamical effects under typical experimental conditions. In particular, hydrogen diffusion on metal surfaces is strongly influenced by nonadiabatic interactions with the conduction electrons. Such "electronic friction" is incorporated into numerical simulations via the generalized Langevin equation (GLE). Additionally, hydrogen possesses substantial zero-point energy and can undergo quantum tunnelling. This is accurately described by "ring-polymer molecular dynamics" (RPMD), an atomistic simulation approach rooted in the path-integral formulation of quantum mechanics. Using a rigorous combination of the GLE and RPMD frameworks, we show that a combination of zero-point motion and non-Markovian (memory) friction are key to the temperature dependence of H-atom diffusion on copper surfaces [1]. In a limited temperature range, the two effects happen to mask each other almost perfectly, creating the appearance of classical, memoryless dynamics. Outside this range, the experiment displays non-Arrhenius behaviour that is not captured by classical dynamics but is readily explained when quantum effects are taken into account. [1] G. Trenins, M. Rossi, Phys. Rev. Lett. **134**, 226201 (2025).

O 11.7 Mon 16:30 HSZ/0401

When plasma meets surfaces - Nitrogen plasma-induced surface transformations on copper — •Ester Perez Penco and Roland Bliem — ARCNL, Amsterdam , The Netherlands

Inside EUVL setups, materials are exposed to challenging conditions, most importantly a plasma generated by the interaction of EUV radiation with the main background gas, hydrogen, and trace elements such as nitrogen. The reactive nature of plasma environments causes even trace gases to significantly influence material properties and affect the condition of surfaces. Copper is widely used in semiconductor technology, including applications as functional parts of the latest generation of chip manufacturing tools using extreme ultraviolet lithography (EUVL), therefore, it is relevant to study its behaviour in such reactive environment.

In this surface science study, we investigate the interaction of plasma-activated nitrogen with Cu(111) surfaces using in situ X-ray photoelectron spectroscopy (XPS) and low-energy electron diffraction (LEED). By systematically comparing the effects of molecular nitrogen, neutral atoms, ions, and nitrogen plasma, we provide detailed insights into how individual plasma species modify the copper surface. Our findings reveal that while radicals modify the very surface layer, higher energy species are required to induce structural disorder and incorporate into deeper layers. The results presented in this study aid in the prediction of plasma-induced changes and the role of trace elements in the EUVL environment.

O 11.8 Mon 16:45 HSZ/0401

From Gold to Copper: N-heterocyclic Carbene Self-Assembly for Area-Selective Deposition — •Franz Thiemann[1], Patrick Melix[1], Emmett Desroche[2], Francesco Tumino[2], Cathleen Crudden[2], and Ralf Tonner-Zech[1] — [1]Wilhelm-Ostwald Institute, Universität Leipzig, Germany — [2]Carbon to Metal Coating Institute, Queen's University, Kingston, Canada

N-heterocyclic carbenes (NHCs) are promising small-molecule inhibitors for area-selective atomic layer deposition (ASD) due to their strong, selective binding to metal surfaces. Using density functional theory with PBE-D4 functionals and periodic surface slabs, this study investigates NHC adsorption on a Cu(111) surface and compares it with previously studied Au(111) systems. In both cases, experimentally observed overlayer formation could be reproduced by DFT calculations and verified using STM images, revealing a distinctive dimer pattern in which NHCs bind to extracted copper adatoms at high density (1.8 NHC/nm^2) with a tilted molecular orientation. Energy decomposition analysis for extended systems revealed the origin of the stable overlayer: strong σ-donation to the surface and π-backdonation, combined with dispersion interactions between the NHC backbones, result in a highly stable blocking layer. [1] Furlan et al. Chem. Mater., 5753, 37 (2025). [2] DesRoche et al., in Preparation. [3] Raupach et al. J. Chem. Phys., 194105, 142 (2015).

Upconversion electroluminescence in VOPc via adsorption-induced interaction of unpaired spin — •Lukas Gerhard[1], Vibhuti Rai[1], Christof Holzer[1], Carsten Rockstuhl[2], and Wulf Wulfhekel[1] — [1]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology (KIT), D-76344 Eggenstein-Leopoldshafen, Germany — [2]Institute of Theoretical Solid State Physics, Karlsruhe Institute of Technology (KIT), D-76131 Karlsruhe, Germany

Molecules with unpaired spins (radicals) promise favourable spin statistics in their electroluminescence. Here, we combine scanning tunneling microscopy induced luminescence and density functional theory to study single vanadyl phthalocyanine molecules, which are stable neutral radicals. Two distinct adsorption geometries of the molecule on NaCl/Au(111) lead to a difference in the interaction of the unpaired electron with the substrate, which in turn allows us to investigate its effects on the light emission process [1]. Remarkably, we observe that up-conversion electroluminescence is gated by the adsorption geometry of the molecule, an effect we attribute to a reordering of excited states and enhanced excited state transition probabilities. The profound influence of the unpaired electron via state reordering opens new possibilities for tuning not only molecular electroluminescence but also many other spin dependent phenomena.

Machine Learning for Atomic-Scale Molecular Discovery from Tip-Enhanced Raman Spectroscopy — Harshit Sethi[1], Markus Juntilla[1], •Orlando J Silveira[1], and Adam S Foster[1,2] — [1]Aalto University, Espoo, Finland — [2]Kanazawa University, Kanazawa, Japan

Tip-enhanced Raman spectroscopy (TERS) combines the nanoscale spatial resolution of scanning probe microscopy with the chemical specificity of Raman spectroscopy, offering a powerful tool for resolving both molecular structure and composition. However, extracting precise atomic-scale information from com-

plex TERS hyperspectral data remains a significant challenge. In this work, we address this gap by developing an automated machine learning framework to decode simulated TERS images for molecular structure discovery. Our approach uses convolutional neural networks (CNNs) to analyze hyperspectral datasets generated by modeling the plasmonic enhancement at a probe tip and the vibrational properties of planar molecules via density functional theory. To handle varying numbers of vibrational modes, we introduce a spectral binning procedure that standardizes the input for network training. This model provides a foundational proof of concept for the autonomous identification of molecular structures from TERS data, advancing the development of automated platforms for atomic-scale materials characterization and discovery.

O 12.3 Mon 15:30 HSZ/0403

THz-induced bilayer stacking dynamics in 1T-TaS_2 — Shaoxiang Sheng[1,2], Yang Yang[3], Mohamad Abdo[1], Li Chen[4], Peize Lin[5], •Kurt Lichtenberg[1], Xinguo Ren[3,5], Sheng Meng[3,5], Susanne Baumann[1], and Sebastian Loth[1,6] — [1]University of Stuttgart, Inst. for Functional Matter and Quantum Technologies — [2]Tsientang Inst. for Advanced Study — [3]IOP, Chinese Academy of Sciences — [4]Songshan Lake Materials Laboratory — [5]Inst. of Light Resources and Environmental Science, Henan Academy of Sciences — [6]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart

The electronic properties of layered materials change dramatically with variations in the interlayer coupling and the stacking order [1]. We employ terahertz pump-probe spectroscopy in conjunction with scanning tunneling microscopy (STM) to investigate the role of stacking order dynamics and of domain structures in layered 1T-TaS2 at the atomic scale. TaS2 exhibits diverse charge-density wave (CDW) phases and an insulating ground state at low temperatures [2]. We show that terahertz pulses can induce insulator-to-metal transitions (IMTs) and reveal hidden electronic phases in 1T-TaS2 by manipulating the bilayer stacking at femtosecond time and atomic length scales. This tunability promises unprecedented ultrafast control over the electronic phases also in other layered materials, suggesting applications in reconfigurable quantum devices and neuromorphic computing.

O 12.4 Mon 15:45 HSZ/0403

Coherent coupling between molecular dipoles probed with STML — •Quentin Stein[1], Jakob Kuhlke[3], Song Jiang[1], Tomas Neuman[2], Michelangelo Romeo[1], Fabrice Scheurer[1], Katharina Kaiser[3], and Guillaume Schull[1] — [1]Université de Strasbourg, CNRS, IPCMS, UMR7504, F-67000 Strasbourg, France — [2]Institute of Physics, Czech Academy of Sciences Cukrovarnick'a 10, Prague, 16200, Czech Republic — [3]Georg-August-Universität Göttingen, Physikalishes Institut, 37077 Göttingen, Germany

The clustering of chromophores allows their excited states to hybridize, enabling the formation of coherently coupled dipoles spanning multiple molecules. This is of key importance for optical processes occurring in both artificial and natural molecular assemblies.

Probing these coherently coupled dipoles with atomic-scale precision cannot be achieved through conventional optical techniques because of the diffraction limit set by Abbe's law. This difficulty has recently been overcome by scanning tunneling microscopy induced luminescence (STML), which relies on the extreme confinement of the electromagnetic field in the plasmonic picocavity formed at the apex of a metallic STM-tip. The radiative decay rate of a molecular exciton placed in such a cavity is greatly increased, allowing for the detection of states that are typically optically dark. It also provides nanometer-resolved maps of molecular transition dipole moments, revealing the spatial character of the excitonic states with atomic precision. In this work, we used this approach to investigate the fluorescence of coherently coupled dipoles within simple molecular assemblies.

O 12.5 Mon 16:00 HSZ/0403

Continuous-wave all-optical microscopy at the atomic scale — •Valentin Bergbauer[1], Felix Schiegl[1], Svenja Nerreter[1], Valentin Giessibl[1], Fabian Sandner[1], Franz J. Giessibl[1], Yaroslav A. Gerasimenko[1], Tom Siday[2], Markus A. Huber[1], and Rupert Huber[1] — [1]Department of Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, 93040 Regensburg, Germany — [2]School of Physics and Astronomy, University of Birmingham, Birmingham B15 2TT, U.K.

Exploring matter at the most fundamental level demands optical microscopy with ever-improving spatial resolution. By confining light to the apex of a sharp metallic tip, scanning near-field optical microscopy (SNOM) circumvents the diffraction limit, though its spatial resolution is still limited by the mesoscopic tip shape, inhibiting atomic resolution. Here, we observe atomically confined optical signals with Ångström-scale lateral modulations using continuous-wave mid-infrared radiation. These signals, characterized by a picometric vertical decay and a distinct optical phase shift, are consistent with emission from lightwave-driven tunnelling currents, a mechanism recently discovered using intense THz pulses. Observing near-field optical tunnelling emission (NOTE) under continuous-wave illumination is surprising, as strong-field effects such as coherent electron driving typically require ultrafast or free-electron lasers. Demonstrating the accessibility of this tunneling-mediated contrast mechanism with standard optical setups paves the way towards routine optical imaging with atomic-scale resolution.

O 12.6 Mon 16:15 HSZ/0403

Tuning Molecular Light Emission Through Atomic-scale Control of the Local Environment — •Thiago G. L. Brito[1], Daniel Arribas[1], Sofia Canola[2], Klaus Kuhnke[1], Tomáš Neuman[2], and Anna Rosławska[1] — [1]Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany — [2]Institute of Physics, Czech Academy of Sciences, 16200 Prague, Czech Republic

Intermolecular distances, adsorption sites, and configurations define a molecule's local environment, but their combined effect on single-molecule emission across different excitation pathways remains unclear. In this study, we measure the singlet emission of zinc phthalocyanine (ZnPc) on NaCl/Ag(111) and introduce platinum phthalocyanine (PtPc) as both a controlled perturbation of the local environment and a probe of ZnPc emission via resonant energy transfer (RET). All measurements were performed using scanning tunneling microscopy induced luminescence (STML) and tip-enhanced photoluminescence (TEPL). By systematically tuning intermolecular distances, restricting molecular rotational motion, and comparing direct electrical excitation with RET-driven and photon excitations, we reveal previously inaccessible regimes of ZnPc singlet emission, including neutral exciton-libron coupling. We further disentangle the environmental factors that influence emission spectra, demonstrating how the local environment actively shapes the optical response of single molecules.

O 12.7 Mon 16:30 HSZ/0403

Dipole-dipole coupling in assembled ZnPc-molecule clusters — •Jakob Kuhlke[1], Quentin Stein[2], Song Jiang[2], Georg Traeger[1], Fabrice Scheurer[2], Tomáš Neuman[3], Katharina Kaiser[1], and Guillaume Schull[2] — [1]Georg-August University Göttingen, IV. Physical Institute, Göttingen — [2]CNRS, Institut de Physique et Chimie des Matériaux de Strasbourg, Département Surfaces et Interfaces, Strasbourg — [3]Institute of Physics, Czech Academy of Sciences Cukrovarnická 10, Prague, 16200, Czech Republic

Dipole-coupled molecules provide a promising platform to build functional structures with tailored optical properties. We use ZnPc molecules as building blocks to investigate the coupling of molecular dipoles in different molecular assemblies.

In contrast to ZnPc monomers, dimers and chains of ZnPc molecules exhibit sharper and red-shifted emission peaks, a phenomenon known as superradiance [1], [2], [3]. Here, we extend this approach to more arbitrary clusters. We use scanning tunneling microscopy-induced luminescence (STML) to study the optical properties of several cluster configurations on the nanometer scale.

[2] Z. Yang, et al. Nature 531.7596 : 623-627 (2016).
[3] J. Dolezal, et al. ACS nano 16.1 : 1082-1088 (2021).

O 12.8 Mon 16:45 HSZ/0403

Selectivity in tautomerization reaction pathways triggered in single molecules on ultrashort time scales — •Niklas Friedrich, Carmen Roelcke, Tzu-Chao Hung, Yaroslav Gerasimenko, Rupert Huber, and Jascha Repp — Institute of Experimental and Applied Physics and Regensburg Center for Ultrafast Nanoscopy (RUN), University of Regensburg, and Halle-Berlin-Regensburg Cluster of Excellence CCE, Germany

Lightwave-driven scanning tunnelling microscopy (LW-STM) is a powerful technique allowing to unravel dynamics of quantum systems on their intrinsic energy, spatial and temporal scales [1,2]. In LW-STM, the electric-field transient of ultrashort laser pulses focused into the junction of a tunnelling microscope acts as a bias-voltage transient and thereby controls tunnelling on ultrashort timescales.

Here, we explore a chemical reaction triggered on ultrashort timescales. We study free-base naphthalocyanine molecules (H2Nc) on 2ML NaCl on Cu(100). In DC-biased experiments, this system switches between different tautomers upon injection of high-energy tunnelling electrons [3]. We find that the same reaction is facilitated by ultrashort voltage transients in LW-STM for transients far exceeding the voltage of the lowest unoccupied molecular orbital. Furthermore, we observe different selectivities in the tautomerization reaction depending on the energy of the tunnelling electron that we tentatively assign to the orbital structure of H2Nc.

Atomic-scale excitonic luminescence nanoscopy of moiré superlattices in van der Waals heterostructures — •Manas Pratim Biswas[1], Fábio J. R. Costa[1], Elise Jouaiti[1], Arnaud Gloppe[1], Katharina Kaiser[1,2], Fabrice Scheurer[1], Stéphane Berciaud[1], and Guillaume Schull[1] — [1]Institut de Physique et de Chimie des Matériaux de Strasbourg (IPCMS), Université de

Strasbourg (CNRS, UMR 7504), Strasbourg, France — [2]4th Physical Institute-Solids and Nanostructures, Georg-August-Universität Göttingen, Göttingen, Germany

Atomically thin two-dimensional materials are susceptible to their environment, and stacking them into van der Waals heterostructures allows precise control of their electronic and optical properties. In semiconducting transition metal dichalogenides, excitons dominate the optical response whose properties can be tuned through interfacial interactions. Twisted and/or lattice-mismatched bilayers form a moiré superlattice that periodically modulates the electronic landscape. However, diffraction-limited optical methods average over micrometer scales, concealing these nanoscale effects. To overcome this, we employ cryogenic scanning tunneling microscope-induced luminescence[1] (STML, <7K, ultra-high vacuum) to probe exciton-moiré interplay in near-aligned WSe_2/WS_2 heterobilayers[2,3]. STML enables simultaneous atomic-scale imaging and local optical readout, with the ultimate aim of demonstrating nano-optical probing of moiré-modulated systems. References: 1. Nat. Mat. 22, 482 (2023) 2. Nat. Phys. 19, 1286 (2023) 3. Nat. Mat. 20, 945 (2021)

Tracing vibrational anharmonicity at the submolecular level with tip-enhanced Raman spectroscopy — •Youngwook Park[1], Ikutaro Hamada[2], Martin Wolf[1], and Akitoshi Shiotari[1] — [1]Fritz-Haber Institute of the Max-Planck Society, Berlin, Germany — [2]The University of Osaka, Suita, Japan

Tip-enhanced Raman spectroscopy (TERS) can achieve atomic-scale vibrational imaging, yet overtones and combination bands remain difficult to access due to weak transition strengths. We show that point-contact TERS enables submolecular-resolution detection of intense overtones and combination bands from a single asymmetric perylene derivative on silicon. A 10-times signal increase upon tip–molecule contact allows us to resolve both mechanical and electrical anharmonicities with Å-level spatial contrast. The mapped mechanical anharmonicity reveals a site-specific vibrational energy exchange pathway, demonstrating TERS as a powerful tool for real-space tracking of intramolecular vibrational energy redistribution.

O 12.11 Mon 17:30 HSZ/0403

Orbital-resolved imaging of coherent femtosecond exciton dynamics in single molecules — •Caiyun Chen — Max Planck Institute for Solid State Research, Heisenbergstraße 1, 70569 Stuttgart

Understanding and controlling excitonic wavepackets is fundamental to uncovering mechanisms underlying energy conversion dynamics in organic molecular systems. We present orbital-resolved imaging of coherent exciton dynamics in single metal-centered naphthalocyanine (MNc) molecules*CoNc, CuNc, and ZnNc*adsorbed on NaCl/Ag(111). Using femtosecond scanning tunneling microscopy, we directly observe time-resolved photocurrent signals and spectroscopic signatures of coherent excitons, enabling selective excitation and control of excitons in isolated and coupled molecules. In single CuNc molecules, we measure a decoherence time (~70 fs), which decreases in dimers due to intermolecular interactions. Time-resolved measurements and photocurrent imaging reveal how central metal atoms in different naphthalocyanine molecules influence decoherence dynamics of the excited electronic state. Notably, a ZnNc molecule has longer decoherence time (~ 300 fs) compared to the CuNc and CoNc (~ 30 fs). Unpaired electrons on Co in CoNc molecule leads to distinct photocurrent imaging contrasts with the closed shell ZnNc and CuNc molecules. The origin of faster decoherence times of the excited states in CoNc and CuNc molecules is linked to conical intersections. These findings underscore the applications of ultrafast STM to probe quantum coherence and energy transfer dynamics at the single-molecule level with atomic-scale spatial resolution.

The Weak Spots of IrO_2: Sampling Defect Landscapes at Operation Conditions — •Jimiben V. Patel, Nikhil Bapat, Karsten Reuter, and Hendrik H. Heenen — Fritz-Haber-Institut der MPG, Berlin

Under the harsh oxidative potentials required for the oxygen evolution reaction, rutile IrO_2 surfaces undergo restructuring that leads to Ir dissolution and undermines catalyst durability, eventually impacting device performance. To mitigate the catalyst degradation via robust design principles, a fundamental atomistic understanding of how surface reconstructions initiate and propagate dissolution is urgently needed. Since high-resolution *operando* characterization remains challenging, atomistic simulations are essential for uncovering the underlying microscopic mechanisms. However, achieving realistic insight requires approaches that go well beyond conventional, idealized modeling frameworks. In this work, we employ machine-learned interatomic potentials trained on density-functional theory to systematically sample vacancy formation across a wide range of electrochemical environments. This allows us to resolve how surface defects nucleate, interact, and evolve under relevant oxidizing conditions. We find that vacancy formation becomes increasingly favorable at higher potentials, with isolated defects stabilizing and subsequently coalescing into larger surface pits – structures that likely act as precursors for accelerated dissolution. These findings provide a first link between applied potential and defect thermodynamics, offering predictive insight into potential-dependent degradation pathways of IrO_2.

O 13.2 Mon 15:15 TRE/PHYS

Electrochemical Free Energy Barriers at Constant Potential — •Elias Diesen, Karsten Reuter, and Vanessa J. Bukas — Fritz-Haber-Institut der MPG, Berlin

Simulating barriers for electrocatalytic reactions is methodologically very challenging due to the intricate dynamics at the electrified solid/liquid interface. In addition, standard atomistic simulations based on periodic density-functional theory (DFT) keep the charge of the simulation cell constant instead of allowing it to fluctuate during the reaction in order to maintain a (fixed) electrode potential. Here, we introduce a method to compute electrochemical free energy barriers under well-defined potential conditions. Our approach relies on umbrella sampling on top of DFT-based molecular dynamics to access the free energy of activation, including both enthalpic and entropic contributions [1]. By carefully sampling the work function along the reaction coordinate, a Legendre transformation of the resulting canonical (constant-charge) energetics is then used to obtain grand canonical (constant-potential) results [2]. The method is demonstrated for proton deposition over Au(111). We extract potential-dependent barriers and examine kinetic scaling relations as well as use our results to benchmark common approximations in the recent literature. This work paves the way for systematic studies under realistic electrochemical conditions at e.g. varying temperatures or considering different proton-donating species.

O 13.3 Mon 15:30 TRE/PHYS

Customizable Electrostatic Potentials in DFT Supercell Calculations: Implementation and Application to Electrified Interfaces — •Samuel Mattoso[1], Jing Yang[1], Florian Florian Deissenbeck[1], Ahmed Abdelkawy[1], Christoph Freysoldt[1], Stefan Wippermann[1,2], Mira Todorova[1], and Jörg Neugebauer Jörg Neugebauer[1] — [1]Max Planck Institute for Sustainable Materials, Max-Planck-Straße 1, 40237 Düsseldorf, Germany — [2]Philipps-Universität Marburg, Renthof 5, 35032 Marburg, Germany

Electric fields drive reactions, reshape surfaces, guide protein folding and dictate selectivity in chemistry and materials science. While Density Functional Theory (DFT) is a standard tool for modelling such phenomena, introducing user-defined customizable electrostatic potentials usually requires invasive code modifications and deep coding expertise. We will present a lightweight, Python-based implementation that allows adding external electric fields to supercell DFT calculations via a new VASP-Python interface. We outline the necessary energy- and force-corrections, describe the computational setup, and provide a streamlined workflow that works entirely within VASP without altering the source code. The method's versatility is demonstrated on several case studies: molecular adsorption on charged surfaces, field-ion microscopy, electrochemical solid-water interfaces, and implicit solvent models. This approach offers a simple, flexible route for researchers to incorporate external fields into DFT simulations, enabling exploration of field-dependent phenomena across chemistry and materials science.

O 13.4 Mon 15:45 TRE/PHYS

Ion-specific charge transfer and capacitance in the compact double layer of solvated cations at metal electrodes — •Fabiola Dominguez Flores, Axel Gross, and Wolfgang Schmickler — Institute of Theoretical Chemistry, Ulm University, 89081 Ulm, Germany

A molecular-scale understanding of the compact double layer is essential for fundamental electrochemistry. Using density-functional theory with a hybrid implicit-explicit solvation model, we investigate the adsorption of solvated cations (K^+, Na^+, Ca^{2+}, Mg^{2+}) on metal electrodes. This approach captures the local hydration structure while modeling a dilute electrolyte where no diffuse layer forms. Our results reveal two distinct physical regimes: alkali ions retain their unit charge, while divalent ions exhibit substantial partial charge transfer, directly quantified by Bader analysis. This charge transfer governs the interfacial capacitance, which we calculate to be 10-20 $\mu F\,cm^{-2}$, in excellent agreement with

experiment. We demonstrate that the electrosorption valency equals the negative of this partial charge. Interpreting these results with a parallel-plate model yields an effective dielectric constant dictated by the polarizabilities of the metal and the water layer. This work provides fundamental microscopic insight into how ion-specific electronic interactions control the properties of the electrochemical double layer.

O 13.5 Mon 16:00 TRE/PHYS

Electrokinetic spectroscopy of ion dynamics near charged surfaces using modulated surface acoustic waves — •Ofer Manor, Li Yifan, and Sudeepthi Aremanda — Technion, Haifa, Israel

We use MHz-level frequency-modulated surface acoustic waves (SAWs) to study the dynamics of ions in the electrical double layer (EDL) to appear near the charged glass/electrolyte interface. The SAW travels in the solid; the EDL exists in the electrolyte; both phenomena are entangled through a field effect, a mechanical evanescent wave, which is invoked in the electrolyte by the SAW and vibrates ions in the EDL to result in the leakage of an electrical field off the glass/electrolyte interface. We show measured spectra of electrolyte comprising different types and concentrations of salts and salt mixtures. This is a spectroscopy of ion dynamics in isolated and unique EDLs.

EDLs are nanometer-thick clouds of ions that appear at the charged interface between a substrate and an electrolyte solution and determines its electrical properties. Ions migrate through the EDL within micro- to nano-seconds: These are the EDL relaxation-times for charging and discharging, which are a product of the EDL structure and ion species therein.

Ion relaxation-times similar to the SAW periodic time result in an ion electromechanical synchronization, which maximizes ion vibration and the leakage of electrical fields off the EDL. The leakage identifies ion relaxation-time spectra for different electrolytes and the presence of ions and the intrinsic rate by which they charge and discharge EDLs.

O 13.6 Mon 16:15 TRE/PHYS

Impact of the Negative Dielectric Responses on Solvation and Adsorption at Electrified Interfaces — •Zhenyu Wang[1], Mira Todorova[1], Christoph Freysoldt[1], Stefan Wippermann[2], and Jörg Neugebauer[1] — [1]Department of Computational Materials Design, Max Planck Institute for Sustainable Materials, Düsseldorf, Germany — [2]Department of Physics, Philipps-Universität Marburg, Marburg, Germany

Understanding processes at electrified solid-liquid interfaces is central to electrocatalysis, corrosion, and water-splitting, yet the dielectric response of interfacial water remains poorly understood. Using a capacitor geometry in which water is confined between oppositely charged electrodes, we perform several hundred nanoseconds-long molecular dynamics simulations to probe both the dielectric behaviour of neat water and the solvation of ions under bias. The simulations reveal pronounced oscillations in the screening of interfacial water, giving rise to regions in which the local dielectric constant becomes negative. This dielectric response gives rise to weakly bound adsorption states. By correlating the computed potential profiles with the evolution of Na^+ and Cl^- solvation shells, we demonstrate that the rate-limiting step is not related to the charge transfer barrier but originates from the reorganization of the ion solvation shell when transferring through the negative-dielectric regions. This insight bridges atomistic dielectric anomalies with macroscopic electrochemical behaviour and provides a quantitative basis to describe ion migration in the vicinity of the electrified interface.

O 13.7 Mon 16:30 TRE/PHYS

Selectivity in Electrochemical Oxidation Reactions: Challenges in Ethylene Epoxidation — •Pauline Schütt and Alexander Bagger — Department of Physics, Technical University of Denmark

Electrochemical technologies play a central role in the sustainable production of fuels and chemicals, but their applications remain limited due to significant overpotentials and challenges in controlling selectivity. Alternative oxidation reactions could potentially generate value-added products on the anode side of electrochemical cells, but typically suffer from competition with the oxygen evolution reaction (OER).[1] Density functional theory (DFT) predictions and concepts from computational catalysis provide useful tools to systematically analyze selectivity and establish trends across different catalyst and reaction systems.[2] We here discuss key challenges restricting such alternative oxidation reactions and their competition with the OER, with a focus on ethylene epoxidation.

O 13.8 Mon 16:45 TRE/PHYS

Bias, Barriers, and Beyond: Perturbative Insights into Electrochemical Reactivity — •Nicolas G. Hörmann and Karsten Reuter — Fritz-Haber-Institut der MPG

Electrochemical processes at solid-liquid interfaces are strongly shaped by the applied potential, yet capturing these effects efficiently remains a central challenge for atomistic modelling. In this talk, I will provide an overview of recent advances made in our group, focusing on perturbative and response-based approaches for electrochemical energetics and kinetics. Building on a rigorous connection between the constant-charge and constant-potential ensembles, we establish general connections between computational formalisms and clarify how potential-dependent properties emerge.

These insights enable efficient Taylor-expanded descriptions of energetics that avoid explicit simulations at different applied biases and allow analytical assessments of non-Nernstian shifts in hydrogen underpotential deposition, potential-dependent symmetry factors and potentiostat-free barrier calculations. Implementing them into bias-aware ML potentials opens the door to long-timescale molecular dynamics and accelerated exploration of electrochemical reaction pathways.

O 13.9 Mon 17:00 TRE/PHYS

Electro-osmotic Flow in Nano-capillaries via Optical Imaging and I/V Measurements: Influence of different salts and concentrations — •Aleksei Overchenko[1], Simon Brauburger[2], Frank Cichos[1], and Ulrich Keyser[2] — [1]Leipzig University, Peter Debye Institute for Soft Matter Physics, Linnéstr. 5, 04103 Leipzig — [2]University of Cambridge, Cavendish Laboratory, JJ Thomson Ave

Electro-osmotic flow (EOF) is of great interest in solid-state nanopores (SSNPs) due to its ability to pump, mix, and separate fluids in micro- and nanofluidic devices without mechanical components. However, EOF remains insufficiently explored at the nanoscale. Although KCl, NaCl, and LiCl are the most commonly used salts for driving matter through nanopores, no systematic qualitative or quantitative study has yet evaluated how different ions and concentrations affect EOF magnitude in nanopores.

We investigated the influence of various salts and their concentrations (10 mM to 1 M) on EOF behavior in 100 nm SiO2 glass capillaries. Flow visualization was performed using dark-field optical microscopy with simultaneous I/V measurements via a custom-designed flow cell. Tracer particles included 250 nm polystyrene and AuNPs.

This study provides higher spatial resolution and more detailed characterization of EOF than previously reported, offering new insights into nanoscale behavior. Understanding EOF under different ionic conditions is essential for future applications, including controlled manipulation of single DNA molecules and proteins.

O 13.10 Mon 17:15 TRE/PHYS

Facet-dependent restructuring and catalytic activity of Cu single crystals during CO electro-oxidation — Matthias Leitner, Francesc Valls Mascaro, •Andrea Auer, and Julia Kunze-Liebhäuser — Institute of Physical Chemistry, University of Innsbruck, Austria

Understanding how surface structure relates to catalytic activity is essential for designing efficient electrocatalysts. Copper (Cu) is known to restructure under reaction conditions, yet the precise impact of this dynamic behavior on activity remains largely unclear. Here, we combine electrochemistry with in situ electrochemical scanning tunneling microscopy (EC-STM) to investigate CO electro-oxidation on Cu(111) and Cu(100) single crystals and correlate activity with facet-specific structural changes. Both surfaces undergo nanometer-scale restructuring, forming undercoordinated Cu adatoms that act as active sites. Their evolution, however, differs significantly: Cu(111) shows dynamic, reversible restructuring that maintains a high density of adatom nanoclusters, whereas Cu(100) forms clusters that evolve less reversibly, with a gradual reduction in density. Interestingly, the evolution of clusters and their density does not directly correlate with the observed catalytic activity for either facet. Instead, we propose that the differences in activity stem primarily from variations in the effective density of the catalytically active Cu adatoms and their distinct interaction with reactants, rather than from different structural motifs. These results underscore the crucial role of dynamic restructuring in guiding the design of Cu-based electrocatalysts.

O 13.11 Mon 17:30 TRE/PHYS

In-situ magneto-optical tracking of redox reactions in NiFe electrocatalysts — •Sandhya Chandola[1,2], Karuppasamy Dharmaraj[2], Jörg Rappich[2], and Norbert Esser[1] — [1]Institut für Festkörperphysik,TU Berlin, Hardenbergstr. 36, 10623 Berlin, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Schwarzschildstr. 8, 12489 Berlin, Germany

Nickel/Iron (NiFe)-based electrocatalysts are known to be efficient catalysts for the oxygen evolution reaction (OER), involved in water splitting. By using a polarization sensitive optical spectroscopy technique, Reflection Anisotropy Spectroscopy (RAS), at near normal incidence, we show how the polarization state of the reflected light can be directly correlated with the oxidation state changes of NiFe catalysts via two entangled magnetic effects, which are the magneto-optical Kerr effect (MOKE) at the surface of the NiFe layer and Faraday rotation within the layer. The polarization state can be used to monitor phase transitions which are not observed in unpolarized absorption spectra.

Increasing amounts of Fe in the NiFe films correspond to greater changes in the RAS/MOKE intensities, up to the solubility limit of ~ 25% Fe, after which the spectra do not show any more changes. RAS/MOKE is shown to be a valuable spectroscopic technique which can probe changes in the redox states for differ-

ent NiFe ratios, due to the indirect influence of magneto-optical effects with the implied role of ferromagnetic ordering in enhancing catalytic activity.

O 13.12 Mon 17:45 TRE/PHYS

Size Dependent Stability of Pt-supported Ceria Nanoparticles in Alkaline Electrolyte — Lukáš Fusek[1], Pankaj Kumar Samal[1], Jiří Kerestеš[1], Ivan Khalakhan[1], Viktor Johánek[1], Yaroslava Lykhach[2], Jörg Libuda[2], Olaf Brummel[2], and •Josef Myslivečeк[1] — [1]Charles University, Faculty of Mathematics and Physics, V Holešovičkách 2, 180 00 Praha 8, Czech Republic — [2]Interface Research and Catalysis, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstr. 3, 91058 Erlangen, Germany

Ceria nanoparticles find applications in electrocatalysis as co-catalysts for alcohol and CO oxidation, and for fuel cell and water electrolysis reactions. Synergistic effects of ceria are expected to critically depend on the cerium phases established under electrochemical conditions.

We perform a combined surface science and electrochemical study of CeO2(111) nanoparticles on Pt(111). Under electrochemical operation conditions, large ceria nanoparticles exhibit a stable redox behavior, while nanoparticles smaller than 5 nm destabilize and convert to a fully hydrated phase. Both types of nanoparticles block OH adsorption and H evolution on Pt(111), but do not block H adsorption, indicating H intercalation.

Our results reveal the nature of the electrocatalytically active cerium phases [10.1039/d3cp03831a] and underline the relevance of combined surface science and electrochemical experiments [10.1021/acs.jpclett.5c01465] for obtaining in-operando information on model electrocatalyst systems.

O 14: Ultrafast electron dynamics at surface and interfaces I

Time: Monday 15:00–18:00 Location: TRE/MATH

Invited Talk O 14.1 Mon 15:00 TRE/MATH

Spin and time-resolved ARPES and the orbital angular momentum of light — Pierre Nonnon[1,2], Romain Géneaux[1], Karol Hricovini[1,2], Christine Richter[1,2], David Bresteau[1], and •Mauro Fanciulli[1,2] — [1]Cergy Paris University, France — [2]LIDYL CEA Saclay, France

I will present the recently developed Panoramix beamline at Attolab, open to users, which allows for spin, time and angle-resolved photoemission spectroscopy (STARPES) experiments. The combination of a high harmonic generation (HHG) setup with tunable repetition rate and pulse duration, and a hemispherical analyzer with a 3D spin detector, permits to study charge and spin ultrafast dynamics in material surfaces. As an example, I will compare the observation of chiroptical resonant control of spin polarized excitons in bulk 2H-WSe2, to how the spin polarization changes for electrons pumped beyond bandgap resonance in the unoccupied conduction band. In the search of ever-increasing multidimensional spectroscopic techniques, I will conclude on the possibility to further include exotic light pulses with azimuthally varying phase or polarization, and how they might affect the photoemission process.

O 14.2 Mon 15:30 TRE/MATH

Disentangling exciton resonances in 2D materials by time-resolved XUV-ARPES — •Gregor Zinke[1,2], Antonius Naujok[1], Franz Spartz[1], Sebastian Hedwig[1], Tobias Eul[2], Martin Aeschlimann[1], and Benjamin Stadtmüller[2] — [1]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern - Landau, 67663 Kaiserslautern, Germany — [2]Experimental Physics II, Institute for Physics, University of Augsburg, 86159 Augsburg

Ultrafast and coherent electron dynamics in 2D materials and their heterostructures are governed by the complex energy landscape of various excitons. These quasi-particles are often separated only by tens of meV, making them difficult to distinguish in conventional time-resolved experiments due to the spectral linewidth of ultrashort pulses. Although interferometric photoemission experiments have shown potential in resolving (coherent) excitation pathways and absorption resonances, they depend mostly on optical pulses, limiting the observable momentum space, leaving high-symmetry points of 2D materials inaccessible. To address these limitations, we present a modified version of interferometric trARPES that employs two active, phase-stabilized IR pump pulses and a fs-XUV probe pulse for photoionization. We demonstrate the capability of our approach by examining the well-known A-exciton transition energies in WSe_2 at different frequencies of our pump spectrum, showing how temporal Fourier analysis of the entire ARPES spectrum allows linking distinct transition energies to congruent excitation paths within the WSe_2 electronic band structure.

O 14.3 Mon 15:45 TRE/MATH

Multi-mode momentum microscopy for studying light-induced metastable states — •Junde Liu[1], Bent van Wingerden[1], Hashima Marukara[1], Paul Werner[1], Daniel Steil[1], G. S. Matthijs Jansen[1], Wiebke Bennecke[1], Jan Philipp Bange[1], Olena Tkach[2], Gerd Schönhense[2], and Stefan Mathias[1] — [1]Georg-August-Universität Göttingen, Germany — [2]Johannes Gutenberg-Universität Mainz, Germany

Light-induced ultrafast phase transitions characterized by domain competition involving interlayer ordering, chirality, and topological defects are attracting growing interest [1]. This calls for time-resolved momentum microscopy, which offers simultaneous spatiotemporal resolution and direct access to band structures [2]. However, conventional high-field setups near the sample are prone to field-emission and space-charge effects, particularly in the case of cleaved crystal surfaces.

Here, using cleaved bulk TaS_2 as an exemplary system, we employ a momentum microscope with a newly designed lens system [3] that minimizes the electric field at the sample in the gap-lens mode to suppress field emission, or applies a retarding field in the repeller mode to remove slow electrons and thereby mitigates space-charge effects. This development paves the way to study cleaved crystals and enables dark-field imaging capabilities of domain-resolved electronic structure, nonequilibrium pathways, and the microscopic mechanisms of light-driven phase transitions. [1] Liu et al., *arxiv:2405.02831* (2024); [2] Reutzel, Jansen, Mathias, *Adv. in Phys. X* 9, 2378722 (2024); [3] Tkach & Schönhense, *Ultramicroscopy* 276, 114167 (2025).

O 14.4 Mon 16:00 TRE/MATH

Tracking ultrafast exciton-polariton propagation and coherent energy exchange in thin WSe_2 films — •Tobias Eul[1,2], Kai Rossnagel[2,3,4], and Michael Bauer[2,3] — [1]Institute of Physics, University of Augsburg — [2]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University — [3]Institute of Experimental and Applied Physics, Kiel University — [4]Deutsches Elektronen-Synchrotron DESY, Hamburg

Efficient charge transfer of electrons and holes after photogeneration is fundamental for light-induced energy conversion. The propagation of bound electron-hole pairs, i.e., excitons, can enhance this efficiency by reducing non-radiative losses before charge separation and extraction. A promising approach to improve exciton propagation is via exciton-polaritons, quasiparticles formed by the strong coupling of excitons and photons. In these hybrid states, the excitation coherently oscillates between exciton and photon character, enabling the photonic component to transport energy over extended distances. Using photoemission electron microscopy, we visualize the propagation of exciton-polaritons in a thin WSe2 film by observing the ultrafast energy exchange between excitons and photons.

O 14.5 Mon 16:15 TRE/MATH

Probing On-Chip THz Generation by Momentum Streaking in Photoelectron Emission Microscopy — •David Huber, Wolfgang Hoppe, Georg Woltersdorf, and Wolf Widdra — Martin-Luther-Universität Halle-Wittenberg

THz electromagnetic radiation provides ultrafast electric fields on the femtosecond timescale. Using THz radiation as a pump in time-resolved photoemission experiments enables sub-cycle probing of induced dynamics e.g. charge and spin currents. The momentum and energy streaking of electrons in vacuum – i.e., their acceleration due to the Coulomb force – has long been shown to reliably probe electric fields and THz radiation.

In a spintronic THz emitter, we generate a spin current through the ultrafast demagnetization of a 3 nm ferromagnetic thin film, which results in a surface charge current in an adjacent 3 nm platinum film due to the inverse spin Hall effect. Similar to dipole radiation, the charge current emits THz radiation into the vacuum. By time-resolved in-plane momentum streaking of photoemitted electrons, we probe the single-cycle THz electric field in front of the surface and deduce the electric surface current. We verify our findings using simulated THz radiation and streaking.

O 14.6 Mon 16:30 TRE/MATH

Interplay between intraband acceleration and interband excitation in Bi_2Te_3 by subcycle time-resolved THz-ARPES — •Tim Bergmeier[1,2], Suguru Ito[1], Jens Güdde[1], and Ulrich Höfer[2] — [1]Fachbereich Physik, Philipps-Universität Marburg, Germany — [2]Fachbereich Physik, Universität Regensburg, Germany

Angle-resolved photoemission spectroscopy (ARPES) using THz driving fields with subcycle temporal resolution offers unique capabilities to investigate the dynamics of lateral Dirac currents in the surface state of topological insulators. Whereas low THz-frequencies result in pure intraband accelerations within the surface state [1], additional interband excitations become possible at higher frequencies [2,3].

Here, we present subcycle-resolved THz-ARPES measurements with 2D momentum imaging resolving the full Dirac cone of Bi_2Te_3. For this purpose, we

generate frequency-tunable two-cycle MIR pulses (20-40 THz) with electric field strengths up to MV/cm at the sample surface, combined with an ultrashort 400 nm two-photon probe (<15 fs), at a repetition rate of 200 kHz. For a frequency of 25 THz, we show that the momentum distribution of the field-driven intraband acceleration is strongly influenced by the Dirac cones hexagonal warping, while being superimposed with resonant interband excitations that are only possible in the materials $\overline{\Gamma M}$ direction.

O 14.7 Mon 16:45 TRE/MATH

Realistic nuclear ensembles for electronic excitation dynamics — •Hannah Bertschi, George Trenins, and Mariana Rossi — MPI for the Structure and Dynamics of Matter, Hamburg, Germany

Understanding how large-amplitude anharmonic nuclear motion influences electronic excitations is essential for explaining related phenomena in weakly-bound systems. To model charge transfer and vibronic spectra, we employ real-time time-dependent density functional theory coupled to multitrajectory Ehrenfest dynamics. In this approach, nuclear anharmonicity is incorporated through the sampling of initial conditions. In contrast to more conventional methods, we generate nuclear configurations and momenta using quantum thermostat molecular dynamics [1]. The resulting distributions of nuclear positions and momenta agree well with exact quantum references obtained from path-integral molecular dynamics, even for systems with large-amplitude motion such as the water dimer. However, the quantum thermostat does not perfectly capture the anharmonic zero-point energy of every degree of freedom, which can be mitigated by carefully choosing the parametrization of the thermostat. We show that the initial nuclear conditions of a water dimer on phenanthrene have a strong impact on both the direction and magnitude of charge transfer. Moreover, the nonadiabatic dynamics can even reverse the direction of the transfer.

O 14.8 Mon 17:00 TRE/MATH

Laser-induced anisotropic electronic response and inverse Faraday effect in hexagonal boron nitride from real-time time-dependent density functional theory — •Cheng Wang, Markus E. Gruner, and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen

The ultrafast electronic response of hexagonal boron nitride (h-BN) is investigated using real-time time-dependent density functional theory (RT-TDDFT) within an all-electron LAPW framework of the Elk code. We vary the light polarization (in-plane vs out-of-plane), dimensionality (monolayer, bilayer, bulk) and photon energy, and resolve the time-dependent projected density of states into orbital channels and identify the microscopic pathways of carrier injection. For out-of-plane linearly polarized light, the charge transfer is suppressed in the monolayer, weak in the bilayer, and strong in the bulk. Under in-plane polarization and a photon energy slightly above the DFT band gap, we identify a direct interband excitation pathway from the N p_z to B p_z orbitals. At higher photon energy, the bulk response is dominated by a local charge redistribution within N p_x-orbitals. Circularly polarized light induces a notable orbital angular momentum, while spin contributions remain negligible.

Funding by DFG within CRC1242 (project C02) and computational time on the MagnitUDE and AmplitUDE supercomputers at the University of Duisburg-Essen are gratefully acknowledged.

O 14.9 Mon 17:15 TRE/MATH

Theory of resonantly enhanced light-induced superconducting pairing in K_3C_{60} — •Juan I. Aranzadi[1], Joseph Tindall[2], Paul Fadler[1], and Michael A. Sentef[1,3] — [1]Institute for Theoretical Physics, University of Bremen/ BCCMS — [2]Center for Computational Quantum Physics, Flatiron Institute, New York, New York 10010, USA — [3]MPSD, CFEL, Hamburg

K_3C_{60} exhibits unconventional s-wave superconductivity with a critical temperature of approximately 20K, where the superconducting state emerges from a balance between strong electronic correlations and Jahn-Teller phonon-mediated pairing [1].

Recent pump-probe measurements have shown that optical excitation induces optical signatures reminiscent of the equilibrium superconducting state at temperatures higher than Tc [2, 3]. Notably, a 10 THz resonance was observed to trigger metastable superconducting-like properties that persist for temperatures up to 300 K [4].

The mechanism underlying this non-equilibrium superconducting state remains poorly understood. To address this question, we investigate a driven three-orbital Hubbard-Kanamori model which serves as a minimal model for equilibrium superconductivity in K_3C_{60} using numerical techniques including exact diagonalization and tensor networks.

O 14.10 Mon 17:30 TRE/MATH

Ultrafast table-top three-dimensional photoemission orbital tomography — •G. S. Matthijs Jansen[1], Wiebke Bennecke[1], Thi Lan Dinh[2], Jan Philipp Bange[1], David Schmitt[1], Marco Merboldt[1], Lennart Weinhagen[1], Bent van Wingerden[1], Fabio Frassetto[3], Luca Poletto[3], Marcel Reutzel[1], Daniel Steil[1], D. Russell Luke[2], and Stefan Mathias[1] — [1]University of Göttingen, I. Physikalisches Institut, Göttingen, Germany — [2]University of Göttingen, Institute of Numerical and Applied Mathematics, Göttingen, Germany — [3]Institute for Photonics and Nanotechnologies CNR-IFN, 35131 Padova, Italy

In photoemission orbital tomography (POT), molecular orbitals can be imaged with femtosecond resolution. Also, when combined with photon-energy-dependent measurements, POT is, so far, the only method that can probe the orbitals of adsorbed molecules in 3D. However, the study of, e.g., hybridization in organic/inorganic heterostructures [Bennecke *et al.*, arXiv:2411.14993 (2024)] by 3D-POT is extremely challenging due to the demanding nature of the experiment. Here, we present a table-top approach for 3D POT: By combining a photoelectron momentum microscope with a pulse-preserving monochromator for laser-generated extreme ultraviolet light, we speed up data acquisition. Moreover, we developed a new reconstruction algorithm that reduces the sampling requirements by about an order of magnitude [Dinh *et al.*, New J. Phys. 26 043024 (2024)]. Our first results achieved on PTCDA/Ag(110) highlight the potential for ultrafast femtosecond time-resolved 3D-POT.

O 14.11 Mon 17:45 TRE/MATH

Temporal Advancement of Photoelectrons emitted via Evanescent Waves — •Luis Maschmann, Andreas Gebauer, Tillmann Schabbehard, and Walter Pfeiffer — Bielefeld University, Universitätsstr. 25, 33615 Bielefeld

Photoelectron emission dynamics in solids is governed both by propagating and evanescent wave components. Here we employ a one-dimensional Kronig-Penney model to investigate the role of evanescent waves on the photoelectron wave packet dynamics based on time-reversed LEED states within one-step theory and time-dependent Schrödinger equation simulations. Using a Kronig-Penney potential with a large bandgap, we can clearly distinguish the dynamics for evanescent and propagating photoelectron emission channels. For emission via evanescent states, i.e., within the final state bandgap, the photoelectron appears temporally advanced and seemingly originates from the bulk-vacuum interface, although the emitter well is located well below the interface. Our results establish a direct analogy to the temporal evolution of a wave packet undergoing quantum mechanical tunneling through a potential barrier and significantly influence the interpretation of attosecond time-resolved photoemission delays.

O 15: Spins on surfaces at the atomic scale I

Time: Monday 15:00–18:00 Location: WILL/A317

Invited Talk O 15.1 Mon 15:00 WILL/A317

Tuning Spin-1/2 Interactions in Graphene: From Long-Range Coupling to Altermagnetic Order — •Beatriz Viña-Bausá[1], Manuel A. García-Blázquez[1], Antonio T. Costa[2], Joao C. G. Henriques[2], Roberto Carrasco[1], Eva Cortés-del Río[1], Diego Expósito[1], Pierre Mallet[3], Jean-Yves Veuillen[3], Joaquín Fernandez-Rossier[2], Juan J. Palacios[1], and Iván Brihuega[1] — [1]Dept. Física de la Materia Condensada, Universidad Autónoma de Madrid, Spain — [2]International Iberian Nanotechnology Laboratory, Portugal — [3]Université Grenoble Alpes, France

Here, we demonstrate that graphene, functionalized with H atoms, serves as a versatile platform for engineering and investigating long-range magnetic interactions. Through scanning tunneling microscopy, we manipulate spin-1/2 moments induced by single H atoms on graphene and quantify their coupling via spin excitations using inelastic electron tunneling spectroscopy[1]. Our measurements reveal robust ferromagnetic and antiferromagnetic exchange interactions in H pairs, extending over nanometer-scale distances. Additionally, guided by symmetry selection, we realize unconventional magnetic phases in our system, namely altermagnets and Lieb ferrimagnets[2]. Our results, supported by mean-field Hubbard and density functional theory calculations put forward hydrogenated graphene as a promising material for simulating exotic spin systems.

O 15.2 Mon 15:30 WILL/A317

versatile building blocks for molecular qubits on surfaces — •Saba Taherpour[1,2], Corina Urdaniz[1,3], Jisoo Yu[1,3], Jose Reina-Galvez[1,3,4], Kevin Lizárraga[1,3], and Christoph Wolf[1,3] — [1]Center for Quantum Nanoscience, Institute for Basic Science (IBS), Seoul 03760, Korea — [2]Department of Physics, Ewha Womans University, Seoul 03760, Korea — [3]Ewha Womans University, Seoul 03760, Korea — [4]University of Konstanz, 78457 Konstanz, Germany

Electron spins are natural quantum objects. Molecules that host an electron spin S=1/2 can therefore be considered qubit candidates provided they have reasonable coherence times. In this work, I will show based on first-principles calculations how the charge transfer across an Ag/MgO interface can be utilized to change the charge and spin state of 3d transition-metal phthalocyanine molecules. Iron(II) phthalocyanine (FePc) emerges as a promising qubit candidate. We present density functional theory calculations and nonequilibrium quantum transport simulations based on recent developments of all electrical electron spin resonance in atomic scale magnetic transport junctions. Our results indicate that FePc on the Ag/MgO substrate can be used as molecular building block of on-surface qubit architectures.

O 15.3 Mon 15:45 WILL/A317

Creating multi-well energy landscapes from coupled orbital memory states — •Kira Junghans, Niek M. M. Aarts, Hermann Osterhage, Julián D. Rojas-Castillo, and Alexander A. Khajetoorians — Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands

The interaction between atomic spins on surfaces is usually dictated by the exchange interaction. Its short-range nature strongly favors spin orientations that are either ferro- or antiferromagnetic. Recently, it was shown that memory can be created from an atomic spin using its valency [1]. Unlike the exchange interaction, it was shown that the interactions between orbital memory elements are long-range. This can lead to complex stochastic dynamics often needed in computational schemes based on theoretical neuroscience [2]. Exploiting this new functionality requires a deeper understanding of the nature of the interaction as well as the uniqueness of this material system.

Here, we study the stochastic dynamics of Co and Fe atoms on black phosphorus with scanning tunneling microscopy and spectroscopy. We quantify how the state favorability and lifetimes are influenced in dimers at different distances and by the neighboring atoms' state. We find that heterogenous dimers can also lead to complex stochastic noise, analogous to multi-well behavior. Furthermore, we investigate the dynamics of multiple coupled atoms and show that the state favorabilities can be tuned by the states of all surrounding atoms.

O 15.4 Mon 16:00 WILL/A317

Single spin control of atomic defects in monolayer MoS_2 — •Kwan Ho Au-Yeung[1,3], Wantong Huang[1,3], Johanna Matusche[1,3], Paul Greule[1,3], Jonas Arnold[1,3], Lovis Hardeweg[1,3], Máté Stark[1,3], Luise Renz[1,3], Affan Safeer[2], Daniel Jansen[2], Jeison Fischer[2], Thomas Michely[2], Wolfgang Wernsdorfer[1,3], Christoph Sürgers[1,3], Johannes Schwenk[1,3], Wouter Jolie[2], and Philip Willke[1,3] — [1]Physikalisches Institut, Karlsruhe Institute of Technology, Karlsruhe — [2]II. Physikalisches Institut, Universität zu Köln, Köln — [3]Center for Integrated Quantum Science and Technology, Karlsruhe Institute of Technology, Karlsruhe

Point defects in two-dimensional (2D) semiconductors host localized quantum states that can function as sensors, single-photon emitters, and qubits, but their controlled realization and individual addressability in atomically thin hosts remain challenging. Here we combine scanning tunneling microscopy with electron spin resonance (ESR-STM) to achieve single-spin control of atomic defect in a monolayer transition-metal dichalcogenide. Using STM manipulation, we create individual point defects, including sulfur vacancies and substitutional impurities in monolayer MoS_2 on graphene/Ir(111). Scanning tunneling spectroscopy and ESR measurements reveal their electronic structures and magnetic properties respectively, while pulsed ESR schemes enable quantum control of their spin states at the atomic scale. Our results demonstrate that monolayer MoS_2 provides a solid-state quantum platform that directly links 2D materials engineering with atomic-scale spin initialization, control, and readout.

O 15.5 Mon 16:15 WILL/A317

Imaging 2D ferromagnetic order with a single nickelocene molecule — •Leonard Edens[1], Trisha Sai[1], Divya Jyoti[1], Stefano Trivini[1], Fabian Schulz[1], and Nacho Pascual[1,2] — [1]CIC nanoGUNE BRTA, 20018 Donostia - San Sebastián, Spain — [2]Ikerbasque, Basque Foundation for Science, 48013 Bilbao, Spain

Lanthanide intermetallic compounds formed on coinage metal (111) surfaces exhibit ferromagnetic ground states with moments robustly aligned towards a polarization axis, even in the single monolayer limit. Characteristic of these 2D magnetic systems is the intricate dependence of the easy axis on 4f occupancy, and the formation of a moiré-induced superstructure with the support, which causes an inhomogeneous local magnetization [1]. Here, we study two representative alloys of this family of materials, $GdAu_2$ and $TbAu_2$, which respectively magnetize in- and out-of-plane. To sense their magnetic state, we employ a single nickelocene molecule adsorbed on the tip of a scanning tunnelling microscope. By quantifying the directional exchange field atom-by-atom, we characterize incommensurate order and local perturbations to the moiré-congruent magnetic texture. Further insight into the nature of the exchange field is gained by studying its dependence on vertical separation and externally applied magnetic fields.

O 15.6 Mon 16:30 WILL/A317

Two-photon transition in an Er-Ti atomic spin pair — •Dasom Choi[1,2], Yaowu Liu[1,2], Stefano Reale[2,3], Jeongmin Oh[1,2], Lei Fang[1,2], We-hyo Seo[1,2], Andreas Heinrich[1,2], Fabio Donati[1,2], and Soo-hyon Phark[1,2] — [1]Department of Physics, Ewha Womans University, Seoul, Republic of Korea — [2]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Seoul, Republic of Korea — [3]QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands

Multi-photon process becomes a key ingredient in quantum information science, offering a promising route to nonlinear quantum transitions and entanglement generation. Extending this to atomic spin qubits on surfaces is of great interest, yet has not been demonstrated. In this work, we investigate a spin-pair of Er and Ti atoms adsorbed on a MgO/Ag(100) surface using a scanning tunneling microscope (STM). By applying pulsed electron spin resonance in the STM, we realize two-photon resonant transitions corresponding to an angular momentum change of $\Delta m = \pm 2$ of the spin-pair, a phenomenon beyond the conventional single-photon processes as shown at the single atom level. Our work demonstrates the ability to coherently control higher-order quantum transitions at the single spin level, which provides a novel pathway towards implementing multi-quantum gate operations in atomic spin qubits, highlighting the potential of single atomic lanthanides on a surface for quantum information processing.

O 15.7 Mon 16:45 WILL/A317

Landau-Zener transitions of multilevel atomic spins — •Lukas Veldman[1,2], Henrik Lichtl[1,2], Nicolaj Betz[1,2], Johannes Schust[1], Laëtitia Farinacci[1,3], Fernando Delgado[4], Susanne Baumann[1,2], and Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies — [2]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart — [3]Carl Zeiss Stiftung Center for Quantum Photonics — [4]Instituto de Estudios Avanzados IUDEA, Departamento de Física, Universidad de La Laguna, Tenerife, Spain

The ability to perform Landau-Zener (LZ) transitions is a powerful and relatively unexplored tool to study and control spins on the nanoscale. LZ transitions provide spectroscopic information about energy level crossings, state populations and can even be used as a driving mechanism for coherent control over quantum spin states. In an idealized picture of a two level system (TLS), these qualities can be relatively easily understood via the LZ model. Here, we show LZ transitions on antiferromagnetic Fe chains on Cu2N/Cu(100) induced by ramping the magnetic field emanating from the tip of a scanning tunneling microscope (STM). Using real time measurement of the spin state we distinguish between classical and quantum tunneling transition processes. We find that avoided level crossings in higher excited states play a significant role in the dynamics between the ground states, showcasing the necessity to go beyond the TLS approximation used in the standard LZ model.

O 15.8 Mon 17:00 WILL/A317

Robustness of zero-energy edge states to disorder in bottom-up designed Fe chains on a superconducting Rashba alloy — •Harim Jang[1], Daniel Crawford[2], Jens Wiebe[1], Stephan Rachel[3], and Roland Wiesendanger[1] — [1]Department of Physics, University of Hamburg, Hamburg, Germany — [2]Department of Physics and Nanoscience Center, University of Jyväskylä, Finland — [3]School of Physics, University of Melbourne, Parkville, Australia

In this talk, we report on the role of disorder for the observation of Majorana zero modes (MMs) and a topological gap in a tailored 1D magnet-superconductor hybrid (MSH) system, showing the robustness of MMs to disorder, even in cases for which the topological gap is fully suppressed. We constructed 1D spin chains from Fe atoms on the Rashba surface alloy BiAg2/Ag(111) with proximity-induced superconductivity from a Nb(110) substrate. While the Fe chains have perfect crystalline order by design, the BiAg2/Ag(111) film exhibits nano-scale potential disorder, observed by scanning tunneling microscopy. However, this doesn't prevent the emergence of zero-energy states at the Fe chain's ends, in agreement with tight-binding calculations which show that they only appear in the topologically non-trivial regime [1]. This may not only explain earlier observations of MMs in disordered MSH systems, but also provides novel perspectives for the realization of robust Majorana qubits. [1] H. Jang et al., arXiv:2506.17414 (2025)

O 15.9 Mon 17:15 WILL/A317

Coherent control of a single 4f electron spin — •Yaowu Liu[1,2], Dasom Choi[1,2,3], Stefano Reale[1,2], Jeongmin Oh[1,2,3], Lei Fang[1,2], We-hyon Soe[1,2], Andreas Heinrich[1,2,3], Soo-hyon Phark[1,2], and Fabio Donati[1,2,3] — [1]IBS Center for Quantum Nanoscience (QNS) — [2]Ewha Womans University, Seoul 03760, Korea — [3]Department of Physics, Ewha Womans University, Seoul 03760, Republic of Korea

Electron spins on surface provide an atomic scale qubit platform for quantum information science using scanning tunneling microscopy (STM). Lanthanide atoms, with their strongly localized 4f electrons, can be potential candidates for single atom qubits with a long quantum coherence. However, STM tunneling current can strongly reduce the coherence time of surface atoms if they are probed directly. To circumvent this issue, it is possible to use an alternative scheme where a Ti (S = 1/2) atom located in a position within a 1 nm distance from a single Er atom on MgO surface can sense the quantum spin states of its 4f electron shells. In this work, we performed pulsed electron spin resonance (ESR) on the Er atom and demonstrated coherent control of 4f-electron spin of a single Er atom. Moreover, we observed a tenfold enhancement of Rabi rate compared to the direct drive of Ti atom from the tip, which is ascribed to the anisotropy of exchange interaction between the two spins.

O 15.10 Mon 17:30 WILL/A317

Kondo physics of composite molecular spins made from coupled nanographenes — •David Jacob — Department of Physics, University of Alicante, Spain

Open-shell nanographenes can now be fabricated by on-surface synthesis (OSS) and stabilized on metallic substrates, enabling access to their intrinsic (multi)radical character. Scanning-tunneling spectroscopy (STS) reveals clear Kondo signatures, demonstrating that these nanographenes host quantum spins whose magnitude reflects their degree of radicality [1]. By covalently linking such magnetic nanographenes, coupled spin systems can be engineered in controlled geometries–including dimers [2], hexagons [3], chains [4], and other topologies–allowing quantum magnetism to be probed at the atomic scale. Here we investigate coupled nanographenes whose constituent units have different spin magnitudes. We show that the composite nature of the resulting effective molecular spin leads to a rich spectrum of spin excitations and to unconventional Kondo behavior.

O 15.11 Mon 17:45 WILL/A317

Site-Specific magnetism of Ho atoms on MgO — •Andrés Pinar Solé[1,2], Merve Ercelik[1,2], Jungseok Chae[1,2], Fabio Donati[3], Dmitriy Borodin[1,2], and Andreas Heinrich[3] — [1]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS) — [2]Ewha Womans University — [3]Department of Physics, Ewha Womans University

Holmium (Ho) atoms on ultrathin MgO films are model systems for single-atom magnetism, where spin stability and relaxation strongly depend on the local crystal field and adsorption site. Isolated Ho atoms on oxygen sites of Ag(100)/MgO exhibit magnetic bistability but lack clear inelastic spin-excitation features; nevertheless, their magnetic states can be switched and read electrically through spin-polarized tunneling.

By extending to Ho dimers, additional spin-flip excitations become accessible, providing deeper insight into the electronic and magnetic states of Ho on MgO. The magnetic behavior of Ho dimers reflects the intra-atomic exchange coupling between the highly localized 4f moment and the outer valence-shell spins. Certain Ho dimers exhibit pronounced inelastic conductance steps, revealing strong magnetic interactions both between the atoms and with the surrounding MgO crystal field. Using STM-based atom manipulation, we precisely assemble Ho dimers on bridge and oxygen sites and probe their magnetic and electronic properties via Kelvin probe force microscopy (KPFM) and inelastic electron tunneling spectroscopy (IETS) in a combined STM/AFM UHV setup.

O 16: Focus Session: Structure and Dynamics of Solvent at Electrochemical Interfaces – Poster

Understanding how solvent molecules organize and move at electrochemical interfaces is central to catalysis, energy conversion, and electrochemical materials science. This Focus Session will bring together experimental and theoretical leaders using complementary surface specific spectroscopies as vibrational sum frequency generation, advanced X ray/electron techniques, and multiscale simulations to reveal intermolecular structure, hydrogen bond networks, ion-solvent coupling, and field driven dynamics from single crystal electrodes to complex battery interfaces. By highlighting recent breakthroughs in time-resolved measurements and operando platforms, the session aims to connect fundamental interfacial physics with macroscopic performance in electrocatalysis, corrosion, and electrochemical energy storage.

Organized by Yujin Tong (U Duisburg-Essen) and Angelika Kühnle (U Bielefeld).

O 16.1 Mon 18:00 P2

Ab initio study of water clusters and thin film adsorption on Bi(111) surfaces — •Yingjie Xie, Adriana Bocchini, Uwe Gerstmann, and Wolf Gero Schmidt — Universität Paderborn, Paderborn, Deutschland

Bismuth, as a semimetal with strong spin-orbit coupling, plays an important role in many electrochemical applications, including electrocatalysis, electrode materials, and seawater desalination [1]. In these environments, interaction between Bi surfaces and water is unavoidable. The Bi(111) surface is both the natural cleavage plane of bulk Bi and the preferred growth surface in epitaxial processes, and is therefore suitable for studying water adsorption. While the atomic and electronic structures of Bi(111) surfaces have been well characterized, understanding of the water-Bi interface remains incomplete, and existing theoretical studies report partially conflicting results [2,3].

In this work, we employ density functional theory (DFT) to systematically investigate the adsorption behavior of isolated water molecules, molecular clusters, and thin water films on Bi(111). We examine the interplay between water-water and water-metal interactions and determine energetically favorable adsorption sites and configurations for water clusters and ultrathin films.

Structure and Dynamics of Na^+ and Cs^+ adsorbed on Cu(111) and solvated by D_2O molecules — Florian Denizer[1], Jayita Patwari[1,2], John Thomas[1], Inga Langguth[2], Karina Morgenstern[2], and •Uwe Bovensiepen[1] — [1]Fakultät für Physik, Univ. Duisburg-Essen — [2]Phys. Chemie I, Ruhr-Univ. Bochum

Alkali cations in liquid water represent widely studied model systems of solvation science in which the water-water interaction competes with the local water-cation coupling. On electrode surfaces additional interactions become relevant. In our investigation using time-resolved two-photon photoemission and low-temperature scanning tunneling microscopy we compare Na^+ and Cs^+ on Cu(111) coadsorbed with individual D_2O molecules. $D_2O/Na^+/Cu(111)$ forms 10 nm wide, flat-lying aggregates. We observe a linear increase of the electronic lifetime of the 3*s* electron transfer resonance at the Cu(111)-Na^+ interface as a function of the number n of adsorbed D_2O molecules per ion combined with a maximal energy transfer to solvent modes ΔE of 0.6 eV at $n = 6-7$ [1]. On $D_2O/Cs^+/Cu(111)$ we find exclusively one or three D_2O attached to Cs^+. This leads to a stepwise increase in the corresponding 6*s* electron lifetime with n. ΔE is half that of $Na^+/Cu(111)$ which we associate with difference in ion core diameter and modified interactions with Cu(111) [2]. Comparing both systems we identify pronounced differences rooted in the microscopic connection between structure and dynamics.

O 17.1 Mon 18:00 P2

Conformational Control of Spin Lifetimes of a Single Molecule Magnet on a Metal Surface — •Sufyan Shehada[1], Corina Urdaniz[2], Manuel dos Santos Dias[3], Christoph Wolf[2], Dmitriy Borodin[2], Andreas Heinrich[2], Ruslan Temirov[1], Jeongmin Oh[1], Yujeong Bae[2], F. Stefan Tautz[1], Taner Esat[1], and Samir Lounis[4] — [1]Peter Grünberg Institute (PGI-3), Forschungszentrum Jülich, Germany — [2]IBS Center for Quantum Nanoscience (QNS), South Korea — [3]Scientific Computing Department, STFC Daresbury Laboratory, United Kingdom — [4]Institute of Physics, Martin-Luther-University Halle-Wittenberg, Germany

We present a first-principles study of a spin-engineered molecular nanostructure: a PTCDA molecule coordinated to two Fe atoms on an Ag(111) surface. This work complements recent STM-based quantum sensing experiments, where upright molecules were assembled on metallic pedestals to enable precise spin manipulation and nanoscale magnetic field detection using electron spin resonance [1-3]. Using density functional theory (DFT), we investigate how adsorption geometry influences exchange interactions and magnetic anisotropy energy in both standing and lying conformations. Incorporating DFT-derived parameters and experimental input, we developed a spin model to simulate spin relaxation dynamics [4-6]. This reveals how conformational control can regulate spin lifetimes at the single-molecule level.

Towards faster dynamics of magnons in atomic spin chains — Christina Mier[1], Alexandra Meerovici Goryn[1], •Michael Schelchshorn[1], Lukas Veldman[2], and Sander Otte[1] — [1]Delft University of Technology, Delft, The Netherlands. — [2]University of Stuttgart, Stuttgart, Germany.

The coherent free evolution of coupled atomic spins [1] as well as electron and nuclear spins within a single atom [2] has previously been demonstrated using ESR-STM. Extending this approach to atomically assembled spin chains, provides a tunable platform for investigating magnon transport and interactions; by exploiting the spectral resolution of ESR-STM, we achieve controlled excitation and tuning of coherent spin-wave modes while pump-probe techniques allow us to directly map their dynamics on a nanosecond time scale. In particular, by engineering stronger exchange coupling both within the chain itself and to the readout atom, we observe many more oscillations within the coherence times, demonstrating dynamical timescales significantly faster than those reported by Veldman et al. [1]. This work addresses the coherent magnon dynamics within precisely engineered atomic spin chains and paves the way for probing more complex collective excitations in larger spin systems.

Development of Time-Resolved Pump-probe SP-STS for Ultrafast Spin Dynamics in SAM — •Yannick Noettger[1] and Artem Odobesko[2] — [1]Wuerzburg University — [2]Wuerzburg University

Achieving coherent control of Single Atom Magnets (SAMs) is necessary for their use in quantum technologies and requires fundamental understanding of their spin dynamics on the atomic scale. Scanning tunneling microscopy (STM) provides a unique platform for probing and manipulating SAMs with atomic precision. One major challenge is minimizing coupling of the SAM to the surrounding as substrate-mediated relaxation strongly limits coherence and lifetime. Usually this is done by placing the SAM on a thin insulating layer on a metal substrate. We used an extended approach by combining the decoupling layer with a superconducting substrate, potentially enabling enhanced lifetimes due to the gap in the SC density of states. We investigate NaCl/Cu(111)/NbOx heterostructures grown by e-beam evaporation, which exhibit substrate induced superconductivity within the Cu(111)-layer up to a film thickness of 3ML. NaCl deposition on Cu(111)/NbOx was achieved, however showing very different growth characteristics than on bare Cu(111). Furthermore we implemented an all-electrical pump-probe spectroscopy scheme into our existing STM setup demonstrating functionalization and precise synchronization with the Lock-In Amplifier, although pump-probe measurements on single Fe atoms on Cu2N/Cu(001) did not yield any measurable lifetimes, highlighting limitations of our current STM setup.

O 17.4 Mon 18:00 P2

Structural characterization of $Sc_3N@C_{80}$ on Ag(111) with scanning probe microscopy — •Caroline Hommel[1,2], Seong-Hyun Hong[1,4], Andrés Pinar Solé[1,2], Merve Ercelik[1,3], Robert Ranecki[1,2], Shinjae Nam[1,2], Dmitriy Borodin[1,2], Andreas Heinrich[1,3], and Lukas Spree[1,2] — [1]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Seoul 03760, Republic of Korea — [2]Ewha Womans University, Seoul 03760, Republic of Korea — [3]Department of Physics, Ewha Womans University, Seoul 03760, Republic of Korea — [4]Department of Physics, Korea University, Seoul 03760, Republic of Korea

Endohedral fullerenes are a fascinating class of compounds, that consist of a number of atoms trapped inside a fullerene cage structure. Among them, the Nitride Cluster Fullerenes (NCF) stand out for their stability and relatively high production yield. $Sc_3N@I_h$-C_{80} is the most abundant species in this class. Its electronic structure and the relatively free rotation of the internal cluster make it a promising candidate for molecular electronics.

In the presented work, we use STM and AFM with a CO functionalized tip to characterize individual $Sc_3N@I_h$-C_{80} molecules on Ag(111). This allows us to resolve their adsorption configuration and study the interaction of cage, cluster, and substrate in highest detail.

Studying $Sc_3N@I_h$-C_{80} at the single molecule level provides direct access to its geometric and electronic characteristics, which are often hidden in bulk measurements.

O 17.5 Mon 18:00 P2

Study of correlated spin interactions in bottom-up assembled molecular structures — •Lars Pütz[1,2,3], Daria Sostina[1,2,3], Stefan Tautz[1,3,4], and Markus Ternes[1,2,3] — [1]Peter Grünberg Institut (PGI-3); Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Experimentalphysik II B, RWTH Aachen University, 52072 Aachen, Germany — [3]Jülich Aachen Research Alliance (JARA), Fundamenatls of Future Information Technology, 52425 Jülich Germany — [4]Experimentalphysik IV A, RWTH Aachen University, 52072 Aachen, Germany

Correlated physics hosts phenomena such as unconventional superconductivity and exotic magnetic phases, yet their theoretical description is often challenging. To provide a starting point, we investigate finite correlated systems. We study NTCDA molecules deposited on an Ag(111) surface using a low-temperature scanning tunneling microscope. These molecules can receive an additional electron from the surface, which turns each of them into a spin-1/2 system. Normally, this spin is screened by the substrate through the Kondo effect. By using molecular manipulation techniques, we built small molecular structures in which the spin-exchange interaction between two neighboring molecular spins overcomes the screening from the surface. In these structures, we observe singlet-triplet excitations. Moreover, these excitations exhibit a spatially varying bias asymmetry in scanning tunneling spectroscopy, reflecting the phase pattern of the triplet wave function and thus providing experimental access to it.

O 17.6 Mon 18:00 P2

Spectra and competing correlations in coupled magnetic impurities on superconducting substrates — •Carlos Quesada Pérez and David Jacob — Departamento de Física, Universidad de Alicante, Spain

The study of magnetic impurities in superconductors is a fundamental challenge in condensed matter physics, crucial for understanding phenomena like in-gap states such as Yu-Shiba-Rusinov (YSR) states. Systems with multiple impurities can potentially host exotic ground states relevant for topological quantum applications. Accurate numerical methods like the numerical renormalization group are computationally too demanding for solving more than two impurity levels. Recently, an efficient impurity solver was proposed, based on the exact diagonalization of a single impurity connected to discretized superconducting reservoirs [1]. In this work, we extend this model to the case of two magnetic impurities coupled to BCS superconductors. By exact diagonalization of the resulting tight-binding Hamiltonian, we study the competition between the impurity-superconductor coupling and the impurity-impurity exchange to form a singlet with the bath or a singlet between the impurities themselves. The results reveal the evolution of YSR states and spin correlations, showing transitions between distinct quantum phases driven by this competition.

O 17.7 Mon 18:00 P2

Atomic-Scale Engineering of Spin Defects in Monolayer MoS_2 — •Johannes Schwenk[1], Wantong Huang[1], Kwan Ho Au-Yeung[1], Johanna Matusche[1], Paul Greule[1], Jonas Arnold[1], Lovis Hardeweg[1], Máté Stark[1], Luise Renz[1], Affan Safeer[2], Daniel Jansen[2], Jeison Fischer[2], Thomas Michely[2], Wolfgang Wernsdorfer[1], Christoph Sürgers[1], Wouter Jolie[2], and Philip Willke[1] — [1]Physikalisches Institut (PHI), Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — [2]II. Physikalisches Institut, Universität zu Köln, Köln, Germany

Solid-state spin defects have become a promising platform for quantum technologies, including quantum sensing, communication, and computing. However, reliably creating and addressing such defects individually remains a major challenge. Here, we create distinct defect types in monolayer MoS_2 using the tip

of a scanning tunnelling microscope, i.e. sulphur vacancies and substitutional impurities. Moreover, we characterize their spin properties using electron spin resonance scanning tunnelling microscopy (ESR-STM) and demonstrate coherent control of the spin defects. By constructing dimers of defects, we show that their spins can be coupled via magnetic exchange, which provides a path to realize larger spin structures. These results open a new avenue to design and engineer quantum states at the atomic scale for applications in quantum sensing and simulations [Nat. Nanotech.19,1782-1788 (2024)].

O 17.8 Mon 18:00 P2

Switching properties of a spin-crossover complex on Cu(111) analyzed from time traces of the tunneling current — •Katharina Biel[1], Jasmeen Jasmeen[1], Sujoy Karan[1], Karl Ridier[2], Gael Reecht[1], and Manuel Gruber[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany — [2]LCC, CNRS and Université de Toulouse, France

Spin-crossover molecules can be switched between two states associated with different spin, a low spin (LS) and a high spin (HS) state. The switching between these two states can be induced by tunneling electrons, among other triggers, which offer the possibility to use a scanning tunneling microscope (STM) to investigate the switching dynamics at the single molecular level.

Here we investigate the spin-crossover molecule $[Fe(HB(1,2,4\text{-trazolyl})_3)_2]$, which forms self-assembled islands on Cu(111) and exhibits efficient switching under electron injection. The switching is monitored via time traces of the tunneling current, exhibiting two levels corresponding to the different spin states. Statistical analysis of these traces provides a detailed view on the switching properties. In particular we studied the influence of the applied voltage and the tunneling current on the switching rate. The influence of the applied voltage and the tunneling current on the switching yield is studied in details.

O 17.9 Mon 18:00 P2

Spin-Electric Control of Individual Spins on Surfaces — Paul Greule[1], Wantong Huang[1], Máté Stark[1], Kwan Ho Au-Yeung[1], Johannes Schwenk[1], Jose Reina-Gálvez[2], Christoph Sürgers[1], Wolfgang Wernsdorfer[1], Christoph Wolf[3], and •Philip Willke[1] — [1]Physikalisches Institut (PHI), Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — [2]Department of Physics, University of Konstanz, Konstanz, Germany — [3]Center for Quantum Nanoscience, Institute for Basic Science (IBS), Seoul, Republic of Korea.

Individual magnetic molecules are promising building blocks for quantum technologies because of their chemical tunability, nanoscale dimensions, and ability to self-assemble into ordered arrays. In this work, we present spin-electric coupling (SEC) for two molecular spin systems, iron phthalocyanine (FePc) and Fe-FePc complexes, adsorbed on a surface. We use electron spin resonance combined with scanning tunnelling microscopy (ESR-STM) to locally address them with the STM tip and electrically tune them using the applied bias voltage. These measurements reveal a pronounced nonlinear voltage dependence of the resonance frequency, linked to the energic onset of other molecular orbitals. We attribute this effect to a transportmediated exchange field from the magnetic tip, providing a large, highly localized, and broadly applicable SEC mechanism. Finally, we demonstrate that the SEC enables all-electrical coherent spin control: In Rabi oscillation measurements of both single and coupled Fe-FePc complexes we show that the spin dynamics can be tuned.

O 17.10 Mon 18:00 P2

Defluorination of F_{16}Cu-Phthalocyanine on Superconducting Pb(100) — •Julian Skolaut, Biswajit Pabi, Alexander Weismann, and Richard Berndt — Institute for Experimental and Applied Physics, CAU Kiel, Germany

F_{16}Cu-phthalocyanine was investigated on a superconducting Pb(100) surface using low-temperature scanning tunneling microscopy. We achieved controllable defluorination of selected lobes. A single defluorinated lobe serves as a pivot point for rotation toward eight different azimuthal orientations. Defluorination of more than one lobe eliminates the ability to rotate. The energy of the lowest unoccupied molecular orbital depends on the degree of defluorination and is lowest when two lobes have been defluorinated. We also observed Yu-Shiba-Rusinov states, which exhibit shifts depending on the adsorption configuration and azimuthal orientation.

O 17.11 Mon 18:00 P2

Investigations of FePc molecular spins on a superconducting substrate — •Luise Renz[1], Máté Stark[1], Jonas Arnold[1], Johannes Schwenk[1], Christoph Sürgers[1], Wolfgang Wernsdorfer[1], and Philip Willke[1,2] — [1]Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Center for Integrated Quantum Science and Technology (IQST), Karlsruhe Institute of Technology, Karlsruhe, Germany

Electron spin resonance (ESR) measurements performed with a scanning tunneling microscope (STM) has emerged as an excellent technique to probe quantum spin systems at the nanoscale. However, the spin lifetimes of surface spins are limited by scattering with substrate electrons[1]. This can be prevented by employing thin insulating layers[1]. Alternatively, superconducting substrates can be used for decoupling[2].

Here, we present results on FePc molecules on a superconducting substrate. First, we characterize the FePc molecules on the new substrate by investigating the Zeeman splitting and the molecular orbitals. Our findings show that FePc resembles a spin-1/2 system, and that the molecular orbitals exhibit a similar pattern as was previously reported on MgO/Ag(001)[3]. Additionally, we perform all electric pump-probe measurements on single FePc molecules. By adjusting the external magnetic field, we can switch between the normal conducting and superconducting state and investigate the influence of the superconductor on the T_1 time of the FePc molecules. O 17.12 Mon 18:00 P2

Spin Screening in MoS_2 Mirror Twin Boundaries on Graphene/Ir(110) — •Kuber Vyas, Tfyeche Tounsi, Jeison Fischer, Affan Safeer, Thomas Michely, and Wouter Jolie — II. Physikalisches Institut, Universität zu Köln, Zülpicher Str. 77, 50937 Köln, Germany

Mirror twin boundaries (MTBs) are line defects that host confined states in the bandgap of monolayer MoS_2(1). The confined states closest to the Fermi energy splits into a singly and a doubly occupied level separated by the Coulomb repulsion U, forming a spin-1/2 system. The spin of the singly occupied state is then screened by the electron bath present in the substrate below, giving rise to a Kondo resonance pinned to the Fermi energy.

In this work, we investigate spin screening in MoS_2 MTBs grown on graphene/Ir(110) using low-temperature scanning tunnelling microscopy and spectroscopy. STS spectra recorded along the boundaries show two pronounced impurity peaks separated by the Coulomb energy U, together with a zero-bias feature which can be attributed to the Kondo resonance. MTBs on Gr/Ir(110) exhibit significantly broadened impurity-level widths, indicating strong hybridization γ with the electron bath provided by the graphene/Ir(110) substrate. This enhanced hybridization results in a Kondo temperature T_K comparable to the measurement temperature (7 K), enabling us to study the phase transition between the Kondo singlet phase below and the magnetic phase above the Kondo temperature. Cost-Efficient Approach for Training MACE Potentials — •Antonia Gerstenberg[1,2], Thomas Bligaard[2], and Andreas Lynge Vishart[2] — [1]currently: Fritz-Haber-Institut der MPG, Berlin, Germany — [2]DTU, Department of Energy Conversion and Storage, Denmark

Machine learning interatomic potentials (MLIPs) such as MACE offer near DFT accuracy at a fraction of the computational cost. However, a limiting factor is the cost of generating high-quality training data. This project investigates the development of a systematic and cost-efficient approach to training robust MACE models. It is therefore explored to what extent models trained on the cheapest available structures (e.g., dimers and trimers) can extrapolate to larger structures such as nanoparticles and vice versa.

To test this, an active learning workflow was implemented, iteratively adding structures with increasing numbers of atoms. The results show that widely used training strategies, including standard active learning workflows, fail to reliably extrapolate to out-of-distribution structures. The results highlight the importance of structural diversity and weight restriction from the outset.

O 18.2 Mon 18:00 P2

The application of classical DFT for describing small molecules diffusion in porous materials. — •Mikhail Suetin and Michael te Vrugt — Institute of Physics, Johannes Gutenberg Universität-Mainz, Staudingerweg 9, 55128, Mainz, Germany.

Metal-Organic Frameworks (MOFs) are relatively new, but promising materials potentially suitable for separation of hydrocarbon molecules for chemical industry aiming reaching the Net-Zero targets. Thousands of MOFs have been obtained experimentally, and about a million computationally. In this study, we conducted computational screening of the CoRE MOF database. Classical molecular dynamics simulations are employed for considering separation via diffusion. More importantly, classical density functional theory (cDFT) approach was employed to dramatically accelerate calculations of diffusion coefficients.

O 18.3 Mon 18:00 P2

Increasing the Transferability of Machine Learning Potentials by Learning Atomic Properties — •Johann Richard Springborn[1,2], Gunnar Schmitz[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

Machine Learning Potentials (MLPs) have become an established tool for describing potential energy surfaces of complex systems. While they significantly speed up the evaluation of the energy and forces in comparison to ab-initio methods, they require high-quality reference data for training. Depending on the systems to be studied, generating this training data can become the computational bottleneck. Therefore it is of high interest to reduce the number and complexity of structures to be computed. We propose to achieve this goal by training MLPs on atomic properties instead of global quantities such as the system's total energy. This approach aims to increase the transferability of the resulting MLPs to more complicated systems while still utilizing easily accessible reference data.

O 18.4 Mon 18:00 P2

Radial Dirac-Fock solver using integral equation method — •Ernests Lazdans, Janis Užulis, and Andris Gulans — University of Latvia, Riga, Latvia

We present a relativistic generalized Kohn-Sham solver for spherically symmetric atoms. It follows the approach introduced in a multi-wavelet code [1] where the Dirac equation is represented in the integral form. The solver supports local and hybrid exchange-correlation functionals and various nuclear distributions (point-like, Gaussian, and spherical). In validation test, we find that it yields Hartree-Fock energies in full agreement for all ten digits given by Visscher *et al.* [2]. However, our numerical tests show that numerical errors in our obtained atomic energies are below 10 nHa, *i.e.*, our solver's precision exceeds that of previously published data. We use the solver for testing performance of multiple exchange-correlation functionals for predicting electron removal energies from core and valence shells in noble gas atoms. The future applications of this tool include integrating it into a linearised augmented plane wave code.

Towards Efficient Time-Dependent Density-Functional Theory through Hubbard On- and Inter-Site Corrections — •Lydia Fichte, Karsten Reuter, and Matthias Kick — Fritz-Haber-Institut der MPG, Berlin

Density-functional theory (DFT) with a Hubbard correction (DFT+U) can mitigate self-interaction errors in a manner similar to hybrid func- tionals, but at significantly lower computational cost. This makes extending DFT+U to the time-dependent regime particularly attractive, as it allows for accurate simulations of electron dynamics at reduced computational expense. However, the on-site subspace defined by DFT+U can be too rigid to describe phenomena involving strong orbital hybridization or charge transfer between sites, necessitating a more flexible definition of the correlated subspace. To address this, we are incorporating inter-site interactions through the +V correction to enable a more complete and adaptable description. We implement this as an efficient real-time time-dependent DFT+U+V framework in the all-electron electronic-structure code FHI-aims, enabling accurate and scalable simulations of correlated electron dynamics. We discuss the current status of the implementation and highlight the pitfalls and intricacies encountered when working with a numeric atom-centered orbital basis, both in the ground state and in time-dependent simulations.

O 18.6 Mon 18:00 P2

Calculating surface energy using machine learning interatomic potentials — •Friedrich Neumann[1], Tom Barnowsky[2,3], Rico Friedrich[2,3], and Jens Kortus[1] — [1]TU Bergakademie Freiberg - Institut für Theoretische Physik, Leipziger Str. 23, 09599 Freiberg — [2]Technische Universität Dresden - Theoretische Chemie, 01062 Dresden — [3]Helmholtz-Zentrum Dresden-Rossendorf e.V., Bautzner Landstraße 400, 01328 Dresden

The surface energy of a material is a fundamental property that governs the behaviour of solid interfaces in a wide range of phenomena. While density functional theory (DFT) provides highly accurate values, its computational scaling limits its applicability for large systems and systematic surface-energy screening. In this work, a workflow was developed to estimate surface energies using machine-learning interatomic potentials (ML-IAPs). Atomic Cluster Expansion (ACE) models were fitted to DFT-based molecular-dynamics data for Al, Pt, and Au, and effective two-body contributions were extracted from the resulting potentials. These were combined with a bond-counting approach to compute surface energies and Wulff constructions. Although in our present ACE model the absolute magnitudes of the pair interactions are influenced by many-body interaction, preventing quantitative reproduction of surface energies, the approach still captures general trends and identifies the dominant facets in the Wulff constructions. In this specific formulation, the results illustrate how many-body interaction can affect the apparent pair contribution.

Contact-Separation phenomenon at the Silica-Gold interface: AFM and ToF-SIMS insights — •Nisha Ranjan, Tolga Acartürk, Kathrin Küster, and Ulrich Starke — Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany

Contact-Separation (CS) electrification at solid interfaces constitutes a fundamental phenomenon. However, it often exhibits uncertainties and irreproducibility [1,2]. The silica-gold contact pair is a model example of a dielectric-metal system with a similar elastic modulus that shows a significant variation in charging properties such as polarity reversal among CS surfaces [3]. We aim to understand the phenomenon with interfacial interactions and chemical composition using direct microscale measurements under ultra-high vacuum conditions at the silica-gold interface. We use Atomic Force Microscope/Force Spectroscopy (AFM/FS) to quantify interfacial interactions, such as electrostatic force, van der Waals interaction, contact area, contact pressure, and deformation. Repeated approach-retraction cycles enabled the correlation of mechanical response with charge accumulation and compositional change. We use Time-of-Flight Secondary Ion Mass Spectroscopy (ToF-SIMS) for surface composition mapping to assess mechanochemistry. Our finding demonstrates that the magnitude of the force is significantly influenced by the charge accumulation. Concurrently, a change in surface composition was also observed. [1] I. Jimidar and J. Méndez Harper, Physics Today 78(8), 54 (2025). [2] D.J. Lacks, Angew. Chem. Int. Ed. 51, 6822 (2012). [3] G. Fatti et al., PRL 131, 166201 (2023).

O 19.2 Mon 18:00 P2

Simulation-Guided GIXPS: Planning faster (HA)XPS measurements while enabling depth-sensitivity — •David Capalbo[1], Oliver Rehm[1], Endrit Kusari[1], Andrei Gloskovskii[2], Christoph Schlueter[2], Lutz Baumgarten[3], and Martina Müller[1] — [1]Fachbereich Physik, Universität Konstanz, Konstanz, Germany — [2]DESY, Hamburg, Germany — [3]FZ Jülich GmbH, PGI-6, Jülich, Germany

(Hard) X-Ray Photoelectron Spectroscopy ((HA)XPS) is an established method for characterizing surfaces, interfaces, and the bulk material properties of thin films, multilayers, and devices. Such measurements, when performed at a synchrotron-based setup, can produce faster and better resolved data compared to a laboratory setup, but beamtime is limited and highly competed for. We present a simulation-based approach that enables faster and more efficient measurements by exploiting grazing-incidence (GI) angle geometries (0.3°-2°). At these GI angles, tunable depth-selective photoelectron emission becomes possible while increasing the signal by up to two orders of magnitude at characteristic angles. In our approach, an additional damping term is added to an already existing simulation model, which enables the user to simulate an accurate GI(HA)XPS response before the beamtime. This enables them to identify and prioritise configurations of interest, reduce the required aquisition time, all while keeping the expected advantages of standard (HA)XPS measurements. O.Rehm *et al.*

Electrospray Ion Beam Deposition for Atomic Resolution Native Protein Structure Investigation at Surfaces — •Stephan Rauschenbach — University of Oxford, Kavli Institute for Nanoscience Discovery, Department of Chemistry, Sherringdon Road, Oxford

Electrospray ion beam deposition (ESIBD) enables controlled deposition of intact biomolecules from solution onto surfaces under ultrahigh vacuum conditions. We present ESIBD as a sample preparation method for cryo-EM, scanning probe, and holography applications, bridging native electrospray ionisation mass spectrometry with surface-based structural characterisation techniques.

The method combines mass-selective soft landing with controlled ice growth embedding protocols. Proteins maintain their native conformations during the gentle electrospray process and deposition. For cryoEM Ice matrix formation occurs post-deposition minimising mechanical stress and denaturation.

Here we discuss the state of the art implementation of this method on commercial and self-built platforms and demonstrate atomic resolution imaging of soluble and membrane proteins deposited on surfaces in vacuum.

O 19.4 Mon 18:00 P2

Analysis of the charge distribution of an insulating sphere in contact electrification processes — •Andre Mölleken, Hermann Nienhaus, and Rolf Möller — Experimental Physics, University of Duisburg-Essen and Center for Nanointegration Duisburg-Essen (CENIDE)

While the mechanisms of contact electrification between metals are well established, non-conductive materials present a more complex scenario due to the emergence of nonuniform surface charge distributions. This study investigates how such charge inhomogeneities on an insulating sphere like Al2O3 or quartz influence the subsequent charge transfer during contact with a planar metal or insulator electrode. We employ a redesigned experimental setup based on an established parallel-plate capacitor concept [1], enabling high-temporal-resolution measurements of induced and transferred charges as the sphere bounces on the lower electrode. By decomposing the measured signal into monopole and dipole components, we extract the net charge, quantify the dipole moment of the surface charge distribution, and determine the rotational frequency of the bouncing sphere. This approach reveals how initial charge patterns evolve dynamically and modulate the efficiency and direction of charge transfer upon impact. The new setup allows controlled manipulation of the sphere's initial surface charge distribution prior to each experiment. The results offer a novel way to study how the charge distribution on the surface influences the contact electrification process. [1] M. Kaponig, A. Mölleken, H. Nienhaus, R. Möller, Dynamics of contact electrification, Sci. Adv. 2021, 7 (22), eabg7595.

Contact electrification between Au and hydrogen-passivated Si(111) surfaces — •Christian Gruber, Andre Mölleken, Tobias Prost, Hermann Nienhaus, and Rolf Möller — Experimental Physics, University of Duisburg-Essen and Center for Nanointegration Duisburg-Essen (CENIDE)

The charge of 1mm Au spheres bouncing on a hydrogen-passivated Si(111) surface under vacuum conditions is measured in a parallel-plate capacitor setup with fC charge sensitivity and microsecond time resolution [1]. The transferred charge between metal and semiconductor is determined as a function of impact velocity ranging from 1 to 0 m/s, of doping and of surface condition after preparation. Light exposure to the semiconductor surfaces during experiments shows no significant influence on the results. On p-doped samples the Au spheres collect a charge of typical a few 100fC with each contact. The dependence on the preparation is not as clear as on n-doped samples, on which the quality of the surface preparation clearly causes a polarity change. On n-doped samples the Au spheres collect a typical charge of a few 100 fC to over 1000 fC. However, in the limit of zero impact velocity the variations between the different samples become negligible and Au is found to be charged negative. The results are compared with predicted charge transfer between Au and Si in static Schottky diode models.

Towards nanoscale EUV spectroscopy of 2D heterostructures using interferometric coherent diffractive imaging — •Hannah Strauch, Jan Mädrich, Daniel Steil, Stefan Mathias, and G. S. Matthijs Jansen — University of Göttingen, 1st Institute of Physics, Göttingen, Germany

Time-resolved spectroscopy in the extreme ultraviolet (EUV) energy range provides element-specific insight into electronic and structural dynamics. Particularly, EUV spectroscopy of nanoscale 2D material heterostructures enables to identify the individual layer contributions due to its element-specificity. For such systems, however, a spatially resolved probe is essential: 2D material heterostructures are both intrinsically micro-scale and highly susceptible to spatial inhomogeneities. The comprehensive understanding of ultrafast dynamics in those systems therefore requires simultaneous spatial, spectral, and temporal resolution, which is a combination that remains experimentally demanding even with state-of-the-art techniques.

We will present our progress towards such a comprehensive measurement approach with our table-top EUV interferometry-based setup, which enables time-resolved spectroscopy with spatial resolution through the combination of Fourier transform holography (FTH) with interferometric Fourier transform spectroscopy (FTS). The surface sensitivity required for few-layer systems is provided through measurements in reflection geometry.

O 19.7 Mon 18:00 P2

Development of a Low Temperature Two-Level System Microscope for Superconducting Quantum Circuits — •David Mazibrada[1], Johannes Schwenk[1], Jürgen Liesenfeld[1], Hannes Rotzinger[1,2], Philip Willke[1], and Alexey V. Ustinov[1,2] — [1]Physikalisches Institut (PHI) — [2]Institut for Quantum Materials and Technologies (IQMT), Karlsruher Institut für Technologie, 76131 Karlsruhe, Germany

Superconducting quantum circuits are among the most advanced platforms for solid-state qubits. Their performance is perturbed, however, by parasitic two-level systems (TLS). The electric fields of the qubit interact with the electrical dipole moment of the TLS, leading to an exchange of photons between the two quantum systems. TLS are mostly of an unknown nature and position, and identifying them locally would help to improve future qubits. Since TLS couple not only to the qubit's microwave field but also to externally applied electric fields, this interaction enables us to probe and localize individual TLS.

We present a microscope combining a cryogenic atomic force microscope (AFM) and a superconducting quantum circuit. By applying a local electric field with the AFM tip and performing microwave spectroscopy, we aim to identify, characterize, and map the position of individual TLS on superconducting quantum circuits.

O 19.8 Mon 18:00 P2

Prospects of ARPES measurements in an external static magnetic field — Dmitry Usanov and •Daniil Yevtushynsky — Laboratory for Quantum Magnetism, EPFL, 1015 Lausanne, Switzeralnd

Angle-resolved photoemission spectroscopy (ARPES) has traditionally been performed in magnetically shielded environments, as external magnetic fields distort electron trajectories and worsen the momentum resolution. This limitation has prevented direct observation of many field-dependent electronic phenomena. Recent studies, however, have demonstrated that applying a strongly localized static magnetic field enables ARPES measurements under external field conditions. We propose to test a newly developed compact magnetic circuit, integrated into a standard flag-type sample holder, capable of generating a high magnetic flux density at the sample position while minimizing its effect on photoelectron trajectories. In the presentation we will discuss the optical action of the designed magnetic field and subsequent aberration corrections for different types of samples. In addition, we will provide estimations of the maximum magnetic field for ARPES in the soft X-ray and VUV ranges. At the end, we will propose different test systems, where moderate magnetic fields can tune the spin order and induce pronounced modifications of the band structure near the Fermi level. Successful implementation will establish a new experimental capability - ARPES in controlled static magnetic fields - opening pathways to study field-dependent band topology and spin-charge coupling across a broad class of quantum materials and heterostructures.

O 19.9 Mon 18:00 P2

New Electrospray Ion Beam Deposition source for wellcontrolled STM sample preparation — •Niclas Przibylla[1], Markus Etzkorn[1], Stephan Rauschenbach[2], and Uta Schlickum[1] — [1]Institute of Applied Physics, TU Braunschweig, Braunschweig — [2]Kavli Institute for Nanoscience Discovery, University of Oxford, United Kingdom

High resolution imaging of complex biomolecules such as peptides, glycans, and photosynthesis building blocks are crucial for advancing their fundamental functionalities and exploring them for quantum technologies, Scanning probe microscopy techniques together with mass-selected electrospray ion beam deposition enable atomic-level structural characterization of these molecules. This project deploys a novel electrospray ion beam deposition (ESIBD) system with Python-based programmable control for depositing non-volatile molecules onto clean surfaces under ultra-high vacuum conditions. The process involves electrospray ionization, mass-to-charge filtering via quadrupole ion guides, and electrostatic focusing onto nitrogen-cooled samples. Key innovations include a modular chamber architecture allowing future expansion, alongside RF-operation using rectangular voltage waves for enhanced mass filtering precision. Frequency-asymmetric and amplitude-asymmetric waveforms will enable systematic investigation of ion stability diagram effects, advancing deposition control capabilities.

Electronoptical Concept of ARPES and RIXS Combined in a Novel Photoelectron Microscope — O. Tkach[1], Y. Lytvynenko[1], C. Fawaz[2], T. Lacmann[3], S. Chernov[4], O. Fedchenko[1,5], H. Agarwal[1], M. Hoesch[4], J. K. Dey[4], J. Dilling[4,6], L. Bruckmeier[4,6], M. Scholz[4], J. Schunck[4,7], S. Roth[2], K. Rossnagel[4,6], M. Beye[8], M. Le Tacon[2], •G. Schönhense[1], and H.-J. Elmers[1] — [1]Univ., Mainz — [2]IQMT, KIT — [3]EPFL, Switzerland — [4]DESY, Hamburg — [5]Goethe Univ. Frankfurt — [6]CAU Kiel — [7]Univ. Hamburg — [8]AlbaNova, Sweden

The instrumentation required for ARPES and Resonant Inelastic X-ray Spectroscopy (RIXS) is usually completely different. ARPES uses electron spectrometers, primarily hemispherical ones, whereas RIXS requires high-resolution X-ray spectrometers with long optical paths to achieve the desired resolution. In a special time-of-flight photoelectron microscope, we combined photoelectron momentum microscopy (MM) - imaging of the backfocal plane of the objective lens, a powerful ARPES approach - with the concept of PAXRIXS [1]. Here, the RIXS photons are converted into photoelectrons using an ultrathin foil. The position at which a RIXS photon hit the converter is a measure for the momentum transfer. For RIXS, the converter foil is moved between the sample and the extractor with fields-of-view of >4 mm. This is facilitated by a novel type of front lens which enables various operating modes. Ultrathin Au, Ag, and Pt converter foils provide energy resolutions between 20 meV and 400 meV.

From Wannier Functions to Optimal Local Orbitals: A Systematic Approach for Accurate Wavefunction Representation — •Ann Chantal Goutier and Michael Schüler — Laboratory for Materials Simulations, Paul Scherrer Institut, Villigen PSI 5232, Switzerland

Electronic structure calculations in solids are commonly carried out using DFT algorithms with large initial basis sets. These basis sets are compressed into smaller basis sets localised around atoms to calculate quantities of interest. It is desireable to be able to do this conversion with only minimal loss of accuracy. The most common algorithm for this is Wannierisation, a unitary transformation of the Hamiltonian into a space of maximally localised wave functions. Wannierisation preserves the Hamiltonian exactly, but Wannier wave functions cannot be used to construct eigenstates explicitly.

We propose new methods to create Local Orbitals directly, building on the idea of Smart Local Orbitals (Gandus, 2020). Our methods maximise the projectability of the Local Orbital basis set onto electronic eigenstates. This can be done either by blockdiagonalisation of a projectability operator, or by singular value decomposition of the overlap. It is advantageous as less information about the system is required and the Local Orbital set can be systematically improved by adjusting projectibility cut-offs. We also showcase the impact of variationally optimising the Local Orbital basis with respect to different parameters to further improve the representation of Kohn Sham states within a minimal basis.

O 21: Surface magnetism – Poster

O 21.1 Mon 18:00 P2

Quantum confinement of spinarons in quantum corrals. — •Raffaele Aliberti[1], Juba Bouaziz[2], Ilias Klepetsans[2], and Samir Luonis[1] — [1]Institute of Physics, Martin-Luther- University Halle-Wittenberg, Germany — [2]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, Germany

For more than two decades, cobalt atoms on noble-metal (111) sur-faces have served as a paradigm for the Kondo effect in scanning tun-nelling spectroscopy (STS) experiments. However, our recent first-principles predictions, supported by high-magnetic-field STS mea-surements, challenge this established view. We showed that the observed transport anomalies originate instead from spin excitations of Co atoms forming a distinct many-body state, the spinaron, which is a polaronic quasiparticle arising from the interaction between an excited magnetic moment and a trapped surface electron. Here, using time-dependent DFT combined with many-body perturbation theory, we investigate quantum-confinement engineering in circular and elliptical quantum corrals hosting a single Co adatom, revisiting the celebrated experiments traditionally interpreted through the lens of the Kondo effect. We demonstrate that confined electronic states significantly modify the underlying electron*boson interactions, thereby altering the amplitude and characteristics of the spinaronic states

O 21.2 Mon 18:00 P2

Spin-polarized LEED and reflectivity in altermagnetic materials — •Sourour Ayari, Aki Pulkkinen, and Jan Minar — New Technologies Research Center, University of West Bohemia in Pilsen, Plzen Czech Republic

Altermagnetic materials exhibit a characteristic non-relativistic spin splitting arising from their unconventional spin-symmetry properties [1-3], which leads to alternating spin textures in momentum space even in the absence of a net magnetization. To probe how these textures manifest at the surface, we use theoretical calculations based on the relativistic Korringa-Kohn-Rostoker multiple scattering method [4-5] to study the spin-polarized low-energy electron diffraction and angle- and spin-resolved reflectivity of electrons. These observables are sensitive to spin-dependent scattering processes and therefore provide a direct window into the surface projections of the altermagnetic spin structure. This approach enables a detailed understanding of the spin-dependent reflectivity in altermagnets and offers deeper insight into their surface electronic and magnetic properties.

O 22: Surface dynamics – Poster

Time: Monday 18:00–20:00 Location: P2

O 22.1 Mon 18:00 P2

Tracing light-induced dynamics of correlated charge order at the atomic scale — •Luis Enrique Parra Lopez[1], Alkisti Vaitsi[1], Vivien Sleziona[1], Fabian Schulz[2], Martin Wolf[1], and Melanie Müller[1] — [1]Fritz Haber Institute, Berlin, Germany — [2]CIC nanoGUNE, Donostia-San Sebastian, Spain

Terahertz-driven scanning tunneling microscopy (THz-STM) is a versatile technique that enables the study of ultrafast dynamics in quantum materials with simultaneous nanometer spatial and femtosecond temporal resolution. Here, we use THz-STM to investigate the local ultrafast response of the charge density wave (CDW) phase in 1T-TaS2. Optical-pump THz-probe measurements reveal coherent oscillations of the THz-driven tunneling current at 2.5 THz, consistent with the amplitude mode of the CDW. In addition, we observe a previously unreported 1.3 THz mode in the vicinity of a structural defect, consistent with predictions for interlayer phonons. Beyond these ultrafast collective dynamics, our measurements uncover an additional slower effect: THz-induced long-lived changes of the local density of states (LDOS). These metastable modifications appear as LDOS peak shifts indicative of local stacking changes. They do not arise from the coherent CDW response, but from a local THz-induced perturbation of the CDW lattice. We demonstrate that these changes appear predominantly near lattice inhomogeneities and are consistent with local misalignments of the stacking configuration. Together these findings highlight THz-STM as a platform for imaging and controlling nonequilibrium quantum phases at their intrinsic spatial and temporal scales.

O 22.2 Mon 18:00 P2

Photonic Structures for Purcell-Enhanced Driving of a Structural Phase Transition — •Nandana Veena Uday[1], Florian Spickmann[1,2], Sebastian Zafra Koch[1,2], Felix Kurtz[1], Claus Ropers[1,2], and Hannes Böckmann[1] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]University of Göttingen, 4th Physical Institute, Göttingen, Germany

Direct integration of silicon photonics with low-dimensional materials connects tailored light-matter interaction with surface-sensitive probing. Here, we explore the remote optical driving of a prototypical Peierls insulator, adsorbed on the surface of a silicon photonic waveguide. Optical gratings couple infrared light to guided modes of a silicon slab, while ultrafast low-energy electron diffraction probes the waveguide-mediated optical quench of the periodic lattice distortion in adsorbed atomic indium chains. These experiments constitute first steps towards engineering photonic environments for surface phase control using tailored lithographic fabrication techniques. Potential avenues range from Purcell-enhanced photoinduced phase transitions to driven states of matter obtained by interfacing surface structures with integrated micro-resonator cavities. [1] Böckmann, Hannes, et al. Structural Dynamics 9.4 (2022)

O 22.3 Mon 18:00 P2

Non-equilibrium phonon dynamics of the kagome metal CsV_3Sb_5 — •Felix Kurtz[1,2], Lukas Jehn[1,2], Alp Akbiyik[1,2], Matthieu Le Tacon[3], Amir-Abbas Haghighirad[3], and Claus Ropers[1,2] — [1]Department of Ultrafast Dynamics, Max Planck Institute for Multidisciplinary Sciences, D-37077 Göttingen — [2]4th Physical Institute, University of Göttingen, D-37077 Göttingen — [3]Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, D-76021 Karlsruhe

Tracking the equilibration processes that follow photoexcitation in materials can reveal couplings between and among electrons and lattice degrees of free-

dom. Thus, a variety of femtosecond electron or X-ray diffraction techniques are used to follow non-equilibrium structural dynamics. Recently, we have introduced ultrafast low-energy electron diffuse scattering (ULEEDS), a surface-sensitive method capable of tracing momentum-dependent phonon populations with out-of-plane polarization [1]. Here, we employ ULEEDS to a second material, the kagome metal CsV_3Sb_5, and reveal non-thermal phonon occupations whose subsequent equilibration is driven by phonon-phonon scattering. Comparing these results to our previous study of $TiSe_2$, we find that while a rapid buildup near the Brillouin-zone boundary still precedes a slower emergence of zone-center acoustic modes, the relaxation times in CsV_3Sb_5 are confined to a much narrower distribution.

[1] F. Kurtz *et al.*, Nat. Mater. **23**, 890-897 (2024)

O 22.4 Mon 18:00 P2

Extending Surface Phase Diagrams to Non-Equilibrium Plasmas — •Maximilian Wünschek, Alper T. Celebi, and Markus Valtiner — Institute of Applied Physics, Vienna University of Technology, Wiedner Hauptstrasse 8-10/E134, Vienna 1040, Austria

Surface phase diagrams are widely used to visualize the stability of surface reconstructions under equilibrium gas conditions. However, many growth and treatment processes use plasmas that operate far from equilibrium, where activated and ionized species are present in substantial concentrations. Examples such as ZnO have shown that unique reconstructions can be found outside the stability range defined by conventional chemical potential axes, highlighting the need to extend surface phase diagrams to non-equilibrium regimes.

Using GaN as a model system, we compile a large dataset of reconstructions for polar GaN surfaces under hydrogen, nitrogen, and oxygen environments. Building on these results, we introduce a framework for applying surface phase diagrams to plasma conditions by incorporating non-thermal species into the chemical potential landscape. A minimal kinetic model estimates plasma composition, and thermochemical properties of the constituent species are combined into an effective plasma chemical potential.

The resulting extended diagrams show how radicals and ions shift phase boundaries and stabilize surface structures inaccessible under equilibrium. This approach provides a basis for understanding and predicting surface configurations formed during plasma-assisted processing.

O 22.5 Mon 18:00 P2

Atomic vibrations in the icosahedral quasicrystal AlPdMn studied with femtosecond electron diffraction — •Moritz Schlechtriem[1,2], Victoria C. A. Taylor[2], Hyein Jung[1,2], Ralph Ernstorfer[1,2], and Yoav William Windsor[1,2] — [1]Technische Universität Berlin — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin

Quasicrystals (QCs) are materials in which the atomic arrangement lacks periodicity but exhibits perfect spatial order. QCs therefore produce sharp diffraction patterns with unconventional features such as 5-fold rotational symmetry. Due to the aperiodic nature of QCs, phonons are insufficient to fully describe atomic vibrations. Phasons are quasiparticles related to atomic motion in the presence of aperiodicity, and their group velocity can exceed the speed of sound. The resulting enhanced thermal conductivity gives rise to potential applications of QCs, e.g. in nanoelectronics.

Here we use pump-probe femtosecond electron diffraction (FED) to study ultrafast atomic vibrations in QCs. This enables us to study the femtosecond evolution of photoinduced atomic motion, shedding light on the coupling mechanisms between electrons, phonons and phasons.

In this presentation we focus on the icosahedral QC alloy AlPdMn. FED results, in which different high-symmetry directions (e.g. the 5-fold rotation axis) are probed, will be presented.

O 22.6 Mon 18:00 P2

Thermo-osmotic flows at the Chemically Patterned Surfaces — •Neerdhi Goswami and Frank Cichos — Universität Leipzig Linnestr. 5 04103 Leipzig Germany

The boundary flows at a solid-liquid interface are governed by the interaction of the solid and liquid, specifically by the excess enthalpy of these interactions. Consequently, chemical modification of surfaces alters boundary flow fields. By generating spatially dependent patterns of solid-liquid interactions, we can not only shape various flow fields but also directly compare excess interaction enthalpies between modified and unmodified regions.

This study analyzes opto-thermo-osmotic flow fields at a thiol-patterned gold-water interface to provide a quantitative microscopic picture of dynamic interfacial interactions through comparative analysis. Thiol stripes were generated through micro-contact printing, creating alternating patterns of modified and unmodified gold regions. Surface plasmon resonance (SPR) imaging confirmed thiol addition by detecting the characteristic frequency shift upon adsorption.

This quantitative characterization of interfacial interactions provides fundamental insights into how surface chemistry modulates boundary flows, with implications for designing responsive microfluidic systems and optimizing interfacial processes in precision separation and manipulation applications.

O 23: Catalysis and surface reactions – Poster

Time: Monday 18:00–20:00 Location: P2

O 23.1 Mon 18:00 P2

Investigating Single Atomic Catalytic Sites within Metal- Coordinated Supramolecular Networks via Submolecular Imaging in correlation with Electrochemical Analysis — •Duong Tran[1], Philipp Wiesener[1], Ying Pan[2], Nieves López- Salas[2], and Harry Mönig[1] — [1]Physikalisches Institut, Universität Münster, Germany — [2]Department of Chemistry, Sustainable Materials Chemistry, Universität Paderborn, Germany

Metal-organic layers serve as an excellent platform for creating single-atom catalysts (SACs). This study focuses on a heat-induced deprotonation reaction of a melem precursor and the formation of a heptazine-based metal-organic network on an Au(111) substrate. To overcome thermal desorption challenges hindering chemisorption, we developed a vacuum reactor chamber with a high-flux evaporator for precursor deposition. The resultant heptazine-based Au-nitride network aligns with previous results on Cu(111) using the same precursors. In particular, the interaction of Au(111) atoms with dehydrogenated nitrogens results in a gold atom flexibly suspended between two nitrogen atoms, indicating promising active sites for oxygen reduction reaction (ORR). Scanning tunneling microscopy (STM), noncontact atomic force microscopy (nc-AFM) with an oxygen-terminated copper tip, and X-ray photoelectron spectroscopy (XPS) confirm the strong chemisorption and stability of the network. A comparison of the catalytic performance of heptazine-based metal-nitride networks on Au(111) and on Cu(111) under ambient conditions enhances the understanding of the ORR electrochemical applications.

O 23.2 Mon 18:00 P2

Support-Dependent Thermal Activation of Pt17 Clusters on HOPG and CeO2: For-mation of Active CO Oxidation Catalysts — Papri Chakraborty[1,2,3], •Johannes Seibel[2], Nicola Da Roit[4], Artur Böttcher[2], Ajai Raj Lakshmi Nilayam[1], Christian Kübel[1], Silke Behrens[4], and Manfred Kappes[1,2,3] — [1]Institute of Nanotechnology, KIT, 76344 Eggenstein-Leopoldshafen, Germany — [2]Institute of Physical Chemistry, KIT, 76131 Karlsruhe, Germany — [3]Institute of Quantum Materials and Technologies, KIT, 76344 Eggenstein-Leopoldshafen, Germany — [4]Institute of Catalysis Research and Technology, KIT, 76344 Eggenstein-Leopoldshafen, Germany

Atomically precise ligand-protected metal clusters are attractive precursors for heterogeneous catalysts, potentially allowing for the precise control of the initial active site composition. However, the transformation from the protected cluster to the active catalyst, specifically the removal of the ligand shell, remains a poorly understood process that depends heavily on the support material. Here, we present a comparative study of the thermal activation of $Pt_{17}(CO)_{12}(PPh_3)_8(NO_3)_2$ on inert graphite, on reactive ceria CeO2 surfaces and in gas phase. For this we combined thermal desorption spectroscopy with high-resolution mass and ion mobility spectrometry to map the decomposition pathway of the cluster. Additionally we probed clusters supported on CeO2 before and after CO oxidation catalysis with transmission electron microscopy. This revealed dissociation of clusters and dispersion of the Pt atoms on the oxide support under certain reaction conditions.

O 23.3 Mon 18:00 P2

From model to powder systems: Sm-doped ceria for CO_2 conversion. — •Raquel Sánchez-Barquilla[1], Sichen Liu[1], Alexander Contreras-Payares[2], Pablo G. Lustemberg[2], Dominic Guttmann[1], Carlos Morales[1], Fabian Rachow[1], Verónica Ganduglia-Pirovano[2], and Jan Ingo Flege[1] — [1]Brandenburg University of Technology, Cottbus-Senftenberg, Germany — [2]Instituto de Catálisis y Petroleoquímica, Madrid, Spain

Reducible oxides are crucial in many heterogeneously catalyzed redox reactions because they can store and release oxygen during the catalytic cycle. Among these, cerium oxide (CeO_2) stands out due to its facile transition between the Ce^{4+} and Ce^{3+} oxidation states. Furthermore, the Ce^{3+} cations have been suggested to provide the active sites for CO_2 activation. Consequently, the catalytic performance of ceria-based catalysts may be significantly enhanced by promoting and stabilizing these sites, e. g., by alloying with trivalent rare-earth (RE) metals that also form cubic sesquioxides (RE_2O_3), such as samarium.

Here, we present a model system composed of (111)-oriented Sm-doped ceria nanoislands studied using X-ray photoelectron spectroscopy under near-ambient pressure. We show that Sm is crucial for CO_2 activation. This activation is accompanied by a charge-transfer process that modifies the measured Ce^{3+}/Ce^{4+} ratio, as explained by density functional theory calculations. Once the reaction mechanism was established, we performed *operando* absorption spectroscopy on powder catalysts with different Sm/Ce ratios to examine the effect of Sm doping under more realistic conditions.

O 23.4 Mon 18:00 P2

Digital Catalysis: Accelerated Discovery Through Human in the Loop — •Charles Pare[1], Aybike Terzi[2], Christian Kunkel[1], Frederik Rüther[2], Frederic Felsen[1], Robert Baumgarten[2], Esteban Gioria[2], Raoul Naumann d'Alnoncourt[2], Christoph Scheurer[1], Frank Rosowski[2,3], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]BasCat - UniCat BASF JointLab, Berlin — [3]BASF SE, Catalysis Research, Ludwigshafen

Catalyst promoters are often key components of stable and efficient industrial heterogeneous catalysts, yet most commercial systems rely mostly on one or two promoters and predominantly leverage their isolated rather than their synergistic effects. This limitation frequently results from the laborious empirical research needed to identify formulations with jointly acting components that enhance performance. To address this challenge, we implement an accelerated catalyst discovery approach that adaptively explores a large catalyst design space using only a limited number of experiments. Its foundation lies in an efficient Design-of-Experiment (DoE), parallelized testing, and iterative integration of experimental feedback. New and competitive promoter chemistries for the non-oxidative propane dehydrogenation to propylene over supported Pt are discovered within a constrained experimental campaign. The results demonstrate the potential of adaptive DoE strategies for directed, data-efficient knowledge generation and optimization in complex catalytic systems of both academic and industrial relevance.

O 23.5 Mon 18:00 P2

Automatic Kinetic Equation Discovery from Experimental Data — •Maryke Kouyate, Gianmarco Ducci, Karsten Reuter, and Christoph Scheurer — Fritz-Haber-Institut der MPG, Berlin

Optimizing and controlling industrial catalytic processes requires effective kinetic models that are both robust and interpretable, capable of predicting how key operating variables affect reactor behavior. We introduce a model-based, adaptive design-of-experiments (DoE) framework that efficiently learns parsimonious, mechanistically meaningful rate expressions from data. At each step, it selects feed conditions to maximize expected information gain.[1,2] Profile reactors further boost per-run information by providing spatio-temporally resolved composition profiles along the reactor axis. Applied to CO oxidation on Pt, the framework automatically constructs a robust, chemically interpretable kinetic model that reproduces the characteristic mid-reactor transition in concentration profiles and reveals the need for a nonlinear term to capture the observed shift from CO poisoning to a non-poisoned regime.

O 23.6 Mon 18:00 P2

Structural development of new defective titanium carbon phosphorus hybrid composites by soft x-ray spectroscopy — •Hesham Hamad — City of Scientific Research and Technological Applications, Alexandria, Egypt — Elettra Sincrotrone Trieste, Trieste, Italy

The discovery of "black" TiO2 nanoparticles with enhanced solar absorption in the visible and near-infrared regions has sparked growing interest in solar energy applications. However, their properties remain incompletely understood. In this work, we explore a sustainable defective titanium*carbon*phosphorous (TCPH) hybrid nanocomposite for photocatalytic applications. TCPH was synthesized and applied in the degradation of methyl orange (MO) dye, a model organic pollutant. Characterization revealed the presence of Ti3+ species, oxygen vacancies, and a core-shell structure, along with a significant increase in surface area. These features enhance charge transport and separation, leading to excellent photocatalytic activity. X-ray photoelectron spectroscopy (XPS) confirmed the Ti3+ modifications in TCPH. To further probe its properties, synchrotron-based X-ray absorption fine structure (XAFS) spectroscopy was employed. This advanced technique provides insights into unoccupied and occupied states, particularly the O 2p and Ti 3d hybrid orbitals, revealing the electronic and crystalline structures of anatase, rutile, Ti metal, and TCPH. The combination of XAFS with complementary methods, including XRD, XPS, and HRTEM, enables a comprehensive understanding of TCPH's morphology, crystallinity, and local electronic structure.

O 23.7 Mon 18:00 P2

Cooperative Co-Fe Effect on the OER Activity of $CoFe_2O_4$ (100), (001) and (111) surfaces — Shohreh Rafiezadeh, •Aparna Chaitram, and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen, Duisburg

Water splitting, a key method for green hydrogen production, is limited by the sluggish anodic half process - the oxygen evolution reaction (OER) [1]. This necessitates finding efficient and affordable electrocatalysts which can reduce the overpotential. Using density functional theory calculations with an on-site Hubbard U term, we study the OER activity of the $CoFe_2O_4$ (001), (100), and (111) surfaces, exploring a wide range of potential active sites and the effect of solvation. The lowest overpotential of 0.20 V is found for an octahedral Co at the A-layer termination of the (100) surface, which contains both Fe and Co. This is attributed to the synergistic stabilization of the *OOH intermediate by binding to a neighbouring Fe site[2]. Remarkably, sites with higher catalytic activity are found to retain bulk like oxidation states. Our results show that such bonding configurations that break the OER scaling relationships reveal new routes to designing catalysts for water splitting.

We acknowledge funding by DFG within CRC TRR 247.

O 23.8 Mon 18:00 P2

Probing the active state of Cu(111) for plasma-catalytic CO_2 hydrogenation — •Luka Babić and Roland Bliem — ARCNL, Materials & Surface Science for EUVL, Science Park 106, 1098 XG Amsterdam, The Netherlands

Plasma catalysis combines the concept of heterogeneous catalysis with the activation of reactants by a plasma discharge. The activation of strong molecular bonds is expected to change the kinetics of challenging reactions such as the hydrogenation of CO_2 to methanol. This reaction proceeds in a mixed H_2/CO_2 plasma, which consists of a multitude of species, including radicals, atoms, and ions with energy stored in various states and degrees of freedom. The state of surfaces interacting with this complex mixture is poorly understood, even for well-defined single-crystalline model catalysts.

Here, we use in situ X-ray photoelectron spectroscopy (XPS) and residual gas analysis to disentangle reaction pathways and the evolution of a Cu(111) model catalyst surface during exposure to radicals generated in plasma. Optical emission spectroscopy (OES) is used to characterize plasma and to assess the species hitting the surface during the exposure. XPS reveals the formation of adsorbed oxygen, followed by Cu(I) and finally Cu(II) oxides. Carbon is fully absent during the reaction with neutral activated CO_2 species. Upon reduction by plasma-activated hydrogen, hydroxides are formed. Depending on the operating conditions, we thus expect the active surface of a Cu plasma catalyst to be either Cu hydroxide or Cu metal.

O 23.9 Mon 18:00 P2

Size selected Pt clusters on a CeO_2(111) support: mobility, reactivity and dimensionality — •Fabian Heisinger, Johanna Reich, Mina Soltanmohammadi, Rasmus Bischoff, Friedrich Esch, and Barbara A.J. Lechner — TU Munich, Germany

Ceria is a renowned material for its exceptional oxygen storage capacity with applications in catalysis. Central to this functionality are oxygen vacancies and their mobility. In interaction with metal catalyst particles, this reducible oxide is highly versatile, as we demonstrate for size-selected Pt clusters on a single-crystalline ceria film. We study oxidation reactions as a function of cluster size, dimensionality, support reduction, and gas environment. With conventional and fast STM, we directly observe the dynamics of surface vacancies and supported clusters to determine cluster shape changes related to defect density and sintering. We combine this cluster height and coverage monitoring with LEED and XPS to characterize the CeO_2 films in crystallinity, thickness, oxidation state, and Pt coverage. We demonstrate that the Pt cluster dimensionality during sintering can be steered by controlling the oxygen vacancy coverage on the support[1]. Through STM, we track the mobility of O vacancies in an effort to correlate their dynamics with cluster properties, and the cluster dynamics to unravel the influence of their shape on stability and catalytic activity. These dimensionality-tuned, size-selected clusters provide an ideal platform to study the structural dynamics of small metal clusters during an ongoing oxidation reaction.

O 23.10 Mon 18:00 P2

Metal clusters on rutile TiO_2(110) as model catalysts: Stability and reactivity under near-ambient pressure conditions — •Jonathan Paul, Marina Isabel de la Higuera Domingo, Lorenz Falling, Florian Kraushofer, Matthias Krinninger, and Barbara A. J. Lechner — Technical University of Munich, TUM School of Natural Sciences, Department of Chemistry, 85748 Garching, Germany

Clusters frequently exhibit strongly size-dependent catalytic properties and have discrete electronic states, often leading to a particularly high activity in heterogeneous catalysis. However, at the elevated temperatures typically employed in industrial applications, clusters tend to sinter into larger particles, which can lead to a decrease in catalytic activity. Reducible oxide supports, such as titania (TiO_2), are effective materials for stabilizing clusters and can further modify their catalytic behavior through encapsulation effects induced by the strong metal-support interaction (SMSI).

Here, we employ near-ambient-pressure scanning tunneling microscopy (NAP-STM) to investigate how reducing, oxidizing and reaction atmospheres influence the stability, structural dynamics and geometry of Pt and Ni clusters supported on rutile TiO_2(110).[1] Structural insights obtained from microscopy are complemented by a highly sensitive sniffer setup for activity measurements, investigation of reaction mechanisms and determination of turnover frequencies.[2]

O 24.1 Mon 18:00 P2

Real-Time Electrochemical AFM Observation of Lithium Plating and Dissolution on HOPG: Surface Morphology and Mechanistic Insights — •Luca Kaufer[1,2], Daniel Ebeling[1], André Schirmeisen[1], and Jürgen Janek[2] — [1]Institute of Applied Physics, Justus-Liebig-University, Gießen, Germany — [2]Institute of Physical Chemistry, Justus-Liebig-University, Gießen, Germany

This investigation demonstrates the utilisation of atomic force microscopy (AFM) to examine the interactions between liquid electrolytes and Highly Ordered Pyrolytic Graphite (HOPG) electrodes. In particular, the focus is on the deposition of lithium on HOPG surfaces, a crucial process in lithium batteries. Atomic force microscopy measurements facilitate precise analysis of the surface structure, topog raphy, and mechanical properties. In addition, they permit observation of dynamic changes during lithium deposition. This, in turn, provides a deeper insight into the mechanisms of electrode surface reactions and the quality of the electrode surface. Such measurements are of great importance to improve the efficiency and lifetime of batteries by helping to understand and control processes such as dendritic growth or non-uniform deposition.[1,2] We will demonstrate the use of Asylum Research's Fast Force Mapping mode in relation to the mechanical changes in HOPG during lithium deposition. [1] J. Phys. Chem. C 2011, 115, 25484*25489. [2] ACS Appl. Mater.Interfaces 2015, 7, 25441*25447

Influence of electrolyte and electrode parameters on the current voltage characteristics during high voltage and plasma electrolysis — •Benjamin Schilling, Lukas Forschner, Justus Leist, Timo Jacob, and Albert K. Engstfled — Ulm University, Ulm, Germany

Electrolysis at gas evolving electrodes at high voltages, up to several hundreds of volts, leads to vivid bubble formation at the electrode, which ultimately leads to the ignition of a plasma in a gas sheath forming around the significantly smaller driving electrode. [1] Depending on the applied voltage, the approach can be used to tailor the electrodes structural properties or to modify the electrolyte, to form nanoparticles or generate H2O2. Systematic studies to elucidate the fundamental physical properties are still scarce [2], which are, however, highly relevant to understand the aforementioned changes on the electrode and electrolyte. In this work we focus on the influence of the electrolyte concentration and composition, voltage scan rate, working electrode geometry and material, electrode distance and electrolyte convection. The electrode structural properties are studied by SEM imaging, the dynamics of the gas film around the electrode are monitored using a high-speed camera and the temperature is proved locally by multiple temperature probes. By correlating these results, we discuss the parameters influencing the temporal changes of the system's properties and their consequences for the application of high-voltage electrolysis. [1] Yerokhin et al., *SURF COAT TECH* **122** (1999) 73-93. [2] Forschner et al., *J. Phys. D: Appl. Phys* **58** (2025) 215204.

O 24.3 Mon 18:00 P2

Predicting Potential-Dependent Binding Energies at the Electrified Metal/Water Interface — •Ann Kathrin Tran, Elias Diesen, Karsten Reuter, and Vanessa J. Bukas — Fritz-Haber-Institut der MPG, Berlin

Density-functional theory studies of electrified metal/water interfaces present many challenges and uncertainties. Even the methodology for computing the thermodynamics of adsorption is not yet well-established, albeit crucial to e.g. heterogeneous electrocatalysis. Here, we discuss common approaches and approximations in a systematic study of electrochemical binding energies. We choose Au(111) as our model system and focus on the adsorption of key intermediates during O_2 electro-reduction. Firstly, we benchmark predictions from three increasingly advanced models of the double layer: an applied sawtooth potential in vacuum, an implicit solvent model, and explicitly modelled H_2O via *ab initio* molecular dynamics (AIMD). This comparison disentangles the purely electrostatic energy contribution from stabilization due to explicit H-bonding with the solvent. The latter contribution can be sizeable, yet is only captured by atomistic H_2O in expensive AIMD. We next address the issue of predicting grand-canonical energetics, that is, energies under realistic constant-potential conditions. In this context, we present workfunction information within constant-charge AIMD data, the emerging workfunction-charge relation, as well as different transformation techniques toward constant-potential results. This analysis reveals notable caveats for each approach and highlights the need for further systematic benchmark studies.

O 24.4 Mon 18:00 P2

molecular dynamics simulations of belite-water interac tions using HDNNPs — •Usman Tafida[1,2], Maite Böhm[1,2], Henry Wang[1,2], Bernadeta Prus[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

Advances in the development of machine learning potentials (MLPs), such as High-Dimensional Neural Network Potentials (HDNNPs), have enabled *ab initio*-level accuracy for molecular dynamics (MD) simulations of high dimensional systems at greatly reduced computational cost. In this work, HDNNPs are trained on DFT-D3 energies and forces data of beta-belite (Ca_2SiO_4) clusters in water, which serve as model systems for complex oxide-water interfaces. Here, we present the dataset construction scheme, training and validation of the potential. Moreover, MD simulations have been performed to study the structural and dynamical properties of interfacial water at these clusters.

O 24.5 Mon 18:00 P2

High-Dimensional Neural Network Potentials for Molecular Dynamics Simulations of Mineral-Water Interfaces — •Maite Böhm[1,2], Bernadeta Prus[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

In recent years, High-Dimensional Neural Network Potentials (HDNNP) have emerged as a popular tool for atomistic simulations of complex systems such as mineral-water interfaces. In this work, we present the construction of an HDNNP based on density functional theory energies and forces for tricalcium aluminate (C_3A)-water interfaces. We discuss the development of a dataset that includes the relevant solid-liquid interface interactions by active learning and propose approaches for an accelerated extension of the dataset. The trained potential is applied in Molecular Dynamics simulations of the (100) surface of C_3A in contact with water, which are further investigated with respect to the structure and dynamics of water on the surface.

O 24.6 Mon 18:00 P2

Developing High-Dimensional Neural Network Potentials for Studying Tricalcium Silicate-Water Interfaces — •Henry Wang[1,2], Bernadeta Prus[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

The emergence of machine learning potentials (MLP) trained on energies and forces from electronic structure calculations has revolutionized the simulation of solid-liquid interfaces by molecular dynamics (MD). For instance, High-Dimensional Neural Network Potentials (HDNNP) have shown excellent accuracy for describing the interaction of water with several solid minerals. In this study, we investigate interfaces of liquid water with alite (Ca_3SiO_5), a calcium silicate forming several polymorphs, which is characterized by a particularly high reactivity with water. Insights into the behavior of water at calcium silicate surfaces at an atomistic level are crucial to reach a better understanding of general hydration reactions of this class of materials. An approach for realizing high-accuracy, large-scale MD simulations is presented.

O 24.7 Mon 18:00 P2

Exploration of the Pt(111)-water interface by high-dimensional neural network potentials — •Daniel Trzewik[1,2], Moritz R. Schäfer[1,2], Alexander L. Knoll[1,2], and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

In-depth knowledge of solid-liquid interfaces is essential for understanding numerous catalytic and electrochemical processes. However, accurately describing these interfaces with first-principles methods is computationally demanding, limiting the system sizes and complexities that can be explored. Modern machine learning potentials offer a powerful alternative, delivering near-first-principles accuracy at a fraction of the cost. In this work, we use high-dimensional neural network potentials (HDNNPs) to examine the Pt(111)-water interface in detail. Trained on DFT reference data, these models enable molecular dynamics simulations which reveal the structural and dynamical behavior of water molecules at the interface.

O 25.1 Mon 18:00 P2

Role of Interfacial Water for CO_2 Reduction Reactions in Ionic Liquid/Acetonitrile Electrolytes — •Björn Ratschmeier[1], Arik Geringswald[1], Alisa Kamaric[1], Angel Cuesta[2], and Björn Braunschweig[1] — [1]University of Münster, Institute of Physical Chemistry, Münster, Germany — [2]Advanced Centre for Energy and Sustainability (ACES), School of Natural and Computing Sciences, University of Aberdeen, UK

Room-temperature ionic liquids (RTILs) such as 1-butyl-3-methyl-imidazolium bis(trifluoromethanesulfonyl)imide ([BMIM][NTf_2]) are promising electrolytes for CO_2 reduction reaction (CO_2RR), where the availability of water at the electrode/electrolyte interface is known to play a decisive role in the reaction mechanism. We find that the addition of acetonitrile (ACN) to [BMIM][NTf_2] with 1.5 M H_2O markedly increases the CO yield, while the onset potential for CO formation remains essentially unchanged. *In situ* IRAS of bulk intermediates formed during CO_2RR are indicative for a reaction pathway [1] via a [BMIM]-COOH intermediate that requires the presence of interfacial H_2O as shown in previous work. In contrast, *in situ* ATR-SEIRAS reveals ACN-induced modifications of the electrode/electrolyte interface. OH vibrational bands increase significantly at cathodic potentials, indicating enhanced water accumulation at the interface, thus, causing larger availability of water for CO_2RR. Ref.: [1] Ratschmeier et al. ACS Catalysis 14, 1773 (2024).

O 25.2 Mon 18:00 P2

Capacitance of Nanoconfined Salt Solutions: Interplay between Concentration and Temperature — •Caterina Sartori, Haoyuan Quan, Louis Lehmann, and Roland Netz — FU Berlin, Fachbereich Physik, Arnimallee 14 14195 Berlin, Germany

The capacitance of confined aqueous salt solutions is important for a variety of applications, including thermal energy conversion, but remains poorly understood. Performing Molecular Dynamics simulations and treating bulk electrolytes as a reservoir, we determine the temperature and bulk-concentration dependent density, slit concentration and capacitance of confined salt solutions. On a microscopic level, the capacitance is determined by the inverse dielectric profile, which we also present. Our results constitute a crucial step towards understanding the electrostatic behavior of confined electrolytes.

O 26.1 Mon 18:00 P2

Extending multiphysics crystallization models for phase-change materials with parameters derived from machine learning — •Luis Schüler[1,2], José Moreira[2], Andrei Lupuleasa[2], Wenjing Lei[2], Keerthika Kalavalapudi[2], Matthias Wuttig[2], Thomas Taubner[2], and Dmitry Chigrin[1,2] — [1]AMO GmbH, Aachen — [2]I. Institute of Physics (IA), RWTH Aachen

Optical metasurfaces based on dielectric or metallic scatterers such as nanoantennas provide advanced control over light-matter interactions. Dynamic tuning can be realized with phase-change materials (PCMs), which can be reversibly switched between amorphous and crystalline states with a strong difference in refractive index. Especially metallic nanostructures can significantly influence the crystallization dynamics of PCMs, resulting in deviations from the expected spectral behavior of the metasurface. Therefore, Multiphysics simulations that couple electrodynamics, heat transport, and crystallization kinetics are essential for understanding these effects and optimizing device geometry. However, it is experimentally challenging to obtain key crystallization parameters, such as viscosity or free energy density, over the relevant temperature range. Here, we use machine-learned interatomic potentials trained molecular dynamics data to compute the required material parameters. Furthermore, we use machine learning to predict the viscosity of chalcogenide-based PCMs using data from related glasses. This approach broadens the range of phase-change materials that can be reliably simulated and provides a pathway toward the systematic design of dynamically tunable metasurfaces.

O 26.2 Mon 18:00 P2

Toward Plasmonic Pump-Probe Spectroscopy of a Hot-Electron-Driven Reduction Reaction — •Marcel Schalling, Lukas Schmidt, Ferdinand Bauer, Thorsten Schumacher, and Markus Lippitz — University of Bayreuth

Plasmon-induced hot electrons offer a promising way to drive surface-catalytic chemical reactions with enhanced efficiency and selectivity. We want to follow the dynamics of the hot carriers by pump-probe spectroscopy.

In our approach, an initial laser pulse excites surface plasmons in the gold taper, generating hot electrons. These subsequently reduce adsorbed metal complexes on the taper's surface. This reduction is expected to locally modify the refractive index, which we probe by a second laser pulse. We show our first steps towards this goal. We start from the opto-electrochemical model system of methylene blue, and gradually add plasmonics and hot-electron generation towards the full implementation of the plasmonic pump-probe concept.

O 26.3 Mon 18:00 P2

Dissipation engineered plasmonic ratchet — •Anna Sidorenko[1], Jan Mathis Giesen[2], Sebastian Eggert[2], and Stefan Linden[1] — [1]Physikalisches Institut, Rheinische Friedrich-Wilhelms-Universität Bonn, 53115 Bonn, Germany — [2]Physics Department and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, D-67663 Kaiserslautern, Germany

This joint theoretical and experimental study presents a new design of a plasmonic ratchet, where directional transport is implemented purely by dissipation. Using Floquet theory, we identify resonant driving regimes depending on driving frequency and dissipation rates. An experimental observation of the ratchet effect in arrays of evanescently coupled plasmonic waveguides is provided by utilizing leakage radiation microscopy. Remarkably, we find that on resonance the transmitted signal shows lower losses for stronger local dissipation.

O 26.4 Mon 18:00 P2

Is the linkng number a topological invariant? — •Maja Manten[1], Alexander Neuhaus[1], Pascal Dreher[1], Phillip Gessler[1], Bettina Frank[2], Tim Davis[1,2,3], Harald Giessen[2], Michael Horn-von Hoegen[1], Karin Everschor-Sitte[1], and Frank Meyer zu Heringdorf[1] — [1]Faculty of Physics and Center for Nanointegration, Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47048 Duisburg, Germany. — [2]4th Physics Institute, Research Center SCoPE, and Integrated Quantum Science and Technology Center, University of Stuttgart, Germany. — [3]School of Physics, University of Melbourne, Parkville, Victoria 3010 Australia

Optical near fields, like they occur in surface plasmon polaritons, exhibit a wide range of topological textures, including skyrmions, merons, and optical vortices carrying orbital angular momentum. Near fields that carry a fractional orbital angular momentum rather than integer orbital angular momentum, however, pose a challenge: they form a complex phase-vortex landscape and break the simple picture of a single vortex carrying the topological charge. When the fields become distorted, the situation becomes more complicated as more and more vortices appear. The sequence of vortices and antivortices can extend to infinity and evade global topological classification in real space. Here we show that a global topological invariant, the linking number, can be found in Fourier space. We show how the linking number of a plasmonic field can be determined from a time resolved polarimetric photoemission microscopy experiment and demonstrate the robustness of the linking number against deformation of the excitation structure.

O 26.5 Mon 18:00 P2

Reconfiguring resonator shapes optically to tailor the resonator modes of phonon polaritons in hBN using In_3SbTe_2 — •Arvid Schick, Lina Jäckering, Lukas Conrads, Matthias Wuttig, and Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University

The van der Waals material hexagonal boron nitride (hBN) hosts hyperbolic Phonon Polaritons (HPPs) with high volume confinement and low losses, suitable for nanophotonic devices [1]. Restricting the HPPs to resonators enables ultra-confined resonances [2]. Conventionally, resonator fabrication requires cumbersome lithography processes. Instead, resonators can be fabricated via optical programming of the phase-change material In_3SbTe_2 (IST), as IST can reversibly be switched between a metallic and a dielectric phase in the infrared [3]. Optical programming of reconfigurable, circular resonators for HPPs in hBN has been demonstrated and allowed for tailoring the field confinement [4]. We investigate square, rectangular and triangular resonators. We reconfigure resonator shape and aspect ratio to tailor the resonator modes that we investigate with scattering-type scanning near-field optical microscopy (s-SNOM). By decreasing the resonator size, we find confinement of up to $\lambda/69$ and a Q-factor of 49. Our results pave the way for rapid and reconfigurable prototyping of confined polariton resonators of arbitrary shape for various 2D materials. Charge reservoir as a design concept for plasmonic antennas — •Rostislav Řepa, Michal Horák, Tomáš Šikola, and Vlastimil Křápek — Brno University of Technology, Brno, Czechia

Plasmonic antennas exploit localized surface plasmons to shape, confine, and enhance electromagnetic fields with subwavelength resolution. The field enhancement is contributed to by various effects, such as the inherent surface localization of plasmons or the plasmonic lightning-rod effect [1]. Inspired by nanofocusing observed for propagating plasmons [2], we test the hypothesis that plasmonic antennas with a large crosssection represent a large charge reservoir, enabling large induced charge and field enhancement. Our study reveals that a large charge reservoir is accompanied by large radiative losses, which are the dominant factor, resulting in a low field enhancement.

Distinct Multiphoton Orders in Photoelectron Spectra of Individual Silver Nanoparticles — Waqas Pervez[1], •Frithjof Harmsen[1], Kevin Oldenburg[2], Moha Naeimi[1], Sylvia Speller[1], and Ingo Barke[1] — [1]Institute of Physics, University of Rostock, Germany — [2]Department of Life, Light & Matter, University of Rostock, Germany

We investigate how the multiphoton photoemission process of individual metal clusters deposited on a non-metallic substrate is affected by the particle shape and its local environment. Here we present photoelectron spectra acquired by time-of-flight spectroscopy using a photoemission electron microscope (PEEM). Size-selected particles produced in a magnetron cluster source are deposited in-situ onto silicon substrates. The cluster source can produce single particles as well as agglomerates with characteristic plasmon modes [1], as revealed by transmission electron microscopy (TEM). Photoelectron spectra are obtained using illumination by a femtosecond laser at wavelengths around 800 nm, where at least 3 photons are required to overcome the work function. In addition, we observe well-separated above-threshold processes (ATP / ATI) of 4th order and up to 7th order for agglomerates. No noticeable resonances are observed across the spectral range, in contrast to illumination around 400 nm [2], i.e., at the plasmon energy. Mechanisms are discussed in view of symmetry properties and dipole selection rules.

O 27.3 Mon 18:00 P2

Plasma-assisted defect modification in hBN studied with cathodoluminescence spectroscopy — •Bharti Garg, Masoud Taleb, and Nahid Talebi — Institute of Experimental and Applied Physics, Kiel University, Germany

In this work, we study exfoliated hexagonal boron nitride (hBN) flakes treated with argon plasma for different durations and compare their optical response using cathodoluminescence (CL) spectroscopy. Emission spectra collected before and after plasma exposure allow us to isolate the effects of the treatment. hBN is known for defect-dependent optical emission, and plasma processing is a commonly used method to introduce or modify the density and the atomic structure of defects. We observe that longer plasma exposure leads to stronger defect-related emission and broader CL features, indicating an increase in defect density. The emission though occurs at the same wavelength before and after the plasma treatment, allowing us to conclude that the atomic structure of the defects remains similar even after the plasma interaction with the surface of hBN. These results clarify the influence of plasma treatment on defect formation in hBN and highlight the role of exposure time in tuning its optical properties.

O 27.4 Mon 18:00 P2

Tunable Stokes-shifted photoluminescence and defect emission from hBN excited with a supercontinuum laser — •Prabhdeep Singh, Bharti Garg, Maximilian Black, Masoud Taleb, and Nahid Talebi — Institute of Experimental and Applied Physics, Kiel University, Kiel, Germany

We investigate the photoluminescence (PL) of hexagonal boron nitride (hBN) flakes placed on holey carbon grids under tunable supercontinuum excitation from 460 to 650 nm. The spectra consistently show a fixed defect emission around 537 nm together with a stokes-shifted peak that moves linearly with the excitation wavelength. The excitation emission energy differences cluster around 0.17 eV and 0.20 eV, matching the in-plane E_1u and E_2g phonon modes of hBN. Cathodoluminescence measurements on the same flakes exhibit only the defect line, along with phonon sidebands. On a gold substrate, we additionally observe a weak third moving peak at the sum of the two phonon energies, arising from surface enhanced Raman spectroscopy scattering (SERS). Spatial PL maps, intensity variations, and measurements with different optical density filters further allow us to evaluate the local emission characteristics and estimate the down-conversion efficiency. The results provide a consistent picture of phonon-mediated optical processes in hBN. Using tunable supercontinuum excitation, we reveal phonon-assisted stokes emission in hBN and a SERS phonon-combination peak on gold an excitation scheme not previously explored for Raman-type processes in this material.

O 27.5 Mon 18:00 P2

Energy and momentum distribution of surface plasmon-induced hot carriers — •Ellen Brennfleck[1], Christopher Weiss[1], Jannis Lessmeister[1], Laurenz Rettig[1], Tobias Eul[2], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, Germany — [2]Institute of Physics, University of Augsburg, Germany

Are the spectroscopic properties of plasmon- and photon-induced carriers fundamentally different? This question is crucial for advancing plasmonic energy conversion. Initial studies have suggested characteristic energy and momentum distributions for the photoemission of both bulk plasmon resonances and surface plasmons. For surface plasmons, however, the separation of plasmon and photon-induced emission patterns by their inherent spatial and temporal dynamics remains challenging [1].

To further characterize the electron emission pattern of surface plasmons, we combine a femtosecond laser system with a spatial light modulator to generate a vector vortex beam to excite surface plasmon polaritons at an annular structure. Our photoemission electron microscope enables us to compare the spectroscopic properties of photoemitted electrons and those generated by plasmonic emission at the center of the structure, providing valuable insights into the distinct emission mechanisms.

O 27.6 Mon 18:00 P2

Hot electron generation in tapered plasmonic waveguides — •Ferdinand Bauer, Valentin Dichtl, Marcell Schalling, Thorsten Schumacher, and Markus Lippitz — University of Bayreuth, Germany

The efficient generation of hot electrons is important for applications such as photochemical catalysis. Hot electron-hole pairs are created by Landau damping of surface plasmon polariton (SPP) and decay through electron-electron scattering.

A symmetric taper in a waveguide enhances the generation of hot electrons. At one end the waveguide is excited by a laser pulse. The emission at the other end is then used as a metric for the transmission and thus the creation of hot electrons.

Numerical simulations (COMSOL) are used to find a high energy density at the hot spot. Within the simulations, Beer's law holds for a broad range of taper lengths and can be used to make geometry optimisation more efficient.

We demonstrate how to maximize energy density in the waveguide hot spot by using numerical simulations and experimental data, thereby optimising the production of hot electrons.

O 27.7 Mon 18:00 P2

Optical Response of Noble Metals based on Metal Boltzmann-Bloch Equations — •Robert Lemke, Andreas Knorr, and Jonas Grumm — Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Berlin, Germany

The optical response of plasmonic noble metals can be attributed to the interplay of electronic intra- and interband processes. These processes are addressed by coupled metal Boltzmann-Bloch equations derived from microscopic many-body theory. The specific properties of noble metals are caused by an anisotropic band structure in the vicinities of the X and L high symmetry points.

In order to analyse the line broadening of intra- and interband excitations we consider linearised electron-phonon and electron-electron scattering. Our approach allows to connect spectroscopic signatures directly to microscopic processes, not possible with phenomenological Drude-Lorentz models.

Probing Reactions at the Plasma-Catalyst Interface — •Maarten van Dorp and Roland Bliem — ARCNL, Amsterdam, The Netherlands

Efficient conversion of CO2 into value-added chemicals is a major step towards tackling climate change. However, chemical activation of CO2 by conventional catalysis requires exceedingly high reaction temperatures, straining energy efficiency and consequently industrial viability. Plasma-assisted catalytic conversion (PLAC) circumvents this by activating CO2 dissociation through the repeated impact of *hot* electrons from a non-thermal plasma, lowering the reaction barrier while selectively heating chemically activated CO2 species. However, to rationally design new PLAC catalysts, and therefore unlock the full potential of PLAC, crucial information about the short-lived intermediates is still unknown.

Here, a NiAl(110) substrate with an epitaxially grown alumina layer (Al10O13) was selected as well-defined support for carrying Cu-nanoparticles as a model system for the hydrogenation of CO2 with PLACIn this model system, a complete characterization of transient intermediates * both within the ECR microwave plasma and on the catalyst surface * requires a combination of complementary spectroscopic techniques, such as XPS, in-situ IRAS, LEED, and OES. . We establish the model system for plasma applications by synthesizing different alumina thicknesses, characterizing them with LEED, and testing their stability during exposure to plasma-activated species using in situ XPS.

O 28.2 Mon 18:00 P2

Influence of sample temperature on electron-beam-induced modifications in ultrathin CaF_2 films on Si(111) — •Luis Witte, Chris Schröder und Joachim Wollschläger — Institute of Physics, University of Osnabrück, Barbarastr. 7, 49076 Osnabrück, Germany

The development of modern transistor technologies based on 2D materials requires gate dielectrics with low defect densities and high chemical stability. CaF_2 layers on Si(111) are well suited for this purpose due to their low lattice mismatch and large band gap. However, a crucial aspect is their stability under electron irradiation, e.g. during LEED analysis of the layers, which can lead to structural and chemical changes.

In this study, ultrathin CaF_2 layers were deposited on Si(111) using molecular beam epitaxy. First, a growth temperature study was carried out at substrate temperatures between 400 °C and 700 °C. In a second step, the influence of the sample temperature during LEED measurements on the structural stability of the layers was studied. The electron beam of the LEED served both as a source of excitation for structural changes and as a probe for detecting these modifications. The measurements were conducted at sample temperatures from −150 °C to 600 °C in order to systematically investigate temperature-related effects. The results show that modifications induced by the electron beam exhibit a pronounced temperature dependence. In addition, ex-situ XPS measurements were performed to analyse chemical changes.

O 28.3 Mon 18:00 P2

Growth of MgO on Ag(100) for promoting charge transfer of organic molecules — •Christian Haberland, Felix Otto, Maximilian Schaal, Jonas Brandhoff, Leon Bojunga, and Torsten Fritz — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

Integer charge transfer between metal substrates and adsorbed organic molecules is a central mechanism governing interfacial electronic structure and thus the functionality of molecular devices. To control this process, ultrathin insulating films offer a powerful strategy by decoupling molecular orbitals from metallic states while still enabling quantized charge exchange. In this work, we report the successful preparation of MgO monolayer films on Ag(100) using controlled deposition of Mg and annealing procedures in an oxygen atmosphere. The resulting MgO/Ag(100) system provides a reliable platform for studying charge-transfer phenomena at oxide-supported interfaces. Comprehensive characterization was performed using photoelectron spectroscopy (UPS, XPS, XPD), revealing the electronic structure and stoichiometry, while scanning tunneling microscopy confirmed atomic-scale order and film continuity. The established growth of MgO serves as a robust model system for investigating integer charge transfer in metal/organic hybrid interfaces.

O 28.4 Mon 18:00 P2

Epitaxy of ultrathin α-Fe_2O_3(0001) and Fe_3O_4(111) on α-Al_2O_3(0001) — •Hanna Laguta, Tobias Pollenske, Chris Schröder, Luis Witte, Felix Johannsmann, and Joachim Wollschläger — Inst. of Physics, Univ. Osnabrück, Barbarastr. 7, 49076 Osnabrück, Germany

Iron oxides have a lot of technological applications and occur in magnetic, catalytic or electronic devices. Fe_3O_4 (magetite) and α-Fe_2O_3 (hematite) belong to the most stable iron oxides which can be found in nature.

Hematite is antiferromagnetic and has a lot of potential to be used for magnetic data storage. Thus it is of interest to study ultrathin hematite films. In this work, on the one hand α-Fe_2O_3 was grown directly onto the α-Al_2O_3(0001)-substrate using MBE. On the other hand Fe_3O_4 was deposited first to be oxidised to hematite in a second step. The magnetite films underwent exposures of oxygen between $6 \cdot 10^{-3}$ mbar·s and $180 \cdot 10^{-3}$ mbar·s, one sample was oxidised step-by-step.

The samples were respectively investigated using Soft and Hard X-ray Photoelectron Spectroscopy to determine the stoichiometries of near-surface and subsurface regions. Low Energy Electron Diffraction is used to determine the surface structure of the ultrathin oxide films and to distinguish hematite (α-Fe_2O_3) from maghemite (γ-Fe_2O_3) films. Additional measurements using SQUID provide insight into the magnetic properties of the samples.

O 28.5 Mon 18:00 P2

STM and LEED studies on the stabilization of two-dimensional scandium oxides on Pt(111) by Ba and Ti incorporation — •Selina Schmechel, Muriel Wegner, Stefan Förster, and Wolf Widdra — Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, 06120 Halle, Germany

The formation of two-dimensional oxides on metal support crucially depends on a charge transfer between the film and the substrate. For the particular case of M_2O_3 transition metal oxide honeycomb (HC) structures, it was found that potentially di- and quadrivalent metal cations form HC structures by charge exchange with the support [1]. This is not possible for trivalent metals and, therefore, they do not form 2D oxides.

Here we study the growth of submonolayer scandium oxide films. We confirm the 3D growth for the binary Sc_2O_3 compound with the bulk lattice parameter of 3.2Å. However, when incorporating Ti an immediate transition into a 2D layer is observed. For different compositions, these mixed Sc-Ti-O films develop long-range ordered 2D wagonwheel structures. By incorporating Ba into Sc_2O_3 we succeed in the formation of a HC structure. In this case, all HC pores are filled with Ba ions, which donate their valence electrons to the substrate. This HC posses a lattice parameter of 6.1Å as determined from LEED. This points to an increased Sc-Sc distance as compared to bulk conditions. This host atom-assisted HC stabilization will be applied to the preparation of lanthanide HC oxides in the future.

O 28.6 Mon 18:00 P2

Oxidation behaviour of nickel on magnesium oxide (001): An in situ study of structural development. — •Tobias Pollenske, Laurenz Hüffmeier, Hannah Hilmer, and Joachim Wollschläger — Inst. of Physics, Univ. Osnabrück, Barbarastr. 7, 49076 Osnabrück, Germany

Precise control of nickel oxidation on magnesium oxide (MgO)(001) surfaces under ultra-high vacuum (UHV) conditions is of fundamental importance for understanding metal/oxide interfaces and developing novel materials with tailored magnetic, electronic or catalytic properties. In this study, an approximately 15 nm thick Ni layer was deposited on MgO(001) using molecular beam epitaxy (MBE) and oxidised in situ at 250°C, 300°C and 400°C under 1×10^{-5} mbar O_2. The structural changes during oxidation were monitored by X-ray diffraction

(XRD) near the MgO(002) Bragg reflection. In addition, GIXRD, XRR and soft XPS measurements were performed between the oxidation steps. The results show that structured NiO formation only occurs at 400°C, while lower temperatures only lead to surface-limited oxidation. The soft XPS data confirm that the Ni surface oxidises almost immediately once a sufficient temperature is reached, with longer exposure to oxygen having little additional effect. Furthermore, the diffraction data show that annealing above 250°C improves the crystalline order of the Ni film. These combined in situ measurements provide a detailed picture of the oxidation kinetics and temperature-dependent structure development at the Ni/MgO(001) interface.

O 28.7 Mon 18:00 P2

Initial stages of gold nanoparticle growth on sapphire — •Hannah Hilmer[1], Chris Schröder[1], Tobias Pollenske[1], Timo Kuschel[2,4], Arno Jeromin[3], and Joachim Wollschläger[1] — [1]Institute of Physics, Univ. Osnabrück, 49076 Osnabrück, Germany — [2]Faculty of Physics, Univ. Bielefeld, 33615 Bielefeld, Germany — [3]Centre for X-ray and Nano Science CXNS, Deutsches Elektronen-Sychrotron DESY, 22607 Hamburg, Germany — [4]Institute of Physics, Johannes Gutenberg Univ. Mainz, 55128 Mainz, Germany

Gold nanoparticles are of great interest for applications in catalysis, sensor technology, and electronics due to their shape- and size-dependent optical, electrical, and chemical properties. Their morphological and electronic properties depend heavily on the growth conditions. $Al_2O_3(0001)$ is particularly well suited as a substrate due to its chemical stability and well-defined surface structure.

For this purpose, gold was deposited in ultra-high vacuum using thermal molecular beam evaporation at different deposition durations and varying substrate temperatures. In addition, thermal post annealing was carried out at different temperatures.

The growth processes of Au on $Al_2O_3(0001)$ substrates were characterized using XRR, XPS and LEED. The results show that gold grows on sapphire in the initial stage according to Volmer-Weber growth as discontinuous islands. SEM and EDX analyses show clearly defined gold particles whose size and distribution depend strongly on the substrate temperature, the evaporation time per interval, and annealing temperature.

O 28.8 Mon 18:00 P2

Local Characterization of Structural and Electronic Properties of the ZnO(0001) Surface — •Yuyang Zhang and Martin Wenderoth — IV Physical Institute, University of Göttingen

Zinc oxide (ZnO) serves as a key model system for understanding Proton-Coupled Electron Transfer (PCET) at interfaces.[1] To unravel electron dynamics on hydrated and doped surfaces, a profound understanding of the pristine surface is the indispensable baseline. Here, high-quality single-crystalline ZnO (0001) surface were prepared under ultra-high vacuum (UHV) conditions. The desired reconstruction was achieved by optimizing cycles of Ar+ sputtering and annealing. The structural properties were characterized by Low-Energy Electron Diffraction (LEED), confirming the long-range order and the intrinsic hexagonal surface symmetry. Similar to [2], Scanning Tunneling Microscopy (STM) revealed an ordered morphology dominated by atomically flat terraces with a high concentration of defects characteristic of polar face. Complementary atomic force microscopy (AFM) measurements provided additional information on the mesoscale morphology. Tunneling current measurements were utilized to probe the local electronic properties, providing insight into the surface band structure. This work was financially supported by the DFG through the CRC1633.

Impact of atomic oxygen on alumina surfaces investigated by molecular dynamics simulations — •Stephen Hocker, Hansjörg Lipp, and Johannes Roth — FMQ, University of Stuttgart, Germany

Oxygen atoms impinging on satellite surfaces in very low earth orbit (VLEO) transfer momentum and energy leading to material degradation as well as drag forces which result in orbital decay of the satellite. The first step in finding solutions to counteract significant drag is to gain understanding of the interaction of atomic oxygen (AO) with material surfaces. We investigate the angular and velocity distributions of reflected AO on crystalline and amorphous alumina surfaces using molecular dynamics simulations. Adsorption processes are evaluated and their influence on the surface structure and resulting changes regarding AO reflection is revealed. A strong dependence on the angle of incidence and the initial velocity is found. A high ratio of specular reflection can be obtained for grazing angles of incidence and hyperthermal initial velocities.

First Principles investigation of the electronic properties and OER activity of (sub)stoichiometric WO_{3-x} (x =0.0, 0.1) — •Jeel Swami and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen

Tungsten trioxide (WO_3) exhibits a rich sequence of temperature and defect-driven structural phase transitions. Using density functional theory (DFT) calculations with the SCAN0 (with and without a Hubbard U term) and HSE06 functionals, we explore the influence of oxygen defects on the electronic properties of WO_{3-x}. For substoichiometric Magnéli phase $WO_{2.9}$ our results show partial localization of charge at the interface exhibiting weak magnetisation and n-type conductivity. We further investigate the application of WO_3 as anode material for the oxygen evolution reaction. At the (001) facet we consider various surface terminations. Gibbs free energy plot reveal that *OOH formation is the potential determining step for WO_3(001) facet.

We acknowledge computation time at the MagnitUDE and AmplitUDE HPC systems at the University of Duisburg-Essen.

O 29.3 Mon 18:00 P2

Interaction of atomic Oxygen with Silica Surfaces — •Ahmad Kassem Arrak, Stephen Hocker, Hansjoerg Lipp, and Johannes Roth — FMQ, University of Stuttgart, Germany

In order to increase the lifetime of VLEO (very low earth orbit) satellites, the drag forces on the satellite and the degradation of the surface material must be reduced. Both arise mainly from atomic oxygen (AO) impinging on the satellite surfaces at hyperthermal velocities. We investigate the influence of AO impact on silica surfaces using molecular dynamics simulations (LAMMPS). A focus is on adsorption, reflection and chemical reactions. Three interaction potentials were used, one from Vashishta, a Tersoff potential and a PACE machine learning potential. We prepared three (001) surface structures of alpha silica differing by their surface layers. The oxygen impact simulations revealed that the interaction processes occurring at the surface depend strongly on the chemical composition of the surface layers. At the oxygen-rich surface the formation and desorption of O2 can be observed while reflection or adsorption of AO is favored at other surfaces.

Structural analyses for S and Te on transition metal chain-like phases on the Ir(100) substrate — •Eric Engel, Alexander Wegerich, and M. Alexander Schneider — Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

The magnetic properties of one-dimensional transition metal oxide chains Ir(100)-(3×1)-MO_2 (M = Mn, Fe) [1,2] may in the case of Mn be tuned by changing the number of oxygen atoms in the chain structure [3]. Here, we present our attempts to replace O by S and Te and the quantitative LEED-IV analyses of the resulting structures.

Dosing H_2S to the MnO_2 or FeO_2 chains leads to the formation of a dominant $c(2\times2)$ superstructure. The structural analyses reveal with Pendry R-factors $R_P < 0.11$, that reduced transition metal chains remain as ordered (3×1) structures in the surface layer. The true unit cell of the system is hence a $c(6\times2)$ but with only little deviations in the S adsorbate layer from a $c(2\times2)$.

For Te, MO_2 chains were reduced in H_2 first, followed by Te deposition. In the case of 1/6 ML Te on the Ir(100)-(3×1)-$FeIr_2$ a (3×2)-Te superstructure emerges, where the Te atoms take positions on pure Ir hollow sites between the Fe-chains (R_P = 0.123). For 1/2 ML Te a dominant $c(2\times2)$ superstructure appears, again with only slight influences of the metal chains in the Ir(100) surface adsorbate positions.

Structure of Standing Tetracyanoethylene Molecules on Cu(111) and Cu(100) — •Lorenz Brill[1], Jonas Brandhoff[1], Christoph Wachter[2], Roman Forker[1], Oliver T. Hofmann[2], and Torsten Fritz[1] — [1]Friedrich Schiller University Jena, Germany — [2]Graz Universtiy of Technology, Austria

Tetracyanoethylene (TCNE) has been predicted to go through a standing-lying transition on Cu(111) depending on the deposition conditions. However, only disordered growth with a mix of standing and lying molecules has been observed in the past. Here, we present the first evidence of well ordered structures of standing TCNE molecules grown on Cu(111) and Cu(100), observed by low energy electron diffraction and scanning tunneling microscopy. We compare the obtained structures to predictions calculated in thermodynamic equilibrium.

Quantitative sputter depth profiling: LEIS measurements and SDTrimSP simulations on silicon oxide — •Julian Pichler, Camil Bocaniciu, Alper Tunga Celebi, and Markus Valtiner — Technische Universität Wien, Wiedner Hauptstr. 8-10, Vienna, 1040, Austria

Precise surface characterization is crucial in semiconductor devices, to guarantee highest quality and optimal device fabrication.

This involves identifying defects, accurate handling of layers and surface contaminations, as well as determining elemental concentrations. This study focuses on a combined interpretation of Low Energy Ion Scattering Spectroscopy (LEIS) measurements on silicon oxide by quantification with references and Monte Carlo simulations with the SDTrimSP code [1]. We calculate surface erosion rates from simulations to deduce layer thicknesses in target materials, under consideration of atomic intermixing effects induced by sputtering.

For silicon oxide on pure silicon we find good quantitative agreement in sputtering depth profiles between LEIS measurements and SDTrimSP simulations for oxide layer thicknesses around 2 nm. We provide an estimation of layer thicknesses within a few Ångstrom and demonstrate intermixing at the interface induced by sputtering.

Should Doping be illegal at inorganic/organic Interfaces — •Aleksey Sokolov, Christoph Wachter, and Oliver T. Hofmann — Institute of Solid State Physics, Graz University of Technology, Graz, 8010, Austria

Organic/inorganic-semiconductor interfaces are central to the performance of devices such as organic light-emitting diodes and photovoltaic cells. The geometric arrangements of the molecules at the interface, known as polymorphism, heavily influence the properties of the interface, such as ionization energy, electron affinity, and charge mobility. Which arrangement molecules assume under given deposition conditions is governed by a variety of factors, such as the molecular size and shape, the intermolecular interactions as well as the molecule-substrate interactions, particularly the adsorption-induced charge-transfer. The amount of charge transfer, however, is critically determined by the substrate's doping concentration. Although there are now successful methods in predicting stable polymorphs, the role of the substrate doping for the interface polymorphism is not sufficiently understood. In this work, we use density functional theory in combination with the machine learning-driven structure search method SAMPLE to investigate how doping-induced charge transfer influences the thermodynamically stable phases of the example of F4TCNQ on ZnO. The results give insight into the interplay between doping, charge transfer, and interface structure, which can be used to generalize the effects in similar systems.

Investigating the native oxide layer of CoCrFeNi(100) by co-adsorption of O_2 and H_2: an XPS study — •Peter Richter, Kavya Harsha Kumar, Susanne Wolff, and Thomas Seyller — Technische Universität Chemnitz, Chemnitz, Deutschland

High-entropy alloys (HEAs) are a relatively new class of materials with potential applications under ambient conditions. Hence, understanding the formation and the properties of their native oxides is essential. In this study, we use X-ray photoelectron spectroscopy to investigate the native oxide layer present on CoCrFeNi(100) as well as on the clean surface subjected to controlled exposures of O_2 and H_2.

To evaluate the stability of the native oxide layer, samples were annealed in ultra-high vacuum at temperatures in the range of 350 to 1100 °C. Oxide reduction increased significantly at 700 °C and was complete at 1100 °C. The exposure of clean CoCrFeNi(100) surfaces to 1 to 1000 L of O_2 leads to controlled oxidation, with Cr contributing most to oxide formation, followed by Co and Fe. The subsequent introduction of H_2 at sample temperatures of up to 500 °C leads to systematic changes in the surface chemistry.

Experimentally, the information of the bonding configuration is best observed in the 2p core levels of Co, Cr, Fe and Ni. However, when using the Al K_α line, several Auger peaks overlap with the Co2p and Fe2p core levels. In addition, multiplet splitting and satellite features further complicate the evaluation of the XPS data. To improve this, we performed reference measurements and developed fitting models for the Auger lines using pure metal foils.

O 31.2 Mon 18:00 P2

Molecular bottom up: Site-selective adsorption of cyclooctyne on partially passivated Si(001) — Jannick A. Peters[1], •Sophie Göbel[1], Dominik Scharf[2], Ulrich Koert[2], and Michael Dürr[1] — [1]Institut für Angewandte Physik and Zentrum für Materialforschung, Justus-Liebig-Universität Giessen, Germany — [2]Fachbereich Chemie, Philipps-Universität Marburg, Germany

Organic molecular structures on the technologically most important Si(001) surface are of great potential for future applications in terms of "more than Moore". The synthesis of organic structures on semiconductor surfaces requires several aspects to be considered, such as precise choice of adsorbates and their functional groups, as well as a well-prepared surface where the reaction sites can be controlled. For a lateral ordering of the organic layer, pre-patterned substrates are seen as promising starting point; e.g., alternating passivated and non-passivated surface areas are generated by means of STM in hydrogen desorption lithography. A self-organized approach might be based on ethylene on Si(001) which is known to show a well-ordered adsorbate structure on Si(001) in the submonolayer regime due to nearest-neigh-bor interactions. The reaction of cyclooctyne and its derivatives on the Si(001) surface pre-passivated with ethylene was studied by means of XPS and STM. Whereas C_2H_4 shows strongly reduced reactivity at the remaining, unreacted silicon dimers, cyclooctyne with its direct reaction channel on clean Si(001) shows high reactivity also at these strongly hindered sites. Furthermore, the reaction of bifunctional cyclooctynes was observed to be more selective than on clean Si(001).

O 31.3 Mon 18:00 P2

Quantitative imaging of surface potential of PTCDA molecules on Ag(111) and Pb(111) — •Sandhya Anchamkudy[1], Janine Lorenz[1,2], Amin Karimi[1], Christian Wagner[1,2], Ruslan Temirov[1,3], Henry Thake[4], Reinhard Maurer[4], Stefan Tautz[1,2], and Felix Lüpke[1,3] — [1]Peter Grünberg Institut (PGI 3), Forschungszentrum Jülich, Germany — [2]Institut für Experimentalphysik IV A, RWTH Aachen, Germany — [3]Institute of Physics II, Universität zu Köln, Germany — [4]Department of Chemistry, University of Warwick, United Kingdom

Scanning Quantum Dot Microscopy (SQDM) enables quantitative imaging of surface dipoles with unprecedented energy and spatial resolution. In the past, SQDM has been applied to molecular adsorbates, adatoms, defects, and atomic assemblies on silver [Phys. Rev. Lett. 115, 026101 (2015), Nat. Mater. 18, 853 (2019)] - and provided valuable benchmarks for theory where metal-organic hybrid systems are particularly challenging. Here, we investigate the adsorption geometry dependent effects of isolated perylene tetracarboxylic dianhydride (PTCDA) molecules on Ag(111). We identified two preferred orientations of PTCDA molecules: along the <1-10> and <11-2> directions of the Ag(111) surface. In SQDM measurements, the two orientations yield distinct dipole moments of -0.51 D and -0.65 D, respectively. In addition, we carried out SQDM of a single PTCDA molecule on superconducting Pb(111) and found that the dipole is seven times larger compared to PTCDA on Ag(111). This difference can be attributed to a significantly higher charge transfer and adsorption height on Pb(111).

O 31.4 Mon 18:00 P2

Redox Molecules on Gold Surfaces: Insights into Triboelectric Behavior through Simulations — •Zohreh Izadi[1,2], Michael Moseler[1,2,3], Michael Walter[1,2,3], and Leonhard Mayrhofer[3] — [1]Cluster of Excellence livMatS @Freiburg Center for Interactive Materials and Bioinspired Technologies(FIT), University of Freiburg, Freiburg, Germany — [2]Institute of Physics, University of Freiburg, Freiburg, Germany — [3]Fraunhofer IWM, MikroTribologie Centrum μTC, Freiburg, Germany

Triboelectricity, the electrostatic charge generated during the contact and separation of materials, remains poorly understood at the microscopic level. Redox-active molecules on metal surfaces provide a controlled platform to probe these charge-transfer processes. We studied donor and acceptor molecules adsorbed on Au(111) and evaluated their adsorption geometries and binding energies, as well as the electronic signatures associated with interfacial charge transfer. We

also considered different environments and found that humidity was a key factor facilitating charge transfer between the molecules and the surface. Our results are in very good agreement with the experimental findings from our joint study, offering insight into how redox-driven charge transfer at metal-molecule interfaces contributes to triboelectric behavior.

TPD Studies of Metal-Substrate Interactions in LOHCs and Polyfluorinated Compounds — Kassandra Zoltner, •Evelyn Versok, Leonard Neuhaus, Stefan R. Kachel, and J. Michael Gottfried — Fachbereich Chemie und mar.quest, Philipps-Universität Marburg, Germany.

Metal-substrate interactions critically govern catalytic reaction pathways and degradation mechanisms. Here, we investigate two chemically contrasting classes of adsorbates - hydrogen-rich liquid organic hydrogen carriers (LOHCs) and fluorocarbons - to clarify their stability and reactivity on metal surfaces. LOHCs such as decalin and tetralin are attractive hydrogen-storage materials but are prone to side reactions and catalyst-induced decomposition. In contrast, fluorocarbons including all-cis-hexafluorocyclohexane and perfluoromethylcyclohexane exhibit exceptional thermal and chemical stability, which is technologically valuable yet contributes to unwanted environmental persistence. Understanding molecule-metal interactions is therefore important for both hydrogen-storage chemistry and fluorocarbon degradation strategies. We employ temperature-programmed desorption (TPD) to determine adsorption energies, reaction kinetics, and product distributions. Systematic analysis of the selected LOHCs and fluorinated compounds on Au(111), complemented by comparison with partially dehydrogenated and defluorinated analogues, reveals detailed metal-induced transformation pathways. These insights advance the mechanistic understanding of hydrocarbon and fluorocarbon degradation on metal surfaces and support catalyst development.

O 31.6 Mon 18:00 P2

Orientation-dependent Adsorption and Manipulation of a Boron-doped Polycyclic Aromatic Hydrocarbon — •Elishka Vaz[1], Matthias Schnitzlein[2], Frank Würthner[2], Matthias Bode[1], and Jing Qi[1] — [1]Physikalisches Institut, Experimentelle Physik 2, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — [2]Institut für Organische Chemie, Organische Chemie II, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

The incorporation of boron atoms into polycyclic aromatic hydrocarbons (PAHs) alters their electronic properties since the boron centres act as π-acceptors [1]. In this contribution, we present a novel boron-centered PAH with terminal bromine-substituents. Upon adsorption on the Cu(111) surface, the B-PAHs adopt twelve distinct azimuthal orientations: six aligned with the crystallographic directions of the (111) surface, and six rotated by 30°. Differential-conductance spectroscopy and apparent-height analyses reveal a pronounced influence of the substrate on both the topographic appearance and electronic structure. Atomic-resolution imaging enables assignment of adsorption sites via interpolation of the surface atomic rows. Moreover, lateral tip-induced manipulation demonstrates controlled stacking along the molecular short axis. Finally, we identify a double-chain arrangement, likely composed of intact molecules, which exhibits a notable spectral shift in the differential-conductance signature relative to isolated adsorbates.

Excitons in molecular solids: from unitary films to donor-acceptor co-crystals — •Gregor Witte — Renthof 7, 35032 Marburg

Their strong light-matter interaction makes organic semiconductors (OSCs) promising candidates for optoelectronic devices. However, the microscopic picture of photophysical excitations and their properties is still incomplete. Reasons for this are the different nature of excitons in inorganic and organic SCs and the frequently used simplified description of excitons in OSCs within the framework of H- and J- aggregates, which disregards high-energy states and the delocalization of wave functions. Optical transmission-absorption measurements on single crystals or films with large crystalline domains enable the spectroscopy of higher energy excitons and, by means of polarization- and direction-resolved measurements, also a correlation with the molecular packing motif. Among OSCs, acenes represent an ideal platform for exciton studies, as they allow both polymorph-selective crystallization and versatile modification of the molecular electronic structure through chemical substitutions. Furthermore, also highly ordered acene-perfluoroacene cocrystals can be produced, which enable detailed characterizations of heteromolecular charge transfer excitons in molecular donor-acceptor systems with well-defined internal interfaces. In this talk I will present some of our recent exciton studies on various acenes, which combine polarization-resolved optical spectroscopy with modern ab initio calculations based on density functional theory and many-body perturbation theory.

During-synthesis functionalization of graphene layers — •Cristina Africh — CNR-IOM, Trieste, Italy

Introducing heteroatoms into graphene is a powerful way to modulate its catalytic, electronic, and magnetic properties. During the last decade, we developed a clean and scalable functionalization strategy that exploits the sponge-like properties of nickel substrates as well as the catalytic role played by transition metal (TM) single atoms at graphene edges during Chemical Vapor Deposition synthesis [1]. Following this route, it is possible to grow N-doped, B-doped and TM-doped graphene as well as co-doped layers [2,3,4]. The potential of the functionalized networks for sensing and, as a perspective, for catalysis, was evaluated by monitoring their response upon gas exposure [5,6].

Heterotriangulene Kagome Graphene Films: Growth and Effect of Kinetic Reaction Parameters — •Wyatt Behn[1], Simon Briesenick[1], Chang Wan Kang[2], Manuel González-Lastre[3], Pablo Pou[3], Rubén Pérez[3], Dmytro Perepichka[2], and Peter Grutter[1] — [1]Dept. of Physics, McGill — [2]Dept. of Chemistry, McGill — [3]Universidad Autónoma de Madrid

Nanoporous graphenes featuring Kagome lattices formed by heterotriangulene units continue to attract interest for their correlated electronic properties. Their symmetry gives rise to flat bands and Dirac cones [1,2]. Covalent organic frameworks (COFs) like these are often synthesized by surface-assisted Ullmann coupling, and are susceptible to defects such as voids, irregular-sided linkages, and limited grain sizes of around 100 nm [3,4]. We perform a series of polymerizations over a range of sample temperatures (180-250 C) for tribromo- and triiodotrioxaazatriangulene precursors on the Au(111) surface. Using scanning tunneling microscopy (STM) and non-contact atomic force microscopy (nc-AFM) we interrogate how deposition conditions and choice of halogen affect the final polymer film quality, which we quantify using minimum spanning tree and persistent homology approaches. We also investigate the prevalence of halogenated edge terminations and of undesired organometallic intermediates. Experimental results are complemented by simulated STM and nc-AFM analyses.

O 33.3 Tue 11:15 HSZ/0201

Defect-Driven Formation of Distinct 2D-Ag Phases at the Graphene/SiC Interface — •Sawani Datta[1], Boyang Zheng[2], Arpit Jain[2], Vibha Reddy[1], Kathrin Küster[1], Joshua A. Robinson[2], Vincent H. Crespi[2] und Ulrich Starke[1] — [1]Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany — [2]Pennsylvania State University, State College, USA

Intercalation of two-dimensional (2D) materials at the graphene/SiC interface is important for improving environmental stability of the intercalant and tuning graphene's electronic properties. However, the underlying mechanisms remain complex and are still not fully understood. In this study, we show that by modify-

ing the intercalation process, specifically through defect engineering, it is possible to selectively stabilize two distinct phases of intercalated silver (Ag). The previously established phase (Ag_1) aligns with nearly (1×1) registry of SiC [1, 2], while the second phase (Ag_2) develops a denser $(3\sqrt{3}\times3\sqrt{3})R30^\circ$ superstructure on a (5×5) SiC unit cell, producing a 6.25×6.25 Moiré pattern with respect to graphene, as seen in the low energy diffraction (LEED) pattern [2]. Angle-resolved photoemission spectroscopy (ARPES) reveals a striking kaleidoscopic modulation of the Ag_2 and graphene bands, absent in Ag_1, along with notable differences in charge transfer between the two phases. These results demonstrate that defect-controlled, phase-selective intercalation offers a promising pathway to design and explore exotic 2D electronic states at graphene/SiC interfaces. [1] PRB 101, 201407(R) (2020). [2] arXiv:2511.07151v1 (2025).

O 33.4 Tue 11:30 HSZ/0201

Strain-Induced 2D Pb phases confined between graphene and SiC — •Sergii Sologub[1,2], Markus Gruschwitz[1], Zamin Mamiev[1], Chitran Ghosal[1], and Christoph Tegenkamp[1] — [1]Institut für Physik, TU Chemnitz, Reichenhainer Str. 70, 09126 Chemnitz — [2]Institute of Physics, NAS of Ukraine, Nauki avenue 46, 03028 Kyiv

The intercalation of metals beneath graphene offers a powerful route to stabilizing and protecting novel 2D phases. We performed a detailed intercalation study of Pb beneath the ZLG on SiC(0001) using low-energy electron diffraction (at the temperatures from 70 to 600° C) as well as scanning electron and tunneling microscopy [1]. Our analysis reveals the formation of different 2D Pb monolayer phases, such as stripes and hexagons, which emerge due to the interplay between substrate pinning and strain within the Pb layer, depending on local coverage. The interface reconstruction of Pb was shown can be tuned by varying the details of the intercalation protocol. Based on our experiments combined with recent simulations [2], an intercalation model, accounting for the different periodicities observed in the interface layer, was proposed. These findings provide new insights into the strain-driven stabilization of intercalated metal layers and highlight the potential of graphene as a versatile platform for engineering low-dimensional materials.

O 33.5 Tue 11:45 HSZ/0201

Strain engineering in graphene on Ru(0001) — Paula García-Mochales[1] and •Antonio J. Martínez-Galera[1,2,3] — [1]Departamento de Física de Materiales, Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [2]Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, E-28049 Madrid, Spain — [3]Instituto Nicolás Cabrera, Universidad Autónoma de Madrid, E-28049 Madrid, Spain

The ability to induce and characterize strain in the atomic lattice of 2D materials, localized within only a few nanometers around specific positions, is a major challenge for the development of straintronics. In this work, the interaction between Si nanoparticles and the surface of graphene/Ru(0001) is employed to induce local strain in the latter. The strain field has been mapped at the nanoscale by scanning tunneling microscopy (STM), using the moiré pattern intrinsic to graphene/Ru(0001) surfaces as a magnifying lens. The induced strain is found to be confined within only a few nanometers around each nanoparticle. To achieve more accurate control, strain engineering at the nanometer scale was successfully performed by manipulating nanoparticles through the STM tip. This approach to controlled strain could provide a key tool for exploring new physics arising by strain in 2D materials.

P. García-Mochales and A. J. Martínez-Galera, Nano Lett. 25, 16097-16103 (2025).

O 33.6 Tue 12:00 HSZ/0201

Subsurface carbon controls graphene growth on Ir(111) — •Smruti Ranjan Mohanty, Lothar Brendel, Marko Kriegel, Niels Ganser, Frank-Joachim Meyer zu Heringdorf, and Michael Horn-von Hoegen — Faculty of Physics, University of Duisburg-Essen, 47057 Duisburg, Germany

The CVD growth of 2D materials is governed by a balance between adsorption, surface diffusion, and nucleation. For transition metal substrates, dissolution into the bulk acts as an additional parameter. By employing in-operando low-energy electron microscopy (LEEM) to monitor graphene growth on Ir(111), the effect of the growth temperature and the precursor pressure on the nucleation behavior is studied. The island nucleation density exhibits two distinct regimes, described as separate cases within Venables nucleation theory [1]. For a critical nucleus size i* = 5, low dosing pressures yield a low nucleation density that is governed by incomplete condensation with a scaling exponent of 2.5. At higher-dosing pressures, adsorptions at island edges dominate over the adatoms loss into the substrate, resulting in a higher nucleation density and a strongly reduced scaling exponent. Kinetic Monte Carlo simulations that incorporate bulk dissolution reveal both nucleation regimes and find a universal, temperature-independent scaling law. The results indicate a universal nucleation behavior for 2D materials with finite, non-negligible solubility in the supporting metal substrate.

Thermodynamics of heteroatom-doped graphene: Brute forcing the partition function — •Lukas Hörmann[1,2], Benedict Saunders[1], and Reinhard J. Maurer[1,2] — [1]University of Warwick, United Kingdom — [2]University of Vienna, Austria

The introduction of dopants into graphene can be used to tune material properties for specific applications, such as electronics, sensors, or catalysis. Achieving such tunability requires precise control over the composition and concentration of dopants within the lattice. This demands a fundamental understanding of the thermodynamics that govern the phase space of heteroatom superstructures in the two-dimensional graphene framework. We present a comprehensive approach to determining dopant structures that enables the near-exhaustive enumeration of all relevant heteroatom superstructures. The approach combines Density Functional Theory and machine learning to build a transferable energy model for dopant formation. Our method's efficient data handling and fast inference enable the evaluation of more than 150 million possible structures, allowing us to effectively brute force the partition function and derive all thermodynamic properties from it. We show the capabilities of our approach for free-standing graphene doped with nitrogen atoms, establishing a thermodynamic model to investigate how temperature affects the configuration space of doped graphene. Our analysis yields physical insights into defect interactions. We observe a characteristic peak in the heat capacity, indicating an order-to-disorder transition, and present a mechanistic understanding of how this peak arises.

From Global Optimization to Transition State Search: Automatic Workflow for Surface Reaction Kinetics — •Hyunwook Jung[1], Emanuel Colombi Manzi[1], Johannes T. Margraf[1,2], Hendrik H. Heenen[1], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Universität Bayreuth

Reaction-barrier calculations present the major bottleneck in the systematic exploration of surface reaction networks via atomistic simulations. Each involved transition-state search introduces a high-dimensional configuration space, comprised of many initial and final state combinations, that must be explored to identify the minimum-energy pathway with the lowest activation barrier. Typically, this task is delegated to human chemical intuition as user-input to e.g. a nudged elastic band (NEB) calculation, since its automation remains a significant challenge. Here, we introduce a fully automated workflow for transition-state optimization that does not require any human intervention. Initial and final geometries are generated through global optimization and subsequent alignment, followed by an atom-mapping and index permutation to arrive at the nonequivalent transition pathways. This process still leads to a large combinatorial number of possible interpolations from which we select a tractable subset using heuristic reaction-distance metrics. We demonstrate the workflow across a range of reactions and surface combinations from the OC20NEB database and discuss its overall performance.

O 34.2 Tue 10:45 HSZ/0204

Machine-learning Driven Approach of Surface Adsorption Energy Prediction — •Karlo Sovic and Johannes Margraf — University Bayreuth, Bayreuth, Germany

Heterogeneous catalysis is a cornerstone technology across industrial chemistry, materials science, and environmental engineering, effectively promoting and redirecting key chemical reactions in various applications. In these processes, control of surface adsorption energies is paramount for designing efficient catalysts. However, in the case of large adsorbates, the high computational cost of accurate DFT calculations limits comprehensive exploration of the corresponding potential energy surface. Machine-learning interatomic potentials offer a promising solution to this challenge. Leveraging recently reported pre-trained models, the complex interactions crucial for accurate surface chemistry can be captured with effectively via fine-tuning.

Here, a data-efficient workflow for describing the glycerol hydrodeoxygenation mechanisms leading to propanediols on M(111) and M(211) surfaces (M=Pt, Cu, Ni) is reported. With our approach, the fine-tuned model yields high-fidelity adsorption energies with near-DFT accuracy at low computational cost. Furthermore, analysis of thermodynamic properties was carried out to accurately determine the overall Gibbs free energetics of investigated reaction pathways. Based on these comprehensive insights, we propose a versatile work-

flow for the accelerated screening of catalytic systems, enabling the rapid construction of adsorption energy databases and exploring relevant reaction mechanisms.

O 34.3 Tue 11:00 HSZ/0204

Modeling Solvothermal Reactions at Surfaces with Machine Learning Interatomic Potentials — •Maciej Baradyn[1], Nils Gönnheimer[1,2], and Johannes T. Margraf[1] — [1]University of Bayreuth, Bayreuth, Germany — [2]Fritz-Haber Institute, Berlin, Germany

Dynamical processes such as adsorption, desorption and diffusion are vital elementary reactions involved in heterogeneous catalytic reactions. In solvothermal reactions, the presence of solvent molecules has significant effects on the dynamics of the adsorbates, which must displace hydration layers to diffuse or adsorb on the surface and undergo resolvation during desorption. The presence of solvent molecules also affects the interactions between surfaces and adsorbates, and can contribute to the (de-)stabilization of the adsorbed species.

In this contribution, we explore the robustness of machine learning potentials based on the MACE-MP-0 foundation model for describing dynamical processes under these conditions. This is demonstrated on a representative system of a glycerol molecule interacting with the Cu(111) surface in explicit water. Enhanced sampling methods are used to compute free energy profiles of the studied processes, and to reflect the experimental reaction conditions under which they occur in industrial applications.

O 34.4 Tue 11:15 HSZ/0204

Converting MoS_2 to MoO_2 by Thermal Treatment Under Dilute O_2 — •Armin Sahinovic[1], Jixi Zhang[2], Osamah Kharsah[1], Marika Schleberger[1], Rossitza Pentcheva[1], and Rodney Smith[2] — [1]Department of Physics and Center for Nanointegration, University of Duisburg-Essen, 47057 Duisburg, Germany — [2]Department of Chemistry, University of Waterloo, ON N2L 3G1 Waterloo, Canada

The reaction of MoS_2 with O_2 at elevated temperatures introduces the risk of structural and functional degradation that decrease the lifespan of MoS_2-based devices [1]. In experiment, variable-temperature Raman measurements indicate that depending on the O_2 concentration in the environment the MoS_2 is converted into either MoO_3 or MoO_2. To elucidate the specific mechanism of this reaction, density functional theory (DFT) calculations were performed including the van der Walls dispersion correction. We show that the S-vacancy formation energy as well as O substitution energy are lowered with increasing O content. DFT calculations show that at high O contents in $MoS_{2-x}O_x$ the $P2_1/c$ phase is energetically preferred over the 2H-MoS_2 structure. A *P-T* phase diagram of the Gibbs free energy obtained from DFT shows that the partial O pressure tunes whether MoO_3 or MoO_2 is the dominant product of the reaction. We explored the band structure of multiple vacancies in MoS_2 and find additional in-gap states compared to the monovacancy. Our results offer insight into the conditions that control the degradation of MoS_2-based devices.

O 34.5 Tue 11:30 HSZ/0204

2D TiS2 Nanoparticles in reductive and oxidative Atmospheres as Model (Photo-)Catalysts — •Niko Kruse[1], Justin Klimek[1], Aaron von Seggern[1], Martin Hedevang[2], Sergi Camposs Jara[2], Jeppe Vang Lauritsen[2], and Lars Morhusen[1] — [1]Carl von Ossietzky Universität Oldenburg, Oldenburg, Germany — [2]iNano Center, Aarhus University, Aarhus, Denmark

Sustainable materials for the thermal and photochemical utilization of (waste) carbon dioxide (CCU) become more and more demanded.[1] Titanium-based 2D materials such as TiS2 can directly harvest sunlight and have demonstrated high CO2 conversion activity.[2] To illuminate atomistic structure-property relationships of such catalytic systems, we present a model system consisting of 2D TiS2 nanoparticles on Au(111) and TiO2 (110) surfaces, rendering it suitable for atomic-level microscopy and spectroscopy. A direct synthesis route was developed by Ti metal evaporation in the presence of benign organic S precursors.[3] The resulting materials were characterized by combined STM, XPS, and NEXAFS experiments, along with DFT calculations.[4] We demonstrate the substrate-dependent structure and compositional detail of the nanoparticles and highlight the chemical potential of S as the relevant shape descriptor. In addition, the surface chemistry of 2D TiS2 nanoparticles in reactive atmospheres will be presented, highlighting the strong stability even in oxidative & reductive conditions. [1] R. Guil-López, N. M. et al., Materials 2019, 12. 3902. [2] A. Aljabour, et al, ACS Catal. 2020, 10, 66. [3] F. Besenbacher et al., J. Catal. 2021, 403, 4. [4] N. Kruse et al., Small 2025, 21, e06023.

O 34.6 Tue 11:45 HSZ/0204

In situ X-ray Imaging of PtPd Core-Shell Nanoparticles under Methane Oxidation Conditions — •Lydia J. Bachmann[1,2], Thomas F. Keller[1,2], Ivan A. Vartanyants[1], and Andreas Stierle[1,2] — [1]Deutsches Elektronen-Synchrotron DESY — [2]University of Hamburg

Due to the high global warming potential of methane, the release of any methane into the atmosphere needs to be avoided. Therefore, catalysts are used for the emission control. Common catalyst nanoparticles (NPs) for methane oxidation consist of Pd or Pt. Combining them allows to build more stable NPs. Since the surface chemical composition is crucial for the activity, segregation and mixing processes need to be taken into account. In this study we successfully tuned the initial chemical composition of one core-shell and one partially alloyed NP. We confirmed these elemental distribution by Bragg coherent diffraction imaging (BCDI). During in situ BCDI measurements under methane oxidation at temperatures between 320°C and 560°C, Pt segregated to the {111} oriented facets of the initial core-shell NP. Conversely, the initially partially alloyed NP did not exhibit such facet-dependent segregation, but rather observed the formation of a Pd core, Pt shell structure at 680°C. Since the initial Pt core, Pd shell NP showed Pd-Pt mixing at 620°C, we hypothesize that this NP would form such an inverted core-shell structure under higher temperatures as well. These results demonstrate opportunities for systematically investigating promising core-shell NPs and their catalytic activity, offering valuable insights for the design of advanced catalysts.

O 34.7 Tue 12:00 HSZ/0204

The mechanism and Rate-Determining Step of Catalytic Ammonia Oxidation on Pd(332) at High Temperatures — •Jan Fingerhut[1], Jessalyn DeVine[2], Rongrong Yin[3], Mark Bernard[2], Alice Bremer[4], Dmitriy Borodin[2], Kai Golibrzuch[2], Theofanis Kitsopoulos[5], Daniel Auerbach[2], Hua Guo[3], and Alec Wodtke[2] — [1]Leiden Institute of Chemistry, Leiden, the Netherlands — [2]Max-Planck-Institute for Multidisciplinary Science, Göttingen, Germany — [3]University of New Mexico, Albuquerque, USA — [4]Georg-August-Universität, Göttingen, Germany — [5]University of Southern Mississippi

Despite its immense practical importance in industrial production of nitric acid, the mechanisms of catalytic ammonia oxidation on platinum group metals remain controversial. In this work, we employ velocity-resolved kinetics to study ammonia oxidation on a model Pd(332) catalyst between 600 and 700 K. We obtain the temporal evolution of gas-phase reactants (NH_3), products (NO, H_2O) and - with the help of femtosecond laser-induced desorption - of a reaction intermediate, N^*. The reaction exhibits the prompt appearance of H_2O and the delayed formation of NO; the rate-determining step is the reaction $N^* + O^* \rightarrow N^*O$ occurring at step sites. This means that N^* is the longest-lived reaction intermediate, an insight that helps explain formation of byproducts like N_2 and N_2O. We present a mechanism that explains all experimental observations, based on transition-state theory calculations and using input from density functional theory. We also show that N^*O desorption is accelerated by coadsorbed oxygen.

O 34.8 Tue 12:15 HSZ/0204

Promoting Role of Isolated Surface Hydroxyls on Selective Dehydrogenation of 2-Propanol over Co3O4 Catalyst — •Jan Smyczek[1], Patrick Hubert[1], Hauke Scheele[2], Carsten Schröder[1], Sharif Najafishirtari[2], Paul Kohlmorgen[1], Malte Behrens[2], and Swetlana Schauermann[1] — [1]Institute of Physical Chemistry, Christian-Albrechts-University Kiel, Max-Eyth-Str. 1, 24118 Kiel, Germany — [2]Institute of Inorganic Chemistry, Christian-Albrechts-University Kiel, Max-Eyth-Str. 2, 24118 Kiel, Germany

This study investigates the catalytic decomposition of 2-propanol to acetone over Co_3O_4 catalysts, examining both powdered materials under ambient pressure and model Co_3O_4(111) surfaces in ultrahigh vacuum. Water pretreatment at elevated temperatures substantially enhanced acetone formation rates. Scanning tunneling microscopy and infrared spectroscopy revealed that high-temperature water pretreatment creates isolated hydroxyl groups (O_sH) involving lattice oxygen atoms, whereas low-temperature deposition forms an extended, partly dissociated OH/H_2O network layer. The role of isolated O_sH groups can most likely be attributed to their function as hydrogen acceptors for H atoms leaving from either 2-propanol or the propoxy intermediate. Critically, dissociation occurs only with isolated O_sH species, not within the extended OH/H_2O network, which nearly completely suppresses both abstraction steps. The isolated O_sH groups function as efficient hydrogen acceptors, proving substantially more effective than adsorbate-free lattice oxygen.

O 35: Organic molecules on inorganic substrates: Adsorption and growth II

Time: Tuesday 10:30–12:15 Location: HSZ/0401

O 35.1 Tue 10:30 HSZ/0401

Phophangulenes on Au(111): comparing the influence of the environment on single molecule rotation — •Wyatt Highland[1], Sajjan Mohammad[1], Paul Philip Schmidt[1], Roberto Robles[2], Milan Kivala[3], Nicolas Lorente[2], Meike Stöhr[1,4], and Sabine Maier[1] — [1]Department Physik, FAU Erlangen-Nürnberg, Erlangen, Germany — [2]CFM/MPC (CSIC-UPV/EHU), Donostia-San Sebastian, Spain — [3]Institute of Organic Chemistry, Heidelberg University, Heidelberg, Germany — [4]University of Applied Sciences of the Grisons, Switzerland

Bowl-shaped phosphangulenes represent a promising class of rotor molecules for molecular energy-storage applications on surfaces, owing to their fixed rotational axis defined by the central phosphorus atom, which simultaneously serves as the anchoring group on gold substrates. For low coverge, the phosphangulenes stay isolated on Au(111). We examined their adsorption configurations and subsequently, the possibility for rotational motion using both the STM tip and thermal activation as external triggers. At higher coverage, phosphangulenes form compact self-assemblies that suppress their rotational motion. To overcome this, we employ porous, hydrogen-bonded trimesic-acid networks to isolate individual phosphangulenes at the surface. Comparing their rotational dynamics inside and outside the pores allowed to directly reveal the influence of the immediate surroundings on the rotational motion.

O 35.2 Tue 10:45 HSZ/0401

Self-assembly and electronic properties of functionalized norbornadiene photoswitches on Au(111) and graphene/Ir(111) — •Shreya Garg[1], Roberto Robles[2], Pedro Ferreira[3], Kasper Moth-Poulsen[3], Nicolas Lorente[2], Meike Stöhr[1,4], and Sabine Maier[1] — [1]Department of Physics, Friedrich Alexander University Erlangen-Nürnberg, Germany — [2]Centro de Física de Materiales CFM/MPC (CSIC-UPV/EHU), Donostia-San Sebastián 20018, Spain, SanSebastián, Spain — [3]Universitat Politecnica de Catalunya, Barcelona, CT, Spain — [4]University of Applied Sciences of the Grisons, Switzerland

The norbornadiene/quadricyclane (NBD/QC) system represents a notable class of photoswitches, in which the low-energy NBD isomer can be transformed into its metastable QC isomer upon exposure to external energy. Here, we investigate the self-assembly and electronic properties of a benzoic acid-functionalized NBD on Au(111) using STM, STS, and DFT. Two distinct adsorption conformations are identified; nevertheless, the overall structure of the self-assembled layers remains governed by hydrogen bonding between the carboxyl groups. To further elucidate molecule-substrate coupling effects, we examined NBD derivatives on graphene/Ir(111), which offers a reduced density of states near the molecular levels, thereby providing partial electronic decoupling. This approach revealed differences in electronic properties compared to Au(111), emphasizing the critical influence of the substrate and contributing to the optimization of their switching performance in future electronic systems.

O 35.3 Tue 11:00 HSZ/0401

Validation of the Rotational Degrees of Freedom in Azobenzene Subphthalocyanine — •Dominik Volavka[1], Wyatt Highland[1], Bartosz Szczefanowicz[1], Rebecci Samuele[1], Roberto Robles[2], Nicolas Lorente[2], Meike Stöhr[1,3], and Sabine Maier[1] — [1]Department of Physics, Friedrich-Alexander Universität Erlangen-Nürnberg, Germany — [2]Centro de Física de Materiales (CSIC-UPV/EHU), Donostia-San Sebastián, Spain — [3]University of Applied Sciences of the Grisons, Switzerland

Azobenzene mounted on Subphthalocyanine (Azo-SubPC) via a single covalent oxygen bond is predicted to exhibit interesting rotational and switching properties due to the single bonding character of the boron-oxygen-carbon. Recent attempts at observing these rotational actions through scanning tunneling microscopy were hindered because of the self-assembling nature of Azo-SubPC when deposited on Au(111) and Ag(111). In each case, one-dimensional arrangements of Azo-SubPC formed, wherein molecules were neighbored by additional Azo-SubPC molecules on both sides. The resulting configuration of the molecules thusly led to a high steric hindrance and ultimate restriction of Azo-SubPC's anticipated rotational degree of freedom. Alternative preparation methods of Azo-SubPC are herein proposed and evaluated in the attempt of depositing and identifying isolated Azo-SubPC molecules with preserved rotational freedom. Isolated Azo-SubPC molecules can give insight into the underlying principles dictating the mechanisms of rotation in rotor molecules.

O 35.4 Tue 11:15 HSZ/0401

TPD/R Investigations of Metal-Substrate Interactions of Polyfluorinated Molecules on Au(111) — •Stefan R. Kachel, Evelyn Versok, Leonard Neuhaus, Kassandra Zoltner, and J. Michael Gottfried — Fachbereich Chemie und mar.quest, Philipps-Universität Marburg, Germany.

Interfaces between organic molecules and metal surfaces are crucial in heterogeneous catalysis, organic electronics, and related nanotechnological and sensing applications. Molecules with large dipole moments are particularly relevant, as dipole enhancement through tailored fluorination can strongly influence adsorption geometries, adsorbate-substrate interactions, and thus the electronic properties of molecule-metal interfaces. Among nonionic, saturated compounds, all-cis-hexafluorocyclohexane (HFCH) exhibits the highest known polarity (μ = 6.2 D). Here, we use temperature-programmed desorption and reaction (TPD/R) to investigate the desorption kinetics and energetics of HFCH and two reference compounds, perfluoromethylcyclohexane and cyclohexane, on Au(111). The polar HFCH shows markedly stronger interactions with the substrate than the two reference compounds, and all systems display desorption behavior that deviates substantially from structurally related aromatic species. The pronounced polarity and stacked packing motif of HFCH render it a promising model system for studies in supramolecular chemistry and organic materials research, including potential applications in organic ion-conducting materials.

O 35.5 Tue 11:30 HSZ/0401

TPD Studies on LOHC-relevant Cycloalkanes and Aromatics on Au(111) — •Kassandra Zoltner, Leonard Neuhaus, Stefan R. Kachel, and J. Michael Gottfried — Fachbereich Chemie and mar.quest, Philipps-Universität Marburg, Germany

Liquid organic hydrogen carriers (LOHCs), such as the decalin/tetralin pair, are promising compounds for hydrogen storage, yet their (de)hydrogenation cycles are limited by catalyst-induced side reactions. In this context, molecule–surface interactions fundamentally determine adsorption strength and reactivity, thereby controlling catalytic selectivity and activity. This work presents surface analytical studies using temperature-programmed desorption (TPD) to investigate the desorption kinetics and energetics of decalin, perhydroazulene, and (partially) dehydrogenated analogues on Au(111). The study focuses on how the degree of hydrogenation, structural motifs including ring connectivity, and configurational isomerism as well as electronic properties influence substrate and intermolecular interaction strengths. The results reveal distinct differences in desorption characteristics: aromatic molecules (naphthalene, azulene, tetralin) exhibit stronger adsorption to the metal substrate and repulsive intermolecular interactions, arising from their π-electron system, whereas saturated hydrocarbons (decalin, perhydroazulene) show weaker substrate binding and intermolecular attraction. The findings provide molecular-level insights into LOHC adsorption properties on metal surfaces and contribute to the development of improved hydrogen storage–catalysis systems.

O 35.6 Tue 11:45 HSZ/0401

MAD-SURF: a general Machine-Learning Potential for molecular adsorption on metal surfaces — •Manuel González Lastre[1], Joakim S. Jestilä[2], Rubén Pérez[1], and Adam S. Foster[2] — [1]Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, E-28049 Spain — [2]Department of Applied Physics, Aalto University, 00076, Espoo, Finland.

Predicting how organic molecules adsorb, assemble and interact on metal surfaces is central to surface chemistry, molecular electronics and scanning probe microscopy. Yet, the application of first-principles simulations to interfaces is hampered by the computational cost for evaluating the electronic structure for the large number of atoms typically involved. Here we present MAD-SURF, a general Machine-Learning Interatomic Potential tailored for molecular adsorption on metal surfaces. Trained on a broad dataset spanning diverse molecules, adsorption motifs, surfaces, molecular dynamics and non-covalent aggregates, MAD-SURF achieves near quantum-mechanical accuracy while enabling simulations that are orders of magnitude faster than Density Functional Theory. The model reliably reproduces energies, forces and adsorption geometries across different surfaces. We demonstrate its versatility by capturing experimentally observed systems, ranging from organic monolayers and polycyclic aggregates to flexible biomolecules and long-range metal surface reconstructions. By combining accuracy, speed, and generalizability, MAD-SURF offers a practical framework for accelerating atomistic simulations in surface science.

O 35.7 Tue 12:00 HSZ/0401

Using Machine Learning to predict molecular conformations from STM images — •Tim J. Seifert[1], Dhaneesh Kumar[2], Stephan Rauschenbach[3], Klaus Kern[2], Markus Etzkorn[1,4], Kelvin Anggara[2], and Uta Schlickum[1,4] — [1]Institute of Applied Physics, TU Braunschweig, Braunschweig — [2]Max Planck Institute for Solid State Research, Stuttgart — [3]Department of Chemistry, Kavli Institute for Nanoscience Discovery, University of Oxford, Oxford, United Kingdom — [4]Laboratory for Emerging Nanometrology LENA, Braunschweig

Single-molecule imaging of biologically essential building blocks such as saccharides and peptides by scanning tunneling microscopy (STM) holds immense promise, enabling key insights into their structure and biological functions. However, automatic structural analysis remains bottlenecked by the lack of

available experimental training data. We overcome this fundamental limitation through a novel workflow that rapidly generates vast datasets of high-fidelity synthetic STM images from geometric molecular models. We train a custom Machine Learning architecture on this synthetic data to predict atomic coordinates directly from STM images, enabling fully automated reconstruction of molecular conformations. Validated on two distinct organic systems - glycans and polypeptides - the method achieves atomic positional accuracies below 4 Å and 2 Å, respectively, with unsupervised conformer classification of polypeptides exceeding 97% accuracy. The trained models transfer robustly to experimental STM data, delivering visually convincing structural predictions.

O 36: Focus Session: Mineral-water interfaces II

The Focus Session discusses recent advances in the understanding of mineral-water interfaces. These interfaces are ubiquitous in nature, host of many geological and biological processes, intimately linked to the global carbon cycle, and therefore highly relevant for Earth*s climate. For example, silicate weathering removes carbon dioxide from the atmosphere on geological timescales, acting as a stabilizing feedback mechanism since weathering rates increase with temperature. In the oceans, carbonates dissolve and precipitate in response to changing atmospheric carbon dioxide concentrations, thus far mitigating part of the anthropogenic impact of CO_2 emissions. In addition, numerous industrial and technological processes involve mineral-water interfaces, including seawater desalination, scaling and incrustation prevention, as well as various biochemical applications. However, and despite their importance, many fundamental aspects of mineral-water interfaces remain poorly understood, including water binding and diffusion, structure formation, ice nucleation, growth, or desorption.

This DPG Focus Session will address these aspects at the molecular level, elucidating fundamental processes involving both single water molecules and bulk water in contact with mineral surfaces. The session brings together scientists investigating mineral-water systems under ultrahigh vacuum conditions as well as at mineral-water interfaces in bulk aqueous environments. We aim for a balanced Session with contribution from both renowned experts and young investigators active in the field.

Organized by Philipp Rahe (U Osnabrück), Angelika Kühnle (U Bielefeld), Jan Balajka (TU Vienna), Wolf Gero Schmidt (U Paderborn).

Time: Tuesday 10:30–12:30 Location: HSZ/0403

Invited Talk O 36.1 Tue 10:30 HSZ/0403

Acidity in nanoconfinement from ab initio and NNPs simulations — Anthony Baldo[2], Muhammad Saleh[1], Kevin Leung[2], and •Marialore Sulpizi[1] — [1]Department of Physics and Astronomy, Ruhr-University Bochum, Universitätsstraße 150, 44801 Bochum, Germany — [2]Geochemistry Department, Sandia National Laboratories, Albuquerque, New Mexico, USA

Chemical and physical properties in nanoconfined systems may substantially differ from bulk, a phenomenon that can be exploited for the development of new industrial processes for energy generation and storage. Here we consider the specific behavior of acids within silica nanopores, a topic of relevance to the geochemistry and the nanofluids communities.

Starting from ab initio molecular dynamics simulations we develop neural network potentials (NNPs) capable of describing the solid/liquid interfaces and the nanoconfined liquids* behavior over a wide range of temperatures. These NNPs can capture the change in acidity constants when e,g acetic acid is confined in nanoscale slit or when it approaches the interface. Our approach can be further extended to more complex geometries and solution compositions.

O 36.2 Tue 11:00 HSZ/0403

Ab initio exploration of water clusters on CaF_2 — •Isaac Azahel Ruiz Alvarado[1], Wolf Gero Schmidt[1], Paul Laubrock[2], Jonas Heggemann[2], and Philipp Rahe[2] — [1]Lehrstuhl für Theoretische Materialphysik, Universität Paderborn, Paderborn, Germany — [2]Institut für Physik, Universität Osnabrück, Osnabrück, Germany

The electronic and structural properties of the CaF_2(111) surface-water interface are investigated from first-principles calculations. The energetic landscape for single molecular adsorption is calculated using standard DFT with London dispersion forces corrections. Single water molecules are found to preferentially adsorb on surface Ca atoms while large diffusion energy barriers are determined that restrict lateral movement of the water molecules. Additionally, the adsorption energies for the intact water molecule are compared to dissociative adsorption.

Multiple water molecules are included in the calculations to simulate the ice-like clusters observed experimentally by high-resolution AFM data acquired with CO-terminated tips. In order to understand the formation of these clusters, hexagonal rings similar to the ice I_h motif are modeled on top of the CaF_2 surface slab. The ice-surface incommensurability coupled with large diffusion barriers and preferred adsorption sites is suspected to limit the formation of a closed water monolayer. Complete water overlayers and additional structures are also calculated using molecular dynamics aided by machine learning force fields trained from ab initio calculations.

O 36.3 Tue 11:15 HSZ/0403

Surface Structure of Polar Silver Iodide (0001) in Various Liquids: No Indication for a Surface Reconstruction — •Kim Noelle Dreier, Annamaria Latus, Ralf Bechstein, and Angelika Kühnle — Physical Chemistry I, Department of Chemistry, Bielefeld University, Universitätsstraße 25, 33615 Bielefeld, Germany

Silver iodide (AgI) has long been known as a material that induces precipitation in clouds. The superior ice nucleation ability is commonly explained by the close lattice match between β-AgI(0001) and the basal plane of ice. However, this surface is polar, indicating that a stabilization mechanism should be present. Here, we investigate the Ag-terminated β-AgI(0001) and the I-terminated β-AgI(000-1) surfaces in water and compare the results with images recorded in n-dodecane, 0.1 M NaCl and 0.1 M KI aqueous solutions. Strikingly, high-resolution images consistently reveal a bulk-truncated structure. These findings align with observations at a larger scale, which neither indicate any surface reconstruction. Although the observed structures reveal a variety of features and depend on the surface termination, some general conclusions can be drawn. Firstly, in solvents with poor AgI solubility, only minor changes are observed. Secondly, the images taken in KI solution exhibit patterns that are characteristic of mineral dissolution and growth. Thus, even in a situation where AgI can and does dissolve, no indication for a surface reconstruction can be found. These results shed new light onto the surface structure of β-AgI(0001), challenging the expectation that a surface reconstruction is present under ambient conditions.

Invited Talk O 36.4 Tue 11:30 HSZ/0403

Living Interfaces: Dissolution and Precipitation Processes at Mineral-Brine Interfaces Revealed by AFM — •Igor Siretanu, Vincenzo Alagia, Saravana Kumar, Shilpa Mohanakumar, Max Nederstigt, Chinmay Shukla, Michel Duits, and Frieder Mugele — Physics of Complex Fluids Group and MESA+ Institute, Faculty of Science and Technology, University of Twente, P.O. Box 217, 7500 AE Enschede, The Netherlands

Mineral-brine interfaces are dynamic systems where dissolution and precipitation govern reactivity and morphology. Using in-situ Atomic Force Microscopy (AFM), we examine olivine ([Mg,Fe]2SiO4) and calcite. Olivine, a candidate for carbon mineralization, shows etch-pit-mediated surface retraction with morphology strongly dependent on solution chemistry. In H2SO4, pits are larger and deeper than in HCl, while oxalic acid induces anisotropic complexation, forming rectangular pits and stepped terraces aligned with crystallographic directions. These changes accelerate step retreat and Mg release, offering mechanistic insight into dissolution kinetics relevant for CO2 sequestration. At calcite-water interfaces near equilibrium, AFM force spectroscopy reveals two regimes: (A) DLVO-type forces with low surface potentials (<5 mV) and (B) long-range viscoelastic repulsion from a soft interfacial layer formed by coupled dissolution-precipitation. This dynamic interphase explains inconsistencies in reported

surface forces and highlights how solution composition, crystallography, and transient phases control mineral reactivity, with implications for geochemistry, biomineralization, and carbon capture.

O 36.5 Tue 12:00 HSZ/0403

Water Organization and Speciation at the Calcite (10.4)-Water Interface at High pH — •Tobias Dickbreder[1], Frank Heberling[2], and Ellen H. G. Backus[1] — [1]Institute of Physical Chemistry, Faculty of Chemistry, University of Vienna, Vienna, Austria. — [2]Institute for Nuclear Waste Disposal, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany

Calcite dissolution and precipitation are central for various environmental processes including the geological carbonate-silicate cycle, buffering of sea- and freshwater pH values and biomineralization. Since these processes take place at the calcite-water interface, the structure and properties of the interface between water and the most stable calcite (10.4) surface have been well studied. Despite this effort the protonation state of surface-bound water and interfacial carbonate groups remains poorly understood, because dissolution and carbonate buffering complicate studying calcite de-/protonation experimentally.

Here, we apply vibrational sum frequency generation (SFG) spectroscopy to directly assess the water species present at the calcite-water interface. As reported previously, the SFG spectrum at neutral pH is almost featureless due to the opposite orientation of the first two water layers [1]. At very high pH, however, we observe the emergence of spectral features suggesting surface charging and the presence of interfacial hydroxyl groups. Our study, thus, confirms the presence of hydroxyl groups at the calcite-water interface, facilitating the development of more-accurate models of the calcite-water interface.

O 36.6 Tue 12:15 HSZ/0403

The mechanism of selenite incorporation into the calcite surface revealed by atomic-scale imaging — •Marie Luigs, Ralf Bechstein, and Angelika Kühnle — University of Bielefeld, Bielefeld, Germany

Selenium is an essential trace element for human health. However, the margin between its required and toxic intake is very narrow, making its distribution in soils and waters an important subject of research. Moreover, the interaction between the nuclear waste component 79Se and minerals in the Earth's crust is relevant for the selection of nuclear waste disposal sites. Selenium in the form of selenite can be incorporated into the mineral calcite by substituting for carbonate ions. However, the mechanism of selenite incorporation into calcite remains unknown. Here we demonstrate that selenite incorporation occurs at step edges during calcite crystal growth. Atomic-scale atomic force microscopy (AFM) images of the calcite surface exposed to a selenite-rich calcium carbonate growth solution shows that calcite layers grown in the presence of selenite displayed a significantly higher defect density than layers that were exposed to selenite only after their formation. These observations indicate that significant selenite incorporation into calcite, reflected by an increased defect density, does not occur via ion exchange on terraces but via step edge growth. Our results give further insights into the conditions required for selenite incorporation into calcite and present the first atomic-scale AFM images of a selenite-rich calcite surface.

O 37: Electronic structure theory I

Invited Talk O 37.1 Tue 10:30 TRE/PHYS

Calculations of excited electronic states by converging on saddle points on the electronic energy surface — •Hannes Jonsson — University of Iceland, Reykjavik, Iceland

Calculations of excited electronic states are important in various contexts, e.g. photocatalysis and molecular motors. They are challenging as commonly used optimization methods are based on minimization and thereby converge on the ground state. A time-dependent formulation of density functional theory (TD-DFT), especially within the linear response and adiabatic approximations, is therefore often used to estimate excited states, but can fail especially when significant charge transfer occurs and when states are close in energy. Alternatively, by converging on a saddle point on the electronic energy surface, the orbitals can be optimised for an excited state to provide a solution of the underlying Kohn-Sham equations with higher energy than the ground state. This turns out to a give more robust estimate of the excitation energy than TD-DFT with computational effort similar to that of a ground state calculation. Several applications of this approach with commonly used density functionals will be presented, as well as calculations using a self-interaction corrected functional giving improved results. In particular, excited states involving twisting of a C=C bond, e.g. in molecular motors, and Rydberg states have been analysed. As a solid state application, the various states involved in the optical preparation of a pure spin state in nitrogen/vacancy defect in diamond will be presented. The results show close agreement with more computationally demanding calculations as well as experiments.

O 37.2 Tue 11:00 TRE/PHYS

Probing quantum coherence with free electrons — •Hebrew Crispin and Nahid Talebi — Christian-Albrechts-Universität, Kiel, Germany

Advances in ultrafast electron microscopy have enabled the study of coherent interactions between free electrons and quantum systems with high spatial resolution. Recent works have examined the coupling of free electrons to two-level systems, including the use of coherently shaped electron wavefunctions to probe coherence in individual or collective quantum emitters. Coherence can also be accessed through sequential time-resolved cathodoluminescence spectroscopy, which has demonstrated the ability to measure ultrafast radiative decay and dephasing in single emitters with femtosecond resolution. In addition, there is increasing interest in time-resolved electron energy-loss spectroscopy (EELS) techniques capable of tracking system dynamics.

Here, we present a general theoretical framework for coherent interactions between free electrons and quantum emitters prepared in arbitrary initial superposition states. We employ a fully quantum, time-dependent description of both the propagating electron wavepacket and the emitter. Quantum coherence manifests as transient oscillations in both the emitter populations and in the zero-loss peak of the spectral energy-loss probability density, even for an unmodulated electron wavepacket. Our work reveals novel coherent dynamics in the interactions between free electrons and quantum systems.

O 37.3 Tue 11:15 TRE/PHYS

Phonons in polar materials: a DFPT extension in the FLAPW method *FLEUR* — •Friedrich Hanrath[1,2], Thomas Bornhake[1,2], Gustav Bihlmayer[1], Gregor Michalicek[1], Daniel Wortmann[1], and Stefan Blügel[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany — [2]Institute for Theoretical Physics, RWTH Aachen University, D-52074 Aachen, Germany

Phonons play a pivotal role in determining many essential properties of solids. Using Density Functional Perturbation Theory (DFPT), a state-of-the-art approach for computing fundamental physical response properties from first principles, phonon calculations have previously been realized [1] within the full-potential linearized augmented plane-wave (FLAPW) method *FLEUR* [2]. In polar materials, zone-center vibrations are altered by their interaction with long-range electric fields, giving rise to the characteristic LO-TO splitting in the long-wavelength limit. In this talk, we present the extension of the DFPT framework in *FLEUR* to a macroscopic electric-field perturbation, enabling the calculation of high-frequency dielectric tensors and Born effective charges, quantities required to describe LO-TO splitting, and compare our results with experiments. This work was supported by the CoE-MaX (EuroHPC Joint Undertaking, Grant 101093374) and DFG through CRC 1238 (Project C01).

Invited Talk O 37.4 Tue 11:30 TRE/PHYS

Many-Body Theory meets Electrochemistry: Electronic Structure of Cathode Materials — •Silke Biermann — Centre de Physique Théorique, UMR7644, Ecole Polytechnique, Institut Polytechnique de Paris, 91128 Palaiseau, France

Progress in dynamical mean field-based electronic structure methods over the last years has provided us with precious tools allowing for a microscopic understanding of electronic mechanisms at work in correlated materials, including functional materials. In this talk, we will focus on layered transition metal compounds studied for battery applications. Analysing the electronic structure, energetics and intercalation voltage, we find that Hund's exchange coupling plays a crucial role for the electrochemistry of these compounds. We identify the battery charging process as a transition from a high-spin Mott insulator to a low-spin correlated metal. We argue that a deeper understanding of the microscopic mechanisms at work in such materials might contribute to paving the way to better battery materials in the future.

O 37.5 Tue 12:00 TRE/PHYS

Massively parallel and GPU-accelerated evaluation of three-center integrals for numerical atomic orbitals (NAOs) — •Moritz Leucke, Antonio F. Delesma, and Dorothea Golze — Julius-Maximilians-Universität Würzburg, Germany

Four-center electron repulsion integrals appear in many electronic structure methods, such as many-body perturbation methods like the Random-Phase-Approximation or GW and others. To reduce their computational cost, the

resolution-of-the-identity (RI) approximation is commonly employed. RI refactors the four-center integrals into three- and two-center integrals, among which the three-center integrals remain a computational bottleneck, particularly when using NAOs.

We present a global RI scheme combined with a local metric (attenuated Coulomb) within an all-electron NAO framework, treating molecules and solids on equal footing. Central to the approach is a novel GPU-accelerated algorithm for computing 3-center integrals that relies on domain decomposition to improve load balancing and strong scaling.

We demonstrate that our RI implementation achieves linear scaling with system size and maintains meV-level accuracy for GW energies. Performance benchmarks show scalability across thousands of CPU cores and substantial speedups with GPU support.

O 37.6 Tue 12:15 TRE/PHYS

Efficient all-electron implementation of the Bethe-Salpeter method using crystal symmetries — Jörn Stöhler, Stefan Blügel, and •Christoph Friedrich — Peter Grünberg Institut, Forschungszentrum Jülich, 52425 Jülich, Germany

We describe an implementation of the Bethe-Salpeter equation (BSE) method in the full-potential linearized augmented-plane-wave (FLAPW) method. As in most implementations, the BSE is solved by the diagonalization of a two-particle Hamiltonian matrix, whose dimension is proportional to the number of **k** points. Due to the large number of **k** points required to converge the spectra, the resulting matrix becomes large even for small unit cells. We describe a method that exploits the crystal symmetries to accelerate the construction and diagonalization of the two-particle Hamiltonian. In particular, we employ group theoretical tools to bring the Hamiltonian into block-diagonal form. It is shown that, in many cases, only one of the blocks needs to be taken into account, which leads to a considerable speedup of the diagonalization step. In the case of Si, for example, the dimension of the Hamiltonian is reduced by a factor of five, giving rise to a speedup factor of 125 in its diagonalization. The optical absorption spectrum calculated with a 60×60×60 **k** mesh is very close to the experimental spectrum. The code allows for the inclusion of spin-orbit coupling and is parallelized with the possibility of storing the Hamiltonian in distributed memory over many nodes. We also show results for LiF and the MoS_2 monolayer.

O 38: Ultrafast electron dynamics at surface and interfaces II

O 38.1 Tue 10:30 TRE/MATH

Ultrafast momentum microscopy of exciton dynamics at ZnO surfaces — •Hashima Marukara, Paul Werner, Jan Philipp Bange, G S Matthijs Jansen, Wiebke Bennecke, Junde Liu, and Stefan Mathias — Georg-August-Universität Göttingen, I. Physikalisches Institut, Germany

ZnO is a prototypical wide-band-gap material with long-lived excitons, making it a central platform for modern optoelectronic and catalytic technologies, especially for investigating exciton-related phenomena [1]. Excitons*bound electron*hole pairs that can exist in various forms near the surface, significantly shape the material*s optical and electronic response and play an essential role in interfacial energy-conversion processes [2]. However, studies that directly characterize these excitons, particularly if they are defect-mediated, localized or mobile, or predominantly Frenkel- or Wannier-type, remain limited.

Here we address these questions using time-resolved momentum microscopy to map the fingerprints of excitons in energy, momentum and time [3]. We present first experimental momentum-space maps of the ZnO(10-10) surface exciton states and track their real-time evolution following photoexcitation. We observe clear signatures of surface exciton formation, including their emergence in the unoccupied band structure and their subsequent relaxation dynamics on ultrafast timescales.

O 38.2 Tue 10:45 TRE/MATH

Investigating the light-induced metallization of ZnO through time-resolved photoemission spectroscopy — Gian Marco Pierantozzi[1], Federico Motti[1], Matteo Gatti[2], •Monika Schied[1], Alice Crosato[3], Thomas Sartori[3], Riccardo Cucini[1], Giorgio Rossi[1,4], Fausto Sirotti[2], and Giancarlo Panaccione[1] — [1]CNR – Istituto Officina dei Materiali (IOM), Trieste, Italy — [2]École polytechnique, Paris, France — [3]Università Ca' Foscari Venezia, Italy — [4]Università degli Studi di Milano, Italy

With a direct bandgap of ~3.4 eV and a high exciton binding energy (~60 meV), ZnO is ideal for optoelectronics and excitonic studies. Under optical excitation, the system shows ultrafast metallization with several relaxation timescales [1,2]. The relevance of defects in stabilizing the photoinduced metallic state is known, but many aspects of the processes remain unclear. Here we investigate the ultrafast dynamics of the optically populated conduction band and the Zn 3d core level with time- and angle-resolved photoemission spectroscopy after resonantly pumping, in order to disentangle the excitations of defect levels. Our experiments cover the whole metallization process in ZnO. We observe a fast rise in the conduction band population within 100 fs, a slower temperature-dependent rise, probably due to carrier transport and redistribution, a decay on the ns timescale and a long-lasting metastable state. All these dynamics occur also pumping below resonance, albeit to a lower extent, highlighting the role of the defect levels.

O 38.3 Tue 11:00 TRE/MATH

Ultrafast electron dynamics in charge-transfer insulators $LaFeO_3$(001) and $BiFeO_3$(001) — •Friederike Wührl, Antonia Rieche, Anne Oelschläger, Kathrin Dörr, and Wolf Widdra — MLU Halle-Wittenberg

The electron dynamics in strongly correlated systems, where electron-electron correlation leads to band gap opening, are highly unexplored. One example is the prototypical charge transfer insulator NiO, which shows a remarkable short lifetime of <10 fs at the conduction band minimum, relaxing in a many-body in-gap state, which couples to the antiferromagnetic spin system [1]. Here we are extending our time-resolved studies to the unoccupied states of epitaxial antiferromagnetic $LaFeO_3$(001) and ferroelectric $BiFeO_3$(001) thin films grown on $SrRuO_3/DyScO_3$(001) substrates. We use two-photon photoemission in a UV-UV pump-probe experiment, exciting electrons across the band gap, which opens between strongly hybridized oxygen 2p/Fe 3d and Fe minority states for both perovskites. We find in both sytems a broad state at ~ 1.3 eV above E_F with a short lifetime of 20 fs, whereas the conduction band minimum shows a multiexponential decay with timescales in the femtosecond to picosecond range. The different decay channels show an energy dependent increase of lifetimes towards the Fermi level. Comparing $BiFeO_3$ and $LaFeO_3$, the decay channels differ solely in their amplitudes, with a higher probability for the fast decay channel in $LaFeO_3$.

O 38.4 Tue 11:15 TRE/MATH

Ultrafast Formation and Annihilation of Strongly Bound Anisotropic Excitons in CrSBr — •Lawson T. Lloyd[1], Tommaso Pincelli[1,2], Mohamed A. Wahada[1], Alessandro De Vita[1,2], Ferdinand Menzel[3], Kseniia Mosina[4], Túlio H. L. G. Castro[1], Alexander Neef[1,2], Andreas V. Stier[3], Nathan P. Wilson[3], Zdeněk Sofer[4], Jonathan J. Finley[3], Martin Wolf[1], Laurenz Rettig[1], and Ralph Ernstorfer[1,2] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — [2]Technische Universität Berlin, Berlin, Germany — [3]Technische Universität München, Garching, Germany — [4]University of Chemistry and Technology Prague, Prague, Czech Republic

Excitons dominate the optical response and determine the functionality of atomically thin semiconductors. In the van der Waals magnetic semiconductor CrSBr, strongly bound, anisotropic excitons couple to the underlying spin order, which could be leveraged in next-generation opto-spintronics. However, mechanisms of exciton formation, dissociation, and interaction with free carriers remain largely unexplored. Employing time- and angle-resolved photoemission spectroscopy, we probe the nature of the exciton in CrSBr by directly imaging the nonequilibrium electronic states, extracting fundamental properties of the excitonic wavefunction and revealing the driving mechanisms of exciton relaxation on ultrafast timescales. Notably, we observe an excitation-density-dependent interconversion between bound excitons and quasi-free carriers, indicating that many-body effects govern the excited state dynamics during the initial stages of relaxation.

O 38.5 Tue 11:30 TRE/MATH

Large relative delays for photoemission final states less than 1 eV apart — •Tillmann Schabbehard, Andreas Gebauer, Walter Enns, Luis Maschmann, and Walter Pfeiffer — Universität Bielefeld, Universitätsstr. 25, 33615 Bielefeld

The reconstruction of attosecond beating by interference of two-photon transitions (RABBITT) allows probing photoemission dynamics in atoms, molecules and solids. However, the interpretation of retrieved relative delays between different emission channels in particular for emission from solids is controversial.

Here we employ spin-orbit delays in GaSe by RABBITT, i.e., relative delays for emission from the different initial states of the spin-orbit doublet, to investigate the relative photoelectron kinetics in emission channels, which differ less than 1 eV in their final state energy (E_{final}). Despite the small spin-orbit splitting for both Ga3d and Se3d the extraction of relative delays for the two spin-orbit doublets yields 180±53 as and 94±45 as. These unexpectedly large delays can neither be attributed to intraatomic delay mechanisms nor to kinetic propagation effects in the final state continuum. This challenges common concepts about photoelectron emission dynamics, which predict much smaller delays for E_{final} differences below 1 eV. Notably, the Se3d spin-orbit delay in GaSe agrees well with those observed in Bi_2Se_3 and WSe_2 indicating a general high variability of emission dynamics as function of the E_{final}. Predictions based on the one step model, which take into account transport via propagating and evanescent states match observations much better, while modelling based on propagation effects in the final state alone fail.

O 38.6 Tue 11:45 TRE/MATH

Lightwave-driven flat bands in a van der Waals crystal — •Changhua Bao[1], Vincent Eggers[1], Manuel Meierhofer[1], Jakob Helml[1], Lasse Münster[1], Suguru Ito[2], Leon Machtl[1], Sarah Zajusch[2], Giacomo Inzani[1], Ludwig Wittmann[1], Marlene Liebich[1], Robert Wallauer[2], Ulrich Höfer[1,2], and Rupert Huber[1] — [1]Department of Physics, University of Regensburg, Regensburg, Germany — [2]Department of Physics, Philipps-University of Marburg, Marburg, Germany

Flat bands lead to an extremely high density of states and suppressed kinetic energy, thereby increasing electronic correlations and leading to intriguing light-matter interaction. Here, we reveal the band structure of the van der Waals crystal $NbOCl_2$ using photoelectron momentum microscopy. We directly map out an electronic band that is flat throughout the entire Brillouin zone and well isolated from both the conduction and remote valence bands. By utilizing subcycle photoemission spectroscopy [1,2], the dynamics of the flat band under atomically strong mid-infrared light fields are explored. Intriguingly, the carrier field of light induces long-lived collective modes, which are resolved with subcycle precision. These collective modes not only accelerate the electrons but also renormalize the energy of the flat band. We investigate the microscopic mechanisms of these dynamics, highlighting novel possibilities of flat bands in strong-field physics.

O 38.7 Tue 12:00 TRE/MATH

Spin-orbit entangled exciton formation in a 2D correlated semiconductor — •Tania Mukherjee[1,2], Lawson T. Lloyd[1], Alessandro De Vita[1,2], Martin Wolf[1], Laurenz Rettig[1], Ralph Ernstorfer[1,2], and Tommaso Pincelli[1,2] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — [2]Technische Universität Berlin, Berlin, Germany

Excitons govern the magneto-optical properties in spin-ordered 2D materials. $NiPS_3$, a layered antiferromagnetic semiconductor, has recently gained significant attention because of its unconventional excitonic behaviour. Previous literature suggests that excitons are composed of bound electron and holes pairs in a highly spin and orbitally entangled Zhang-Rice-singlet state, resulting in strong coupling with the underlying magnetic ordering.However, the microscopic mechanism that governs the exciton formation remains elusive and unexplored. Using time- and angle-resolved photoemission spectroscopy, we map the electronic structure and the excited state dynamics of $NiPS_3$ across the magnetic phase transition and, for the first time, observe directly the long-lived exciton footprint below the Néel temperature. This paves the way for exploring similarly complex excitonic behavior in other layered correlated materials.

O 38.8 Tue 12:15 TRE/MATH

Understanding resonantly enhanced light-induced superconductivity in K3C60 — •Michael A. Sentef[1,2], Juan I. Aranzadi[1], Paul Fadler[1], and Joseph Tindall[3] — [1]Institute for Theoretical Physics, University of Bremen — [2]Max Planck Institute for the Structure and Dynamics of Matter, Hamburg — [3]Center for Computational Quantum Physics, The Flatiron Institute, New York

Light-induced superconducting-like responses have been observed in K3C60 when driving with mid-infrared laser pulses [1], with a pronounced 10 THz resonance reported more recently [2]. Here we address the microscopic origin of this resonance. Using numerical calculations on finite clusters for a realistic multi-orbital model of K3C60 we simulate the effect of a periodic drive on the strongly correlated system. We find a sharp enhancement of pairing correlations when the drive frequency is tuned close to 10 THz, in agreement with experiment. The microscopic origin of this enhancement and its potential implications for a light-induced hidden phase [3] will be discussed. Our results thus provide a microscopic explanation for the resonantly enhanced light-induced superconducting-like state in K3C60 and strengthen its interpretation as being closely connected to superconducting pairing rather than to purely optical or nonthermal population effects.

O 39: Focus Session: Structure and Dynamics of Solvent at Electrochemical Interfaces I

Understanding how solvent molecules organize and move at electrochemical interfaces is central to catalysis, energy conversion, and electrochemical materials science. This Focus Session will bring together experimental and theoretical leaders using complementary surface specific spectroscopies as vibrational sum frequency generation, advanced X ray/electron techniques, and multiscale simulations to reveal intermolecular structure, hydrogen bond networks, ion-solvent coupling, and field driven dynamics from single crystal electrodes to complex battery interfaces. By highlighting recent breakthroughs in time-resolved measurements and operando platforms, the session aims to connect fundamental interfacial physics with macroscopic performance in electrocatalysis, corrosion, and electrochemical energy storage.

Organized by Yujin Tong (U Duisburg-Essen) and Angelika Kühnle (U Bielefeld).

Influence of Tip Apex Modification on Force Microscopy at the Solid-Liquid Interface — •Lucas Andreas Scheibel and Andrea Auer — Institute of Physical Chemistry, Innsbruck, Austria

Recent advances in electrochemical atomic force microscopy (EC-AFM) at the electrified solid-liquid interface using stiff, self-sensing quartz cantilevers (qPlus sensors [1]) have enabled high-resolution imaging of both electrode surfaces and interfacial solvent structures.[2,3] This interfacial region plays a decisive role in determining the performance of electrocatalysts, fuel cells, and electrochemical processes. In this work, we introduce chemically modified Si tips functionalized with charge-neutral hydrophobic or hydrophilic groups to identify how charge buildup at the tip apex influences the ability to resolve solvent structures and distinguish water from ion layering at the Au(111)-electrolyte interfaces across a range of pH values. These strategies provide new insight into atomic-scale contrast mechanisms of liquid AFM and highlight the role of tip-apex chemistry[2] in resolving the interfacial organization of solvent molecules at well-defined electrified solid-liquid interface.

High-Resolution Hydration Layer Mapping: Does a Hydration Structure above Gold Imply a Clean Surface? — •Antonia Köhler[1], Ralf Bechstein[1], Michael Reichling[2], and Angelika Kühnle[1] — [1]Bielefeld University, Bielefeld, Germany — [2]Institut für Physik, Osnabrück, Germany

Solid-liquid interfaces are pivotal in a broad range of fields, including electrochemistry, catalysis and geochemistry. In electrochemistry, the molecular structure of the electrode-water interface is decisive for understanding and improving electrochemical reactions. In this context, the Au(111) surface constitutes a prototypical model system as gold is believed to be a relatively inert and well-characterized sample material. So far, however, little is known about the hydration structure at the Au(111)-water interface at the molecular level. Here, we present atomic force microscopy data on a gold sample carefully cleaned according to standard electrochemistry preparation recipes. Our three-dimensional atomic force microscopy data reveal a vertically ordered hydration structure with layer-to-layer distances of 0.36 nm as expected for water. Strikingly, despite our extensive cleaning efforts (validated by cyclic voltammetry measurements), our

two-dimensional data reveal stripe-like structures at the Au(111)-water interface. The dimensions of these structures differ from the well-known herringbone reconstruction of the gold surface, which is why we interpret them as surface contamination. Our work, hence, demonstrates that the presence of a hydration structure is no evidence for a clean gold surface.

Invited Talk O 39.3 Tue 11:00 WILL/A317

Electric double layer of platinum electrodes — •Marc Koper — Leiden University

Platinum is the most studied electrode material in electrocatalysis, but its electric double layer properties are still incompletely understood. Only Pt(111) has a true double layer window, which charges purely electrostatically. However, the properties of the electric double layer of Pt(111) do not follow the classic Gouy-Chapman-Stern theory. Lower coordination sites and facets on platinum are always covered by either hydrogen or hydroxyl adsorbates, which have an important influence on its double layer properties, as will be illustrated by recent results of double-layer measurements on stepped Pt single-crystal electrodes combined with ab initio molecular dynamics simulations and mean-field modeling. In addition, we show that at low electrolyte concentrations, which are often necessary for double-layer measurements, Pt(111) displays strong constant-phase element behavior, which complicates the accurate measurement of its double layer capacitance. The possible origin of this nonideality will be discussed. Finally, the effect of adsorbates on the electric double layer of platinum will be discussed on the basis on hydrogen-covered Pt(111).

O 39.4 Tue 11:30 WILL/A317

Nonequilibrium density-potential functional theoretical approach of electrochemical plasmonics — •Lulu Zhang[1,2], Michael Eikerling[1,2], and Jun Huang[1,2] — [1]Forschungszentrum Juelich GmbH, Juelich, Germany — [2]RWTH Aachen University, Aachen, Germany

Electrochemical plasmonics enables in-situ optical probing and modulation of electrochemical interfaces. Experiments have revealed that localized surface plasmon resonance (LSPR) in metal nanoparticle-solution systems is sensitive to surface charge, morphology, electrolyte composition and chemisorption. However, resolving nanoscale interfacial structures from the measured LSPR is rarely practiced; all existing theoretical methods fall in short of simulating the electrochemical plasmonics of nanoparticles under realistic conditions, namely, at a constant electrode potential for a particle with a diameter above 10 nm immersed in an electrolyte solution with a moderate concentration below 100 mM. We are developing a nonequilibrium density-potential functional theoretical (DPFT) approach to enable LSPR simulations under realistic conditions, considering coupled electron-ion-solvent interactions under a terahertz electromagnetic perturbation and on the mesoscale. It ensures constant-potential simulations, scalability to realistic systems, consistency for electronic effects under equilibrium and nonequilibrium, and systematic analysis under working conditions. The fundamental insights into coupled light-electron interactions at electrochemical interfaces are provided, including the extinction spectra, enhanced electric fields and perturbed electron densities.

O 39.5 Tue 11:45 WILL/A317

Insights into the Structure and Dynamics of Co_3O_4–Water Interfaces Using a High-Dimensional Neural Network Potential — •Amir Omranpour[1,2] and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

Co_3O_4 is an important catalyst for the oxygen evolution reaction and for the oxidation of organic molecules in the liquid phase. Therefore, understanding the Co_3O_4–water interface is essential for understanding the mechanistic aspects of those catalytic processes. The interactions at such complex interfaces, including hydrogen-bond fluctuations, hydroxylation, proton transfer, and solvent structuring, are inherently reactive atomistic processes that cannot be fully described by continuum or implicit-solvent models. On the other hand, *ab initio* molecular dynamics with explicit solvent remain restricted to only a few picoseconds and a few hundred atoms. In this work, we overcome these limitations by training a high-dimensional neural network potential (HDNNP) on density functional theory data, which enables us to greatly extend the accessible time and length scales. Using this HDNNP, we carry out simulations that uncover the structure, dynamics, and reactivity of Co_3O_4–water interfaces in detail. Our simulations show that different surface terminations give rise to significantly different hydration structures. They also reveal how each termination templates the interfacial water network, affects hydroxylation, and determines the degree of structural ordering at the interface.

Invited Talk O 39.6 Tue 12:00 WILL/A317

First-principles modelling of electrochemical interfaces — •Axel Gross — Institute of Theoretical Chemistry, Ulm University, 89069 Ulm

Electrochemical processes occur at the interface between an electron conductor, the electrode, and an ion conductor, the electrolyte. From an atomistic point of view, the liquid nature of electrolytes requires appropriate statistical averages which can be numerically rather demanding. Still it has become possible to model these interfaces using using first-principles quantum chemical methods [1,2]. In this talk I will present which insights can be gained from such studies, but I will also identify limititations of this approach and discuss how they can be overcome, contrasting the cases of solvated cations and anions [3, 4] as one example.

O 40: Ultrafast electron dynamics at surface and interfaces – Poster (joint session O/TT)

Time: Tuesday 14:00–16:00 Location: P2

O 40.1 Tue 14:00 P2

Nonequilibrium phonon dynamics after laser-excitation — Tobias Held, Christopher Seibel, Markus Uehlein, •Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau

Electron-phonon coupling is a fundamental process governing the energy relaxation dynamics of solids excited by ultrafast laser pulses. While this coupling is often described in terms of an effective electron temperature, recent works have highlighted the important roles of both nonequilibrium electronic distributions and detailed phononic properties.

In this study, we investigate how nonequilibrium electron occupations, phonon stiffness, and wavenumber-resolved coupling collectively shape the energy exchange between electrons and the lattice in metals. We find that deviations from thermal electronic distributions can substantially modify the coupling parameter, challenging the conventional assumption that electron temperature alone determines the coupling strength. We further identify a roughly quadratic scaling of the coupling parameter with phonon stiffness, with high-wavenumber phonon modes consistently dominating the interaction. Finally, we demonstrate that this preferential coupling leads to the emergence of hot phonons near the Brillouin-zone boundary, which in turn induces a collapse of the overall energy transfer rate and significantly delays electron-phonon equilibration.

O 40.2 Tue 14:00 P2

Comparing temperature change during light-matter interaction of thermal and athermal electron systems — •Fabio A. Müller, Tobias Held, Christopher Seibel, Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau

When an ultrashort laser pulse irradiates a metal, the electronic system initially absorbs energy and is driven far from equilibrium. This transient nonequilibrium distribution modifies the light-matter interaction, in part through changes in Pauli blocking, while electron-electron scattering concurrently drives the system toward a hot Fermi-Dirac distribution. Consequently, ultrashort laser pulses of the same fluence but different duration lead to different absorption, even in the linear regime.

Here, we investigate how the capability of an electron ensemble to absorb photons depends on its instantaneous energy distribution. Specifically, we compare the absorption arising from nonequilibrium electron distributions with that of Fermi-Dirac distributions carrying the same energy density. Our results show that, for realistic materials, the relative absorption is highly sensitive to the photon energy, a behavior that can be traced back to distinct features in the electronic density of states.

O 40.3 Tue 14:00 P2

Role of non-thermal electrons on energy dissipation and phase transition in laser excited metals — •Lukas Jonda, Tobias Held, Markus Uehlein, Christopher Seibel, Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics andResearch Center OPTIMAS, RPTU Kaiserslautern-Landau

The influence of non-equilibrium electrons on energy dissipation and phase transitions is not well understood. It is known that during femtosecond laser irradiation of a surface, electrons are excited to a state of non-equilibrium in space and energy. These highly excited electrons then transport energy ballistically into the bulk. On a picosecond timescale, electrons transfer energy to the lattice via electron-phonon collisions. If the transferred energy is large enough to reach the melting point, the crystal lattice can undergo a phase transition.

We developed a hybrid model that combines a kinetic Monte Carlo simulation and a two-temperature model. The latter describes diffusive transport as well as electron-phonon equilibration, and the former describes primary electron excitation by the laser pulse, transport of non-equilibrium electrons, and secondary electron generation.

We present results for gold, where the influence of non-equilibrium electrons on energy transport is expected to be significant, due to the long mean free path of its electrons. Finally, we are interested in the influence of non-equilibrium electrons on the melting process.

O 40.4 Tue 14:00 P2

Capturing thermalization through electron-electron scattering with machine learning — •David L. Kaiser, Tobias Held, Christopher Seibel, Markus Uehlein, Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau

Ultrafast excitation of metals by optical laser pulses induces nonequilibrium energy distributions in the electron system. This nonequilibrium gives rise to complex electron-electron scattering processes, which typically restore a Fermi-Dirac distribution on a femtosecond timescale. Accurately modelling the thermalization requires evaluating the full electron-electron collision integral, which is however computationally costly.

In this study, we explore the possibility to use machine learning to emulate the dynamics generated by the full collision integral. Our goal is to significantly accelerate these calculations, enabling efficient simulations of bulk and multilayer systems. This approach opens the door to uncovering new relaxation pathways and predicting the response of complex material systems to ultrafast excitation.

O 40.5 Tue 14:00 P2

Studies of laser ablation of band-gap materials — •Markus Bonifer[1,2], Sebastian T. Weber[1], Nils Cremer[2,3], Gabriel Schaumann[2,3], and Baerbel Rethfeld[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, Germany — [2]Focused Energy GmbH, Im Tiefen See 45, 64293, Darmstadt, Hessen, Germany — [3]Institute of nuclear physics (IKP), Technische Universität Darmstadt, Darmstadt, Germany

We aim to explore laser ablation as a possible approach for creating clean, well-defined microholes in polymers used for laser fusion targets where symmetry and control of surface roughness are important. Because polymers differ widely in their properties, general insights into laser material interaction are sought through modeling of density-dependent excitation in band-gap materials.

The theoretical models used are based on the density-dependent two-temperature model (nTTM) and extended multiple rate equations (EMRE). These calculations are intended to guide experimental studies carried out in collaboration with Focused Energy to identify suitable processing conditions and improve overall feature quality.

O 40.6 Tue 14:00 P2

Thermalization of optically excited electrons in metals: electron-electron scattering dynamics — •Stephanie Roden, Christopher Seibel, Tobias Held, Markus Uehlein, Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau

When a metal is irradiated with a short-pulsed optical laser, the electron distribution is disturbed into a state far from equilibrium. On a femtosecond timescale, the non-thermal electrons thermalize by collisions with each other, which drives the electrons towards a hot Fermi distribution.

In this work, we present a derivation of the full electron-electron Boltzmann collision integral within the random-$\boldsymbol{k}$ approximation. Building on this approach, we trace the temporal evolution of the electron energy distribution in metals after ultrafast excitation. Furthermore, we examine to which extent the resulting dynamics can be captured by the numerically simpler relaxation time approach, applying a constant and an energy-dependent relaxation time derived from Fermi-liquid theory.

We find a better agreement with the latter, while specific features caused by the balance of scattering and reoccupation can only be captured with a full collision integral.

O 40.7 Tue 14:00 P2

Time-resolved PEEM and μARPES using a 100 kHz ToF momentum microscope — •Isabella Alexandra Hofmeister[1,2], Michael Herb[1,2], Maria Federl[1], Franz Seitz[1], and Isabella Gierz[1,2] — [1]University of Regensburg, Regensburg, Germany — [2]Regensburg Center for Ultrafast Nanoscopy - RUN, Regensburg, Germany

Momentum microscopy provides energy-resolved imaging in real and reciprocal space with < 100 meV resolution, combining PEEM (Δx < 40 nm lateral resolution) and μARPES (Δk < 0.02 Å^{-1}) capabilities. We implemented an ultrafast setup with a time-of-flight momentum microscope and a 100 kHz laser system delivering 6 eV probe pulses and pump pulses tunable from the mid-infrared to visible range. Procedures for converting time-of-flight to kinetic energy and for establishing spatial and temporal pump-probe overlap are discussed. Proof-of-principle time-resolved PEEM and μARPES experiments on the topological insulator Bi_2Se_3 demonstrate femtosecond-resolved carrier dynamics with high spatial and momentum precision.

O 40.8 Tue 14:00 P2

First steps with a qPlus-based MIR AFM — •Furkan Özyigit, Lukas Böhm, Leonie Weiss, Jay Weymouth, Rupert Huber, and Franz Giessibl — University of Regensburg, 93053 Regensburg

We report initial progress in an ultrafast non-contact atomic force microscope/scanning tunneling microscope (NC-AFM/STM) platform based on qPlus sensors, integrated with a CEP-stabilized mid-infrared (MIR) pump-probe system and tunable optical parametric amplifier (OPA) for versatile excitation. In first experiments, we successfully induced transient tunneling currents on Cu(111) using MIR pulses, demonstrating precise control of ultrafast electronic excitation at the atomic scale via laser-coupled tunneling. While the tunneling cur- rent reflects the ultrafast electronic excitation dynamics, the qPlus sensor permits complementary force detection to monitor subsequent structural or electrostatic interaction changes, such as those resulting from induced charge redistribution or lattice relaxation. This enables simultaneous probing of electronic and mechanical dynamics with fem- tosecond time and sub-nanometer spatial resolution. Beyond investi- gations of transient electrostatic forces, this versatile system facilitates a broad class of ultrafast nanoscale experiments, including scattering- type scanning near-field optical microscopy (s-SNOM) for imaging car- rier and phase dynamics, time-resolved tip-enhanced spectroscopy for molecular states, and pump-probe tunneling spectroscopy.

O 40.9 Tue 14:00 P2

Image potential states of oxide quasicrytals — •Barbara Drobinski[1], Friederike Wührl[1], Richard Kraska[1], Konrad Gillmeister[1], Stefan Förster[1], Cheng-Tien Chiang[2], and Wolf Widdra[1] — [1]Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, 06120 Halle, Germany — [2]Institute of Atomic and Molecular Sciences , Academia Sinica, Taipeh, Taiwan

Quasicrystals are aperiodically ordered materials that lack translational symmetry. Their aperiodic potentials give rise to an infinitely dense set of Fourier components, which can induce gaps and mini-gaps in the electronic band structure. Here, we investigate this phenomenon for nearly free-electron-like image-potential surface states, where electrons propagate in front of the surface while experiencing the aperiodic potential. Using momentum-resolved two-photon photoemission, we determine both the electronic dispersion and relaxation dynamics of oxide quasicrystals (OQCs) based on Ba-Ti-O/Pt(111) [1] and Eu-Ti-O/Pt(111). The latter is obtained via Eu decoration of a Ti_2O_3 honeycomb precursor [2]. In both systems, we observe n=1 and n=2 image potential states, located 340 meV (360 meV) and 150 meV (190 meV) below the vacuum level for Ba-Ti-O (Eu-Ti-O), respectively. The states exhibit parabolic dispersions without apparent gap openings. We discuss the momentum-dependent electron lifetimes in the context of possible mini-gaps in the underlying aperiodic potential.

O 40.10 Tue 14:00 P2

Ultrafast Electron Diffraction Study of Lattice Dynamics in Elemental Chromium — •Justus Richter[1,2], Victoria Taylor[1], Hyein Jung[1,2], Ralph Ernstofer[1,2], and Yoav William Windsor[1,2] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Institut für Physik und Astronomie, Technische Universität Berlin

Femtosecond electron diffraction (FED) allows to quantitively study ultrafast atomic motion. Here we use FED to study photoinduced atomic motion in Cr. We saw that measurements taken above- and below T_N exhibit qualitatively different responses from the lattice, hinting to the effect of the spin-induced periodic lattice distortion within the antiferromagnetic Cr phase, though further investigation is required. A two temperature model (TTM) was used to model the energy flow between the electronic and lattice subsystems by which we extract an estimate for the electron-phonon coupling constant $G_{ep} = (4.8 \pm 0.6) \times 10^{17}$ Jm^{-3}K^{-1}, which fits into the wide range of values reported in literature. Finally, we measured Cr side-by-side with Pt and demonstrate qualitative differences in their temporal responses, including a significantly faster thermalization of the Cr lattice and differences in the shape of their temporal response.

O 40.11 Tue 14:00 P2

Ultrafast electron dynamics in the valence-fluctuating intermetallic $EuIr_2Si_2$ — •Abeer Arora[1], Túlio de Castro[1], Amine Wahada[1], Lawson Lloyd[1], Tommaso Pincelli[2], Kristin Kliemt[3], Cornelius Krellner[3], Denis V. Vyalikh[4,5], Yoav Will Windsor[2], Martin Wolf[1], Ralph Ernstorfer[1,2], and Laurenz Rettig[1] — [1]Fritz Haber Institute of the Max Planck Society, Berlin, Germany — [2]Institut für Physik und Astronomie, TU Berlin, Germany — [3]Physikalisches Institut, Göthe-Universität Frankfurt, Germany — [4]Donostia International Physics Center, San Sebastián, Spain — [5]Ikerbasque, Basque Foundation for Science, Bilbao, Spain

$EuIr_2Si_2$ is a valence-fluctuating intermetallic compound that, despite its non-magnetic bulk, develops 2D ferromagnetic order below 48 K in the topmost Eu

layer due to a stable Eu^{2+} configuration. Its heavy Ir ions generate strong Rashba spin-orbit coupling, which interacts with magnetic exchange and influences the surface electronic states. Probing the non-equilibrium dynamics of the 2D electrons in the Si-Ir-Si surface layer offers a direct way to study the coupling of the spin-orbit and surface magnetic interaction. Using femtosecond XUV time- and angle-resolved photoemission spectroscopy, we investigate how the surface states evolve following photoexcitation with a 1.55 eV pulsed laser. Our preliminary results show an ultrafast quenching of the surface-state splitting, which we discuss in terms of demagnetization of the Eu 4f moments and modified spin-orbit coupling.

O 40.12 Tue 14:00 P2

Ultrafast STEM locked to GHz sample excitation — •Andreas Wendeln[1], Alexander Schröder[1], Sakal Singla[1], and Sascha Schäfer[1,2] — [1]Department of Physics, University of Regensburg, Regensburg, Germany — [2]Regensburg Center for Ultrafast Nanoscopy (RUN), Regensburg, Germany

Ultrafast transmission electron microscopy (UTEM) has been an established method for investigating nanoscale dynamics for several years, combining the nanometer spatial resolution of TEM with the femtosecond temporal resolution of a pump-probe approach. In recent years, there have been numerous advances in the development of new femtosecond electron sources, such as laser-driven Schottky [1] or cold-field emitters [2]. A combination of these sources with advanced electron optical elements, such as a probe aberration corrector, is expected to deliver even smaller electron spot sizes and to increase the available pulsed current but was not yet demonstrated. Here, we present a measurement scheme for ultrafast STEM with a focus on magnetic imaging, utilizing an aberration corrector and a laser-driven cold-field emitter. In initial measurements using a continuous photoelectron beam, the measurement method is characterized regarding experimental parameters, such as probe currents, focal spot sizes, and stability. Subsequently, we report the locking of femtosecond electron pulse train at repetition rates between 100 kHz up to 80 MHz to GHz radiofrequency currents which we aim to employ for DPC and ptychography imaging schemes of current-driven magnetic dynamics. O 40.13 Tue 14:00 P2

Probing Ultrafast Structural Dynamics in Multilayer Graphene Using ULEEM — •Simon Briesenick[1,2,4], Johannes Otto[1,2,4], Leon Brauns[1,2], Philip Schädlich[3], and Claus Ropers[1,2] — [1]Department of Ultrafast Dynamics, Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Göttingen, Germany — [3]Institute of Physics, TU Chemnitz, Chemnitz, Germany — [4]authors contributed equally

Multilayers of graphene (MLG) exhibit electronic and structural properties that vary strongly with, e.g., layer number and stacking order, making MLG a suitable model platform for studying ultrafast phenomena in two-dimensional materials [1]. We investigate the behavior of MLG after excitation with ultrashort light pulses using our newly developed ultrafast low-energy electron microscope (ULEEM) [2]. The instrument allows for the investigation of surface structural dynamics with sub-picosecond and nanometer spatial resolution, utilizing low-energy ($\leq$ 100 eV) ultrashort probe electron pulses. We present first data on the light-induced Debye-Waller effect in MLG, demonstrating the potential of ULEEM studies for resolving ultrafast structural behavior in MLG.

O 40.14 Tue 14:00 P2

Hot-electron dynamics in moiré structures studied with resonant scanning tunneling spectroscopy — •Martin Lülff, Marta Przychodnia, Maciej Bazarnik, and Anika Schlenhoff — Institute of Physics, University of Münster, Germany

To study hot-electron dynamics in Gr-metal heterostructures, image-potential states (IPSs) serve as ideal model system. While their energies are known to be highly sensitive to the respective Gr-metal distance variation within the moiré unit cell [1, 2], recent two-photon photoemission experiments suggest moiré-site dependent lifetimes [3].

Here, utilizing the high spatial resolution of resonant scanning tunneling microscopy (STM) and spectroscopy (STS) we study the moiré-site dependent IPSs' lifetimes for highly corrugated Gr/Fe/Ir(111) and Gr/Ir(111), respectively. Comparing these resonant STS data with those recorded on bare Fe/Ir(111) and Ir(111), respectively, enables the influence of the varying Gr-metal distance on the lifetimes to be distinguished from that of the underlying metal substrate. We analyse the IPSs' lifetimes for a Stark shift in their energies by applying various electric field strengths in current-dependent STS series, and discuss the results in terms of their resulting energetic positions with respect to the underlying unoccupied electronic band structure. Our work contributes to an in-depth understanding of electron transfer processes at Gr-metal interfaces.

O 40.15 Tue 14:00 P2

Photo-induced electron pressure drives THz phonon in Platinum-Copper superlattice — •Jan-Etienne Pudell[1], Maximilian Mattern[2,3], Marc Herzog[2], Alexander von Reppert[2], Daniel Schick[3], Chandan Singh[4], Peter M. Oppeneer[4], Michel Hehn[5], Ulrike Boesenberg[1], Angel Rodriguez-Fernandez[1], Roman Shayduk[1], Wonhyuk Jo[1], Johannes Möller[1], Jörg Hallmann[1], James Wrigley[1], Matias Bargheer[2,6], and Anders Madsen[1] — [1]European XFEL — [2]University Potsdam — [3]MBI, Berlin — [4]Uppsala University — [5]IJL, Université Lorraine — [6]HZB Berlin

Using ultrafast X-ray diffraction (UXRD) at the MID end-station at the European XFEL, we investigate the ultrafast lattice dynamics of metal-metal superlattice (SL) with few atomic layers of Pt and Cu upon femtosecond photoexcitation. Our results reveal that the absorbed optical energy is rapidly localizes within the Pt layers, driving the excitation of a coherent artificial THz phonon mode defined by the superlattice period. The signal's amplitude and phase modulation of the SL Bragg peaks induced by the lattice excitation i.e. the artificial THz phonon, are predominantly driven by electron pressure within the first picosecond. This response is faster than the Debye-Waller effect, which is limited by the electron-phonon coupling time.

O 40.16 Tue 14:00 P2

Experimental realization of an interferometric XUV-trARPES experiment with phase-stabilized IR pulses — •Antonius Naujok[1], Gregor Zinke[1,2], Franz Spartz[1], Sebastian Hedwig[1], Tobias Eul[2], Martin Aeschlimann[1], and Benjamin Stadtmüller[2] — [1]Department of Physics and Re search Center OPTIMAS, RPTU University Kaiserslautern- Landau, 67663 Kaiserslautern, Germany — [2]Experimental Physics II, Institute for Physics, University of Augsburg, 86159 Augsburg

Layered 2D van der Waals materials, such as TMDCs, have been extensively studied for their optical properties and coherent responses. However, exploring coherent excitations and dephasing processes in such materials using time-resolved ARPES is challenging because the key points of the materials' band structure cannot be accessed using phase-stabilized pulses in the visible regime, as has been done in most experiments thus far [1]. To overcome this limitation, we introduce a modified version of coherent multidimensional spectroscopy. This new method is based on time-resolved ARPES and utilizes a pair of phase-stabilized femtosecond infrared (fs-IR) pulses in combination with femtosecond XUV pulses for photoionization. We demonstrate the feasibility of our approach by focusing on the A-exciton excitation and the subsequent carrier dynamics in WSe_2. Through temporal Fourier-analysis of the entire ARPES spectrum, we're able to resolve distinct frequency components within characteristic features of the WSe_2 electronic band structure. [1] M. Aeschlimann et al., Phys. Rev. B. 105, 205415 (2022)

O 40.17 Tue 14:00 P2

Implementation of white light continuum probing for pump-probe spectroscopy — •Joris Wicker, Tim Titze, Maximilian Staabs, Jacob Kutzner, Stefan Mathias, and Daniel Steil — University of Göttingen, 1. Institute of Physics, Göttingen, Germany

We integrated a white-light continuum (WLC) probe together with a prism spectrometer in a conventional two-color femtosecond pump-probe setup. Further, we developed a custom measurement program using Microsoft's .NET Framework and Python, enabling instrument control, automated measurement sequences, and preliminary data analysis. To test the modified setup and software, we investigated the transient evolution of the reflectivity in metallic thin film systems and perovskite oxides using 1030 nm pumping. Spectrally and temporally resolved reflectivity variations were observed, confirming the proper functionality of the system. Furthermore, the stability of the WLC source was characterized. Possible future improvements include integrating a Wollaston prism to enable spectrally and time-resolved magneto-optical Kerr effect (MOKE) measurements.

O 40.18 Tue 14:00 P2

Investigation of the light-dressed bandstructure of graphene — •Lina Segerer[1], Marco Merboldt[1], Mattis Langendorf[1], Paul Werner[1], Jan Philipp Bange[1], Junde Liu[1], Wiebke Bennecke[1], Marcel Reutzel[2], and Stefan Mathias[1] — [1]Georg-August-Universität Göttingen, I. Physikalisches Institut, Germany — [2]Philipps-Universität Marburg, Germany

Time-periodic driving of solids with strong laser fields enables optical control of material properties. Photon-driven systems not only exhibit replicas of their equilibrium band structure, known as Floquet-Bloch states, but can undergo non-trivial topological phase transitions when excited with circularly polarized light. Recent advances in angle-resolved photoemission spectroscopy (ARPES) have shown that Floquet-Bloch states can be generated in graphene using linear polarized laser pulses [1,2]. However, the oblique incidence angle of the pump pulse so far has limited the realization of a purely circularly polarized light field. In this study, we overcome this challenge by integrating an extra beam path in our ultrafast momentum microscopy (MM) setup enabling backside normal-incidence excitation with linearly and strictly circularly polarized IR

pump pulses. We observe light-induced Floquet-Bloch states and investigate the polarization dependence of Floquet-Volkov interference as well as modifications in the light-dressed band structure of epitaxial graphene.

O 40.19 Tue 14:00 P2

Table-top 3D ultrafast momentum microscopy with a time-preserving EUV-monochromator — •Lennart Weinhagen[1], Wiebke Bennecke[1], Jan Philipp Bange[1], David Schmitt[1], Marco Merboldt[1], Bent van Wingerden[1], Thi Lan Dinh[2], Fabio Frasetto[3], Luca Poletto[3], Marcel Reutzel[1], Daniel Steil[1], D. Russel Luke[2], Stefan Mathias[1], and G.S. Matthijs Jansen[1] — [1]1st Institute of Physics, University of Göttingen, Göttingen, Germany — [2]Institute for Numerical and Applied Mathematics, University of Göttingen, Göttingen, Germany — [3]Institute for Photonics and Nanotechnologies CNR-IFN, Padova, Italy

Photoemission momentum microscopy with tunable probe-photon energy gives unique access to electronic and molecular structures, enabling Fermi-surface imaging, photoemission electron diffraction (PED) and 3D orbital tomography (3D-POT). However, such measurements have largely relied on synchrotron radiation, thus limiting their use in femtosecond-resolved experiments. Here, we present a table-top EUV source with a time-preserving monochromator driven by a 1030 nm femtosecond laser, using an off-plane grating at grazing incidence to reduce spatial chirp. Integrated into our time-resolved momentum microscope [1], it delivers femtosecond, photon-energy-tunable EUV probe pulses. Demonstrated on PTCDA/Ag(110), the setup enabled full 3D reconstruction of the frontier orbitals highlighting the potential of laboratory-scale, energy-selective momentum microscopy [2].

O 40.20 Tue 14:00 P2

Multimode momentum microscopy of cleaved 1T-TaS_2 crystals — •Bent van Wingerden[1], Olena Tkach[2], Hashima Marukara[1], Jan Philipp Bange[1], Wiebke Bennecke[1], Marcel Reutzel[3], Junde Liu[1], Gerd Schönhense[2], and Stefan Mathias[1] — [1]Georg-August-Universität Göttingen, Germany — [2]Johannes Gutenberg-Universität Mainz, Germany — [3]Philipps-Universität Marburg, Germany

Ultrafast momentum microscopy has evolved as one of the most powerful tools to study non-equilibrium electronic structure dynamics of 2D quantum materials [1]. However, the large electric field strength generated by the immersion lens limits its versatility in terms of sample systems. One critical issue is related to vacuum-cleaved van-der-Waals-crystals that often show microscopic protrusions, which are prone to field-induced electron emission and flashovers, both of which can destroy the sample itself as well as the microscope's electronics. In our work, we test the momentum imaging capabilities of a newly designed multi-mode momentum microscope [2,3] in combination with an EUV table-top HHG source. Using vacuum-cleaved bulk crystals of *1T*-TaS_2, we show that operating in modes of reduced electric field strength at the sample position suppresses field emission, while still preserving the field-of-view and imaging quality. We carry out detailed comparisons of different operating modes with the new lens system.

O 40.21 Tue 14:00 P2

Towards time-resolved momentum microscopy of plasmon excited quantum materials — •Mattis Langendorf[1], Lina Segerer[1], Paul Werner[1], Marco Merboldt[1], Jonas Pöhls[1], Tobias Meyer[1], Daniel Steil[1], Junde Liu[1], Jan Philipp Bange[1], Wiebke Bennecke[1], G. S. Matthijs Jansen[1], R. Thomas Weitz[1], Marcel Reutzel[2], and Stefan Mathias[1] — [1]Georg-August-Universität Göttingen, Germany — [2]Philipps-Universität Marburg, Germany

For the realization of Floquet*Bloch engineering as well as for the study of formation and propagation of excitons in two-dimensional quantum materials using time- and angle-resolved photoemission spectroscopy (ARPES), a highly localized excitation on a micron scale seems ideal [1]. However, achieving such spatial confinement poses a significant experimental challenge. Surface plasmon polaritons (SPPs) offer a promising solution, as these collective charge-carrier oscillations enable strong electromagnetic field localization and can therefore provide the required tightly focused excitation conditions [2]. In combination with femtosecond momentum microscopy that enables spatiotemporal access to electron and exciton dynamics [3], we investigate the concept of exploiting SPPs as a driving field to excite quantum materials.

O 41: Topology and symmetry protected materials & Topological insulators – Poster (joint session O/TT)

Time: Tuesday 14:00–16:00 Location: P2

O 41.1 Tue 14:00 P2

Manipulation of topological surface states by switchable molecules. — Lukas Staiger[1], Jannis Lessmeister[1], •Ralf Hemm[1], Juliusz Wolny[1], Volker Schünemann[1], Martin Aeschlimann[1], and Benjamin Stadtmüller[2] — [1]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, 67633 Kaiserslautern, Germany — [2]Institute of Physics, University of Augsburg, 86159 Augsburg, Germany

Three-dimensional topological insulators host spin-momentum-locked surface states protected by time-reversal symmetry, giving them potential for spintronic devices. Controlling these states remains challenging but is crucial for opening gaps, shifting the Dirac point and tailoring spin textures for applications. In our work, we utilize a monolayer of the spin-crossover complex $Fe(phen)_2(SCN)_2$ on the topological insulator Bi_2Se_3 to break the time-reversal symmetry of the substrate. Employing angle-resolved photoemission spectroscopy, we trace the evolution of the electronic structure as a function of molecular coverage and temperature. Despite a conspicuous energy shift and modified dispersion, there is no clear evidence for a band gap opening after deposition of a molecular monolayer. Concurrently, additional spectral weight from molecular orbitals emerges, and thermally and optically driven spin-crossover transitions in the $Fe(phen)_2(SCN)_2$ layer induce changes in the Dirac-point energy and spectral weight. Our findings demonstrate that a spin-crossover overlayer can quantitatively alter the dispersion of topological surface states, while allowing them to exist due to strong interactions between molecules and surfaces.

Deciphering the complex surface of the topological phase in the polar semiconductor BiTeI — •Adrian Weindl, Christoph Setescak, and Franz J. Giessibl — Faculty of Physics, University of Regensburg, D-93053 Regensburg, Germany

BiTeI is a semiconductor consisting of polar layers that can form Rashba spin-split p-n junctions on its surface due to stacking faults. It has been shown that gentle annealing can transform the surface of BiTeI into a topological insulator with spin-polarized surface modes exhibiting linear dispersion. Previous LEED and RHEED measurements revealed that the surface undergoes a structural change from a non-centrosymmetric triple-layer structure to a quintuple-layer structure. However, the exact surface structure remains elusive. Using scanning tunneling microscopy, atomic force microscopy, and Kelvin probe force spectroscopy we study the surface before and after annealing with atomic resolution. We show that the annealing results in different surface phases that are highly sensitive to the annealing temperature: a chemically homgeneous phase at around 240°C and a inhomogeneous phase with strong charge disorder at 250°C. We determine the termination of each phase and confirm that the surface exhibits the signature of a topological surface state even in the strongly disordered phase.

O 41.3 Tue 14:00 P2

THz-driven nonlinear dynamics studied with high-power THz sources — Atiqa Arshad[1,2], Jan-C Deinert[2], Igor Ilyakov[2], Andreas Gebauer[2], Anjan Kumar N M[1], and •Stefan Kaiser[1] — [1]TU Dresden,Germany — [2]HZDR, Dresden,Germany

THz pump-photoelectron spectroscopy (ARPES) probe is currently being implemented at the THz facility TELBE at Helmholtz-Zentrum Dresden-Rossendorf. This unique combination of high-field terahertz excitation and tr-ARPES probe will enable groundbreaking experiments on solid surfaces and interfaces. To this aim we have set up a high-repetition rate THz source driven by a 180 W laser source yielding > 50 mW THz output power. We report on the THz generation and characterization scheme as well as on first experiments. A highly promising material class to be studied with these light sources is BiTeI, a dual topological insulator that exhibits two different types of surface states on different interfaces. We present our study on the complex nonlinear dynamics, in particular THz harmonic generation in these compounds.

O 41.4 Tue 14:00 P2

The quasi one-dimensional van der Waals material α-Bi_4Br_4 — •Jonathan K. Hofmann[1,2], Serhii Kovalchuk[1,3], Mingqian Zheng[4], Yuqi Zhang[4], Vasily Cherepanov[1], Timofey Balashov[1], Jin-Jian Zhou[4], Zhiwei Wang[4], Yugui Yao[4], Irek Morawski[3], F. Stefan Tautz[1,2], Felix Lüpke[1,5], and Bert Voigtländer[1,2] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — [2]Experimentalphysik IV A, RWTH Aachen University, Germany — [3]Institute of Experimental Physics, University of Wrocław, Poland — [4]Key Laboratory of Advanced Optoelectronic Quantum Architecture and Measurement, Beijing Institute of Technology, China — [5]II. Physikalisches Institut, Universität zu Köln, Germany

α-Bi_4Br_4 is a quasi-one-dimensional material: covalently bonded Bi_4Br_4 chains are arranged in parallel, side-by-side and layer-by-layer, with van der Waals gaps in between. Bulk α-Bi_4Br_4 is higher-order topological insulator. At step edges on the (001) surface, quantum spin Hall (QSH) edge states are present. Using a scanning tunneling microscope (STM), we observe a significant shift of the chains, relative to each other, which we attribute to shear stress. Scanning tunneling spectroscopy reveals that the edge states are robust against the strain. Density functional theory confirms that a strained monolayer of Bi_4Br_4 is a QSH insulator with $\mathbb{Z}_2 = 1$. Furthermore, we use a four-tip STM to analyze the electrical transport of α-Bi_4Br_4 *in situ*.

O 42: Electronic structure of surfaces: Spectroscopy, surface states – Poster

Plasmonic lenses for nano-spectroscopy of Van der Waals materials — •Natalie Lehmann[1], David Huber[2], Daiyu Geng[1], Jiabao Yang[1], Stuart Parkin[1], Wolf Widdra[2], and Niels Schröter[1] — [1]Max Planck Institute of Microstructure Physics, Halle (Saale), DE — [2]Martin-Luther-University Halle-Wittenberg, Halle (Saale), DE

Surface plasmon polaritons excited at the edge of Archimedean spirals carved into a gold (111) surface can be focused to a sub-micrometer spot at the spiral center [1, 2]. We aim to use this nano-focused electric field to spectroscopically investigate 2D materials, which are often only a few micrometers in size. Here we present our measurements on gold/graphene samples. Notably, the plasmonic focus remains intact, and the gold surface is effectively cleaned by the graphene; even without sputtering the gold, its characteristic surface state is observed. Furthermore, the measured k-space spectrum shows replicas of the sp orbitals above the Fermi edge, reflecting the dynamics of an excited electron system. We propose that the laser pulse is pumping the system while the plasmon is probing the excited states. These findings demonstrate the feasibility of ultrafast pumped, nano-focused spectroscopy using a single micrometer-sized laser beam.

O 42.2 Tue 14:00 P2

Hydrogen Plasma Cleaning of Fe_3Sn_2 single crystals for surface-sensitive measurements — •Felix Müller[1], Lu Lyu[1], Lilian Prodan[1], Jannis Lessmeister[2], Tobias Eul[1], Martin Aeschlimann[2], István Kézsmárki[1], and Benjamin Stadtmüller[1] — [1]University of Augsburg — [2]RPTU University Kaiserslautern-Landau

Preparing clean and well-defined surfaces is essential for high-resolution photoemission spectroscopy (PES) and other similarly surface-sensitive studies. Typical preparation methods to realize high-quality surfaces include in situ cleaving under ultrahigh vacuum (UHV) conditions. However, this method cannot be universally applied to all crystal structures. Alternative approaches can rely, for instance, on H_2-based plasma cleaning using H_2 sources integrated into a UHV system. Here, we investigate the effectiveness of this method in preparing Fe_3Sn_2 surfaces for spectroscopy and discuss its potential as a general cleaning technique for other topological bulk materials.

We show that the hydrogen plasma efficiently removes common surface contaminants, particularly oxygen and carbon, while preserving the intrinsic surface structure. This enables the observation of sharp spectroscopic features over the whole energy range and significantly enhances the signal quality of subsequent PES measurements. Our results show that plasma can be a simple and reproducible method for achieving contamination-free surfaces of topological bulk materials for surface-sensitive spectroscopy applications.

O 42.3 Tue 14:00 P2

WTe2: a Cool Look at 330 mK — •Rian A.M. Ligthart, Kevin Hauser, Alexander LaFleur, Gleb Neplyakh, and Fabian D. Natterer — Department of Physics, University of Zurich, Winterthurerstrasse 190, CH-8057 Zurich, Switzerland

As silicon-based electronics reach their size limit, two-dimensional (2D) materials, particularly Transition Metal Dichalcogenides (TMDs), emerge as promising alternatives to enhance efficiency at the same length scale. Among them, WTe2 stands out due to its unique properties including topological states, Weyl semimetal character and graphene-like high electron mobility.

We investigate cleaved bulk WTe2 using a Scanning Tunneling Microscope at 330 mK. With scanning tunneling spectroscopy, the electronic properties and their dependence on vector magnetic fields are studied on the surface of bulk WTe*, as well as at step edges and twin domain boundaries. We scrutinize the topological nature of the edge states and observe a reduced density of states around zero bias in bulk WTe2.

O 42.4 Tue 14:00 P2

Chiral-Induced Spin Selectivity in Thia-Bridged Triarylamine Hetero[4]helicenes SAMs: Structural Insights from XPS and NEXAFS — •Yichen Jin[1], Jan Böhnke[1], Lapo Querci[2], Niccolò Giaconi[2], Cornelius Gahl[1], Dominik Stemer[3], Roberta Sessoli[2], Matteo Mannini[2], and Martin Weinelt[1] — [1]Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany — [2]University of Florence, Via della Lastruccia 3-13, Sesto Fiorentino 50019, Italy — [3]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195 Berlin, Germany

Helicene enantiomers act as efficient spin filters when assembled on metallic surfaces, making them promising candidates for organic spintronic applications. Previous magnetic conductive AFM studies reported spin polarizations of up to ~60% through the respective chiral enantiomers of Thia-Bridged Triarylamine Hetero[4]helicenes (HelSAc) self-assembled monolayers (SAMs) ascribed to the chirality-induced spin selectivity (CISS) effect. To understand the structural origins underlying this behavior, we investigated HelSAc SAMs on Au(111) using XPS and NEXAFS. Angle-dependent XP spectra of sulphur 2p reveal three chemically distinct components assigned to S*C, S*Au, and atomic sulfur. NEXAFS shows pronounced polarization dependences of the σ^* and π^* resonances, demonstrating the parallel alignment of the HelSAc to the Au surface. Together, these results establish a well-defined chemical and structural picture of HelSAc SAMs, providing the essential foundation for interpreting spin-dependent photoelectron spectroscopy and understanding the CISS effect in this chiral system.

O 42.5 Tue 14:00 P2

Structure and Electronic Properties of (Bi, Pb) Atom Layer Structures studied by ARPES and STM — •Lars Konermann[1], Wen Si[2], Hiroko Abe[1], Masaki Imamura[3], Masahiro Haze[2], Kazutoshi Takahashi[3], Yukio Hasegawa[2], and Akari Takayama[1,4] — [1]Waseda Univ., Shinjuku, Japan — [2]ISSP, Univ. of Tokyo, Kashiwa, Japan — [3]SL Center, Saga Univ., Tosu, Japan — [4]IMRAM, Tohoku Univ., Sendai, Japan

In Single-atom layer (SAL) structures comprised of heavy elements on semiconductor substrates, spin-split electronic states occur due to strong spin-orbit interactions and the breaking of the spatial inversion symmetry, known as the Rashba effect. For (Bi, Pb) on Si or Ge, spin-splitting electronic bands have been demonstrated both theoretically and experimentally. Furthermore, the possibility of a superconducting transition is anticipated suggesting spin-triplet superconductivity. Albeit, experimental confirmation has not yet been obtained.

We investigated the atomic and electronic structures of (Bi, Pb)/Si(111) and Ge(111) structures using cryogenic scanning tunneling microscopy (STM) and spectroscopy (STS), as well as angle-resolved photoemission spectroscopy (ARPES) with synchrotron radiation. A series of experiments was conducted to evaluate the sample: observation of the periodic atomic arrangement, determination of the Pb/Bi composition ratio, detailed band dispersion, and investigation of the electronic states at ultra-low temperatures.

In this presentation, we will present these experimental results and discuss the potential for superconductivity with the Rashba effect.

Line-Moiré Phases of an Epitaxial Honeycomb Monolayer AgTe/Ag(111) — •Romana Ganser — Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ctd.qmat, Universität Würzburg

Moiré heterostructures offer a versatile platform for engineering electronic band structures by precise control over long-range superlattice potentials that particularly give rise to emergent phenomena [1]. Here, we present angle-resolved photoemission spectroscopy (ARPES) measurements on a highly tunable one-dimensional (1D) epitaxial moiré heterostructure. We show that the electronic structure is strongly altered by the moiré superlattice hosting replica bands and sizable hybridization gaps. From our experimental data, we can trace back to the local, spatially-varying interlayer coupling, shaping the moiré potential. The latter leads to a 1D confinement of the electrons and, interestingly, also gives rise

to Dirac nodal lines, which are robustly protected by the superlattice symmetry.

O 42.7 Tue 14:00 P2

Realization of an Acoustic Kagome lattice — •Louis Müller[1,3], Noah Endres[1,3], Begmuhammet Geldiev[1,3], Simon Widmann[2,3], Maximilian Ünzelmann[1,3], and Friedrich Reinert[1,3] — [1]Exp. Physik VII, JMU Würzburg, Germany — [2]Technische Physik, JMU Würzburg, Germany — [3]Würzburg-Dresden Cluster of Excellence ctd.qmat

Hosting Dirac cones, flat bands, and saddle points in their band structure, Kagome materials have recently attracted great attention. We realize an acoustic Kagome lattice using 3D-printed resonators, enabling direct measurement of amplitude and phase to reconstruct wave functions and extract the band structure. Our experiment resolves the flat band, identifies the sublattice character of the van-Hove singularities, and clearly reproduces the Dirac cones in good agreement with tight-binding calculations. This platform provides a highly flexible and intuitive way to investigate lattice-driven effects that are difficult to isolate in electronic Kagome systems. Finally, we compare this data to angle-resolved photoemission spectroscopy measurements on a prototypical Kagome superconductor.

O 42.8 Tue 14:00 P2

Excitation of spin-polarized electrons by Deep-UV Pulses with Orbital Angular Momentum from Au(111) and Cu(111) — •Ruwen Quenter, Paul valerian Möllers, and Helmut Zacharias — Center for Soft Nanoscience (SoN), University of Münster, Busso-Peus-Str. 10, 48149 Münster, Germany

Photoemission can, depending on the substrate and the circularly polarization of the light, result in a longitudinal spin polarisation of the excited electrons. The angular momentum of the light influences the final state determined by the selection rules in a way that corresponds to a specific total angular momentum. Spin-orbit interactions cause an energetical separation of states with different total angular momenta, resulting in a spin imbalance of the excited electrons. This can be measured by e.g. Mott scattering. Orbital angular momentum light has a helical wavefront that carries its orbital angular momentum as a degree of freedom wich may have an influence on the electron orbital angular momentum in the electron excitation process. Spin-resolved photoemission measurements could determine if this influence could result in a changed photoelectron spin polarization. We present preliminary results from measurements on Au(111) and Cu(111).

O 42.9 Tue 14:00 P2

Wavefunction confinement of deeply buried As δ-layers in Si(001) measured with hard and soft X-ray angle-resolved photoemission spectroscopy — •Emily C. McFarlane[1], Enrico G. Della Valle[2], Procopios C. Constantinou[2], Taylor J. Z. Stock[3], Kieran Spruce[3], Christoph Schlueter[4], Sergii Chernov[4], Thiago R. F. Peixoto[4], Moritz Hoesch[4], Gerd Schönhense[5], Hans-Joachim Elmers[5], Vladimir N. Strocov[2], Neil J. Curson[3], Steven R. Schofield[3], and Niels B. M. Schröter[1] — [1]Max Planck Institute of Microstructure Physics, Halle (Saale), DE — [2]Paul Scherrer Institute, Villigen PSI, CH — [3]London Centre for Nanotechnology, University College London, London, UK — [4]Deutsches Elektronen-Synchrotron (DESY), Hamburg, DE — [5]Johannes Gutenberg University, Mainz, DE

Vertically confined regions of high concentration dopants in silicon, so-called "δ-layers", are potential building blocks of future quantum devices. A momentum-resolved understanding of the wavefunction confinement of the electrons in such systems is required for their future development, which so far has been limited to shallow samples. Here we present both hard and soft X-ray photoelectron spectroscopy studies of shallow (~3nm) and deeper (~7nm) buried As δ-layers measured with a momentum microscope and hemisphere at PETRA-III and the SLS. We find that the deeper buried sample has smaller electron confinement than the shallower δ-layer, and different quantum well states are located at different depths of the sample. In contrast, in shallow δ-layers all quantum well states are located near the surface.

O 43: Scanning probe microscopy: light matter interaction at atomic scales – Poster

Modelling the near-field enhancement for tip-enhanced photoluminescence on non-conductive layers — •Jinhui Guo and Laerte Patera — Department of Physical Chemistry, University of Innsbruck, 6020 Innsbruck, Austria

While scanning tunnelling microscopy (STM)-based tip-enhanced photoluminescence (TEPL) has been demonstrated for molecules adsorbed on 2-3 monolayers (ML) of NaCl/Ag(111) [1], nonradiative quenching due to charge tunnelling through the insulating layer is expected to affect the exciton lifetime. Employing sufficiently thick insulating layers (> 14 ML) strongly suppresses electron tunnelling [2], potentially preserving the photoexcited state. However, such thick insulating layers are incompatible with STM operation, making atomic force microscopy (AFM) an ideal choice. To elucidate the field enhancement in AFM-based TEPL experiments, we performed three-dimensional finite element method (3D-FEM) simulations [3] for various AFM Cu tip geometries and Cu substrates with and without NaCl layers up to 20 ML. Our results indicate that below the tip, a pronounced electric field enhancement in the plane parallel to the sample surface ($E_{/\!/}$) persists even on a 20 ML-thick NaCl layer. This effect arises mainly from the reduced screening of $E_{/\!/}$ within the NaCl layers compared to the metallic Cu substrate. These findings support the exploitation of non-conductive layers for TEPL experiments.

Sub-nanoscale photochemistry without plasmons: Debromination of dibromoterphenyl on Au(111) — Hao Jiang[1,2], Youngwook Park[1], Adnan Hammud[1], Martin Wolf[1], Qiang Sun[2], and •Akitoshi Shiotari[1] — [1]Fritz Haber Institute of the Max Plank Society, Berlin, Germany — [2]Materials Genome Institute, Shanghai University, Shanghai, China

Local control of light-induced reactions is a crucial process for developing molecule-based optodevices and designing photocatalysis. Nanometer- and angstrom-scale photoreaction controls have been demonstrated using scanning tunneling microscopy (STM) combined with laser irradiation [1,2]; however, so far they rely on localized surface plasmon resonance (LSPR) using plasmonic metal tips. Here we report a novel light-assisted reaction that can be induced locally without LSPR. Using laser-coupled low-temperature STM, we observed 4,4"-dibromo-p-terphenyl (DBTP) on Au(111), which is a representative system undergoing Ullmann coupling by heat or far-field illadiation [3,4]. By tuning both the bias voltage at the STM junction and the wavelength of the incident visible laser, the debromination of DBTP is induced at the sub-nanometer scale using non-plasmonic tips. This research opens up the prospect of performing the single-molecule photochemistry for various non-plasmonic systems.

Photoisomerization of azobenzene derivatives on Au (111) using various photon energies and polarizations — •Haraprasad Mandal[1], Paul Schöngrundner[1], Stefan Hecht[2], and Leonhard Grill[1] — [1]Department of Chemistry, University of Graz, Austria — [2]Department of Chemistry, Humboldt-Universität zu Berlin, Germany

Azobenzene derivatives continue to serve as model systems for studying photoisomerization at surfaces. Among them, tetra-tert-butyl azobenzene (TBA) is particularly suitable due to its chemical stability, large steric groups, and well-defined trans and cis configurations that can easily be identified in scanning tunnelling microscopy (STM) images. In this work, we systematically studied the photon-energy- and polarization-dependent trans-to-cis isomerization of TBA, using a tunable femtosecond laser in combination with STM (working in ultra-high vacuum and at low temperatures). Illumination is done through an optical port, and STM imaging is used to identify the configuration of individual molecules before and after laser exposure. The switching efficiency was then studied for a variety of wavelengths in the range between 350 nm and 800 nm as well as different (s/p) polarization directions of the incoming light. Our results provide direct insight into the parameters that steer TBA photoisomerization on Au(111) and demonstrate the capability of our laser STM platform for controlled photochemical studies of single molecules.

O 43.4 Tue 14:00 P2

Focal phase evolution of single-cycle THz near-field pulses in a scanning tunneling microscope — •Andrea Rossetti, Vivien Sleziona, Alkisti Vaitsi, Luis Enrique Parra Lopez, Martin Wolf, and Melanie Müller — 1Department of Physical Chemistry, Fritz Haber Institute, 14195 Berlin, Germany

Lightwave scanning tunneling microscopy (LW-STM) employs single-cycle THz pulses as femtosecond bias, enabling imaging at sub-nanometer spatial and sub-picosecond temporal resolution. Control over the polarity and carrier-envelope phase (CEP) of such THz voltage transients is thereby crucial in determining which electronic states contribute to the ultrafast tunneling current. A simple approach for continuous CEP control of the single-cycle THz transients in LW-

STM is via the Gouy phase. In this work, using a spintronic THz emitter, we use photoemission sampling from the point-like apex of the STM tip to monitor the local CEP of the tip-enhanced THz pulses along the focal axis of a focused THz beam. We find that the CEP exhibits a non-trivial evolution through the focus that strongly deviates from the expected Gouy phase shift for a monochromatic beam. Using analytical models and numerical calculations, we discuss the influence of the broad bandwidth of the THz pulses as well as their coupling to the STM tip for the local CEP in LW-STM.

Development of Cryogenic Photoinduced Force Microscopy: Introduction and Progression — •Shuxia Chen[1], Claudia Felser[1], Lukas Eng[2], and Fabian Menges[1] — [1]Max Planck Institute for Chemical Physics of Solids — [2]Technische Universität Dresden

Photo-induced Force Microscopy (PiFM) provides access to optical properties at atomic length scales through the detection of near-field optical forces. To date, PiFM experiments have been largely restricted to ambient conditions, with only limited demonstrations in extreme environments such as cryogenic temperatures or high magnetic fields. In this work, we aim to expand PiFM operation to low temperatures and large external magnetic fields. This development opens the door to exploring light matter interactions over an expanded parameter space and in exotic quantum materials.

O 43.6 Tue 14:00 P2

Investigation of atomic defects in quasi-freestanding MoS_2 with THz-STM — •Caroline Firschke, Junyoung Sim, Vibhuti N. Rai, Paul Wiechers, Florian Faaber, Christian Lotze, and Katharina J. Franke — Freie Universität Berlin, Germany

Transition metal dichalcogenides (TMDCs) are an interesting class of materials due to their 2D-like nature and unique band structures. These materials tend to host different types of defects, heavily influencing their optoelectronic properties. THz-driven scanning tunneling microscopy is a unique technique to investigate the nature of these defects on atomic scales with ultrafast time resolution (1).

Here, we grow monolayers of MoS_2 on Au(111) via chemical vapor deposition, which host quasi-freestanding monolayers of MoS_2 with a band gap of around 2.7 eV, the so called "pits" (2). We find structural defects in these pits, which are decoupled from the metal substrate, and show sharp positive ion resonances in the band gap.

These sharp non-linearities of the I-V curve provide favorable conditions for their investigation via THz pulses. We find that these defects show sharp resonances in the light-wave-driven scanning tunneling spectroscopy, which vary depending on the THz field strength, DC bias voltage and tip-sample distance. The THz response of these resonances cannot be modeled with a simple convolution of THz pulses with the static I-V of the junction, suggesting a modulation of the charge state of the defects on ultrafast timescales.

O 43.7 Tue 14:00 P2

Photo-switching of azobenzene derivatives on Au(111) — •Matthew J. Timm[1], Robert di Vora[2], Stefan Hecht[3], Birgitta Bernhardt[2], and Leonhard Grill[1] — [1]Institute of Chemistry, University of Graz, Austria — [2]Institute of Experimental Physics, Graz University of Technology, Austria — [3]Department of Chemistry & IRIS Adlershof, Humboldt-Universität zu Berlin, Germany

The light-induced trans-cis isomerization of azobenzene and its derivatives is of great scientific and technological interest as these molecular photo-switches can be used for nano-scale sensing or information storage. Particularly, 3,3',5,5'-tetra-tert-butylazobenzene (mTBA) adsorbed upon Au(111) has seen much interest, being studied at sub-monolayer coverage (around 0.1 ML) by scanning tunneling microscopy (STM) [1,2] and near monolayer (ML) coverage (0.9 ML) by two-photon photoemission [3]. However, missing is a single-molecule level insight into whether photo-switching at low coverage differs from that at higher but still sub-monolayer coverage - does it matter if only small or large areas of the surface are covered? Here, we combine STM with a self-designed computer-vision algorithm to study photoisomerization induced by pulsed laser radiation (λ = 518 nm) at a rather high surface coverage of 0.6 ML. This approach can track the isomerization state of thousands of individual mTBA molecules and enables us to detect subtle variations in switching yields among densely packed, similarly oriented molecules. [1] M. Alemani, et al. JACS 128 (2006) 14446. [2] M. J. Comstock, et al. Phys. Rev. Lett. 99 (2007) 038301. [3] S. Hagen, et al. Chem. Phys. Lett. 444 (2007) 85-90.

O 43.8 Tue 14:00 P2

Sub-10-fs compression of NIR pulses for phase-resolved sampling of MIR lightwave transients — •Justus Hess, Ugaitz Elu, Andrea Rossetti, Martin Wolf, and Melanie Müller — Department of Physical Chemistry, Fritz Haber Institute, 14195 Berlin, Germany

Lightwave scanning tunneling microscopy (LW-STM) employs single-cycle THz pulses as femtosecond bias [1], enabling imaging at sub-nanometer spatial and sub-picosecond temporal resolution. Ultrashort phase-stable mid-infrared (MIR) pulses promise to increase the time resolution in LW-STM. Phase-resolved characterization of the incident and STM tip-enhanced MIR transients requires sampling pulses with a duration of ideally less than 10 fs. For future MIR excitation in our LW-STM, we implement a MIR source and a pulse-compression scheme based on supercontinuum generation in a photonic crystal fiber (PCF) at 2 MHz in our existing LW-STM setup. Near-infrared (NIR) pulses with a duration of ~40 fs at a center wavelength of 1030 nm are spectrally broadened via self-phase modulation in the PCF to a Fourier-limit of 6 fs. Subsequent dispersion control with a transmission-grating compressor yields few-cycle pulses at 30mW average power sufficient for MIR waveform sampling in LW-STM. [1] T. Cocker et al., Nature 539, 263*267 (2016)

O 43.9 Tue 14:00 P2

Excitation of phonons by THz near fields in a quasi-suspended nanoscopic monolayer of MoS2 — •Junyoung Sim, Vibhuti Rai, Caroline Firschke, Christian Lotze, and Katharina J. Franke — Freie Universtiät Berlin, Department of Physics, Arnimallee 14, 14195 Berlin, Germany

Phonons play a central role in describing fundamental physical properties of materials, such as heat capacity and resistivity, and also govern many-body phenomena such as superconductivity and charge-density waves. To resolve ultrafast lattice vibrations at the atomic scale, terahertz scanning tunneling microscopy (THz-STM) has provided important groundworks, where such vibrations are influenced by the presence of atomic-scale defects [1, 2].

In this work, we investigate the phonon dynamics in a monolayer molybdenum disulfide (MoS2) grown on a Au(111) surface. We focus on nanoscopic regions, where the MoS2 layer is suspended and the electronic structure is minimally hybridized with the substrate [3]. We observe an oscillatory behavior in the THz-STM pump-probe spectra on these suspended regions, which we assign to a coherent vibrational mode excited and measured by the tip-enhanced THz near field. To elucidate the excitation mechanism of the phonon modes, we vary the pump/probe field and investigate the influence of defects within the suspended area.

O 43.10 Tue 14:00 P2

THz-driven plasmonic STM luminescence — •Alkisti Vaitsi, Luis Enrique Parra López, Vivien Sleziona, Martin Wolf, and Melanie Müller — Fritz Haber Institute of the Max Planck Society, Berlin, Germany

We combine THz scanning tunneling microscopy (THz-STM) with visible light detection to investigate ultrafast STM- luminescence (STML) luminescence from atomic-scale plasmonic junctions. The luminescence is driven by single-cycle THz pulses which act as a quasi-static ultrafast bias. This enables femtosecond gating of ultrafast tunneling currents and the excitation of localized surface plasmon (LSP) modes via ultrafast inelastic tunneling. Our measurements, combined with numerical reconstruction of THz-STML spectra from static STML spectra, show that a quantum cutoff is often absent in THz-STML. In addition, THz-STML spectra frequently exhibit a distinct spectral shape that differs from that predicted from quasi-static, single-electron tunneling-induced luminescence. We discuss the role of overbias emission, hot luminescence, and femtosecond plasmon dynamics in THz-gated STML.

O 43.11 Tue 14:00 P2

Design of a light-coupled high-magnetic-field Scanning Tunneling Microscope — •Colin Geuder[1], Marco Mönnich[1], Kurt Lichtenberg[1], Susanne Baumann[1], and Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies. — [2]2Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart.

Light-matter interaction at the nanoscale lies at the heart of many fundamental phenomena ranging from light harvesting to ultrafast lightwave electronics. However, accessing magnetic degrees of freedom through light-matter interaction at the atomic scale presents unique challenges. Scanning tunneling microscopy (STM) is the ideal tool, that can locally probe and excite these different interactions at atomic length scales. Here, we present the design of an STM that combines optical access with a large numerical aperture, magnetic fields up to 5 T, and temperatures below 2 K. We mitigate thermal loads introduced by the high-NA optical access through a combination of fiber coupling and radiation blocks at several stages of the cryostat's shields. This instrument enables studies of magnetic degrees of freedom in nanoscale light-matter interaction, such as magnon-photon coupling or exciton-magnon transport in layered materials.

O 43.12 Tue 14:00 P2

strong-field theory model for ultrafast electron transport in laser-assisted STM — •Boyang Ma[1], Melanie Mueller[1], and Michael Krueger[2] — [1]Department of Physical Chemistry, Fritz Haber Institute, 14195 Berlin, Germany — [2]Department of Physics, Technion, Israel Institute of Technology, 32000 Haifa, Israel

In ultrafast scanning tunneling microscopy (USTM), the classification of light-driven currents is usually based on the well-known Keldysh parameter. Similar to the description of strong-field photoemission, it is often used to distinguish photon-driven (weak-field) and field-driven (strong-field) tunneling regimes. Here, we discuss the limitations of the Keldysh parameter in classifying light-induced electron transport in nanoscale gaps, and present a theoretical study of laser-induced electron transport in STM [1,2]. In contrast to strong-field effects in spatially extended systems, we show that the Keldysh parameter alone is insufficient to capture the electron transmission dynamics in a confined nanogap. Instead, it must be complemented by an additional parameter, ζ, defined by the laser field strength, frequency, and junction width [2]. Notably, in the THz-STM, ζ alone becomes the decisive parameter, superseding the role of the Keldysh parameter. This reflects the fact that the Keldysh parameter accounts solely for properties of the driving field and neglects geometric confinement of the tunneling junction.

Addressing Atomic-scale optical Stark-shift Microscopy — Xabier Arrieta[1,2], Sofia Canola[3], Ruben Esteban[1,4], Javier Aizpurua[2,4,5], and •Tomas Neuman[3] — [1]Centro de Física de Materiales (CFM-MPC), CSIC-UPV/EHU, Donostia- San Sebastián 20018, Spain — [2]Department of Electricity and Electronics, FCT-ZTF, UPV/EHU, Leioa 48940, Spain — [3]Institute of Physics, Czech Academy of Sciences, Cukrovarnická 10, Prague, 16200, Czech Republic — [4]Donostia International Physics Center, Donostia-San Sebastián 20018, Spain — [5]IKERBASQUE, Basque Foundation for Science, Euskadi Plaza 5, Bilbao 48009, Spain

An applied external electric field can shift the optical transition energies of molecular emitters through the optical DC Stark effect. Conventional Stark-shift spectroscopy applies spatially homogeneous electric fields, allowing to probe variations in molecular dipole moment and polarizability upon photoexcitation. In contrast, molecules in natural environments experience strongly inhomogeneous internal electric fields, where the Stark effect follows different selection rules. We extend the theory of Stark-shift spectroscopy to account for such nanoscale field. Similar field localization naturally arises in light-assisted scanning tunneling microscopy, which could provide spatially resolved access to the electronic response of individual molecules under optical excitation [1,2]. We demonstrate the potential of this technique to develop into atomic-scale Stark-shift microscopy. [1] Roslawska et al., Phys. Rev. X, 12, 011012 (2022). [2] Imada et al., Science, 373(6550), 95-98 (2021).

O 43.14 Tue 14:00 P2

Light emission from dibenzoterrylene (DBT) molecules studied with STML — •Yannis Hilgers, Andreas Reutter, Markus Etzkorn, and Uta Schlickum — Institute of Applied Physics, LENA - TU Braunschweig, Braunschweig, Germany

Scanning Tunneling Microscopy induced Luminescence (STML) has gathered great interest since its development in the late 1980s as it allows studying optical properties with atomic spatial resolution. With this technique, it has become possible to study quantum light sources like individual molecules exhibiting single photon emission, but obtaining high and reproducible photon yields has proven to remain challenging. With our self-built STML-setup, we achieve count rates about an order of magnitude higher than what has been reported in the past, allowing for measurements on more sensitive systems. Here, we present optical properties of dibenzoterrylene (DBT) molecules which have been reported as single photon sources when encapsulated inside a host lattice of Anthracene and Naphthalene. However, since both materials are not stable, we combine DBT molecules with a host lattice consisting of C_{60} multilayers, which is much more robust and even stable in air at room temperature. We found that light emission of individual DBT on C_{60} multilayers is indeed preserved. The emitted light was analyzed by means of photon maps and photon energy spectra.

O 43.15 Tue 14:00 P2

Influence of Polarons on Tunneling and Optical Spectra of Molecules Adsorbed on Dielectric Layers — •Jan Friese — Institute of Physics, Czech Academy of Sciences, Cukrovarnicka 10, Prague, 16200, Czech Republic

Light-assisted scanning tunneling microscopy has enabled the simultaneous probing of transport and optical properties of individual molecules with atomic-scale precision. This technique relies on electronically decoupling the molecules from the metallic substrate by depositing them on dielectric spacer layers. However, these spacers are often formed by ionic crystals, such as NaCl. The phononic response of these ionic layers can significantly impact the observed experimental features due to polaronic effects. Their understanding requires a bottom-up theoretical description accounting for the dynamics of the dielectric layer triggered by electronic transitions in the molecule.

Here we address this challenge and use the polaron-formalism to model the interaction of phonons in the dielectric layer with changes of the charge density in the molecule due to optical or charge transfer excitations. With that, two-time correlation functions and consequently spectral functions can be derived to account for the dynamics involved in substrate reorganization processes following a change of charge density in an adsorbed molecule. The results can be used to calculate features like the reorganization energy, and positions, widths and shapes of peaks in tunneling and optical spectra.

O 43.16 Tue 14:00 P2

Optics of Edge-Modified Graphene Nanoribbons: A Theoretical Perspective — •Jian Cheng Wong[1], Song Jiang[2], Guillaume Schull[2], and Tomáš Neuman[1] — [1]Institute of Physics, Czech Academy of Sciences, Cukrovarnická 10, 16200 Prague, Czech Republic — [2]Université de Strasbourg, CNRS, IPCMS, UMR 7504, F-67000 Strasbourg, France

Atomic-scale engineering of graphene nanoribbons (GNRs) provides a versatile means to tune their electronic and optical properties. We present a theoretical study of edge-modified GNRs that describe the process resulting in excitonic emission under scanning tunneling microscopy-induced luminescence (STML). The modified edge structure forms localized states in GNR similar to the end states studied formerly[1]. From the electroluminescence maps, we explore how interactions between two of these localized states change the optical properties depending on the GNR structure. For this, we construct a many-body model which describes the dynamics of tip-induced charging/discharging and relaxation that eventually leads to light emission.

O 43.17 Tue 14:00 P2

Utilizing a Tunable Laser for Tip Enhanced Photoluminescence of Single Molecules — •Maximilian Rödel[1], Rodrigo Cezar De Campos Ferreira[1], Jiři Doležal[1], and Martin Švec[1,2] — [1]Institute of Organic Chemistry and Biochemistry (IOCB), Czech Academy of Sciences, Flemingovo náměstí 542/2. CZ16000, Praha 6, Czech Republic — [2]Institute of Physics, Czech Academy of Sciences, Cukrovarnická 10/112, CZ16200, Praha 6, Czech Republic

The study of organic molecules and their optical properties provides insight into molecular interactions, guiding the design of materials for advanced optoelectronic devices. In this contribution, we present a tip-enhanced photoluminescence (TEPL) scanning tunneling microscope (STM) setup by utilizing a tunable Ti:Sapphire laser not only for resonant excitation of organic molecules like MgPc, but, moreover, for disentangling optical signals.

For this purpose, a parabolic mirror is used for coupling the laser into the nanocavity, ensuring wavelength-independent imaging and minimizing aberrations, enabling a consistent performance across the entire visible wavelength range. By doing so, high-resolution spectra of single-molecule MgPc at temperatures of <7 K on a Ag111/NaCl surface can be detected and by changing the excitation wavelength the vibronic contribution and the Raman signal can be distinguished. With this model system, we are able to complement our optical data set and even hope to establish photoluminescence excitation spectroscopy for future measurements.

O 44.1 Tue 14:00 P2

Determining the electrical transmission to the junction of a scanning tunneling microscope — •Guido Hiller, Gaël Reecht, and Manuel Gruber — University of Duisburg-Essen

Stochastic resonance spectroscopy has recently been implemented in STM to probe dynamics at the atomic scale over a wide range of timescales, down to the picosecond range [1]. A key requirement for this method is a modulation voltage at the STM junction with an amplitude independent of the frequency. This, in turn, demands an accurate characterization and compensation of the frequency-dependent transmission of the cabling.

Several studies have focused on quantifying such transmissions. In particular, Paul et al. [2] quantitatively analyzed the radio-frequency induced broadening

of a sharp feature in dI/dV spectra. Building on this method, we carried out such analysis in the Fourier space and discuss the associated advantages.

O 44.2 Tue 14:00 P2

Upgrading an LT-STM with a qPlus-AFM system — •René Knispel, Patrick Härtl, and Matthias Bode — Physikalisches Institut, Experimentelle Physik 2, Julius-Maximilians-Universität Würzburg, Am Hubland, 97074 Würzburg, Germany

The invention of the scanning tunneling microscope (STM) by Binnig and Rohrer in 1981 enabled direct imaging of atomic-scale structures in real space [1]. Shortly thereafter, the recognition of tip–sample interactions enabled the development of the atomic force microscope (AFM) [2]. In 1995, Giessibl achieved true atomic resolution with AFM [3] by measuring the force gradient-induced resonance frequency shifts of a silicon cantilever. Quartz-based cantilevers with enhanced stiffness and sensitivity enabled the development of the so-called qPlus-AFM technique, which surpasses STM in spatial resolution and allows STM measurements to be performed concurrently.

To extend the capabilities of our low-temperature STM, we upgraded it with a qPlus-AFM system. The Pan-type scanner was redesigned to enable cantilever excitation and to integrate both differential oscillation signals and the STM tunneling current. A UHV-LT preamplifier for the oscillation signals was also build and mounted inside the liquid-helium shield of the cryostat. The technical implementation and performance of the upgraded microscope will be demonstrated using suitable test samples.

[1] G. Binnig *et al.*, Phys. Rev. Lett. **49**, 57 (1982).
[2] G. Binnig *et al.*, Phys. Rev. Lett. **56**, 930 (1986).

O 44.3 Tue 14:00 P2

Multifrequency Tunnelling Spectroscopy — •Gleb Neplyakh, Philipp E.J. Maier, Carolina A. Marques, Berk Zengin, Kevin Hauser, Rian Ligthart, Alexander LaFleur, and Fabian D. Natterer — Department of Physics, University of Zurich, Winterthurerstrasse 190, CH-8057, Switzerland

Scanning tunnelling spectroscopy (STS) probes the local density of states by measuring differential conductance as a function of energy. Traditional STS acquires N energy points by sweeping a DC bias with a small modulation superimposed. This requires N sequential measurements, making it impractical for large mapping tasks.

We have developed Parallel Spectroscopy (PS) to overcome this limitation. PS exploits the nonlinearity in the $I(V)$ curve of the materials: a single or multitone AC voltage drive generates a set of higher harmonics that encode the full spectrum. Demodulating N harmonics within one leakage-free integration window enables the energy dependence to be recovered in a single measurement, providing substantial speedups.

We compare conventional STS and single- and multi-frequency PS with respect to signal-to-noise ratio, potential artefacts, and spectral resolution. Using PS in conjunction with compressive sensing could allow us to conduct high-resolution studies of many-body effects in quantum materials.

O 44.4 Tue 14:00 P2

Tip-enhanced Raman Microscopy simulation methods — •Pablo Planelles Prensa, Harshit Sethi, Orlando Silveira Junior, and Adam Foster — Konemiehentie 1, 02150 Espoo / P.O. Box 15600, FI-00076 AALTO

Tip-enhanced Raman Microscopy (TERS) has emerged as a promising technique that overcomes Abbe diffraction limit, which dictates that for green light around 500 nm the spatial resolution is limited to only 250 nm, which is insufficient for studying nanomaterials. In TERS, by using a strongly localized plasmonic field produced at the tip apex, the Raman signal is significantly enhanced, and submolecular resolution can be achieved.

Similar to Scanning Tunneling and Atomic Force Microscopy techniques, TERS relies on a sharp tip. TERS offers the additional advantage of providing not only topographic information about the sample, but also chemical.

Despite the rapidly increasing interest in TERS, progress remains limited by the difficulty of interpreting the resulting experimental images.

In this context, we aim to contribute by presenting ab-initio simulation methods and demonstrating how they can be used to greatly facilitate the interpretation and prediction of TERS images. Moreover, we will study the influence of the substrate on the images, and how different tip geometries and materials affect resolution and induce image asymmetry. We will also compare several simulation methods with different levels of complexity and computational cost.

O 44.5 Tue 14:00 P2

Automatic tip functionalization with CO on Ag(111) using machine learning — •Johanna Schnorrenberg, Jonas Heggemann, Paul Laubrock, and Philipp Rahe — Universität Osnabrück, Institut für Physik, Barbarastraße 7, 49076 Osnabrück, Germany

Functionalization of scanning probe microscopy tips with CO molecules enables high-resolution imaging, sub-molecular contrast and access to charge distributions of adsorbed molecules. [1, 2]

However, the manual functionalization procedure is time-consuming and limits experimental throughput. To address this, tip functionalization can be automated. [3]

Here, we implement a full pipeline for CO tip functionalization on Ag(111). The process includes localizing a CO molecule during scanning the surface, performing the pick-up of this CO molecule and evaluating the resulting tip condition. Tip quality is assessed by imaging CO molecules on the substrate and classifying the achieved resolution as "good" or "bad" for a CO-tip using a convolutional neural network (CNN). The CNN performance is compared to a conventional image analysis algorithm, in this case a template matching algorithm.

We expect this automated approach to significantly improve the efficiency of AFM experiments and thereby enabling faster and more systematic data acquisition on molecular systems.

Spectral interferometry scanning near-field optical microscopy; investigating resonant tip-sample near-field interactions — •Tom Jehle, Sam S. Nochowitz, Juanmei Duan, and Christoph Lienau — Institute of Physics, University of Oldenburg, 26129 Germany

Localized phonon polaritons and plasmon polaritons resonantly enhance near-field mediated light matter interactions and are key for strong coupling between single quantum emitters and nanocavities (1). Localized polariton resonances with high oscillator strength show tip-sample distance dependent frequency shifts in scanning probe experiments, requiring spectroscopic analysis at explicit tip-sample distances (2). Here, we introduce a broadband interferometric scattering-type SNOM technique (3) to reconstruct spectral amplitude and phase of visible light scattered from a gold taper. Harmonic sampling with a fast line camera allows reconstruction of spectra with high tip-sample distance resolution. Spectral amplitude, phase and the evaluation of the distance dependence of the near-field interaction allows the retrieval of the temporal near-field dynamics with sub-cycle precision. We demonstrate our technique by measuring the tip-sample distance dependent time dynamics of the near-field at the apex of a resonant gold taper coupled to its image. Our results pave the way towards hyperspectral imaging in the visible with nm spatial resolution and fs temporal resolution of the reconstructed time dynamics. (1) S. Hu et al., Nat. Commun. 15, 6835 (2024); (2) H. Wang et al., Nat Commun. 9, 2005 (2018); (3) J. Zhan et al., Nano Lett. 24 (49),15738 (2024)

O 44.7 Tue 14:00 P2

Cryogenic Band Pass Amplifier for measuring Atomic Shot Noise — •Benjamin Frölich, Kevin Hauser, Lebin Yu, Gleb Neplyakh, Ajla Karić, and Fabian D. Natterer — Department of Physics, University of Zurich, Winterthurerstrasse 190, CH-8057, Switzerland

Scanning tunneling microscopy provides access to the texture and correlation of charge carriers in quantum materials by listening to their characteristic shot noise signatures that reveal 1e and 2e charge quantization effects at the atomic scale. Previous studies introduced a band pass amplifier with center frequency of 3 MHz based on their in house made high electron mobility transistor (HEMT) and LC tank circuit to measure such shot noise. Here we build a similar band pass amplifier with a center frequency of 17 MHz based on a comercially available InP HEMT. Another goal is the evaluation of resonating circuits like the LC tank at cryogenic temperatures. We achieve 26 dB single stage amplification at liquid nitrogen temperatures. Simulations suggest a noise figure of < 0.12 dB. Experiments at even lower temperatures present challenges impacting implementation into the cryostat.

O 44.8 Tue 14:00 P2

all-in-one preparation stage of STM/AFM QPlus sensors for ultrahigh vacuum — •reza habibipour, jakob pelster, marco pratzer, michiel reul, and markus morgenstern — II. Institute of Physics B, RWTH Aachen University and JARA-FIT, Germany

QPlus sensors enable the combination of atomic force microscopy (AFM) and scanning tunneling microscopy (STM) with high resolution. We developed a compact preparation stage for positioning, glueing, annealing and tip etching of wires with diameters down to 7.5 um and length down to 200 um. The QPlus sensors are based on a piezoelectric quartz tuning fork with nominal frequency of 32.6 kHz. A tip wire is attached to one prong with the other prong is fixed to a ceramic block on the ultrahigh-vacuum (UHV) sample holder. Two tuning-fork contacts connect to the sample plate for AFM oscillatory function and for STM current. Sensor preparation utilizes a long-working-distance optical microscope (~6 cm) and micrometer manipulators for precise glue and wire positioning. A heater is used to cure the glue. A tungsten-carbide flush cutter trims the wire to within 0.2 mm of the prong edge. Alternatively, an etching ring is employed for tip shaping. Afterwards contacts can be checked in-situ by a Keithley instrument. Q-factors at room temperature and UHV amount to 16.000. The resulting

QPlus sensors will be employed in a 300 mK STM/AFM cryostat mostly for maneuvering towards stacks of 2D materials by AFM prior to STM measurements.

O 44.9 Tue 14:00 P2

Iron Implantation from a Ferrocene Ion Source — •Urs Boison, Ajla Karić, Berk Zengin, Lebin Yu, and Fabian D. Natterer — Department of Physics, University of Zurich, Winterthurerstrasse 190, CH-8057, Switzerland

The scattering of electrons on defects in low dimensional materials provides insight into the electronic structure using quasiparticle interference or tunneling spectroscopy. Since natural defects are mostly spin averaging and obscure magnetic textures, using magnetic impurities would allow a richer inspection of the underlying magnetic properties. At present, magnetic impurities are difficult to produce because chemically active defects are required to chemisorb magnetic atoms, such as hydrogen. We use metal ions in a volatile molecule that can easily and directly be delivered to ion sources commonly used for sample cleaning. Using a conventional sputtering source and heated ferrocene (vapor pressure of 1773 Pa at 400 K), we implant ferrocene molecules between 100 and 3000 eV and use different vapor pressures to investigate the ion implantation efficiency and possible defect generation. We test the optimal dose as a function of these parameters using ion current measurements and mass deposition on a quartz crystal microbalance. To verify successful implantation, we use scanning tunneling microscopy on graphene and superconducting layers. Magnetic defects should exhibit signatures related to Yu-Shiba-Rusinov states, confirming the conservation of their spin upon implantation.

O 44.10 Tue 14:00 P2

Development of a Low-Temperature Scanning Probe Microscope — •Tingwen Miao — Tsung-Dao Lee Institute, Shanghai, China

We independently designed and constructed a low-temperature ultrahigh-vacuum scanning probe microscope (SPM) system which is equipped with a single-axis 9T magnetic field and can be cooled down to 400mK. The system integrates the functionalities of atomic force microscopy (AFM) and scanning tunneling microscopy (STM) into the scanning head, enabling in-situ measurements of both electrical signals and force signals. The cooling curve, current noise, non-contact AFM and STM imaging and I(V) spectroscopy are characterized to verify that the system achieve the fundamental SPM capabilities. Subsequent magnetic field test and low-temperature test will be performed to confirm that the system can achieve all designed performance.

O 44.11 Tue 14:00 P2

Correlative AFM-SEM-EDS microscopy on nanoparticles and -wires — Chris Schwalb[1], •Lukas Stühn[1], Hajo Frerichs[1], Sebastian Seibert[1], Darshit Jangid[1], Marion Wolff[1], Kerim Arat[2], Hamed Alemansur[2], Afshin Alipour[2], Andreas Amann[2], Luis Montes[2], Jost Diederichs[2], Jeff Gardiner[2], Will Neils[2], and Stefano Spagna[2] — [1]Quantum Design Microscopy GmbH, Pfungstadt, Germany — [2]Quantum Design Int., San Diego, USA

Correlative AFM-SEM-EDS microscopy enables multimodal nanoscale analysis but is often hindered by complex sample transfers and the lack of a joined coordinate system. Our approach integrates these techniques to allow simultaneous acquisition of topographical, mechanical, electrical, SEM and EDS data from the same region of interest[1]. We illustrate the advantages of such in-situ correlative measurements through several case studies, including hard-to-access structures such as bone lacunae, individual nanowires on 5 nm TEM grids, and nanoparticles relevant for multimodal characterization workflows[2]. In addition, we present first results on individual ZnO nanowires for energy-harvesting concepts, where SEM enables rapid localization and AFM provides mechanical and electrical characterization[3,4]. Overall, the presented in-situ correlative strategy, the FusionScope, expands the analytical capabilities for nanoscale inspection and process control across a wide range of materials and devices. [1] https://doi.org/10.1093/mictod/qaad083 [2] https://doi.org/10.1093/mam/ozae044.233 [3] https://doi.org/10.3390/mi16080927 [4] https://doi.org/10.1002/adfm.202310110

O 44.12 Tue 14:00 P2

Distance dependent of local work function on Pb/Si(111) islands — •Ajay Kumar[2], Thomas Späth[1], Ben Lottenburger[2], Zeineb Ben Tanfous[3], Daniel Rothhardt[2,4], Paul P. Schmidt[2], Manuel Schulze[2], Ralf Metzler[2], Kurt Busch[3], Gino Wegner[3,5], and Regina Hoffmann-Vogel[2] — [1]Institute of Physics and Astronomy, University of Potsdam, Karl-Liebknecht-Str. 24-25, 14476, Potsdam, Germany — [2]Physikalisches Institute, Karlsruhe Institute of Technology (KIT), 76131 Karlsruhe, Germany — [3]Humboldt University of Berlin, 12489 Berlin, Germany — [4]Swiss Federal Laboratories for Materials Science and Technology, CH-8600 Dübendorf, Switzerland — [5]Max-Born-Institute, 12489 Berlin, Germany

A quantitative description of the measured local contact potential difference (LCPD) as a function of tip-sample separation is essential for a deeper understanding of Kelvin probe force microscopy (KPFM), since it permits a more complete characterization of the sample's electronic properties and of the forces acting on the probe. We employ Pb islands on the Si(111)-7*7 reconstruction as a model system of metallic islands on a semiconducting substrate. Using a frequency-modulation scanning force microscope, we have performed frequency-shift bias-approach measurements at 115 K on these Pb islands and have studied the variation of the LCPD with tip-sample distance.

O 44.13 Tue 14:00 P2

Nonlinearity mapping using adaptive control schemes in scanning force microscopy — •Lukas Böttcher[1], Hannes Wallner[2], Niklas Kruse[2], Franziska Dorn[1], Wolfram Just[2], Ingo Barke[1], Jens Starke[2], and Sylvia Speller[1] — [1]Institute of Physics, Universität Rostock, Germany — [2]Institute of Mathematics, Universität Rostock, Germany

When probing surfaces by scanning force microscopy methods using oscillating cantilevers, bistabilities may occur [1,2]. This is a result of nonlinearities arising due to tip-sample interactions. In this work we focus on the attractive regime. Using an adaptive control scheme we track branches of unstable periodic orbits of the oscillating cantilever, arising between the two stable states [3]. Combining this with a topography scan of a polymer blend surface we explore spatial changes of the unstable branch. Parameters, such as the frequency width of the bistable region or the slope at the unstable branch can serve as nonlinearity parameters and respective maps can be acquired. The aim is to connect such nonlinearity maps to material-related properties such as density and elasticity.

O 44.14 Tue 14:00 P2

Realizing Spin-Polarized Scanning Tunneling Microscopy for an Atomic-Scale Study — •Leon Bojunga, Felix Otto, Jonas Brandhoff, Maximilian Schaal, Christian Haberland, Lorenz Brill, and Torsten Fritz — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

Spin-polarized scanning tunneling microscopy and spectroscopy (SP-STM/STS) is a powerful tool for investigating spin structures with real-space resolution down to the atomic scale. By combining a spin-sensitive tip with controlled magnetic fields at cryogenic temperatures, SP-STM/STS enables the study of phenomena such as Kondo resonances, spin excitations, organic radicals, and magnetism. Realizing SP-STM/STS requires, beyond standard low-temperature STM stability, a magnetically sensitive tip and a precisely tunable external magnetic field. In this work, we fabricate Ni tips by electrochemical etching and verify their apex geometry via SEM to ensure high quality. This is achieved using a home-built etching setup that enables a reproducible process with consistent results. Testing of the fabricated tips is carried out using an STM at cryogenic temperatures, which, together with a perpendicular magnetic field of up to 3 T, allows controlled magnetization of the tip. To assess the magnetic sensitivity and spatial resolution of the Ni tips, we employ Co bilayer islands on Cu(111), whose well-defined magnetic structure provides an ideal benchmark for validating tip polarization and imaging performance.

O 44.15 Tue 14:00 P2

Low latency, galvanically isolated data transfer architecture for distributed low-level precision measurements — Toni Marković, Shane O'Neill, Aitziber Herrero, David Zurbriggen, Daniel Uehli, and •Alessandro Pioda — SPECS Zurich GmbH, Technoparkstrasse 1, 8005 Zurich

Many recent achievements in the field of quantum devices, spintronics, novel materials and surface science, have been possible thanks to the ability to cool samples to temperatures significantly below 1 Kelvin and to the use of state of the art measurement electronics. Requirements for signal resolution, precision and quality increase significantly at low temperatures, while the growing complexity of experiments and higher measurement throughput require a growing number of signals, larger bandwidths, and push the cost of measurement electronics upwards.

Here we present a data transfer architecture that enables a low-latency, synchronous transfer of raw DAC and ADC data from multiple signal generation and acquisition interfaces to a central processing core. The architecture allows transfer of very high-resolution data with microsecond resolution, high resolution data with nanosecond resolution or a combination thereof. The use of off-the-shelf optical fiber cables for data transfer allows for decentralized measurements, simultaneous experiments on different experimental set-ups, as well as galvanic isolation between the processing core and the signal interfaces. The architecture can handle hundreds of signals, all synchronous and with no multiplexing. We also discuss state of the art signal interfaces and typical applications for this novel architecture.

O 44.16 Tue 14:00 P2

Development of low noise cryogenic circuitry for shot noise measurements in STM — •Anne-Catherine Oeter, Soumyaranjan Jhankar, Christian Ast, and Klaus Kern — Max Planck Institut for Solid State Research

Tunneling currents of electrons are subject to shot noise. Measuring shot noise in a scanning tunneling microscope (STM) can give more insight into the tunneling dynamics and the properties of the tunneling charges. Our goal is to measure shot noise at low tunneling currents simultaneously with the dc tunneling current. To this end, we are developing a low-noise cryogenic pre-amplification circuit. It is made up of a tank oscillator circuit, to filter and amplify the white noise signal at a frequency beyond flicker noise, as well as a HEMT based cryogenic amplification circuit. We will discuss how we want to improve the shot noise circuitry already used in the literature, for example, how to enhance the quality factor of the inductances used to filter the ac signal.

O 44.17 Tue 14:00 P2

Realization of laser-assisted UHV sample surface preparation for STM — •Clara Marie Nieder, Soumyaranjan Jhankar, David Sousa, and Christian Ast — Max Planck Institute for Solid State Research

Scanning tunneling microscopy (STM) enables the study of the electronic properties of superconductors such as vanadium. To achieve reliable STM measurements, the preparation of clean and well-defined metal surfaces under ultra-high vacuum (UHV) conditions is essential. This requirement becomes particularly demanding for reactive transition metals, where surface oxides can form even under high-quality UHV conditions. In this work, we present a laser-assisted UHV sample preparation approach to obtain clean vanadium surfaces. For this method, we utilize a diode laser directed at the front surface of the sample to achieve high temperatures. To prevent mechanical or electrical complications inside the UHV chamber, we place all optical and diagnostic components, including pyrometric temperature monitoring, outside the chamber. This enables a controlled and localized high-temperature annealing for oxide removal. Therefore the method represents a promising way to reproducibly prepare reactive and superconducting surfaces for subsequent STM measurements.

O 45: Organic molecules on inorganic substrates: Adsorption and growth – Poster

Time: Tuesday 14:00–16:00 Location: P2

O 45.1 Tue 14:00 P2

Domain mixing of coronene and nonahelicene with CuO_x species on Cu(110) — •Max Halbauer, Martin Wolf, and Akitoshi Shiotari — Fritz-Haber-Institute, Faradayweg 4-6, 14195 Berlin, Germany

Various surfaces are known to reconstruct as a result of surface energy minimization (e.g. Pt(110)-(2×1), Si(111)-(7×7)). For certain systems, the surface reconstruction is induced by the adsorption of molecules or atoms (e.g. C_{60}/Cu(111) [1]). In this work, we show how the organic molecules, coronene and nonahelicene, interrupt the growth of copper oxide rows of the typical Cu(110)-p(2×1)O reconstruction and mediate the formation of mixed domains instead. The resulting adlayer domains on Cu(110) were imaged by scanning tunneling microscopy (STM) and non-contact atomic force microscopy (NC-AFM) under ultrahigh vacuum and cryogenic conditions. Models for the adsorption structures of the molecules and CuO_x species are discussed and confirmed with simulated images. A mechanism for the mixed domain growth is proposed, whereby surface diffusion and favourable lateral interactions between the molecules and oxide species drive the formation of the observed coordination framework. The finding opens prospects for controlling the lateral chemical and electronic interactions between adsorbed molecules by partial oxidation of the Cu(110) surface.

O 45.2 Tue 14:00 P2

Importance of Electrostatic Effects for Interpretation of X-ray Photoemission Spectra of Self-Assembled Monolayers — •Michael Zharnikov — Angewandte Physikalische Chemie, Universität Heidelberg, Im Neuenheimer Feld 253, 69120 Heidelberg, Germany

The subject of this contribution is electrostatic effects in X-ray photoemission (XP) from self-assembled monolayers (SAMs), which are application-relevant ultrathin molecular films, coupled to the substrate by a suitable anchoring group. Whereas, in most cases, the standard concept of chemical shift is fully sufficient to describe XP spectra of these systems, consideration of electrostatic effects is frequently necessary for their proper interpretation. Due to the insulating character of the SAM matrix, decoupled electronically from the substrate, the introduction of a dipolar "sheet" at the SAM-substrate interface or within this matrix creates a potential discontinuity, shifting the energy levels above the "sheet" with respect to those below it. This shift is reflected then in the matrix-related spectra, resulting in shifts and splitting of the characteristic photoemission peaks. Representative examples in this context underline the importance of electrostatic effects in photoemission and suggest that they should be considered on equal footing with the chemical shift.

O 45.3 Tue 14:00 P2

Self-assembled quasi-one-dimensional metal-organic framework — Jonas Brandhoff, Jule S. Hölzer, Felix Otto, Torsten Fritz, and •Roman Forker — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

We compare condensed monolayers of 4,5,9,10-pyrenetetrone (Py4O) on Cu(111) in two fundamentally different configurations, namely with and without adatoms. To this end, we employ density-functional theory (DFT) calculations to understand the structural configurations as well as the electronic properties. We uncover the coupling between the organic molecule, surface, and possible adatoms. Furthermore, we demonstrate how a quasi-one-dimensional arrangement including a Cu adatom is thermodynamically stable. This interpretation is substantiated by means of scanning-tunneling microscopy (STM) experiments, along with low-energy electron diffraction (LEED) patterns. Additionally, we use photoelectron spectroscopy to assess the electronic structure. Finally, we elucidate the bond formation between the d-orbitals of the Cu adatom and the p-orbitals of the molecular oxygen.

O 45.4 Tue 14:00 P2

Landing-Energy-Controlled Surface Conformation of Electrosprayed Foldamer Molecules on Au(111) — •Jue Wang[1], Dennis Meier[1,2], Shengming Zhang[1], Patrick Lawes[1], Pengfei Zhao[1], Jinhua Wang[3], Victor Maurizot[3], Andreas Walz[1,4], Annette Huettig[1,4], Hartmut Schlichting[1,4], Anthoula C. Papageorgiou[1,5], Joachim Reichert[1], Ivan Huc[6,7], and Johannes V. Barth[1,7] — [1]TU Munich, DE — [2]Tufts University, US — [3]CNRS, Univ. Bordeaux, FR — [4]pureions GmbH, Gilching, DE — [5]National and Kapodistrian University of Athens, GR — [6]LMU Munich, DE — [7]Cluster of Excellence e-conversion, DE

Preserving the structural integrity of biomimetic foldamers upon surface deposition is essential for their integration into functional molecular architectures. In this study, we investigate the electrospray ion beam deposition of foldamer molecules in ultra-high vacuum and examine how their conformation depends on the mean landing energy during deposition. With a low mean landing energy of about 0.6 eV, intact foldamers are observed on the surface. Higher landing energies predominantly result in unfolded molecules. The unfolded conformation are further accessible by annealing of the adsorbed folded molecules. These results highlight the importance of soft-landing conditions to maintain hydrogen bond-stabilized architectures on surfaces, offering a model platform for studying the structure-function relationship of surface-supported thermolabile biomolecules

O 45.5 Tue 14:00 P2

Adsorption, Dissociation and Chain Formation of 2NHC-azo-iPrI on Au(111) — Ebru Cihan[1], Natasha Khera[1], Franz Plate[1], Ningwei Sun[2], Soyoung Park[2,3], Franziska Lissel[2,3], and •Francesca Moresco[1] — [1]Center for Advancing Electronics Dresden, TU Dresden, Dresden, Germany — [2]Institute of Macromolecular Chemistry Leibniz Institute of Polymer Research, Hohe Strasse 6, Dresden, Germany — [3]Institute for Applied Polymer Physics, TU Hamburg, Hamburg, Germany

In this study, we investigated 2NHC-azo-iPrI molecules on the Au(111) surface. While the central azobenzene core is clearly visible in STM images, in most cases, only two isopropyl groups are present per molecule. Our results indicate the possibility of a reaction between I- counterions and the isopropyl (iPr) side groups, which may lead to the dissociation of iPrI upon heating. Furthermore, experiments using STM lateral manipulation, which facilitate the separation of chain structures on azobenzene bridges, suggest that the chains are likely connected to each other by weak van der Waals or hydrogen bonds. Additionally, to further investigate the azobenzene core of the molecule, voltage pulses were applied to the molecule using the STM tip. This investigation reveals the potential for cis-trans isomerization in the azobenzene core.

O 45.6 Tue 14:00 P2

Tuning molecular self-assembly of BDA on $CsPbBr_3$(100) — •Hannah Loh, Milan Möller, and M. Alexander Schneider — Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

$CsPbBr_3$ is a promising alternative to organic-inorganic perovskites in solar cells and light emitting diodes [1]. In these devices, organic layers are often used as

charge transport layers and hence interface properties are of particular interest. Depending on the termination of the $CsPbBr_3$ substrate [2] the adsorption properties can be tuned [3].

In this contribution we invesitgate the self assembly of 4-4-biphenyl dicarboxylic acid (BDA) on epitaxial $CsPbBr_3$ thin films on Au(100). Independent of surface termination the BDA molecules lie flat and form compact islands. On the CsBr-terminated surface, molecules follow a head to tail hydrogen-bridge stabilized arrangement. The interaction with the PbBr terminated surface is stronger causing partially a slight tilt of the molecules to adapt to the substrate unit cell and deprotonation.

Force mapping of a pyridyl-functionalized platform molecule by noncontact atomic force microscopy — •Hyeji Choi[1], Behzad Mortezapour[2], Martin Wolf[1], Richard Berndt[2], and Akitoshi Shitotari[1] — [1]Fritz-Haber Institute of the Max-Planck Society, Berlin, Germany — [2]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, Kiel, Germany

Platform molecules based on trioxatriangulenium (TOTA) form triangular adsorption motifs on metal surfaces with a functional group protruding to the vacuum [1]. However, probing the atomic-scale structure of such steric molecules remains challenging. Here, we study pyridyl-TOTA on Ag(111) and perform single-molecule force mapping, using noncontact atomic force microscopy (NC-AFM) at 6 K. We obtained force and potential maps of the pyridyl group interacting with a metal tip by measuring frequency shift as a function of tip height and location. These maps reveal anisotropy depending on the direction relative to the pyridyl ring plane. Simulations using Lennard-Jones potential reproduce the map appearances, enabling estimation of the preferred ring orientation and directional stiffness. We thus demonstrate the high potential of single-molecule force mapping for the structural characterization of steric adsorbate.

O 45.8 Tue 14:00 P2

Decoupling of Organic Monolayers from Cu(111) Using Blue Phosphorene — •Felix Otto, Wiebke Makowski, Jonas Brandhoff, Maximilian Schaal, Roman Forker, and Torsten Fritz — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

Two-dimensional (2D) materials are promising for future electronics due to their tunable properties. Since graphene's discovery in 2004, materials like MoS_2, h-BN, and Blue Phosphorene (BlueP) have been synthesized, offering high charge mobility and adjustable band gaps. BlueP can be grown on substrates such as Cu(111), making it suitable for decoupling organic layers. This study investigates whether BlueP can effectively decouple PTCDA monolayers from Cu(111). Two BlueP phases – hexagonal and chiral – were prepared and characterized, revealing structures with hexagonal unit cells but significantly stretched lattices compared to free-standing BlueP. Despite structural differences, both phases exhibited similar chemical and electronic properties. PTCDA was deposited on both phases, forming ordered herringbone structures. On the chiral phase, a single structural model sufficed, while two were necessary for the hexagonal phase. Spectroscopic analyses indicated weak interactions and evidence of integer charge transfer, supporting the idea that BlueP acts as an effective decoupling layer. These findings contribute to understanding how 2D-materials can be used to electronically isolate organic monolayers, advancing their application in nanoelectronics.

O 45.9 Tue 14:00 P2

Density functional study of the geometric and electronic properties of a tetracene-adduct molecule on Ag(110) — •Fabian Dixer[1], Eric Fackelman[2], Veronika Schmalz[3], Monja Stettner[2], François C. Bocquet[2], Andrei C. Matetskii[2], Serguei Soubatch[2], Ulrich Koert[3], Frank Stefan Tautz[2], and Peter Puschnig[1] — [1]Institute of Physics, University of Graz, Austria — [2]PGI-3, FZ Jülich and RWTH Aachen University, Germany — [3]Department of Chemistry, Philipps-Universität Marburg, Germany

We present a density-functional theory (DFT) investigation of the adsorption behavior of the tetracene-maleic anhydride Diels-Alder adduct (4A-MAD) on Ag(110). This molecule serves as a model system for studying light induced retro 4+2 cycloadditions on surfaces. Using a repeated-slab approach with a van-der-Waals corrected GGA functional, we explore the adsorption energy landscape by sampling multiple initial configurations and performing local relaxations. The most favorable geometries are examined in terms of work-function changes, charge-density-difference distributions, and projected densities of states. We further simulate photoemission momentum maps of the frontier molecular orbitals within photoemission orbital tomography and compare them with angle-resolved and angle-integrated photoemission data from our experimental collaborators. This combined analysis provides a comprehensive picture of the molecule-substrate interaction and lays the groundwork for future studies of on-surface photochemical cleavage of the Diels-Alder adduct.

O 45.10 Tue 14:00 P2

Theoretical Investigation of Halogenated Polycyclic Aromatic Hydrocarbons on Clean and Coated Metal Surfaces — •Florian Pfeiffer[1], André Schirmeisen[2], Daniel Ebeling[2], and Simone Sanna[1] — [1]Institute for Theoretical Physics, JLU Giessen, Germany — [2]Institute for Applied Physics, JLU Giessen, Germany

Halogenated organic precursors are the building blocks for the on-surface synthesis of complex structures with precisely tuned properties. While chemical synthesis is typically performed on clean metallic surfaces, a NaCl bilayer might be employed to electronically decouple substrate and adsorbates, increasing mobility and thus simplifying manipulation.

To improve our understanding of the fundamental interactions of halogenated precursors on (isolated) surfaces, we examined charge redistribution as well as the adsorption geometry, distance, and energetics for several substrate-adsorbate systems, e.g. Dibromopyrene and Iodotriphenylene on NaCl/Cu and halotetracenes on coinage metals.

The Vienna Ab initio Simulation Package [1] implementation of density functional theory was used to calculate potential energy surfaces and nudged elastic bands for modelling adsorption behaviour and diffusion pathways, respectively. Comparability with experimental results [2] was achieved by simulation of atomic force microscopy using the Probe-Particle Model [3].

Formation and Electronic Interaction of Donor–Acceptor Heterostructures — •Philipp Janzen, Jonas Brandhoff, Felix Otto, Maximilian Schaal, Roman Forker, and Torsten Fritz — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

Combining donating and accepting molecules lies at the heart of many electronic devices. These molecular heterostructures allow for a delicate tailoring of charge-transfer interfaces. In this work, we investigate such heterostructures formed by the adsorption and structural organization of 1,4,5,8,9,11-hexaazatriphenylenehexacarbonitrile (HATCN) and 2,3,6,7,10,11-hexahydroxytriphenylene (HHTP) on Au(111). Owing to their shared symmetry, HHTP and HATCN form a well-matched co-assembly on the surface. Employing scanning tunneling microscopy (STM) and low-energy electron diffraction (LEED), we are able to resolve the structural properties of the individual systems, as well as the combined heterostructure. Additionally, X-ray photoelectron spectroscopy (XPS) and photoemission orbital tomography (POT) provide insights into charge-transfer processes and the electronic structure at the interface.

O 46: Organic molecules on inorganic substrates: electronic, optical and other properties – Poster

Time: Tuesday 14:00–16:00 Location: P2

O 46.1 Tue 14:00 P2

Investigation of chiral helicene molecules on the superconducting substrate Pb(111) — •Melvin Grumser[1], Rahel Specht[1], Vincent Herzog[1], Wenhui Niu[2], Narcis Avarvari[3], and Katharina J. Franke[1] — [1]Freie Universität Berlin, Berlin, Germany — [2]Max Planck Institute of Microstructure Physics, Halle, Germany — [3]University of Angers, Angers, France

Chiral molecules have recently garnered a lot of attention for their ability to partially spin polarize currents running through them, which is of interest for the emerging field of spintronics. Chirality induced spin selectivity (CISS) typically manifests itself in experiments in which a current passes through a chiral molecule, as has been done down to the single-molecule scale using scanning tunneling microscopy [1]. However, recent studies suggest that the adsorption of chiral molecules might already lead to magnetization in the surface layer which could locally interact with the Cooper-pairs of a superconducting substrate [2]. Here, we investigate the effect of adsorbed chiral molecules on the elemental superconductor Lead. For this, [7]-Helicene and [6]-Helicene derivatives were evaporated onto a Pb(111) surface and investigated via STM and AFM. The molecules form ordered islands with different orientations of the molecules. In addition, we use scanning tunneling spectroscopy and identified the energy of the HOMO and LUMO. However, we do not observe any signatures of an

alteration of the local superconducting behavior.

O 46.2 Tue 14:00 P2

On-Surface Reaction of Naphthothiadiazole Derivatives on Au(111) — •Mohsen Ajdari[1], Jakob Steidel[1], Larissa Winkelmann[1], Felix Landwehr[1], Jakob Sawatzki[1], Jakob Roth[1], Christian Huck[1], Hendrik Hoffmann[2], Uwe H. F. Bunz[2], and Petra Tegeder[1] — [1]Institute for Physical Chemistry — [2]Institute for Organic Chemistry, Heidelberg University, Germany

Naphthothiadiazole (NTD) and its halogenated derivatives (NTD-Br/Cl) are promising electron acceptor candidates for use in (opto)electronic applications.

In a multi-technique approach, this study utilizes scanning tunneling microscopy, two-photon-photoemission spectroscopy, and temperature-programmed desorption to identify on-surface reactions of adsorbed NTD-Br/Cl on Au(111).

Our findings suggest that the halogenated molecules undergo temperature (NTD-Br) and photo-induced (NTD-Br/Cl) dehalogenation reactions. As a result, we found work function changes, differences in the energy-level alignment as well as changes in the adsorption structure.

O 46.3 Tue 14:00 P2

Second Harmonic Generation in Thin Films of Chiral Organic Molecules — •Martin Richter[1], Gayani Liyanage[1], Marjan Krstic[2], Erik Misselwitz[3], Milan Kivala[3], Carsten Rockstuhl[2], and Petra Tegeder[1] — [1]Institute for Physical Chemistry, Heidelberg University, Germany — [2]Institute of Theoretical Solid-State Physics, Karlsruhe Institute of Technology, Germany — [3]Institute of Organic Chemistry, Heidelberg University, Germany

Nonlinear optical (NLO) techniques enable increased sensitivity to chiroptical features. In contrast to linear circular dichroism (CD), second harmonic generation (SHG) chiroptical features can be explained within the dipole approximation. This includes electric as well as magnetic dipolar contributions. The latter are usually much weaker and specific measurement schemes are required to detect them. Here, we investigated thin films of chiral organic molecules using SHG-CD and SHG-ORD (optical rotatory dispersion) to probe the nonlinear CD and optical rotation. Continuous rotation of a quarter-wave plate generates circular and elliptical light to gain insights into the relative amplitudes of the second-order susceptibilities from electric χ^{eee} and magnetic (χ^{mee} and χ^{eem}) dipolar contributions. Our theoretical modelling allowed us to disentangle electric and magnetic dipole contributions.

O 46.4 Tue 14:00 P2

Electronic structure of spiro-bridged N-heterotriangulenes on Au(111) — •Jakob Roth[1], Jakob Sawatzki[1], Christian Huck[1], Angelina Jocic[2], Milan Kivala[2], and Petra Tegeder[1] — [1]Institute for Physical Chemistry — [2]Institute of Organic Chemistry, Heidelberg University

N-heterotriangulenes are versatile p-type organic semiconductors combining enhanced planarity with sterically defined bridges, enabling highly stable amine-centered radical cations, making them promising candidates for semiconducting and energy storage applications.

Here, we investigated the adsorption and electronic structure of two model systems - dimethylmethylene-bridged N-heterotriangulene (TN) and spirofluorene-bridged N-heterotriangulene (FTN) - deposited on Au(111). The spiro-annulated fluorenyl groups of FTN are expected to elevate the molecular core and hence reduce the electronic coupling strength to the metal substrate. Scanning tunnelling microscopy reveals that both species form well-ordered monolayers. Two-photon photoemission spectroscopy quantitatively resolves occupied and unoccupied electronic (transport levels) as well as excitonic states (optical gaps). These results highlight how molecular design controls surface coupling and electronic level alignment in Triphenylamine-based materials.

O 46.5 Tue 14:00 P2

Deprotonation of quinacridone on Ag(100) - an NIXSW/XPS study of the phase transition — Lucas Hirschfeld[1], Morris E. L. Mühlpointner[1], Anna J. Kny[1], Sergey Subach[2], and •Moritz Sokolowski[1] — [1]Clausius Institute for Physical and Theoretical Chemistry, University of Bonn, Germany — [2]Peter Grünberg Institut, Forschungszentrum Jülich GmbH, Germany

Quinacridone (QA) forms two different phases on the Ag(100) surface. When QA is deposited at room temperature, the formation of the α-phase with a point-on-line (*pol*) structure is observed. After annealing, the commensurate β-phase is irreversibly formed [1]. The mechanism, involving the loss of intermolecular hydrogen bonds, was not disclosed so far. Thus we have performed a detailed Normal Incidence X-ray Standing Waves (NIXSW)/XPS study.

The N1s XPS spectra exhibit a second peak shifted by 2.2 eV to lower binding energies when going from the α- to the β-phase. This reveals that the irreversible reaction from the α- to the β-phase is explained by a deprotonation of 50 % of the amine groups. The deprotonated N-atoms form stronger bonds to the Ag(100) surface, indicated by a drastic approach of the respective N adsorption height from 4.3 Å in the α-phase to 3.4 Å in the β-phase. These results show that the reaction is driven by the energy gain related to N/Ag interfacial bonds, which overcompensate the loss of intermolecular hydrogen bonds.

Support by Diamond Light Source is acknowledged.

O 46.6 Tue 14:00 P2

Fluorescence Spectroscopy of Quinacridone Molecules on thin Epitaxial KCl(100) films. — •Morris E. L. Mühlpointner and Moritz Sokolowski — Clausius-Institut für Physikalische und Theoretische Chemie der Universität Bonn, Germany

Quinacridone forms one-dimensional chains on metal surfaces and thin epitaxial KCl films grown on Ag(100) [1]. TD-DFT predicts the transition dipole moment in the direction of chain growth. The resulting J-like coupling suggests superradiance which can be enhanced by chemical modifications that increase the inter-chain distance. However, no data on the optical properties of QA on KCl surfaces exist.

We have measured the fluorescence at cryogenic temperatures (7 K) of quinacridone (QA) and its fluorinated derivative (FQA) on ultrathin KCl films grown on Ag(100). Isolated QA molecules on KCl have a 0-0 transition at 20200 ± 200 cm^{-1}. The spectral lines have asymmetric shapes with large line widths (400 to 700 cm^{-1}). We relate the broadening to the weak bonding interactions of the molecule and the substrate.

Upon forming a 2D aggregate on the surface, we observe a significant red shift by 1600 cm^{-1} for QA and FQA. This can be understood by the attractive of the transition dipoles.

On-Surface Coupling of Feringa-Type Molecular Motors — •David Le[1], Grant J. Simpson[1], Matthew J. Timm[1], Dongdong Liu[2], James M. Tour[2], and Leonhard Grill[1] — [1]University of Graz, Austria — [2]Rice University, Houston, USA

Artificial molecular motors are fundamental components of nanoscale machines that convert external energy into uni-directional motion. On metallic surfaces, their operation can be probed with sub-molecular precision, allowing observation of rotational pathways and intermediates. In nanomachines, it could be advantageous to have not only one, but several motor units incorporated. However, the synthesis of such complex molecules is very challenging. Here, we studied whether individual Feringa-type motor units can be coupled covalently directly on a Au(111) surface to form bimotors, thus avoiding the complex synthesis and difficult deposition of molecules that contain more than one motor unit. Using low-temperature scanning tunnelling microscopy (STM) under ultrahigh vacuum conditions, we identified individual bimotor molecules after the coupling and could resolve distinct conformations. Moreover, conformational transitions and lateral translation could be induced by STM tip manipulation. The results for bimotors are compared with the mono-motors, i.e. before the coupling. Our results demonstrate controlled reactions and manipulation of molecular motors on a metallic surface, supporting the development of more complex nanomachines.

O 46.8 Tue 14:00 P2

Optical properties of pi conjugated molecule on insulator films supported by metal surface — •harshita malik — Clausius Institute for Physical and Theoretical Chemistry , University of Bonn,Bonn,Germany

Quinacridone (QA) is a pi-conjugated molecule whose optical properties are strongly influenced by hydrogen bonding and by its local environment. To establish consistent reference data, we determined the gas-phase and solution-phase excitation energies of QA using CCSD, TDDFT, and GW-BSE, and compared the results with available experimental spectra. These calculations provide reliable values for the ionization potential, the lowest singlet excitation, and the main vibronic features.

We then examined several structural variants of QA, including tautomers, substituted derivatives, and solid-state polymorphs. Their different packing motifs lead to measurable shifts in excitation energies, which we quantified using periodic GW-BSE.

To investigate QA on insulating surfaces, we used machine-learning potentials (MACE) combined with Bayesian optimization (BOSS) to identify stable adsorption geometries on KCl(100). The monomer and dimer structures obtained from this approach agree with DFT benchmarks and serve as starting points for further excited-state calculations on KCl films supported on Ag(100). I am currently working on computing excitons and other optical properties for QA adsorbed on these KCl/Ag surfaces to understand how substrate screening and adsorption geometry modify its electronic and optical response.

O 46.9 Tue 14:00 P2

Photoemission intermittency from organic quasi-one-dimensional crystals coupled with silver nanoparticles — •Moha Naeimi[1,2], Waqas Pervez[1,2], Frithjof Harmsen[1,2], Ingo Barke[1,2], and Sylvia Speller[1,2] — [1]Institute of physics, University of Rostock — [2]Department of life, light & matter, University of Rostock

Organic, quasi-one-dimensional crystals are suitable platforms for triplet exciton migration, latter only requiring minimal orbital coupling [1]. In organic molecules, triplet excitons can be generated via singlet fission, where excited singlet states convert into two long-lived triplet states [2]. We recently prepared long quasi-one-dimensional rubrene crystals on silicon substrates with a native thin silicon oxide layer (SiO2) [3]. After depositing Ag nanoparticles, we observe strong photoemission intermittency (blinking) at the interface sites and weak blinking on the rod crystal itself. In this work, we characterize the blinking in terms of its time traces and time-of-flight electron spectra. The blinking is consistent with exciton propagation that becomes trapped at nanoparticle-containing interface sites, where apparent electron binding energies shift to lower values. These molecule-nanoparticle systems offer promising pathways for directed energy transport and guided exciton migration.

Tip-induced hysteretic switching in copper-coordinated bipyridine (BIPY) thin films — •Sunny M P Gautam, Ankita Jaiswal, Thiruvancheril G Gopakumar, and Sandeep Verma — Indian Institute of Technology, Kanpur, India

In this work, we present a rationally designed hypoxanthine-based ligand, 1,9-bis(pyridine-2-ylmethyl) hypoxanthine (BIPY), specifically tailored for constructing functional surface-confined metal-organic networks (SMONs). The ligand integrates a π-conjugated purine core with flexible pyridyl donor arms, creating a nitrogen-rich, tridentate coordination environment ideal for forming robust 2D frameworks. Its conformational adaptability around metal centers enables dynamic metal*ligand interactions, offering a pathway toward SMON-based molecular switching driven by electronic-state transitions rather than geometric changes. Such electronically mediated bistability provides enhanced stability and potentially faster switching compared to conventional conformational molecular switches. Our results highlight BIPY as a promising platform for developing adaptive, switchable SMON architectures with potential applications in sensing, spintronics, data storage, and molecular logic systems.

O 46.11 Tue 14:00 P2

Monolayers of Thiols with Very High Dipole Moments Show Surprisingly Small Work Function Changes — Michael Gärtner[1], Andreas Terfort[1], and •Michael Zharnikov[1,2] — [1]Institut für Anorganische und Analytische Chemie, Johann Wolfgang Goethe Universität Frankfurt, 60438 Frankfurt am Main, Germany — [2]Angewandte Physikalische Chemie, Universität Heidelberg, 69120 Heidelberg, Germany

The recently introduced concept of distributed dipoles in molecular self-assembly was combined with the standard dipolar tail group decoration in the context of electrostatic engineering of surfaces and interfaces by self-assembled monolayers (SAMs). To this end, thiol-anchored molecules, containing dipolar 2,5-bipyrimidine units within their molecular backbones, were decorated with either nitrile or dimethylamino tail groups and assembled on Au(111). The directions of the distributed and tail group dipoles were aligned either upwards or downwards to the anchor to achieve the maximum effect on the work function (WF) of the substrate. Despite a dense molecular packing and an upright molecular orientation, the decoration of the bipyrimidine thiols with the tail groups not only provided no WF gain but even had a detrimental effect in the dimethylamino case. This behavior is explained by the upside-down orientation of a part of the molecules in the SAMs, driven by the minimization of the energy associated with the strong dipole-dipole interaction between the SAM-forming molecules.

Energy-resolved tip-orbital fingerprint in scanning tunneling spectroscopy based on the revised Chen's derivative rule — Ivan Abilio[1,2] and •Krisztián Palotás[1] — [1]HUN-REN Wigner Research Center for Physics, Budapest, Hungary — [2]Budapest University of Technology and Economics, Budapest, Hungary

The revised Chen's derivative rule for electron tunneling [1] is implemented to enable computationally efficient first-principles-based calculations of the differential conductance dI/dV for scanning tunneling spectroscopy simulations [2]. By taking pristine and boron- or nitrogen-doped graphene sheets as sample surfaces, the reliability of our implementation is demonstrated by comparing its results to those obtained by the Tersoff-Hamann and Bardeen's electron tunneling models. It is highlighted that the energy-resolved direct and interference contributions to dI/dV arising from the tip's electron orbitals result in a fingerprint of the particular combined surface-tip system. The significant difference between the electron acceptor boron and donor nitrogen dopants in graphene is reflected in their dI/dV fingerprints. The presented theoretical method allows for an unprecedented physical understanding of the electron tunneling process in terms of tip-orbital-resolved energy-dependent dI/dV maps that is anticipated to be extremely useful for investigating the local electronic properties of novel material surfaces in the future.

Innovative Approaches to Semiconductor Surface Oxidation Studies Using Active Learning and MLIP — •Ondrej Krejci[1,2], Shola Adyemi[2], Konstantinos Konstantinou[2], and Milica Todorović[2] — [1]Department of Chemistry and Materials Science, Aalto University, Espoo, Finland — [2]Department of Mechanical and Materials Engineering, University of Turku, Turku, Finland

Oxygen passivation of InAs surfaces critically affects material performance in electronic devices, but the nature of the oxide surface reconstruction is not well characterized. To address this, we employ a machine learning (ML) driven workflow. Starting from the $\zeta(4\times2)$ reconstruction of pristine InAs(100) [1], we use Bayesian Optimization [2] to identify oxygen binding sites. This allows us to populate the surface with increasing number of oxygen atoms. The oxide models serve as input for a ML interatomic potential based on the MACE model [3], trained via the active learning method PALIRS [4]. The potential is used for molecular dynamics simulations to identify promising candidates for the oxidized InAs(100) surface reconstruction. Our workflow enables an efficient exploration of configurational space surpassing traditional computational approaches.

Complete basis limit with hybrid functionals using LAPW — •Janis Uzulis and Andris Gulans — University of Latvia, Riga, Latvia

We present a systematic framework for achieving the complete basis limit (CBL) for molecules and solids in hybrid functional calculations with density functional theory using the linearized augmented plane wave (LAPW) method. Standard LAPW calculations with nonlocal exchange employ radial basis functions and core orbitals obtained from a (semi)local functional, leading to inconsistencies that prevent the calculations from converging to CBL. We address this issue and achieve the same level of precision that previously was attainable only with local functionals. By applying this method, we obtain the Hartree-Fock total energy for crystals with a few μHa precision. Aside from high-quality reference data (reaction energies, cohesive energies and equation of state) for computational-chemistry and band-structure codes, our work provides an insight into the range of applicability of the standard approach to hybrids in LAPW.

Electric-field induced formation of a two-dimensional adatom gas on cryogenic Li(110) — Shyam Katnagallu[1], Samuel Mattoso[1], Huan Zhao[1,2], Se-Ho Kim[1,3], Jing Yang[1], Baptiste Gault[1,4], •Christoph Freysoldt[1], and Jörg Neugebauer[1] — [1]MPI for Sustainable Materials, Düsseldorf Germany — [2]State Key Laboratory for Mechanical Behavior of Materials, Xi'an Jiaotong University, Xi'an, China — [3]Department of Materials Science and Engineering, Korea University, Seoul, Korea — [4]Department of Materials, Royal School of Mines, Imperial College London, UK

The field evaporation behavior of Li at 60 K in atom probe tomography (APT) shows very inhomogeneous distribution on the detector hit map with hot-spot sites accounting for thousands of evaporations, implying an unusual high surface mobility. We therefore investigated the ad-atom energetics and diffusion behavior on the prototypical Li(110) surface in the presence of the very high fields (10^{10} V/m) by density-functional theory. Two key effects are found to jointly explain the experimentally observed behavior. Firstly, free ad-atoms become energetically favorable over kink sites at fields above 10 V/nm, making sizeable ad-atom densities in thermodynamic equilibrium. Secondly, the ad-atom diffusion barrier vanishes at ~11 V/nm due to a degeneracy of the on-top and bridge sites. We suggest that a highly dynamic ad-atom gas forms, that enables efficient transport to evaporation hotspot sites. Our static calculations are corroborated by molecular dynamics simulations, that show the spontaneous ad-atom emission from a kink-site enabled by the field.

O 48.2 Tue 14:45 HSZ/0204

Structural analysis of the interaction of H_2S with the FeO_2 chain phase on Ir(100) — •Alexander Wegerich, Eric Engel, and M. Alexander Schneider — Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

On the Ir(100) surface, a self-organised growth of oxide chains of the form Ir(100)-(3 × 1)-MO_2 (M = Mn, Fe, Co and Ni) can be observed. These transition metal oxide chains are shifted by half an Ir(100) lattice constant with respect to the iridium rows [1]. Furthermore, it is possible to reduce these oxide chains to an Ir(100)-(3 × 1)-MIr_2 (M = Mn, Fe, Co and Ni) surface alloy by annealing under H_2 atmosphere, now with the reduced chains aligned to the Ir rows [2].
Using quantitative LEED-IV analyses, STM and DFT, we examine whether the iron oxide chain phase can be structurally changed and/or tuned by reaction with S, the only other non-metallic chalcogen. In contrast to oxygen, sulphur does not create a Ir(100)-(3 × 1)-FeS_2 chain-like phase, but a c(6 × 2) superstructure. Prepared by annealing the FeO_2 chains under a H_2S atmosphere, the oxide chains are reduced and sulphur adsorbes on them. The so-formed c(6 × 2) can be interpreted as a c(2 × 2)-S adphase on the Ir(100)-(3 × 1)-$FeIr_2$ chains.

STM study of surface evolution and phase stability in Sn/Pt(111) systems — •Qing Shi, Fumio Komori, Masaki Mizuguchi, and Toshio Miyamachi — Nagoya University, Nagoya, Japan

The formation of Pt_3Sn surface alloys on Pt(111) is of considerable interest for applications in catalysis and topological electronics. Depositing Sn on Pt(111) followed by annealing offers a route to realize atomically flat, single-crystalline Pt_3Sn(111) surfaces suitable for detailed surface studies. Here, we reveal how the annealing process directly controls the surface morphology and local electronic structure in Sn/Pt(111) systems by scanning tunneling microscopy and spectroscopy (STM/S).

In the lower-temperature regime (< 400 K), where a Sn overlayer is stabilized, Sn atomic layers preferentially attach to step edges. The STS measurements indicate that the Sn overlayer is metallic due to hybridization with the Pt substrate. Upon annealing to higher temperatures, the surface undergoes Pt-Sn alloying, leading to the formation of a Pt3Sn phase across the surface. This transition is accompanied by pronounced island coarsening, morphological rounding, and an increase in local disorder, driven by thermally activated atom processes. Equilibrium shape analysis of the alloy islands reveals nearly isotropic step free energies, indicating minimal energetic differences between alternating A- and B-type step edges. Spectra acquired on the Pt_3Sn terraces show a high density of states near the Fermi level, corresponding to contributions from both bulk and surface electronic states.

O 48.4 Tue 15:15 HSZ/0204

Enhanced thermal switching of an azobenzene derivative via metal doping on graphitic surfaces. — •Nidhi Rawat[1], Hariom Birla[2], and Thiruvancheril G. Gopakumar[3] — [1]Indian Institute of Technology Kanpur, Kanpur, India — [2]Indian Institute of Technology Kanpur, Kanpur, India — [3]Indian Institute of Technology Kanpur, Kanpur, India

The thermal isomerization (switching) of azobenzene derivatives is often limited by high activation barriers, limiting efficient switching between trans and cis configurations induced by heat. In this study, we first examined the thermal induced switching of pristine azobenzene-based thin films and observed no isomerization upon heating. Upon introducing a metal dopant into the films, several morphological changes are observed, across varying molecular coverages, upon heating confirming that thermal switching is readily induced in the doped films. The analysis of the morphology and microscopic structure of the film is analysed using AFM and STM. These results clearly demonstrate that metal doping can effectively modulate the energy barrier and facilitate thermally driven molecular switching. This approach offers a promising pathway to tailor the isomerization dynamics of molecular systems, providing new opportunities for the development of thermally responsive devices.

O 48.5 Tue 15:30 HSZ/0204

Evolution of surface superstructures on altermagnetic MnTe thin films — •Marco Dittmar, Franziska Beisler, Hannes Haberkamm, Lena Hirnet, Maximilian Ünzelmann, and Friedrich Reinert — Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ctd.qmat, Universität Würzburg, Germany

MnTe has recently attracted significant attention as a workhorse altermagnet, where real space spin arrangements give rise to symmetry-driven, momentum-dependent spin splitting without net magnetization. In terms of basic research as well as for enabling high-quality interfaces in potential devices, the investigation of the surface atomic structure of MnTe becomes very important. In this talk, we present an electron diffraction surface analysis of epitaxially grown MnTe thin films, highlighting the factors that govern their surface atomic structure. In particular, we discuss how variations in Te flux and surface evaporation conditions guide the formation and stability of different surface reconstructions, we have found experimentally.

O 48.6 Tue 15:45 HSZ/0204

Atomic structure of MBE-grown Ta-Ge alloy on Ge(001). — •Suhani Singh[1], David Sommers[1], Patrick Strohbeen[2], Yi-Hsun Chen[1], Javad Shabani[2], Arkady Fedorov[1], and Peter Jacobson[1] — [1]School of Mathematics and Physics, University of Queensland, St. Lucia, Queensland 4072, Australia — [2]Center for Quantum Information Physics, Department of Physics, New York University, New York, New York 10003, USA

Tantalum-germanium (Ta-Ge) alloys are a promising option for superconducting devices.[1] Here, we study the atomic-scale structure and thermal evolution of an MBE-grown Ta-Ge alloy film on Ge(001) using scanning tunnelling microscopy (STM) and synchrotron-based soft x-ray photoemission (XPS). A series of annealing steps between 673 K and 873 K smoothed the initially corrugated surface and enabled atomic-resolution STM. Short anneals at 873 K, reveal threefold symmetric surface domains. Longer anneals at 873 K led to the appearance of square lattice consistent with Ta(100), coexisting with more corrugated regions. Further temperature increase made the surface progressively rougher and difficult to image. Synchrotron-based XPS shows higher temperature annealing produces a Ge-rich surface, suggesting Ta migrates into the bulk. These preliminary results map out how thermal processing affects the Ta-Ge surface and will guide strategies to obtain cleaner, sharper superconductor-semiconductor interfaces.

Beyond-Dipole Approaches to Generating and Applying Twisted Light — •Esra Ilke Albar[1], Franco Bonafé[1], Valeriia Kosheleva[1], Heiko Appel[1], and Angel Rubio[1,2] — [1]Max-Planck-Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, DE — [2]Center for Computational Quantum Physics (CCQ), The Flatiron Institute, 162 Fifth Avenue, New York, New York 10010, USA

We perform numerical electrodynamics simulations where a nanoplasmonic Archimedean spiral is targeted with a circularly polarized, 8-cycle plane wave pulse to probe the generation of twisted pulses, i.e., fields with orbital angular momentum(OAM). We identify mismatches between the generated pulse and the ideal OAM beams, which motivates us to discuss the spatiotemporal optical vortices (STOVs). All realistic electromagnetic fields are finite pulses, while the structural properties of plasmonic OAM generators are often adjusted to the central wavelength. As a next step, we employ a two-particle point charge system to map the local OAM density and confirm the space dependence of the generated pulse. This pushes us to expand beyond the known electric dipole approximation(EDA). We introduce our beyond dipole formalism and present high harmonic generation results computed within this approach.

O 49.2 Tue 14:45 HSZ/0403

Electro-Optic Phonon Polaritons — •Michael S. Spencer[1], Olga Minakova[1], Maximilian Frenzel[1], Joanna M. Urban[1], Martin Wolf[1], and Sebastian F. Maehrlein[1,2,3] — [1]FHI Berlin — [2]HZDR — [3]TU Dresden

Ultrafast control of fundamental excitations and order parameters represents a major driving force for the rising field of terahertz (THz) cavity electrodynamics. However, most efforts to date have not taken full advantage of THz sampling capabilities. By using an electro-optic crystal to fill a cavity, we directly measure intra-cavity electric fields, and polarizations arising from dipole-active excitations, all in the time domain. We identify that under cryogenic conditions, and in high-quality cavities, a polaritonic state is formed from the superposition of cavity photons and optical phonons. We explore the relationship between the light-matter coupling strength and temperature, and between the polariton splitting and cavity quality factor. With our novel electro-optic cavity design, we are able to investigate the detuning-dependence of the strong coupling behavior, obtaining the full picture of light-matter interactions. Furthermore, we reveal fluence-dependent polariton dynamics, indicative of significant coupling beyond the harmonic approximation. This identification of strong light-matter interactions in electro-optic cavities opens an important new testing ground for measuring novel, light-matter-entangled states.

O 49.3 Tue 15:00 HSZ/0403

Femtosecond and attosecond correlations in multi-electron pulses — •Rudolf Haindl[1,2], Valerio Di Giulio[1,2], Armin Feist[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Göttingen, Germany

In femtosecond electron emission from nanoscale field emitters, Coulomb interactions result in structured few-electron states exhibiting strong correlations in energy [1,2], transverse momentum [1], and time [3]. Here, we combine femtosecond-gated, event-based detection with inelastic electron-light scattering to directly map the phase-space distribution of two-electron states [4].

Our experiments reveal a bimodal structure in longitudinal phase space, distinguishing contributions from interparticle interaction and dispersion. Furthermore, we demonstrate that global phase modulation coherently shapes the few-electron distribution to exhibit attosecond temporal correlations. We show how this controlled phasing drives a multi-electron quantum walk, a phenomenon that can be harnessed to produce tailored excitations and superradiance via two-electron energy post-selection.

O 49.4 Tue 15:15 HSZ/0403

Quantum-electrodynamical density-functional theory for periodic solid-state materials — •Benshu Fan[1], I-Te Lu[1], Michael Ruggenthaler[1], and Angel Rubio[1,2] — [1]Max Planck Institute for the Structure and Dynamics of Matter — [2]Center for Computational Quantum Physics (CCQ), The Flatiron Institute

Quantum-electrodynamical density-functional theory (QEDFT) has emerged as a powerful first-principles framework for describing properties of materials coupled to quantized electromagnetic fields. While it has been successfully applied to capture cavity-induced modifications of electronic structures mainly for atoms and molecules, a consistent treatment of phonon-related and optical properties for periodic solids remains elusive. In this work, we present a unified QEDFT framework that incorporates collective light-matter coupling in the electronic ground state, density functional perturbation theory for phonons, and real-time time-dependent QEDFT for optical excitations. This approach enables ab initio calculations of cavity-modified electronic and phononic dispersions, Born effective charges, dielectric tensors, and both non-resonant and resonant optical absorption spectra for solids. Using wurtzite gallium nitride (GaN) embedded in an optical cavity as an example, we show how the quantized vacuum field reshapes electronic and phononic properties and gives rise to possible experimentally observable signatures in the dielectric function and absorption spectra. Our results establish QEDFT as a general first-principles framework for exploring and predicting cavity-modified properties of quantum materials.

O 49.5 Tue 15:30 HSZ/0403

Anyonic Chern Insulator in Graphene Induced by Surface Electromagnon Vacuum Fluctuations — •Xinle Cheng[1], Emil Viñas Boström[1], Frank Y. Gao[2], Edoardo Baldini[2], Dante M. Kennes[1,3], and Angel Rubio[1,4] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany — [2]Department of Physics, The University of Texas at Austin, Austin, Texas, 78712 — [3]Institute for Theory of Statistical Physics, RWTH Aachen University, 52056 Aachen, Germany — [4]Initiative for Computational Catalysis, The Flatiron Institute, Simons Foundation, New York City, NY 10010, USA

Sub-wavelength cavities have emerged as a promising platform to realize strong light-matter coupling in condensed matter systems. Previous studies are limited to dielectric sub-wavelength cavities, which preserve time-reversal symmetry. Here, we lift this constraint by proposing a cavity system based on magnetoelectric materials, which host surface electromagnons with non-orthogonal electric field and magnetic field components. The quantum fluctuations of the surface electromagnons drive a nearby graphene monolayer into an anyonic Chern insulator, characterized by anyonic quasi-particles and a topological gap that decays polynomially with the graphene-substrate distance. Our work opens a path to controllably break time-reversal symmetry and induce exotic quantum states through cavity vacuum fluctuations.

O 50: Electronic structure theory II

O 50.1 Tue 14:30 TRE/PHYS

Efficient DFPT for 2D Films in the FLAPW Code FLEUR — •Thomas Bornhake[1,2], Alexander Neukirchen[1], Gregor Michalicek[1], Daniel Wortmann[1], Gustav Bihlmayer[1], and Stefan Blügel[1,2] — [1]Peter Grünberg Institut, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — [2]Institute for Theoretical Physics, RWTH Aachen University, 52074 Aachen, Germany

Interest in structural instabilities, magnetism, transport, and superconductivity in 2D films is rapidly increasing, and all of these phenomena involve phonons. However, *ab initio* phonon calculations for films typically require large supercells, which include substantial vacuum. As a result, they become computationally expensive. In this talk, we present an efficient and unique DFPT implementation in the context of the all-electron FLAPW code FLEUR [1,2] that treats films as single slabs in a truly 2D geometry perfectly embedded in semi-infinite vacuum [3]. We outline the key features of the method, benchmark it against the commonly employed supercell approach, and show first results on how a homogeneous external electric field modifies the phonon properties.

This work was supported by the CoE-MaX (EuroHPC Joint Undertaking, Grant 101093374) and DFG through CRC 1238 (Project C01).

Valence only FLOSIC with pseudo core electrons — •Simon Liebing and Jens Kortus — Institute of Theoretical Physics, TU Bergakademie Freiberg, 09599 Freiberg, Germany

Over the past decade, the FLOSIC method [1, 2] has demonstrated its versatility and applicability to a wide range of systems. However, it has been observed that this method can require significant computational time, particularly when adjusting the core electrons in the case of heavier elements. Previous work has shown that FLOSIC calculations can be effectively carried out using pseudopotentials [3]. In the case of heavier atoms, however it is possible that the valence orbital descriptors may shift too close to the core region due to the limitations of pseudopotentials. In this work, the authors introduce a novel approach to also account for the repulsive interactions between the core and valence electron FLOSIC descriptors in case of pseudopotentials. This method has the potential to significantly reduce the computational cost typically associated with SIC calculations compared to standard DFT methods. References: [1] M. R. Pederson et al., J. Spectroscopy of chemisorped systems from a first-principles local-orbital representation — •Simiam Ghan and Jens Nørskov — Technical University of Denmark DTU

We present a local-orbital representation of density functional theory (DFT) which elucidates the properties of chemisorped systems. A direct calculation of orbital overlap and coupling matrix elements between the adsorbate and surface allows us to construct the hybridization function, familiar from e.g. Anderson-Newns-Grimley models, which encodes rich orbital phase interactions[1]. Beyond a qualitative tool, we demonstrate the quantitative correspondence of this object to observables in ultrafast spectroscopy and scanning-tunneling spectroscopy. The scheme is generally useful to assess the coupling between a local state and its environment from first principles.

O 50.4 Tue 15:15 TRE/PHYS

Quantum-mechanical analysis of the 4H-SiC surface — •Kateřina Dočkalová[1,2], Martin Friák[2], and Jana Pavlů[1] — [1]Dept. Chem., Masaryk Uni., Brno, Czech Rep. — [2]Inst. Phys. Mater., Czech Acad. Sci., Brno, Czech Rep.

Silicon carbide (SiC) is a key wide-bandgap semiconductor employed in high-power and high-voltage electronic devices. Among its polytypes, 4H-SiC is particularly promising for next-generation power electronics. We investigated the atomic and electronic structure of the 4H-SiC (0001) surface with a specific focus on the challenges of modelling polar orientations. To accurately capture the intrinsic surface properties, we evaluate the planar-averaged electrostatic potential and the electron localisation function (ELF) using various models (differing in bottom-surface termination, passivation with pseudohydrogens, and vacuum thickness) and applying electrostatic corrections. These strategies suppress artificial dipole moments and eliminate spurious internal electric fields that often compromise surface calculations. We find that either carbon termination at the bottom surface or pseudohydrogen passivation can individually introduce a spurious internal electric field manifested in the vacuum potential. Interestingly, applying electrostatic corrections does not improve the electrostatic-potential profile for models in which the vacuum region is already sufficiently thick. Financial support from the Czech Academy of Sciences (Praemium Academiae, M.F.) and Masaryk University (MUNI/A/1691/2024) is acknowledged. Computational resources were provided via e-INFRA CZ (ID:90254).

O 50.5 Tue 15:30 TRE/PHYS

Quantifying conductance variations in single molecule junctions using machine learning — •Hector Vazquez — Inst. of Physics, Czech Academy of Sciences

In single molecule circuits, conductance (the inverse of resistance) is strongly dependent on the junction geometry. Break-junction experiments are often carried out at room temperature, where many molecular conformations are sampled during the measurements. In contrast, the computational cost of DFT-NEGF calculations restricts them to only a few geometries.

We recently developed a computationally efficient method to calculate molecular conductance within DFT for thousands of geometries, based on small Au-molecule-Au clusters [1,2]. Their geometry is taken from MD simulations of the junction at room temperature. We can thus compute within DFT the conductance for tens of thousands of thermally-accessible molecular geometries.

We study typical conjugated and alkane molecules and interpret these large conductance datasets with machine learning methods including regression models, feature importance techniques, and SHAP analysis. Our work identifies which of the bond lengths, angles, or dihedral angles in the molecule, all of which are changing continuously and simultaneously, have a larger impact on conductance.

Towards Accurate Surface Adsorption Through a Numeric-Orbital FDET Framework — •Danjo De Chavez[1] and Reinhard J. Maurer[1,2,3] — [1]Department of Chemistry, University of Warwick, UK — [2]Department of Physics, University of Warwick, UK — [3]Faculty of Physics, University of Vienna, AT

Multiscale embedding methods balance accuracy and computational efficiency in modeling extended materials by combining high-level treatments of active regions with lower-level descriptions of their environments. We implemented Frozen Density Embedding Theory (FDET) with Freeze-and-Thaw (F&T) cycles in the numeric atomic orbital code FHI-aims, enabling consistent cluster and periodic calculations. Initial electron densities are constructed from free-atom superpositions, with one subsystem kept frozen while the other is optimized. The implementation leverages the efficient parallelization of FHI-aims. Embedding potential and subsystem density are decomposed using an auxiliary basis set via an RI framework, facilitating reconstruction in the real space. This method enables accurate predictions with high-level theory for adsorption, bond dissociation, optical excitation, and charge-transfer phenomena relevant to surface catalysis and spectroscopy.

O 50.7 Tue 16:00 TRE/PHYS

Brillouin zone sampling in ONETEP — •Chengcheng Xiao, Peter Haynes, and Arash Mostofi — Department of Material, Imperial College London, London SW7 2AZ, United Kingdom

ONETEP is a parallelised linear-scaling density-functional theory (DFT) simulation software package designed for large-scale calculations of properties of materials. It was engineered under the premise that, for self-consistent calculations of systems with thousands of atoms, the Brillouin zone only needs to be sampled at its centre - the Gamma-point.

Whilst this is a suitable approximation for large systems, it often leads to the unnecessary use of large supercells of structures where periodicity can be exploited. For those systems, a more suitable method is to sample the Brillouin zone along the periodic directions.

In this work, we introduce a new Brillouin zone sampling technique in ONETEP where the localisation constraint imposed on the basis functions is selectively lifted along the periodicity directions, making it possible to perform a "hybrid" calculation where the best scaling can be achieved by incorporating both Brillouin zone sampling and linear-scaling techniques. Furthermore, if the unit cell is small along all directions, all localisation constraints can be lifted, which effectively turns ONETEP into a plane-wave code. This enables us to compare the algorithmic accuracy of ONETEP to other DFT codes on the same footing. These developments enable much more efficient calculations on short and intermediate-scale periodic systems, such as bulk crystals, nanowires, surfaces, and interfaces.

O 51: Focus Session: Structure and Dynamics of Solvent at Electrochemical Interfaces II

Understanding how solvent molecules organize and move at electrochemical interfaces is central to catalysis, energy conversion, and electrochemical materials science. This Focus Session will bring together experimental and theoretical leaders using complementary surface specific spectroscopies as vibrational sum frequency generation, advanced X ray/electron techniques, and multiscale simulations to reveal intermolecular structure, hydrogen bond networks, ion-solvent coupling, and field driven dynamics from single crystal electrodes to complex battery interfaces. By highlighting recent breakthroughs in time-resolved measurements and operando platforms, the session aims to connect fundamental interfacial physics with macroscopic performance in electrocatalysis, corrosion, and electrochemical energy storage.

Ultrafast aqueous electric double-layer dynamics — •Mischa Bonn — Max Planck Institute for Polymer Research

The formation of electric double layers (EDLs) at solid-liquid interfaces is universal, yet their molecular structure and dynamics remain incompletely understood. Building on recent advances in interface-specific spectroscopy and nanofluidic model systems, this talk will address how interfacial polarization, geometric confinement, and charge density collectively shape the structure and dynamics of water at electrochemical interfaces. We will highlight new femtosecond-resolved optical spectroscopy measurements that access the genuine ultrafast response of the aqueous EDL, revealing that field-driven ionic rearrangements and solvent reorganization occur on time scales of only a few tens to hundreds of picoseconds - significantly faster than expected from classical diffusion-limited models. These results demonstrate that collective many-body interactions and short-range correlations dominate the EDL response long before macroscopic diffusion sets in. Taken together, the studies provide a molecularly consistent picture in which interfacial polarization and charge act in concert to control water structure and dynamics across electrochemical interfaces, with direct implications for energy conversion, ion transport, and operando spectroscopies of electrified surfaces.

O 51.2 Tue 15:00 TRE/MATH

Second-order nonlinear vibrational spectroscopy: from depth-resolved studies at charged aqueous interfaces towards determining excitonic-vibrational coupling in hybrid heterostructures — •Debojyoti Roy, Sarabjeet Kaur, Álvaro Díaz Duque, Martin Wolf, Alexander P. Fellows, and Martin Thämer — Fritz-Haber-Institut of the Max Planck Society, 14195 Berlin, Germany

The properties of charged aqueous interfaces are governed by interfacial electric fields that influence ion distributions in the liquid phase, forming an electric double layer. While the evolution of the electric potential is relatively well described by theoretical models, much less is known about the influence of the DC fields on the interfacial molecular structure of water and its evolution with depth. Using our recently developed combined sum- and difference-frequency generation spectroscopy (SFG/DFG), we investigate the depth-dependent water structure at charged interfaces as a function of ionic strength, obtaining deep insight into the anisotropic orientational distribution of water and detailed information on the properties of the hydrogen bond network at different distances from the phase boundary.

Besides depth-resolution, the complementary information from SFG and DFG responses can also be used to isolate coupling terms in doubly-resonant studies. Here we also explore this possibility conceptually and propose such studies on exciton-vibrational coupling in 2D material/organic interfaces, which have various applications in solar cells but still lack understanding of their physicochemical properties.

Invited Talk O 51.3 Tue 15:15 TRE/MATH

Interface-specific nonlinear THz spectroscopy — •Chuanshan Tian — Department of Physics, Fudan Univ. China

Quantum confinement and proximity effects at material interfaces give rise to a range of novel physical and chemical phenomena, substantially advancing our ability to understand and control material properties. The development of in situ and interface-sensitive characterization techniques is therefore critical for uncovering the microscopic mechanisms governing interfacial systems and for improving device performance. This presentation will outline recent advances in interface nonlinear optical spectroscopic techniques, with a particular focus on their extension into the (multi-)terahertz spectral regime. Applications of these methods in probing interfacial microstructures and dynamic processes will be discussed, highlighting their potential for resolving complex interfacial phenomena with high specificity.

Dynamics of catalytically active, atomically precise clusters on reducible oxide supports under the (fast) scanning tunneling microscope — •Friedrich Esch — TU Munich, Garching, Germany

Reducible oxides are versatile supports for catalytically active particles. Their reducibility offers the possibility to steer fundamental properties such as cluster stability and shape, charge transfer, lattice oxygen reverse spillover, or encapsulation. In this talk, I present our fundamental studies on the dynamics of atomically precise Pt clusters on two complementary supports, $Fe_3O_4(001)$, where reduction leads to interstitial diffusion and hole formation, and $CeO_2(111)$, where it leads instead to the formation of surface-near vacancies. As a local probe, we employ scanning tunneling microscopy (STM) at elevated temperatures and under reactive gas environments, upgraded with sophisticated tools for fast movie acquisition and cluster tracking. We complement this structural characterization with integral pulsed valve molecular beam "sniffer" activity and x-ray photoemission measurements. While on magnetite stabilization of even very small clusters via encapsulation is observed [1,2], on ceria, a dimensionality crossover from 3D to 2D clusters occurs, triggered by the degree of surface reduction [3].

Segregation effects in 2D mixed oxide nano-islands: edge structure and composition in V(2-x)FexO3 monolayer islands — Ying Wang[1], Piotr Igor Wemhoff[1], Ghada Missaoui[1], Niklas Nilius[1], Jacek Goniakowski[2], and •Claudine Noguera[2] — [1]Carl von Ossietzky Universität Oldenburg, D-26111 Oldenburg, Germany — [2]CNRS-Sorbonne Université, Institut des Nanosciences de Paris, Paris, France

Low-coordinated atoms located at the surface or edges of oxide nanostructures play a crucial role in adsorption and reaction processes in heterogeneous catalysis. Contrary to binary compounds, there is a significant lack of information on their nature and behavior available for ternary materials. In this study, high-resolution scanning tunneling microscopy, DFT calculations and Monte Carlo simulations have been used to decipher the edge structure and composition of mixed V(2-x)FexO3 honeycomb monolayer islands grown on Pt(111).

DFT calculations and MC simulations demonstrate that, in contrast to a clear preference for VO-terminated edges in the pure V2O3 system, Fe segregation to the edges of mixed films tends to produce undercoordinated edge Fe cations, with a ratio of Fe/VO edge species highly sensitive to the oxygen environment. We show that the different oxygen affinity of V and Fe cations, yielding different bonding strengths of terminal vanadyl and ferryl groups are the main cause of the segregation pattern. The sensitivity of edge composition to the oxygen environment thus represents a lever for manipulating the edge configurations and tuning their catalytic response.

O 52.3 Tue 15:15 WILL/A317

Ultra-high THz-confinement in $LaAlO_3$ twin-walls — •Jakob Wetzel[1], Javier Taboada-Gutiérrez[2], Susanne C. Kehr[1], Alexey B. Kuzmenko[1,3], Lukas M. Eng[2], and Samuel D. Seddon[1] — [1]TU Dresden, Institute of Applied Physics, Nöthnitzer Straße 61, 01187 Dresden, Germany — [2]University of Geneva, Department of Quantum Matter Physics (DQMP), Geneva 1211, Switzerland — [3]ct.qmat: Dresden-Würzburg Cluster of Excellence EXC 2147, TU Dresden, 01062 Dresden, Germany

Recent advancements in polaritonics and nano-photonics have focused on the confinement of optical modes in ultra-thin films, 2D materials, and interfaces in order to uncover pathways toward ultra-compact nanophotonic circuits and sub-diffraction imaging technologies. Such approaches to THz-confinement face fundamental challenges such as inherent strain, defects, and lattice mismatches.

Here we present the experiment- and simulation-based investigations of ferroelastic twin-walls in $LaAlO_3$, which provide a *perfect* strain-free interface to explore optical effects emergent from the coincidence of two equal but directionally rotated optical axes. Scanning near-field optical microscopy (s-SNOM) in combination with the HZDR free electron laser FELBE shows an ultra-high confinement (>250) of THz-fields at these twin-wall. Experimental results are reproduced by COMSOL-simulations and understood with an adapted dipole model.

O 52.4 Tue 15:30 WILL/A317

Atomic-scale effects of surface modifications on mixed conducting oxides — •Matthäus Siebenhofer, Claudia Steinbach, and Jürgen Fleig — TU Wien, Institute of Chemical Technologies and Analytics, Vienna, Austria

Mixed ionic and electronic conducting (MIEC) oxide surfaces play a critical role in various technologies due to their high catalytic activity for processes such as oxygen reduction, oxygen evolution, and (photo)electrochemical water splitting. Recent advances have shown that even minute amounts of surface modifications can dramatically alter the work function and the catalytic performance but the detailed mechanisms behind these effects remain poorly understood.

This contribution discusses our efforts to understand the fundamental processes that occur during modification of MIEC oxide surfaces with ultra-thin oxide layers and acidic contaminants. We employ in-situ impedance spectroscopy during pulsed laser deposition (i-PLD) to monitor changes in the oxygen exchange activity of pristine thin film surfaces; X-ray photoelectron spectroscopy (XPS) and density functional theory (DFT) provide insights into atomic-scale processes induced by these modifications.

Our results demonstrate that surface modifications introduce charge redistribution between the modification and the MIEC oxide. These effects are governed by the ionic potential and acidity of both the host material and the modifying species. Based on these observations, we provide design strategies to tailor optimized material combinations for targeted catalytic applications.

O 52.5 Tue 15:45 WILL/A317

Probing electron-transfer between layers of a CrOx/Pt(111) thin film via workfunction and adsorption measurements in the STM — •Ghada Missaoui[1], Claudine Noguera[2], Jacek Goniakowski[2], and Niklas Nilius[1] — [1]Carl von Ossietzky University, Institute of Physics, D-26111 Oldenburg, Germany — [2]CNRS-Sorbonne University, UMR 7588, INSP, F-75005 Paris, France

Low-temperature tunneling spectroscopy has been employed to probe the workfunction of atomically flat Cr-oxide single- and double-stack films grown on Pt(111). The single-stack Cr3O6 trilayer exhibits an exceptionally high workfunction of more than 7.0 eV, decreasing to 5.0 eV for Cr6O11 double-stacks. The charge redistribution behind this workfunction drop was analyzed by density functional theory. The high workfunction of Cr3O6 trilayers originates from a massive electron transfer from the Pt(111) support into empty Cr-states that reduces 2/3 of the oxide cations from their formal 4+ to a 3+ charge state. The negative surface dipole diminishes upon growing a Cr-O honeycomb plane on top of the trilayer, forming a Cr6O11 double-stack. The ad-layer acts as electron donor, allowing the charge transfer from the platinum to decrease substantially. The charge redistribution not only triggers the detected workfunction drop but also leads to a different reactivity of single- versus double-stack CrOx films, as demonstrated with MgPc adsorption experiments performed with the STM.

Single-Atom Catalysis: Insights From Model Systems — •Gareth S. Parkinson — Institute of Applied Physics, TU Wien, Vienna, Austria

Single-atom catalysis promises maximal atom efficiency, tunable active sites and improved selectivity, and is now a key concept in the design of sustainable catalysts. Yet many of the central claims about what single-atom catalysts are, how they operate, and whether they remain truly isolated under reaction conditions are still under debate. In this overview talk I will use oxide-supported single atoms as case studies to examine what can really be established about structure, stability and mechanism, and where the evidence remains ambiguous. I will show how atomically well-defined model surfaces, probed by STM, noncontact AFM, XPS and vibrational spectroscopy, in tight integration with theory, can test key assumptions about single-atom catalysis. I will close with a perspective on outstanding challenges, from adsorbate induced restructuring and water to the transfer of insight from model systems to working catalysts.

Advanced Characterization of Black Silicon via AFM and XPS: Geometric and Chemical Insights for better characterization of PV materials — •Jens Neurohr[1], Hendrik Hähl[1], Karin Jacobs[1], Michael Klatt[2], and Frank Müller[1] — [1]Experimental Physics and Center for Biophysics, Saarland University, Campus E2 9, 66123 Saarbrücken, Germany — [2]German Aerospace Center (DLR), Institute for Material Physics in Space, 51170 Köln, Germany

Understanding the link between surface geometry and chemical properties is crucial for photovoltaic (PV) applications, especially in nanostructured materials like black silicon (b-Si). RMS roughness is commonly used to describe nanorough surfaces, but it cannot capture their complexity or predict behaviors such as bacterial adhesion [1] or chemical composition.

On steep, irregular surfaces, chemical analysis techniques such as X-ray photoelectron spectroscopy (XPS) becomes challenging. To overcome this, we use Minkowski functionals and tensors [2,3] to relate XPS data to detailed Atomic Force Microscopy (AFM) topography.

Our results show that nanoscale geometry strongly influences chemical surface analysis and that geometric descriptors provide a powerful framework for studying complex surfaces.

Systematic Investigation of Colloidal Au Nanoparticles for High-Density III-V Nanowire Growth — •Pavithira Manoharan, Chris Yanic Bohlemann, Peter Kleinschmidt, Thomas Hannappel, and Juliane Koch — Fundamentals of Energy Materials,Technical University of Ilmenau, 98693 Ilmenau, Germany

Over the past two decades, nanoscale structures such as III-V nanowires (NWs) have become versatile components for electronic and photonic applications, including high-performance photovoltaic and photoelectrochemical systems. Many simulation studies show that the density and lateral arrangement of NWs play a decisive role in optimizing light absorption, charge separation, and surface reactions. However, growing ordered NW arrays remains technologically challenging and costly. In this work, we present a simple and cost-effective method for producing high-density, disordered III-V NW using commercially available Au colloid solutions as a source of the catalyst particles. We perform a systematic study on how experimental parameters, such as surface preparation and substrate deposition conditions, affect the resulting nanowire density and diameter. This comprehensive approach provides insight into catalyst behavior prior to the vapor-liquid-solid growth and enables controlled modification of the NW structures. We also evaluate the limitations and potential of this method for NW-based energy conversion architectures.

O 54.3 Wed 11:00 HSZ/0201

Imaging the transition from diffusive to Landauer resistivity dipoles — •Serhii Kovalchuk[1,2], David Kämpfer[1,3,4], Jonathan K. Hofmann[1,3,4], Timofey Balashov[1,3,5], Vasily Cherepanov[1], Bert Voigtländer[1,3,4], Ireneusz Morawski[2], F. Stefan Tautz[1,3,4], and Felix Lüpke[1,6] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Institute of Experimental Physics, University of Wrocław, 50-204 Wrocław, Poland — [3]Jülich Aachen Research Alliance (JARA), Fundamental of Future Information Technology, 52425 Jülich, Germany — [4]Lehrstuhl für Experimentalphysik IV A, RWTH Aachen University, 52074 Aachen, Germany — [5]Lehrstuhl für Experimentalphysik II A, RWTH Aachen University, 52074 Aachen, Germany — [6]II. Physikalisches Institut, Universität zu Köln, 50937 Köln, Germany

A point-like defect in a current-carrying conductor produces an electrochemical potential dipole that opposes the applied field. When the carriers mean free path is shorter than the defect size, the dipole reflects diffusive transport; when it is longer, ballistic scattering leads to a size-independent residual resistivity dipole as predicted by Rolf Landauer.

We investigate this behaviour around nanoscale holes in thin Bi films on Si(111) using scanning tunneling potentiometry. The measured dipole amplitudes show a clear crossover from linear to constant scaling with decreasing hole size, marking the transition from diffusive to Landauer-type dipoles. This crossover allows us to extract the Fermi wave vector and estimate the carrier mean free path in the Bi films.

O 54.4 Wed 11:15 HSZ/0201

Current-driven Rb^+ intercalation for on-chip tuning of superconductivity in Rb_xC_{60} thin films — •Konstantin Shchukin[1,2], Oliver Gallego Lacey[3], Baptiste Coquinot[4], Jacek Jakowski[5], Jingsong Huang[5], Patrik Staudenmayer[1], Yannic Falke[2], Ram Prakash Pandeya[1], and Alexander Grüneis[1] — [1]Institut für Festkörperelektronik, Technische Universität Wien, Gußhausstraße 25, 1040 Vienna, Austria — [2]II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany — [3]CEA, Université Grenoble Alpes, IRIG-Pheliqs, 38000 Grenoble, France — [4]Institute of Science and Technology Austria (ISTA), Am Campus 1, 3400 Klosterneuburg, Austria — [5]Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, Tennessee, 37831, USA

Superconducting fullerides are usually synthesised by thermal or solution intercalation of alkali ions, which limits control of stoichiometry. We use electro-intercalation to drive Rb^+ into C_{60} thin films. Our on-chip setup combines *in-situ* growth, Raman spectroscopy and four-terminal transport, so that the stoichiometry x of Rb_xC_{60} is obtained from the $A_g(2)$ mode and linked to the superconducting transition temperature Tc. By varying the Rb/C_{60} ratio, we tune the films to superconducting Rb_3C_{60} and change T_c from 7 K to 26 K. Time-dependent Raman and transport data show that the Rb^+ electro-intercalation follows Butler-Volmer-type kinetics. Electro-intercalation enables precise, on-chip control of superconductivity in ultrathin fulleride films and is extendable to other porous and layered materials.

Mesoporous Cobalt Ferrite Thin Film Oxygen Evolution Electrocatalysts: The Role of Fe-Content on Structure, Activity and Stability — •Ann-Kristin Stief, Barbara Gonzalez-Navarrete, Stefan Lauterbach, Jan Philipp Hofmann, and Marcus Einert — TU Darmstadt, Darmstadt, Germany

Cobalt Ferrite is a promising alkaline Oxygen Evolution Reaction (OER) catalyst to replace state-of-the-art but expensive Ir- and Ru-based acidic OER catalysts in green hydrogen production. Given the limited and contradictory literature on the optimum stoichiometry of $Co_{3-x}Fe_xO_4$, we conducted a systematic stoichiometry study from x = 1.0 - 2.0 in increments of 0.2. To this end, mesoporous thin films were synthesized via dip-coating combined with soft-templating, using the commercially available polymer Pluronic F-127 for the first time. Electrochemical testing revealed that the x = 2.0 composition achieved the lowest iR-corrected overpotential (342 mV at 10 mA/cm^2), the smallest Tafel slope, and the lowest charge transfer resistance. Structural characterization disclosed enhanced crystallinity, reduced grain size and higher degree of inversion upon Fe-enrichment. X-ray Photoelectron Spectroscopy (XPS) further indicated that Fe-rich precatalysts form higher surface concentrations of hydroxide or defective oxide. Together, these findings contribute to the understanding of composition-structure-activity relations of Cobalt Ferrite OER catalysts, thereby laying a foundation for tailoring their catalytic performance. This work was supported by BMFTR within SINATRA (TWOB, Award Nr. 033RC036).

O 54.6 Wed 11:45 HSZ/0201

Probing Electromagnetic Chirality in Nanoresonators Using Scanning Reflection Anisotropy Microscopy — •Fabian Haake — ETH Zurich, Switzerland

We report on the application of a Scanning Reflection Anisotropy Microscope (SRAM) to study metasurfaces consisting of chiral nanoresonators. SRAM is a polarization-modulated optical method previously applied to strain mapping in crystalline materials and, more recently, demonstrated for amorphous systems (Sendra *et al.*, 2023; APL. 124, 171102, 2024). The structures were fabricated on Si_3N_4 TEM membranes using electron-beam lithography and metal deposition. Arrays of left- and right-handed resonators were fabricated and probed, showing a wavelength-dependent RAS contrast between the two enantiomorphic forms. Finite-element simulations under circularly polarized illumination reproduce the observed handedness-dependent responses. The results demonstrate that SRAM sensitively resolves enantiomer-specific optical signals at the microscopic scale, enabling direct characterization of electromagnetic chirality in metasurfaces.

O 54.7 Wed 12:00 HSZ/0201

Self-assembly of linear three-ring aromatic thiols on Au(111) and their conversion into 2D molecular materials — •Verena Müller[1], Anna-Laurine Gaus[2], Daniel Hüger[1], Julian Picker[1], Christof Neumann[1], Max von Delius[2], and Andrey Turchanin[1] — [1]Friedrich Schiller University Jena, Institute of Physical Chemistry, Lessingstrasse 10, 07743 Jena, Germany — [2]Ulm University, Institute of Organic Chemistry, Albert Einstein Allee 11, 89081 Ulm, Germany

Self-assembled monolayers (SAMs) allow surface modification at the molecular level and moreover have the ability of crosslinking with low-energy electrons to form mechanically stable and transferable 2D materials, so-called carbon nanomembranes (CNMs).

We investigate the self-assembly of linear, three-ring aromatic thiols on Au(111) and their subsequent electron-induced conversion into carbon nanomembranes (CNMs). Our study examines terphenylthiol (TPT) derivatives with distinct terminal groups (-F, $-CF_3$, $-NO_2$) as well as a pyridinebiphenyl compound. Utilizing complementary surface science techniques - X-ray photoelectron spectroscopy (XPS), low-energy electron diffraction (LEED), and scanning tunneling microscopy (STM) - we elucidate the structural properties of the resulting self-assembled monolayers (SAMs) and investigate their transformation into CNMs. The resulting CNMs exhibit tunable gas permeation characteristics, governed by the chemistry of the precursor molecules and the SAM structure.

O 54.8 Wed 12:15 HSZ/0201

Liquid Flame Spray Enables Durable, Transparent, and Super-repellent Silica Coatings — •Suhad Sbeih — German Jordanian University, Amman, Jordan

Developing coatings that are simultaneously transparent, durable, and highly water-repellent remains a long-standing challenge in materials science. In this work, we show that the liquid flame spray (LFS) technique offers a fast and scalable solution. In this process, a silica precursor is combusted to generate nanoparticles that deposit on moving substrates, forming a hierarchical surface texture in a single step. By carefully adjusting the burner-substrate distance, precursor concentration, and coating velocity, we produced coatings that combine optical clarity with extreme water repellency, reaching contact angles above 150° and roll-off angles below 10°.

Beyond these surface properties, the coatings exhibited outstanding durability and retained their performance after rinsing, condensation, tape, and scratch tests. The results highlight LFS as a versatile approach for engineering multifunctional surfaces that bring together transparency, robustness, and superrepellency. Such coatings open new opportunities for large-area applications in optics, energy devices, and biomedical technologies.

Modulated structures in complex 2D oxides — •Muriel Wegner, Loi V. Tran, Oliver Krahn, Stefan Förster, and Wolf Widdra — Martin-Luther-Universität Halle-Wittenberg, Germany

Crystalline materials are typically characterized by a set of lattice vectors that reflect the materials dimensionality. In surface science we are used to two vectors spanning the lattice. However, systematic lattice modifications, which can be displacive in nature or connected to a different periodicity in a given materials property like magnetism, can call for the need of additional modulation vectors for a proper interpretation of the diffraction pattern. Such modulated structures are rarely discussed in surface science. Here we present the structure of a Ba-Ti-O monolayer film grown on Pd(111) and Pt(111). On Pd(111) this structure is commensurate and fully determined by two lattice vectors. In contrast, on Pt(111) four vectors are needed, two describing the average structure and two

additional modulation vectors. This Ba-Ti-O structure is a complex network of Ti-O rings, in which 53% of the rings are decorated with Ba atoms. On Pd(111) it forms a rhombic structure with a periodicity of 23.2 Å and an inner angle of 129.7°. On Pt(111) it grows with the identical lattice parameters. However as a consequence of the modified substrate spacing, the domain size is restricted by systematic inclusions of defects, which cause a modulation period of about 100 Å.

O 55.2 Wed 10:45 HSZ/0204

How coordination preferences dictate the mixing behavior of 2D oxide films: Fe/Cr spinel-type oxides on Pt(111) — Ghada Missaoui[1], Claudine Noguera[2], Jacek Goniakowski[2], and •Niklas Nilius[1] — [1]Carl von Ossietzky University, Institute of Physics, D-26111 Oldenburg, Germany — [2]CNRS-Sorbonne University, UMR 7588, INSP, F-75005 Paris, France

Fe/Cr mixed oxide films, prepared by reactive co-deposition of both elements on Pt(111), are analyzed by STM and DFT calculations. The mixed oxide grows into bi- (h=0.5 nm) and tri-stack films (h=0.7 nm) terminated either by open (2x2) (bi-stacks) or dense (1x1) atomic patterns (bi- and tri-stacks). The former is identified as Cr6O11 phase composed of an interfacial O-Cr-O trilayer and a Cr2O3 honeycomb plane. The latter develops upon substituting Fe into the surface plane, where it forms a hexagonally dense-packed Fe-O bi-layer. Two polymorphs with different mixing enthalpy occur as a function of mixing ratio. At high Fe content, X6O9-type bi-stacks prevail (X = Fe,Cr) with Cr preferentially accumulating in octahedral sites at the interface and Fe filling tetrahedral sites at the surface. At low Fe content, the Cr interface stack reconstructs to stabilize more oxygen, while the surface stack remains Fe-dominated. The resulting film has X6O11 stoichiometry and deviates from the X6O9 structure not only by the oxygen content but also by its workfunction and surface buckling, in agreement with STM data. The observed cationic stacking, with alternating Fe and Cr planes resembles the bulk ilmenite structure (FeCrO3).

Invited Talk O 55.3 Wed 11:00 HSZ/0204

Cationic Mixing in Ultrathin Oxide Films: How substrate and oxygen conditions control nanoalloying. — •Jacek Goniakowski — Institut des NanoSciences de Paris, CNRS & Sorbonne Université, Paris, France

While alloying is a powerful strategy for tuning material properties, the fundamental physics and chemistry of cation mixing in metal-supported ultrathin oxide films, including those relevant to inverse catalysts, remain poorly understood, and only a few doped or mixed phases have been characterized at the atomic scale. Here, density functional theory, combined with recent surface science experiments, is used to elucidate how oxygen conditions and substrate properties govern the formation of mixed two-dimensional oxide phases through a subtle interplay of structural and electronic effects.

The study shows that, although bulk V-Fe-O mixed oxides are rare, reduced V-Fe-O monolayers on Pt(111) are stable across a wide range of cation compositions. However, oxidation of the film strongly narrows the accessible compositional window. Likewise, substrate passivation (e.g., oxidized Ru(0001)) restricts the range of stable compositions. For somewhat thicker films, exemplified by V-Cr-O bistacks, the presence of crystallographically distinct cation sites further promotes mixing, enabling the stabilization of spinel-like V-Cr phases with no direct bulk counterparts. Our results highlight key effects governing compositionally complex supported ultrathin oxide films and suggest pathways to explore novel mixed phases.

O 55.4 Wed 11:30 HSZ/0204

Surface reconstruction of the polar spinel $MgAl_2O_4$(001) surface — David Kugler[1], Andrea Conti[1], Johanna I. Hütner-Reisch[1], Soumyajit Rajak[2], Matthias Meier[1], Nan Jiang[2], Florian Mittendorfer[1], Michael Schmid[1], Ulrike Diebold[1], Gareth S. Parkinson[1], and •Jan Balajka[1] — [1]Institute of Applied Physics, TU Wien, Vienna, Austria — [2]Department of Chemistry, University of Illinois Chicago, USA

The atomic-scale surface structure governs the surface chemistry of materials. Magnesium aluminate ($MgAl_2O_4$) spinel, a wide-gap insulator, poses considerable challenges for experimental surface characterization. Using noncontact atomic force microscopy (nc-AFM), we resolve the atomic structure of the $MgAl_2O_4$(001) surface. The surface adopts a c(2×4) reconstruction accompanied by altered surface stoichiometry. The reconstructed surface is enriched in aluminum and contains ordered pairs of octahedrally coordinated Mg atoms that, in bulk, occupy tetrahedral sites. This cation redistribution stabilizes the otherwise polar $MgAl_2O_4$(001) termination. The resulting structure closely resembles reconstructions observed on other spinel oxides, suggesting a common mechanism for polarity compensation across the spinel group.

O 55.5 Wed 11:45 HSZ/0204

Size Matters: Size-dependent non-equilibrium dynamics of fluxional subnanoclusters — •Patricia Poths[1], King Chun Lai[2], Christoph Scheurer[1], Sebastian Matera[1], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der Max-Planck Gesselschaft, Berlin — [2]Max Planck Computing and Data Facility, Garching

Sub-nanoclusters are known to be fluxional, thermally populating multiple structural isomers, and to have size-dependent catalytic behavior. Due to computational limitations, only quasi-static equilibrium properties could be addressed by first-principles methods so far. Here, we investigate the kinetic evolution underlying isomer fluxionality by coupling machine-learned interatomic potentials (MLIPs) with our recently introduced automatic process explorer (APE) [1]. With this methodology, we construct comprehensive isomerization networks of Pdn (n=3-11) clusters deposited on the MgO(100) surface, and evaluate the corresponding state-to-state dynamics. Using methods from Markov State Modeling, we find that the intrinsic timescales for equilibration can vary by several orders of magnitude based on cluster size. Furthermore, intrinsic timescales for each cluster isomer can vary by multiple orders of magnitude, indicating the existence of metastable sets with quasi-liquid behavior, i.e. rapid conversion between isomers within the set but only slow transition to isomers outside. These simulations reveal that the prevalent quasi-static picture is of limited use for nonequilibrium problems like catalysis, but also that relaxation dynamics should be observable on experimental timescales.

O 55.6 Wed 12:00 HSZ/0204

Structural and electronic evolution of noble metal-deposited CeO2 catalysts: from model to powder systems — •Zairan Yu, Shuang Chen, Wangtao Li, Alexei Nefedov, Christof Wöll, and Yuemin Wang — Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), 76344 Eggenstein-Leopoldshafen, Germany

The interaction between noble metals and oxide supports is crucial in heterogeneous catalysis, governing key reactions such as CO oxidation and the water-gas shift. Pt- and Pd-ceria systems show particularly strong electronic and structural metal-support interactions among these reactions. Despite extensive investigation, the atomic-scale structure and reactivity of these interfaces remain incompletely understood. Here, we combine polarization-resolved IRRAS on single-crystal surfaces and in situ UHV-FTIR transmission studies on ceria nanoparticles, using CO as a probe to elucidate surface structural dynamics and active sites. For Pt/CeO2(111), IRRAS and DFT results reveal that isolated Pt single atoms are not stabilized on the surface, but instead migrate into subsurface interstitial sites at low coverages, giving rise to a characteristic blue-shifted CO band at 2169 cm-1. In the Pd/CeO2/γ-Al2O3 system, highly dispersed Pd cations embedded in the ceria matrix with nearby interfacial oxygen vacancies are identified, correlating with superior catalytic performance in STD reactions. This work was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation)-Project-ID 426888090-SFB 1441.

O 55.7 Wed 12:15 HSZ/0204

Titanium intermixing into cuprous oxide thin films: An STM and XPS study — •Bo-Yi Zhong and Niklas Nilius — Carl-von-Ossietzky University, Institute of Physics, D-26111 Oldenburg, Germany

According to DFT calculations, gap size and p-type conductivity of binary Cu2O can be tuned over wide ranges by doping the material with transition metal ions. To test this assumption, we have prepared Cu/Ti mixtures and exposed them to different oxidation conditions. Mixing is only revealed at low temperature and gives rise to amorphous oxide films without diffraction pattern. Annealing in oxygen triggers a gradual phase separation, with TiOx moving to the surface and CuOx remaining at the interface to the Pt(111) support. The phase separation produces a distinct intensity behavior of the Ti 2p and Cu 2p XPS peaks as a function of temperature. Morphologically, the Ti ions get embedded into the surface reconstruction of Cu2O(111) at low Ti content, as observed in atomically resolved STM images. With rising Ti level, the surface Ti-O forms large crystallites exposing distinct stripe-patterns on their surface, suggesting a TiO2(110)-type morphology. Moreover, STM spectroscopy finds a gap state at 1.5 eV in Ti-poor preparations, compatible with the empty-state resonance of the Ti impurities. At higher Ti content, the gap state broadens and evolves to the TiO2 conduction band. The electronic response of the phase-separated system, with Cu2O at the interface and TiO2 at the surface, resembles the one of a pn-junction.

Time: Wednesday 10:30–12:15 Location: HSZ/0401

O 56.1 Wed 10:30 HSZ/0401

Simulation of coupled AFM and constant current STM images — •Marvin Krenz[1,2], Miguel Wiche[1,3], Daniel Ebeling[1,3], and Simone Sanna[1,2] — [1]Center for Materials Research, Justus-Liebig University, Giessen, Germany — [2]Institute of Theoretical Physics, Justus-Liebig University, Giessen, Germany — [3]Institute of Applied Physics, Justus-Liebig University, Giessen, Germany

We present a simulation method for AFM images with a constant current STM feedback loop. In contrast to regular AFM constant height images, those images can picture the features of bulky or corrugated molecules, as shown by experiment [1].

The method is based on the electronic density of the molecules, and thus applicable to virtually any DFT code. We apply this method to two test systems, the 6F-Pentacene molecule at Cu(111) and the iodotriphenylene at Ag(111), at different level of approximation.

Both systems compare well to the experimental images; at the highest level of approximation nearly all features of the experiment are reproduced.

O 56.2 Wed 10:45 HSZ/0401

High spatial resolution of Si(111)-7x7 using LFM with a CO-tip — •Shinjae Nam[1,2], Thomas Holzmann[1], Franz Giessibl[1], and Alfred Weymouth[1] — [1]University of Regensburg, Regensburg, Germany — [2]Center for Quantum Nano Science, Seoul, South Korea

The Si(111) 7x7 reconstructed surface has long served as an iconic benchmark for proving the capabilities of scanning probe microscopes. Since STM first resolved the 7x7 pattern in 1983, advances in frequency-modulation AFM have enabled true atomic resolution and quantitative access to short-range chemical and frictional interactions. In this work, we report unprecedented atomic resolution and quantitative mapping of site-dependent lateral forces on the Si(111) 7x7 surface using a qPlus-based lateral force microscope. The tip is terminated with a CO molecule, and oscillating laterally with an amplitude of 50 pm. Unlike reactive Si tips, the CO tip provides a chemically inert and well-defined probe apex, enabling exceptionally sharp contrast and resolving subtle differences between faulted and unfaulted half-cells. The measured lateral force maps agree quantitatively well with theoretical models. These results establish CO-tip LFM as a powerful technique for probing lateral interactions with single-atom precision.

O 56.3 Wed 11:00 HSZ/0401

Spatially Resolved Mode Analysis of Ultra-Long qPlus Probes for STM/AFM — •Aleksander Bogucki[1,3], Yeon-Ji Kim[1,2], Yewon Kim[1,2], Sarah Yi[1,2], German Orlov[1,3], Lei Fang[1,3], Wonjun Jang[1,3], and Andreas Heinrich[1,2] — [1]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Seoul 03760, Republic of Korea — [2]Department of Physics, Ewha Womans University, Seoul 03760, Republic of Korea — [3]Ewha Womans University, Seoul 03760, Republic of Korea

Combined scanning tunneling and atomic force microscopy (STM/AFM) based on quartz tuning forks (qPlus) typically relies on short tip lengths (<0.5 mm) for optimal performance. However, restricted sample environments such as liquid cells or setups requiring significant clearance for high-numerical-aperture optical elements demand probe geometries far exceeding standard dimensions. While tips in the 1-3 mm range have been recently explored [1], the dynamics of significantly longer tips are less well characterized.

We present a systematic study of qPlus sensors with ultra-long tips (>8 mm). We correlate electrical response spectra with spatially resolved optical vibrational analysis to map eigenmodes and identify non-vertical components. Supported by FEM simulations, we demonstrate that tip material and geometry can be optimized to tune the spectral response. Finally, we assess the potential of these ultra-long designs for specialized SPM setups.

Comparative Analysis of SPM-Based Work Function Measurement Techniques with Application to Work Function Engineering of Superconducting Nb(110) — •Daryoush Nosraty Alamdary, Matthias Bode, and Artem Odobesko — Physikalisches Institut, Lehrstuhl für Experimentelle Physik 2, Julius-Maximilians-Universität Würzburg, Germany

The engineering of the work functions at the interface of complex materials for energy band tuning [1] requires precise and reliable measurement methods, sensitive to atomic monolayer thin films. While there are handful of established methods that allow a precise determination of the work function, scanning probe microscopy-based methods constitute a class of their own since they are based on a local probe. In this work, we present a comparative study of three techniques, i.e., $I(z)$ spectroscopy, field emission resonances, and Kelvin probe force spectroscopy, regarding their complexity and reliability to determine the local work function. For a few well-studied model systems we analyze the respective benefits and challenges. Using the most reliable methods, established by the comparative analysis, we systematically study the coverage-dependent crystal structure and work function of epitaxial Ir films on superconducting Nb(110) [2] and discuss the suitability for work function engineering towards induced superconductivity.

Towards Atomically Precise Fabrication through STM with Flat, Crystalline Probes — •Marc Savoie, Eduardo Barrera Ramirez, Bheeshmon Thanabalasingam, and Marco Taucer — CBN Nanotechnologies Inc, Ottawa, Canada

Scanning Tunneling Microscopy (STM) enables the fabrication of atomically precise structures. Traditionally, STM probes manipulate atoms on the sample surface, but this presents challenges for fabricating covalently bonded structures. The high strength of covalent bonds means that detailed knowledge and control over both the probe and sample sides of the tunneling junction is required to form the desired bond and avoid unwanted changes. We introduce inverted-mode STM, an approach that reverses the roles of probe and sample to enable mechanically controlled chemical reactions for atomically precise fabrication. We have developed flat, crystalline Si(100) STM probes that act as the substrate for atomic manipulations. The flat probe is imaged by tailored, 3D molecules deposited on a surface. By determining the orientation of the molecule, the challenge of knowing the atomic configuration on both sides of the junction is effectively resolved. Treating the two sides of the tunnel junction as reagents whose relative positions can be controlled with sub-angstrom precision, we show that hydrogen atoms can be reproducibly abstracted from a locally flat, crystalline region of the probe apex at zero volts using a novel molecule terminated in an alkynyl radical. Multiple surface-bound reagents can sequentially address the same build site on a probe apex. The approach is expected to apply to abstraction and donation of other elements and moieties.

O 56.6 Wed 11:45 HSZ/0401

Atomically Precise Si Abstraction by Inverted-Mode STM — •Rosemary Cranston, Zehra Ahmed, Eduardo Barrera, Brandon Blue, Adam Bottomley, Christian Imperiale, Alex Inayeh, Mathieu Morin, Marco Taucer, and Bheeshmon Thanabalasingam — CBN Nano Technologies Inc., Ottawa, Canada

Direct 3D manipulation of covalently bonded atoms remains a challenge for atomically precise fabrication. Here, we introduce inverted-mode scanning tunneling microscopy (STM) as a new approach for controlled atomic-scale reactions and demonstrate its application to individual Si atom abstraction. A Si probe chip (SPC) with an atomically clean Si(100)-2x1 crystalline terrace at the apex serves as the probe, while a Si wafer bearing isolated, custom-synthesized, surface-bound molecular tools act as the sample. These molecules function both as imaging agents and as tools for chemical manipulation. As the sample is scanned with the SPC, each protruding molecule provides a mirror image of the probe apex and can immediately participate in surface reactions. For subtractive Si patterning, we employ tripodal molecules featuring an ethynyl iodide moiety. After bias-induced cleavage of the iodine, the resulting radical is aligned with a target Si dimer of the SPC. A controlled approach-retraction process transfers a Si atom to the molecule, leaving unique Si vacancies at the target site. Imaging with new iodinated molecules elsewhere on the sample surface confirms changes to the SPC lattice, and allows iterative targeting for the next abstraction, thus enabling a new method for atomically precise fabrication, and the manipulation of Si atoms in 3D.

Graphene Coated Nanoprobes for Local Conductivity Measurements — •Maria Saavedra-Fredes, Valeria del Campo, and Tomas P. Corrales — Universidad Técnica Federico Santa María, Valparaíso, Chile.

Here we explored the fabrication of AFM cantilevers coated with graphene (Gr) with the aim of detecting local electrical currents. The fabrication process begins with the growth of Gr on copper foils via Chemical Vapor Deposition (CVD). Subsequently, the copper substrate is dissolved using a ferric nitrate solution and then replaced with water, leaving a Gr film floating at the water air interface. This film is transferred onto an AFM cantilever using a three-axis hydraulic micromanipulator. Raman spectroscopy and SEM confirm the presence of graphene on our Gr-coated nanoprobes This technique differs from traditional methods because the Gr is collected directly from the air water interface without the use

of polymer films in the process (10.3390/cryst7090269). Then, to detect currents using conductive mode AFM (10.1002/adma.201200579) and study the conduction between our Gr-coated nanoprobe and a graphene layer deposited on silicon.

From Plasmonic Near-Fields to Electron Dynamics - A Photoemission Perspective — •Pascal Dreher — Faculty of Physics and Center for Nanointegration, Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47048 Duisburg, Germany — Present Address: Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg

Electromagnetic near-fields are ubiquitous in solid-state physics. At surfaces, interfaces, and in nanostructures they control dynamical processes and shape optical and electronic material properties. By concentrating electromagnetic energy to subwavelength volumes, near-fields enable tailored nanoscale light-matter interactions relevant to plasmonics, nanophotonics, and ultrafast carrier dynamics. A detailed understanding of these interactions, however, requires experimental access to the full three-dimensional, time-dependent vectorial structure of near-fields, ideally in conjunction with direct probes of the electronic excitations they launch.

In this talk, I will address these needs using two complementary experimental approaches: polarimetric photoemission microscopy that maps vectorial near-fields at surfaces, and time- and angle-resolved photoemission that probes the resulting charge-carrier dynamics. Using surface plasmon polaritons as a prototypical platform, it will be demonstrated how these methods allow to relate near-field dynamics and light-matter interactions at the native length, momentum, time, and energy scales.

O 57.2 Wed 11:00 HSZ/0403

Steps Towards Excitation of Quantum Emitters with Switchable Nonlinear Near Fields — •Valentin Dichtl, Thorsten Schumacher, and Markus Lippitz — Experimental Physics III, University of Bayreuth

The third-order nonlinear material response of noble metals enables the formation of the third-harmonic near field around a plasmonic nanostructure. The corresponding spatial emission pattern of the third-harmonic hot spots changes drastically when the fundamental wavelength is slightly tuned over a linear resonance of the nano antenna [1]. This effect can be used to spatially tailor the near field for excitation of various emitters – such as molecules or quantum dots – beyond the diffraction limit.

We identified distinct differences in the nonlinear scattering behavior between the complentarry plasmonic structures rod and slit [2]. Building on this insight we compare these geometries in terms of their suitability for single emitter excitation.

We demonstrate non-destructive third-harmonic generation in close proximity to fluorescent dyes. Finally, we discuss spectral and temporal strategies for discriminating photons originating from fluorescence versus those from harmonic generation.

O 57.3 Wed 11:15 HSZ/0403

Intrinsic plasmon canalization in the natural biaxial van-der-Waals material $MoOCl_2$ — •Farid Aghashirinov[1], Andrea Manchini[2], Lin Nan[2], Giacomo Venturi[2], Nicola Melchioni[2], Florian Mangold[1], Bettina Frank[1], Antonio Ambrosio[2], and Harald Giessen[1] — [1]4-th Physics Institute, University of Stuttgart, Stuttgart, Germany — [2]Vectorial Nano-Imaging, Istituto Italiano di Tecnologia, Milano, Italy

We investigate directional near-infrared plasmon polaritons in exfoliated $MoOCl_2$ flakes on SiO_2 substrates, excited using gold disk nanoantennas and probed with scattering-type scanning near-field optical microscope (s-SNOM). $MoOCl_2$ is a natural van der Waals material that supports low-loss, in-plane hyperbolic plasmons and exhibits strong optical anisotropy: polarization along the short axis yields metallic behaviour, while alignment with the long axis produces a dielectric response [1]. Using a widely tunable broadband laser from Stuttgart Instruments, we map the polariton dispersion across a broad spectral range and identify distinct propagation regimes. In our work, we observe plasmon-polariton canalization for the first time, where wavefronts propagate without divergence. These measurements highlight $MoOCl_2$ as a broadband, highly directional natural polaritonic platform.

O 57.4 Wed 11:30 HSZ/0403

Toward Plasmonic Neuronal Architectures at the Nanometer Scale — •Christopher Weiss[1], Tobias Eul[2], Emily Kruel[1], Mario Pfeiffer[1], Bert Lägel[1], Benjamin Stadtmüller[2], and Martin Aeschlimann[1] — [1]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, Germany — [2]Experimentalphysik II, Institute of Physics, University of Augsburg, Germany

Classical von-Neumann computers face severe energy and speed limitations when operating large artificial neural networks, motivating alternative computing concepts beyond the traditional architecture. Plasmonic nanostructures offer a promising route toward ultrafast and highly integrated neuromorphic systems by enabling strong optical confinement at the nanoscale. We present a concept for a plasmonic neuronal cell that combines multiplexed signal reception, static weighting, and nonlinear activation within a single device. Optical inputs encoded in the orbital angular momentum of light are directed into separate dielectric-loaded surface-plasmon-polariton waveguides. Synaptic weighting is implemented through nanoscale gaps, whose attenuation characteristics are analyzed using finite-difference time-domain simulations and experimentally validated by photoemission electron microscopy. Nonlinear activation is provided by plasmon-enhanced two-photon photoemission. These results establish the essential functional components required for ultrafast plasmonic neuromorphic architectures.

O 57.5 Wed 11:45 HSZ/0403

Optical resonance tuning of single polystyrene microspheres using the phase-change material In_3SbTe_2 as a switchable mirror — •Rebecca Rahmel, Hristiyana Kyoseva, Lukas Conrads, Thomas Taubner, and Gero von Plessen — I. Institute of Physics (IA), RWTH Aachen University

The optical resonances of dielectric nanoparticles and microparticles can be modified via their size, shape and configuration [1]. Dielectric particles in particle-on-mirror (PoM) geometries show rich optical responses due to their low losses and electric and magnetic multipolar Mie modes [2]. Cueff et al. introduced the concept of a switchable mirror to tune the resonances of dipole emitters using the phase-transition material VO_2 [3]. Here we tune the infrared multipolar Mie resonances of dielectric polystyrene (PS) microspheres using a switchable mirror made of the phase-change material In_3SbTe_2 (IST). IST exhibits a phase change between an amorphous dielectric and crystalline metallic phase in the infrared [4,5] and can be locally switched under the PS microspheres, creating a PoM geometry. Measuring the scattering spectra of the PS microspheres before and after switching, we achieve huge shifts of the resonance wavelength from 5.2 to 8.9 μm. Our work is a first step towards the controlled tuning of multipolar Mie modes of various particles using reprogrammable IST mirror structures.

Spectral tuning of hyperbolic shear polaritons in monoclinic gallium oxide via isotopic substitution — •G. Carini[1], M. Pradhan[2], E. Gelzinyte[1], A. Ardenghi[3], S. Dixit[4], M. Obst[5,6], A. S. Senarath[4], N. S. Mueller[1], G. Alvarez-Perez[1,7], K. Diaz-Granados[4], R. A. Kowalski[4], R. Niemann[1], F. G. Kaps[5], J. Wetzel[5], R. B. Iyer[2], P. Mazzolini[8], M. Schubert[9,10], J. M. Klopf[11], J. T. Margraf[12], O. Bierwagen[3], M. Wolf[1], K. Reuter[1], L. M. Eng[5,6], S. Kehr[5,6], J. D. Caldwell[4], C. Carbogno[1], T. G. Folland[2], M. R. Wagner[3], and A. Paarmann[1] — [1]FHI, Berlin, Germany — [2]University of Iowa, Iowa City, IA, USA — [3]PDI, Berlin, Germany — [4]Vanderbilt University, Nashville, TN, USA — [5]TUD, Dresden, Germany — [6]EXC 2147 (ct.qmat), Dresden, Germany — [7]IIT, Lecce, Italy — [8]University of Parma, Parma, Italy — [9]University of Nebraska, Lincoln, NE, USA — [10]Lund University, Lund, Sweden — [11]HZDR, Dresden, Germany — [12]University of Bayreuth, Bayreuth, Germany

This contribution reports a significant spectral tuning of hyperbolic shear polaritons (HShPs) in monoclinic gallium oxide (bGO) via isotopic substitution. HShPs are imaged in real-space with near-field optical microscopy, allowing for a model-free estimation of the frequency shift. Complementary far-field measurements and *ab initio* calculations - in good agreement with the near-field data - confirm the effectiveness of this estimation. This combined study demonstrates the possibility to support such highly directional polaritons in a hitherto inaccessible range, with great promise for future applications.

O 57.7 Wed 12:15 HSZ/0403

Vibrationally Induced Resonances in Nanolasers based on Plasmonic Cavities — •Kai Müller[1], Kimmo Luoma[2], and Christian Schäfer[3] — [1]Institut für Theoretische Physik, Technische Universität Dresden, D-01062 Dresden, Germany — [2]Department of Physics and Astronomy, University of Turku, 20014 Turku, Finland — [3]Institute of Applied Physics, TU Wien, Wiedner Hauptstrasse 8-10/134, Vienna, 1040, Austria

Optical circuits and light sources, such as lasers, undergo continuous miniaturization. In recent years, this trend has been taken to its extreme with lasers comprising only a few molecules confined in plasmonic nanocavities. Here, we use a novel method that combines the Bogoliubov-Born-Green-Kirkwood-Yvon (BBGKY) hierarchy with the hierarchical equations of motion (HEOM) to provide theoretical predictions for the quantum dynamics of this few-emitter lasing system. Our approach is informed from first principles and explicitly accounts for the entire vibrational manifold of each molecule in addition to the cavity. We show how the form of the vibrational spectrum influences the lasing process and uncover resonant enhancements in the lasing intensity, which are absent if the coherent drive and vibrational relaxation are combined into the commonly used effective incoherent drive.

Probing weak chemical interactions of metal surface atoms with CO-terminated AFM tips identifies molecular adsorption sites — Jalmar Tschakert[1], Qigang Zhong[1], Alexander Sekels[1], Pascal Henkel[2], Jannis Jung[2], K. Linus H. Pohl[2], Hermann A. Wegner[3], Doreen Mollenhauer[4], André Schirmeisen[1], and •Daniel Ebeling[1] — [1]Inst. of Applied Physics, Justus Liebig University Giessen — [2]Inst. of Physical Chemistry, Justus Liebig University Giessen — [3]Inst. of Organic Chemistry, Justus Liebig University Giessen — [4]Inst. for Technical and Environmental Chemistry, Friedrich Schiller University Jena

Understanding reaction mechanisms of adsorbed organic molecules is key to neat on-surface synthesis of functional nanomaterials. Low temperature atomic force microscopy has become an invaluable tool for studying on-surface reaction mechanisms as it allows to visualize the chemical structure of the reactants and products. However, directly accessing the molecule-surface interactions that are responsible for the pathway of on-surface reactions is difficult. Here, we measure chemical interactions between CO-terminated tips and coinage metal surface atoms in all spatial directions with picometer resolution. Identifying the small covalent bonding contributions in the background of the dispersion-dominated interaction enables revealing insights into the nature of chemical bond formation with metal surface atoms and a reliable determination of molecular adsorption sites. The latter can serve as a starting point and for a comparison with theoretical studies.

Rare earth modified silicon surfaces: A promising template for ordered organic growth — •Milan Kubicki, Philipp Gruber, Marie-Louise Fraser, Mario Dähne, and Martin Franz — Technische Universität Berlin, Institut für Physik und Astronomie, Berlin, Germany

The formation of self-assembled layers of organic molecules on solid surfaces is an important research field because of their possible application in advanced (opto)electronic devices. While the formation of self-assembled layers is well established on metal surfaces, the growth on silicon surfaces, which are still the material of choice in present semiconductor technology, is much less studied. On pure silicon, however, the formation of ordered organic films is usually hindered by its high dangling bond density, so that an appropriate surface modification is required.

Here we demonstrate the high potential of a rare-earth modification of the Si(111) surface for promoting ordered growth. Using scanning tunneling microscopy, the adsorption of different organic molecules on rare-earth modified silicon surfaces was examined, exemplarily for highly reactive N-heterocyclic carbenes and less reactive transition metal phthalocyanines. Our data demonstrate that single molecules remain mobile on the surface at room temperature. At a coverage of one full monolayer highly ordered films can be formed, demonstrating the great potential of rare-earth modified silicon surfaces as template for organic film growth.

N-Heterocyclic Carbenes on GaAs: From Chain Formation to Ordered Monolayers — •Martin Franz[1], Ankita Das[2], Sandhya Chandola[3], Milan Kubicki[1], Mowpriya Das[2], Andrea Sette[4], Domenico Corona[4], Maurizia Palummo[4,5], Letizia Chiodo[6], René Schöder[1], Preeti Chahar[2], Benjamin Fuhrmann[1], Jonathan Engelhardt[1], Oskar Düren[1], Mario Dähne[1], Conor Hogan[4,7], Norbert Esser[1,3], and Frank Glorius[2] — [1]Technische Universität Berlin, Institut für Physik und Astronomie, 10623 Berlin, Germany — [2]Organisch-Chemisches Institut, Universität Münster, 48149 Münster, Germany — [3]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, 14109 Berlin, Germany — [4]Dipartimento di Fisica, Università di Roma "Tor Vergata", Rome 00133, Italy — [5]CNR Centro S3, CNR-Istituto Nanoscienze, Modena 41125, Italy — [6]Department of Engineering, Università Campus Bio-Medico, Rome 00128, Italy — [7]CNR-Istituto di Struttura della Materia (CNR-ISM), Rome 00133, Italy

N-Heterocyclic carbenes (NHCs) have emerged as well-established ligands for metal surfaces. First studies on silicon exist as well, while III-V compound semiconductors are the materials of choice for opto-electronic devices. Here, the adsorption behavior of NHCs on GaAs is studied in detail [1]. A covalent binding to the surface and a formation of well-ordered monolayers is found, accompanied by exceptionally large work function reductions. The monolayers consist of NHC chains being the result of an attractive interaction between the molecules.

O 58.4 Wed 11:15 TRE/PHYS

Tuning the adsorption of Subphthalocyanine molecules on Au(111) by peripheral and axial functionalization — •Franz Plate[1], Soyoung Park[2,3], Ebru Cihan[1], Natasha Khera[1], Ningwei Sun[2,3], Dmitry A. Ryndyk[1], Franziska Lissel[2,3], and Francesca Moresco[1] — [1]Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany — [2]Institute of Macromolecular Chemistry Leibniz Institute of Polymer Research, Hohe Strasse 6, Dresden, Germany — [3]Institute for Applied Polymer Physics, TU Hamburg, 21073 Hamburg, Germany

Subphthalocyanine (SubPc)-based molecules have been shown to be chemically versatile and tunable molecules, which can be functionalized with a variety of different chemical groups. This makes them promising candidates for designing single molecule machines to store and convert energy. Examples include vertical molecular rotors on surface. Although SubPc is nonplanar, SubPc-based molecules have been shown to form well-ordered molecular assemblies on surfaces, enabling them to function as modular rotor bases. Their chemically stable and rigid core, allows for a functionalization with different axial ligands as well as extensions at the peripheral positions of the π-conjugated base, which leads to different orderings on the surface. We have studied different SubPc based molecules with different axial and peripheral functionalizations on Au(111) using low-temperature scanning tunneling microscopy, supported by simulations. Depending on the peripheral functionalization with methoxy and thiophene groups, we found different adsorption behaviors, ordering, and intermolecular interactions.

O 58.5 Wed 11:30 TRE/PHYS

From Inert Nitrogen to Reactive Metal Nitrene: An On-Surface Route to N-Heterocycles — •Marco Thaler[1], Ricardo Ruvalcaba Briones[2], Shadi Fatayer[2], and Laerte Patera[1] — [1]Department of Physical Chemistry, University of Innsbruck, Innsbruck, Austria — [2]Applied Physics Program, Division of Physical Science and Engineering (PSE), King Abdullah University of Science and Technology (KAUST), Thuwal, Saudi Arabia

Nitrenes are highly reactive intermediates in organic chemistry and play a key role in the synthesis of nitrogen containing compounds. In solution, nitrenes are typically generated from chemically activated precursors (e.g., azides), whereas direct conversion of primary amines remains challenging due to the inherent strength of N-H bonds. On surfaces, reactive nitrenes have likewise been formed from organic azides [1]; however, azides are thermally and photochemically labile and can decompose violently upon exposure to heat, light, or mechanical shock, posing safety risks. Here, using combined scanning tunneling microscopy (STM), non contact atomic force microscopy (nc AFM), and density functional theory (DFT), we demonstrate the thermally activated formation of a surface stabilized metal-nitrene intermediate from a chemically inert amine, which mediates the on-surface formation of a nitrogen-containing heterocycle. Our findings establish non activated nitrogen functionalities as viable nitrene precursors and reveal new mechanistic pathways for on-surface synthesis of N-heterocyclic compounds.

O 58.6 Wed 11:45 TRE/PHYS

Mirror domains and adsorption induced dipoles in organic semiconductor films revealed by LEEM and μLEED — •Franz Niklas Knoop, Klaus Stallberg, and Winfried Daum — Institute of Energy Research and Physical Technologies, TU Clausthal, Germany

We apply low-energy electron microscopy (LEEM) and microspot low-energy electron diffraction (μLEED) to study the film growth of nonpolar para-sexiphenyl (*p*-6P) molecules on natively oxidized silicon. In their second monolayer, the molecules form μm-sized, 2D-crystals with a bulk-like unit cell. LEEM reveals dark lines that split individual islands along their long axis into two domains of roughly equal size. The corresponding diffraction patterns are laterally shifted relative to each other, allowing for dark-field imaging of each domain. We attribute this apparent shift in k-space to the presence of lateral electric fields pointing in opposite directions on either side of an island. Given *p*-6P's large polarizability, we ascribe these fields to induced electric dipole moments in the tilted molecules. Thus, the observed dark lines represent boundaries between adjacent domains of mirrored tilt. Since the shift in k-space is independent of the LEEM extractor field, the dipoles must be inherent to the adsorbed molecules on the Si substrate. We observe an increased work function for the second-layer islands compared to the substrate. This and temperature-dependent measurements support our conclusion that adsorption-induced charge transfer causes the polarization of the molecules.

O 58.7 Wed 12:00 TRE/PHYS

The Role of Metal Ions in Metal-Phthalocyanine Adsorption on Oxide Surfaces — Matthias Blatnik[1], Fabio Calcinelli[2], Andreas Jeindl[2], Michael Schmid[1], Ulrike Diebold[1], Peter Jacobson[3], Oliver T. Hofmann[2], and •Margareta Wagner[1] — [1]TU Wien, Austria — [2]TU Graz, Austria — [3]University of Queensland, Australia

The interaction of conjugated organic molecules with surfaces is of fundamental interest and also important in many applied areas. Surface science investigations have advanced understanding of organic/metal interfaces, but the second electrode in organic optoelectronic devices – typically the transparent conductive oxide In_2O_3 – remains largely unexplored. Our work aims at closing this gap by examining the model system phthalocyanines on indium oxide surfaces.

Phthalocyanines adsorbed on the In_2O_3(111) surface were studied experimentally with low temperature STM and AFM, combined with DFT calculations. A key aspect is the comparable size of the molecules and the surface unit cell, which allows a (1×1) arrangement despite the differing symmetries. Various metal phthalocyanines (MPc: CuPc, CoPc, etc.) are investigated to reveal the influence of the metal ion in the selection of adsorption sites, 2D condensation, and the formation of the first layer. We identify a common, robust adsorption site for different MPc that forces the molecules to overlap in the (1×1) structure of the first layer, and a less common site, where a (1×1) packing without overlap is realized.

O 58.8 Wed 12:15 TRE/PHYS

***In Situ* Field-Induced Switching of Global Chirality in Halogen-Bonded Kagomé Networks** — •Nico Kubetschek, Jana Dietrich, and René Matzdorf — Institute of Physics, University of Kassel, Kassel, Germany

We used small organic molecules to construct a chiral Kagomé lattice on the Ag(111) and Au(111) surfaces. The chirality arises from triple halogen bonds that form windmill-like structures. Under certain conditions, we observe a switching in the rotational sense of whole terraces while scanning with STM. The total molecular coverage was used to tune the switching probability between the two chiral states. We demonstrate a bias-dependent attraction or repulsion of the molecules relative to the STM tip position, explaining the observed perturbation leading to the switching events.

Polarons in epitaxial single-layer $MnBr_2$ — •Affan Safeer, Oktay Güleryüz, Guangyao Miao, Wouter Jolie, Thomas Michely, and Jeison Fischer — II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany

We investigate polaron formation in insulating single-layer $MnBr_2$ grown by molecular beam epitaxy on three different substrates: graphene on Ir(110), graphene on Ir(111), and Au(111). The polaron number densities and species depend strongly on the underlying substrate, underscoring the crucial role of the substrate. Our findings show that modeling of polarons in such single-layer insulators in contact with conducting substrates must explicitly include the substrate. For $MnBr_2$ grown on graphene/Ir(110), we identify four distinct polaron species, three of which closely resemble those reported for $CoCl_2$ on graphite. These polarons can be created, converted, and laterally manipulated by the STM tip when a tunneling current flows at suitable bias voltages. For graphene on Ir(110) as a substrate, mobile polarons in $MnBr_2$ are guided by the periodic potential imposed by the super-moiré pattern arising from the interaction of $MnBr_2$ with graphene and Ir(110).

O 59.2 Wed 10:45 TRE/MATH

Chirality in the Kagome Metal CsV_3Sb_5 — •Tom P. Lammerskötter[1], H.J. Elmers[2], G. Schönhense[2], O. Tkach[2], Y. Lytvynenko[2], H. Agarwal[2], S. Chernov[3], M. Hoesch[3], D. Kutnyakhov[3], M. Fedchenko[1] — [1]Goethe-Universität Frankfurt (Germany) — [2]JGU Mainz (Germany) — [3]DESY Hamburg (Germany) — [4]Universität zu Kiel (Germany) — [5]AGH University of Krakow (Poland) — [6]KIT Karlsruhe (Germany) — [7]DIAMOND (UK) — [8]Universität Würzburg (Germany)

Kagome metals AV_3Sb_5 (A = Cs, K, Rb) exhibit flat bands, Dirac points, and van Hove singularities that drive unconventional charge-density-wave (CDW) order and topological states. We study chirality in CsV_3Sb_5 using angle-resolved photoemission spectroscopy (ARPES) and x-ray photoelectron diffraction (XPD) with circularly polarized photons. XPD reveals a local crystal chirality in the CDW phase. ARPES shows pronounced magnetic circular dichroism (MCD), demonstrating a chiral electronic structure and indicating orbital moments possibly linked to loop-current order. To probe orbital-moment coupling, we study Nb-doped CsV_3Sb_5, where band broadening and enhanced Dirac-like gaps occur. In the CDW phase, the strongly increased MCD indicates time-reversal-symmetry breaking and couples to the three van Hove singularities at the M points.

O 59.3 Wed 11:00 TRE/MATH

Ab initio and group theory ananlysis of monolayer BiTeI — •Josep Mas-Garcia, Jorge Cervantes-Villanueva, Alejandro Molina-Sánchez, and Alberto García-Cristóbal — ICMUV - University of Valencia - Spain

Monolayer BiTeI is a prototypical polar semiconductor whose remarkable Rashba spin splitting, rooted in strong spin-orbit coupling and non-centrosymmetric structure, offers a fertile landscape for advancing two-dimensional spintronics. This work presents and ab initio and group-theoretical analysis of BiTeI. Employing fully relativistic density functional theory and GW calculations, we obtain electronic structures that serve as benchmarks for the group-theory based Hamiltonian model. Leveraging the systematic method of invariants, we construct symmetry-constrained k-p Hamiltonians near the Γ point. Our implementation of the method of invariants enables precise fitting of the Hamiltoninan eigenvalues to ab initio band dispersions for the obtention of the parameters, and yields a highly compact analytic model that reproduces Rashba splitting and symmetry-dependent features. This framework facilitates straightforward evaluation of key physical quantities, such as effective masses or spin textures, and perturbative responses including electric and magnetic fields and strain effects within a unified and transparent formalism. Moreover our methodology establishes a versatile template for the symmetry-guided modeling of nonmagnetic semiconductors with strong spin-orbit coupling.

O 59.4 Wed 11:15 TRE/MATH

Production of Interstitials in 2D Transition-Metal Dichalcogenides (TMDs) by Ion Irradiation: ab-initio Simulations — •Silvan Kretschmer[1], Joel Davidsson[2], and Kristian S. Thygesen[1] — [1]CAMD, Technical University of Denmark — [2]Department of Physics, Linköping University, Sweden

Defects critically shape the properties of two-dimensional (2D) materials and can be purposefully introduced to tune magnetic, electronic, and optical behavior. Low-energy ion irradiation has recently emerged as an effective route for generating specific defect types via direct implantation [1,2].

First-principles simulations are essential for understanding irradiation-induced defect formation [3], but DFT-based molecular dynamics (MD) is computationally costly and limits broad exploration of materials and irradiation conditions. Machine-learning (ML) interatomic potentials provide a high-accuracy, low-cost alternative, enabling efficient screening of large datasets such as the Impurities in 2D Materials Database [4].

Here, we benchmark a ML potential against ab-initio MD, emphasizing accurate treatment of the short interatomic distances occurring during ion impacts. We apply the fine-tuned ML to study interstitial defect formation in TMDs under low-energy ion irradiation, providing defect formation probabilities and identifying suitable ion-beam parameters for targeted defect engineering in 2D materials.

O 59.5 Wed 11:30 TRE/MATH

Long-living metastable electronic states in substituted $1T$-TaS_2 — •Gaël Reecht[1], Jesumony Jayabalan[1], Ričards Knipšis[2], Florian Diekmann[3], Friedemann Queisser[2], Ping Zhou[1], Walter Schnelle[4], Kai Rossnagel[3,5], Ralf Schützhold[2], Manuel Gruber[1], and Uwe Bovensiepen[1] — [1]University Duisburg-Essen, Germany — [2]HZ Dresden-Rossendorf, Germany — [3]CAU of Kiel, Germany — [4]MPI for Chemical Physics of Solids, Dresden, Germany — [5]DESY, Hamburg, Germany

$1T$-TaS_2 is a prototypical correlated material whose low-temperature phase exhibits a commensurate charge density wave forming Star-of-David (SOD) clusters. Each SOD hosts a single electron close to E_F and, due to strong on-site Coulomb repulsion, the system enters a Mott insulating state. Adding or removing an electron creates doublon or holon excitations, which typically relax within few femtoseconds [1]. Here, we manipulate the lifetime of the quasiparticle excitations by substituting some Ta with an electron richer element. Using LT-scanning tunnelling microscopy and spectroscopy (STM/STS) and time-resolved photoemission spectroscopy, we observe metastable doublons with lifetimes ranging from fs to hours. STM/STS further shows that these excitations are locally confined. The experimental observations are corroborated by a theoretical description based on a Fermi-Hubbard model. The disorder induced by the random substitution leads to a spatial localization of holon and doublon wavefunctions at the origin of the long lifetimes observed experimentally.

Fingerprints of Excitonic Collective Modes in the Two-Dimensional Electron Gas — •Jakob Wolff[1,2,3], Silvana Botti[2,3], Lucia Reining[4,3], and Matteo Gatti[4,3,5] — [1]Institut für Festkörpertheorie- und Optik, Friedrich-Schiller-Universität Jena, Germany — [2]Research Center Future Energy Materials and Systems, University Alliance Ruhr and Interdisciplinary Centre for Advanced Materials Simulation, Faculty of Physics and Astronomy, Ruhr University Bochum, Germany — [3]European Theoretical Spectroscopy Facility (ETSF) — [4]LSI, CNRS, CEA/DRF/IRAMIS, École polytechnique, Institut Polytechnique de Paris, France — [5]Synchrotron SOLEIL, Gif-sur-Yvette, France

We investigate the collective charge excitations of the two-dimensional homogeneous electron gas in the low density regime within the framework of time-dependent density functional theory. We show that beyond the well-known plasmons new collective excitonic modes emerge, which leave characteristic fingerprints in experimentally accessible quantities, such as asymmetric peak structures in the loss function and enhanced Friedel oscillations. Further, at sufficiently low densities the collective modes become imaginary, indicating an instability towards the formation of a charge-density-wave phase with excitonic origin.

O 59.7 Wed 12:00 TRE/MATH

Moir'e modulated quantum spin liquid candidate 1T-TaSe2 — Ziying Wang, Adolfo O. Fumega, Ana Vera Montoto, Mohammad Amini, Büsra Gamze Arslan, Ales Cahlik, Yuxiao Ding, Jose L. Lado, •Robert Drost, and Peter Liljeroth — Aalto University, Department of Applied Physics

Quantum spin liquids continue to fascinate with their highly entangled quantum states and promises of fractional many-body excitations. Yet there are few tools to probe these materials, and none sensitive enough for applications in 2D materials. This seriously hampers the study of monolayer QSL candidates such as α-RuCl3 and 1T-TaSe2. Scanning tunneling microscopy and spectroscopy may overcome this challenge, as they can access the fundamental excitations of 2D samples through inelastic tunneling spectroscopy. These low-energy excitations can be compared against theoretical models and provide fingerprints of QSL states. We employ this approach against the quantum spin liquid candidate 1T-TaSe2. We observe the emergence of a root 3 reconstruction driven by the substrate, equivalent spectroscopy across all spin sites, and the coexistence of zero and finite energy excitations. These observations are consistent with a QSL ground state. Our results demonstrate that IETS provides a powerful route to obtain atomic-scale insight into the magnetic excitations of two-dimensional materials. Spectral fingerprints may help to identify exotic phases of matter that are otherwise difficult to detect.

O 59.8 Wed 12:15 TRE/MATH

Long-Range Interactions in Twisted Bilayer Materials with Machine Learning for the Electronic Density — •Zekun Lou[1], Alan Lewis[2], and Mariana Rossi[1] — [1]MPI for the Structure and Dynamics of Matter, Hamburg, Germany — [2]Department of Chemistry, University of York, York, U.K.

Moiré superlattices in twisted bilayer (TB) 2D materials exhibit extraordinary quantum phenomena, but first-principles understanding remains limited by computational costs. While most machine learning (ML) methods for density functional theory (DFT) acceleration are based on the locality assumption, we demonstrate that accurate moiré electronic structure prediction requires long-range encoding due to charge rearrangement, orbital hybridisation, and moiré potential modulation. Using long-range representations [1] for electronic-density prediction [2,3], we achieve low-energy band-structure predictions with <15 meV errors across twisted bilayer graphene (TBG), hBN, and transition-metal dichalcogenides (TMDCs), while ~100 times faster than DFT. Descriptor requirements are material-dependent: homoatomic systems (e.g., TBG) are well-described by local descriptors, while hBN and TMDCs require long-range encoding. We summarise the physical implications of these findings that marry machine learning and the fundamental physics that governs the electronic density of twisted bilayer materials.

O 60: Focus Session: Unoccupied States by Inverse Photoemission I

The Other Half of the Picture: 50 Years of Direct Access to Unoccupied States by Inverse Photoemission

In 1981, J. Pendry evaluated the experimental access to electron states in solids: "Currently only half of the picture can be seen with photoemission. Inverse photoemission provides the other half." A complete picture of electron states needs both occupied and unoccupied states in order to describe, understand, and finally tailor macroscopic material properties. In 1976, V. Dose had submitted a first paper on Bremsstrahlung Isochromat Spectroscopy in the VUV range: "The physics involved may be most simply described as an inverse photoelectric effect." The first experiments provided surface-sensitive information on the density of unoccupied states. Later, momentum and spin resolution were added to investigate the spin-dependent E(k) dispersion of unoccupied electron states. During five decades, the technique was further developed by several groups worldwide to enhance the intensity and improve the resolution in energy, momentum, and spin. A wealth of information was gained about metals, semiconductors, ultrathin films as well as adsorbate systems. The experimental studies were accompanied by several theoretical approaches, which are able to accurately describe the unoccupied electronic structure and model the inverse photoemission process. In 2012, H. Yoshida extended the energy range to the near-UV range (low-energy inverse photoemission), which is especially suited to study organic samples due to a lower damage risk caused by the exciting electron beam.

Current research fields for inverse photoemission are, e.g., spin textures of exchange- and/or spin-orbit-induced influenced systems and topological insulators, gap structures in transition metal dichalcogenides, LUMO levels in semiconductors for photovoltaic applications, electronic structure of atomic-layer and quantum materials. This focus session will highlight recent advances obtained by inverse photoemission in different fields and material systems. Also, it will bring together researchers from different areas for addressing current trends and future applications of inverse photoemission from experimental as well as theoretical perspective.

Organized by Markus Donath, Fabian Schöttke and Peter Krüger (U Münster).

Invited Talk O 60.1 Wed 10:30 WILL/A317

Disentangling the origins of spin polarization in (inverse) photoemission from solid surfaces — •Jürgen Henk — Martin Luther University Halle-Wittenberg, Halle, Germany

The spin polarization of electronic states in solids can be probed by various photoemission-based techniques. We discuss how optical excitation modifies the spin polarization of the initial electronic states. Illustrative examples include Rashba-type surface states observed in photoemission (PE) from Au(111), the Dirac-like surface state in inverse photoemission (IPE) from W(110), and magnetic contrast in photoemission electron microscopy (PEEM) from Fe(001). Instead of employing a full group-theoretical analysis, we introduce a simplified symmetry-based approach that enables a clear separation of the different contributions to the photoelectron spin polarization—arising from light polarization, spin-orbit coupling, and intrinsic spin textures. This framework facilitates the interpretation of spin-resolved measurements at surfaces without relying on fully relativistic photoemission calculations.

O 60.2 Wed 11:00 WILL/A317

Inverse photoemission - just the inverse of photoemission? — •Markus Donath — University of Münster, Germany

Photoemission (PE) is known as the most powerful experimental technique to investigate the occupied energy levels of electrons in matter. The photoelectric effect, where electrons are detected after excitation with light, was first observed by H. Hertz and W. Hallwachs in 1887/1888. The reverse effect, the emission of Bremsstrahlung after irradiation of electrons was discovered by W.C. Röntgen in 1895. Bremsstrahlung spectroscopy provides access to unoccupied states. The first Bremsstrahlung spectroscopy experiment in the vacuum ultraviolet (VUV) range was performed by V. Dose fifty years ago [1]. In 1980, J.B. Pendry named this technique inverse photoemission (IPE) [2]. By using light in the VUV spectral range, PE and IPE became valuable complementary tools for studying the energy vs momentum dispersion of electron states below and above the Fermi level, even with spin resolution. After some historical remarks, this talk will review strengths and challenges as well as future perspectives of IPE.

A Retrospective on Spin-Resolved IPES in Milan — •Alberto Calloni, Gianlorenzo Bussetti, and Franco Ciccacci — Dipartimento di Fisica, Politecnico di Milano, Piazza Leonardo da Vinci 32, 20133 Milano, Italy

For over thirty years, the Milan group led by Franco Ciccacci has been a key contributor to the development of spin-resolved Inverse Photoemission Spectroscopy (SR-IPES), advancing both the experimental methods and the study of empty electronic states in solids and interfaces. The activity began in the early '90s, when a dedicated system for spin- and angle-resolved measurements was conceived and built in Milan, drawing on the experience gained earlier with one of the first IPES setups using a UV grating. The new apparatus, featuring a spin-polarized GaAs electron source and a solid-state photon detector that ensured efficient detection of the weak IPES signal, enabled the direct investigation of spin-dependent unoccupied states at a time when such studies were still in their infancy. Building on this capability, the group has carried out a broad range of SR-IPES studies on metallic surfaces, magnetic thin films and multilayers, addressing phenomena such as spin-polarized quantum-well states and surface- or interface-induced spin polarization. More recently, together with studies on systems in which spin-orbit effects define the spin texture of the unoccupied states, the IPES setup has also been applied to hybrid organic/inorganic and molecule/ferromagnet interfaces, offering insight into the stability of the unoccupied states and their possible modifications upon interaction with the surrounding environment.

O 60.4 Wed 11:30 WILL/A317

Spin-Orbit Effects in Atomic-Layer Materials: Tl on Ag(111) — •Sven Schemmelmann[1], Peter Krüger[2], Patrick Härtl[3], Matthias Bode[3], Yuichiro Toichi[4], Kazuyuki Sakamoto[4], and Markus Donath[1] — [1]Physikalisches Institut, Universität Münster, Germany — [2]Institut für Festkörpertheorie, Universität Münster, Germany — [3]Experimentelle Physik II, Universität Würzburg, Germany — [4]Department of Applied Physics, The University of Osaka, Japan

Growing Tl on Ag(111) results in several structures of the Tl adlayers. For low coverage a $TlAg_2$ surface alloy is formed [1]. The Tl monolayer and bilayer exhibits moiré superstuctures with a continuous rotation of the Tl adlayer. Interestingly, all these structures exhibit characteristic spin-orbit-induced effects in their unoccupied electronic structure revealed by spin- and angle-resolved inverse photoemission. The surface alloy is predicted to exhibit states with a Rashba-type spin splitting. In experiment, the intensity of these states is too low for a spin analysis [1]. In the Tl monolayer, spin-dependent hybridization of different overlayer states is observed [2]. Surprisingly, also an image-potential state located in front of the surface is found to hybridize with Tl states. The Tl bilayer, in contrast, exhibits a non-Rashba-like spin-polarized Fermi surface whose origin is found in the dispersion of the unoccupied states.

O 60.5 Wed 11:45 WILL/A317

Surface state on Au(111): Shockley vs topology — •Patrick Geers, Fabian Schöttke, and Markus Donath — University of Münster, Germany

The *L*-gap surface state on Au(111) is the famous prototype for a Rashba-split Shockley surface state (SS). In 2015, Yan *et al.* posed the question whether Shockley-type SSs may be interpreted as variation of SSs in topological insulators, as both states exist in inverted band gaps [1]. The behaviour of the SS

away from $\overline{\Gamma}$ is important to answer this question. It is crucial to know whether the SS potentially closes the inverted band gap between $\overline{\Gamma}$ and $\overline{M}$. An analysis of not only the existence of SSs but also their spin textures is necessary to show a potential topologically nontrivial character of such SSs.
Inverse photoemission (IPE) as a technique to study the unoccupied electronic states is capable to measure these SSs with spin resolution at expected energies of about 4 eV above the Fermi level. In this talk, we present spin-resolved IPE results for Au(111) showing the energy vs momentum range between $\overline{\Gamma}$ and $\overline{M}$, where the SS merges into the bulk bands.

O 60.6 Wed 12:00 WILL/A317

Combining Spin Polarized Inverse Photoemission Spectroscopy with Angle-resolved X-ray Magnetic Circular Dichroism — •Takashi Komesu[1], Arjun Subedi[1], Bharat Giri[1], Ather Mahmood[1], Will Echtenkamp[1], Mike Street[1], Alpha N'Diaye[2], Xiaoshan Xu[1], Christian Binek[1], and Peter Dowben[1] — [1]University of Nebraska-Lincoln, Lincoln, NE, U.S.A — [2]Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA, U.S.A

While angle-resolved magnetometry and angle-resolved X-ray Magnetic Circular dichroism (XMCD) might provide hints of spin or moment canting at a surface, even XMCD taken in the total electron yield (TEY) mode cannot convincingly implicate the surface. Spin Polarized Inverse Photoemission Spectroscopy (SPIPES) is hugely surface sensitive, which is an advantage for characterizing boundary polarization of materials. With in-plane SPIPES, we have convincing proof of deviation from the expected perpendicular anisotropy for boron (B) doped $Cr_2O_3(0001)$ and at the surface of $NiCo_2O_4(001)$. For $NiCo_2O_4(001)$, the Ni magnetic moments are canted slightly off the surface normal, as evident in elemental specific angle-resolved XMCD and consistent with the very surface sensitive SPIPES. In this presentation, we will show the great value of combining SPIPES with XMCD and magnetometry. Furthermore, we can provide an example where an exponential decay of spin polarization is not evidence of a finite paramagnetic correlation length, as in the case of thickness dependent Pd over layers on $Cr_2O_3(0001)$, where Pd is no longer paramagnetic.

O 60.7 Wed 12:15 WILL/A317

On the sign of the Rashba parameter in image-potential states — •Fabian Schöttke[1], Kaishu Kawaguchi[2], Kenta Kuroda[3], Peter Krüger[1], Thorsten Deilmann[1], Sven Schemmelmann[1], Ayumi Harasawa[2], Shuntaro Tani[2], Yohei Kobayashi[2], Takeshi Kondo[2], and Markus Donath[1] — [1]Universität Münster, Germany — [2]Institute for Solid State Physics, The University of Tokyo, Japan — [3]Hiroshima University, Hiroshima, Japan

Image-potential surface states are simple model systems, where spin-dependent effects can be studied in view of spintronic applications. The Rashba effect in surface states at high-Z materials is related to both the strong spin-orbit interaction in heavy atoms and the orbital angular momentum arising from the inversion-symmetry breaking at the surface. Our studies with spin- and angle-resolved inverse photo-emission and three-photon photoemission on image-potential states at Re(0001), Bi_2Se_3 and Bi_2Te_3 show a clear correlation between orbital angular momentum and spin directions. A key factor of our analysis is spin resolution, which enhances the effective resolution to separate spectral features considerably, provided they have different spin character.

O 61: Organic molecules on inorganic substrates: electronic, optical and other properties II

Time: Wednesday 15:00–17:45 Location: HSZ/0201

O 61.1 Wed 15:00 HSZ/0201

Circular dichroism in the photoelectron angular distribution of achiral molecules — Christian Simon Kern[1], Xiaosheng Yang[2], Giovanni Zamborlini[1,3], Simone Mearini[3], Matteo Jugovac[3], Vitaliy Feyer[3], Umberto De Giovannini[4], Angel Rubio[4], Serguei Soubatch[2], Michael G. Ramsey[1], •Frank Stefan Tautz[2], and Peter Puschnig[1] — [1]Institute of Physics, University of Graz, Austria — [2]PGI-3, FZ Jülich & RWTH Aachen University, Germany — [3]PGI-6, FZ Jülich & Universität Duisburg-Essen, Germany — [4]MPI for the Structure and Dynamics of Matter, Hamburg, Germany

Circular dichroism in the angular distribution (CDAD) is the effect that the angular intensity distribution of photoemitted electrons depends on the handedness of the incident circularly polarized light. CDAD has been reported also for achiral organic molecules at the interface to metallic substrates. For this latter case, we investigate two prototypical pi-conjugated molecules, namely tetracene and pentacene, whose frontier orbitals have a similar shape but exhibit distinctly different symmetries. By comparing experimental CDAD momentum maps with simulations within time-dependent density functional theory, we show how the final state of the photoelectron must be regarded as the source of the CDAD in such otherwise achiral systems. We gain additional insight into the mechanism by employing a simple scattering model for the final state, which allows us to decompose the CDAD signal into partial wave contributions.

O 61.2 Wed 15:15 HSZ/0201

Many-body electronic structure of acenes on an MoS2 monolayer — •Jan-Phillip Topmöller and Michael Rohlfing — Institute of Solid State Theory, University of Münster, Germany

TMDCs show great potential in terms of their applicability in optical electronics. Due to their large surface, molecules can easily bind to the TMDC and affect its electronic properties. Here we investigate acenes as a prototypical class of molecule.

We use DFT (GGA) and DFT-D3 to determine the most stable adsorption position of acenes like benzene, naphthalene and anthracene on MoS2. Subsequently, we use many body perturbation theory to calculate the electronic structure of the adsorbate system and its individual components (MoS2 and the molecule) in order to investigate the effect of the molecule on the MoS2 electronic and optical spectrum.

O 61.3 Wed 15:30 HSZ/0201

Azimuthal-Scanning SFG Microscopy for Mapping Packing Motifs and In-Plane Disorder in Molecular Films — •Nasim Mirzajani, Ben John, Alex Fellows, and Martin Thaemer — Fritz-Haber-Institut, Berlin, Germany

Phase-resolved vibrational sum-frequency generation (SFG) microscopy is a powerful tool for probing anisotropic and heterogeneous structure of molecular films. As a second order nonlinear technique, SFG is uniquely sensitive to disorder in film morphology but it has not been yet used to quantify order in molecular film assemblies. Here, we introduce an azimuthal-scanning SFG microscopy approach that extracts detailed information on structure as well as in-plane orientational order by analyzing the full set of rotational frequencies arising from azimuthal dependence. Applying the method to a lipid monolayer, we determine the full 3D structure of the lipids, the packing motif as well as the degree of its in-plane disorder. This technique provides a general framework for probing packing structure in thin films and is broadly applicable to diverse molecular and phononic materials.

O 61.4 Wed 15:45 HSZ/0201

Synthesis and Characterization of a Polyradical Hexaazacycloarene — •Zilin Ruan, Olaf A. Kleykamp, Tim Naumann, Faming Kang, Jörg Sundermeyer, and J. Michael Gottfried — Department of Chemistry, Philipps University Marburg, 35037 Marburg, Germany

Cycloarenes have drawn considerable research interest owing to their unique electronic and topological features. The synthesis of large zigzag-edged cycloarenes, which are predicted to exhibit exotic polyradical ground states, has remained elusive. Here, we report the synthesis of a zigzag-edged hexaazacycloarene incorporating six graphitic nitrogen atoms within its macrocyclic backbone, achieved through a combined in-solution cyclization and on-surface cyclodehydrogenation on a Au(111) surface. The structural and electronic properties of the resulting macrocycle were investigated by STM/STS, nc-AFM and KPFM. DFT and multireference CASSCF calculations reveal that the isolated molecule has an open-shell singlet ground state with six unpaired electrons and undergoes a spontaneous symmetry breaking from C6 to C2, driven by strong electron-electron correlations and a pseudo-Jahn-Teller instability. Notably, the expected low-energy spin excitations are absent on Au(111), which is rationalized by the hybridization between the molecular π-system and the substrate, effectively quenching the intrinsic magnetism. These results provide crucial insight into correlation-driven magnetism and represent a significant advance toward the realization of cycloarenes with π-magnetism.

O 61.5 Wed 16:00 HSZ/0201

Vibrational Spectra of Materials and Molecules with Path Integrals and Machine Learning — •Jorge Castro, Krystof Brezina, and Mariana Rossi — Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

Vibrational spectroscopy provides fundamental insight into molecular structure and dynamics. Nuclear quantum effects (NQEs) can critically modulate vibrational peak positions, shapes, and intensities. Recently, we showed that the partially adiabatic elevated-temperature centroid molecular dynamics (PA-T_e-CMD) [1] accurately reproduces vibrational spectra across molecular and condensed-phase systems, including low-temperature regimes where NQEs are strongest. This approach enables the simulation of quantum infrared and Raman responses in diverse spectroscopic settings. Tip-Enhanced Raman Spectroscopy (TERS) [2] achieves sub-nanometer spatial resolution and is uniquely sensitive to single-molecule vibrational motion and surface defects. Building on

first-principles finite-field formulations of TERS [3], we combine this framework with PA-T_e-CMD to quantify the role of nuclear quantum motion and anharmonicity in near-field Raman observables. As a first application, we investigate hydrogen-bonded chains of 2,5-diamino-1,4-benzoquinonediimine (DABQDI) and discuss how NQEs imprint on vibrational signatures in simulated TERS images.

Quasiparticle level alignment in anthracene-MoS_2 heterostructures — •Hsin-Mei Ho, Michael Lorke, and Peter Kratzer — Faculty of Physics, University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany

Stacking atomically thin materials through van der Waals (vdW) interaction has opened a new paradigm for fundamental and applied sciences. While preserving the advantages of individual components, heterostructures are predicted to exhibit emergent properties at the interfaces. In the presence of external perturbations, since the behavior of a hybrid system is strongly related to the electronic band structure, it is of interest to find a methodology beyond the ground-state formalism of density functional theory (DFT). In this work, we begin with DFT calculations and consider the organic-inorganic heterostructures composed of anthracene molecules on monolayer MoS_2. Motivated by studies on the crystallinity of organic films, interfacial configurations with different coverage and orientation of anthracene are investigated. We find that both the bandgap values and band offsets are sensitive to whether the molecules are closely packed and whether they adopt perpendicular or parallel orientations on MoS_2. Whereas DFT predicts type-II level alignment, inclusion of quasi-particle corrections via the GW approximation yields type-I alignment. These findings highlight the importance of level-alignment predictions for interpreting experiments and for guiding the design of organic-TMDs heterostructures.

O 61.7 Wed 16:30 HSZ/0201

Magnetic interactions between spins in the Metallacrown CuCu4: bulk vs adsorbed molecule on Au(111) — •Ariyan Tavakoli[1], Stefan Lach[1], Frederik Pütz[1], Dominic Stephan[1], Anne Lüpke[2], Dominik Laible[2], Siegfried Kaidisch[3], Andreas Winidischbacher[3], Eva Rentschler[2], Peter Puschnig[3], Christiane Ziegler[1], and Hans Christian Schneider[1] — [1]RPTU University Kaiserslautern-Landau, Germany — [2]Johannes Gutenberg University Mainz, Germany — [3]University of Graz, Austria

Metal-organic complexes featuring multiple metal ions with unsaturated spin structures are intriguing because of their potential to tune molecular magnetic properties. In this study, we compare the magnetic and electronic properties of the CuCu4 metallacrown [1] in bulk, gas-state, and adsorbed on an Au(111) surface. Using the broken-symmetry approach, we benchmark various (range-separated) hybrid functionals against the computationally efficient GGA+U method to evaluate exchange coupling constants in different states [2]. We compare ultraviolet photoemission spectroscopy (UPS) combined with ab-initio calculations to show how the exchange interactions between Cu spins shift significantly, resulting in a transition from a low-spin state (S = 1/2) in the bulk to a higher-spin state (S = 3/2) on Au(111).

Vectorial spin-to-charge conversion by supramolecular chirality — •Sophie Knewitz[1], Guillaume Schweicher[2], Ashish Moharana[1], Yves Geerts[2], and Angela Wittmann[1] — [1]Johannes Gutenberg-Universität, Mainz, Germany — [2]Université Libre, Bruxelles, Belgium

The chiral-induced spin selectivity (CISS) effect describes how electrons get spin-polarized due to the presence of chiral molecules. The high polarization efficiency makes it promising for future sustainable hybrid chiral molecule magnetic applications. While there are many experimental reports of different aspects of the CISS effect, a complete understanding of the fundamental mechanisms remains an open challenge. In this work, we investigate the role of supramolecular chirality and atomic spin-orbit coupling on the CISS effect in hybrid metal thin film / chiral organic crystal heterostructures. Using spin pumping to inject a pure spin current in the metal thin film, we probe the spin-to-charge conversion at the chiral interface. Based on our recent finding that CISS is a vectorial effect [1], we use a molecular chiral crystal to probe the CISS effect in a well-ordered system in order to maximize the polarization efficiency. Our angle-dependent measurements confirm that the spin selectivity of the chiral supramolecular crystal is highly sensitive to its orientation relative to the spin direction in the metal thin film under the applied magnetic field. These results open new ways for the vectorial manipulation of hybrid spintronic devices by chirality.

Chiral recognition of enantiomers on a superconducting surface — •Lorenz Meyer, Nicolas Néel, and Jörg Kröger — Institut für Physik, Technische Universität Ilmenau, D-98693 Ilmenau, Germany

The adsorption of a racemic mixture of heptahelicene on Pb(111) gives rise to enantiopure domains, in which left-handed and right-handed variants are spatially resolved with submolecular structure. For molecules inside the domains the molecular spiral is oriented along the surface normal, while at domain boundaries the spiral axis is tilted. Both enantiomers leave the Bardeen-Cooper-Schrieffer energy gap of the substrate invariant and exhibit an elevated energy difference between the occupied and unoccupied frontier orbitals. Funding by the Deutsche Forschungsgemeinschaft through KR 2912/21-1 and the Bundesministerium für Bildung und Forschung is acknowledged.

O 61.10 Wed 17:15 HSZ/0201

Unveiling the precise configuration of a molecular junction — Joshua Scheidt[1,3], Jonas Lederer[3], Mong-Wen Gu[1,2], Hadi Arefi[1,2], Jose M. Guevara[1,2], Amin Karimi[1,2], Rustem Bolat[1,2], Marvin Knol[1,2], Klaus-Robert Müller[3], F. Stefan Tautz[1,2], and •Christian Wagner[1,2] — [1]PGI-3, Forschungszentrum Jülich, Germany — [2]JARA, Fundamentals of Future Information Technology, Germany — [3]Institut für Softwaretechnik und Theoretische Informatik, Technische Universität Berlin, Germany

Exploring structure-property relationships of molecular junctions is crucial for future single-molecule applications. While, e.g., a strong scattering of conductance values is found in break-junctions, the responsible structural variations cannot be identified. Here, we describe NC-AFM/STM-based two-contact manipulation experiments on PTCDA (3,4,9,10-perylene-tetracarboxylic dianhydride) on Ag(111) and analyze them using a DFT-based machine learning model of the junction. Our approach allows solving the inverse problem of configuration identification from force gradient data[1] and reveals the origin of the 3-4 fold conductance variations observed upon sub-Angstrom changes in the junction geometry.

Topological obstruction in twisted bilayer graphene — Florie Mesple[1], Pierre Mallet[2], •Guy Trambly de Laissardière[3], Clement Dutreix[4], Gérard Lapertot[5], Jean-Yves Veuillen[2], and Vincent T. Renard[5] — [1]Dept. Physics, Univ. of Washington, Seattle, USA — [2]CNRS, Univ. Grenoble Alpes, Inst. Néel, Grenoble, France — [3]CY Cergy Paris Univ., CNRS, LPTM, Cergy-Pontoise, France — [4]Univ. Bordeaux, CNRS, LOMA, Talence, France — [5]Univ. Grenoble Alpes, CEA, IRIG, PHELIQS, Grenoble, France

The rich physics of magic angle twisted bilayer graphene (TBG) results from the Coulomb interactions of electrons in nearly flat bands of non-trivial topology [1]. Here [2], we perform STM/STS measurements on a moiré pattern generated in a TBG tilted by 4.3°, focusing on a point-like defect. We observe quasiparticle interferences (QPIs) resulting from intravalley backscattering between Dirac cones of graphene layers 1 and 2. Rationalized by tight binding calculations and T-matrix theory, our work shows that the QPIs are strongly impacted by the relative chirality of the Dirac cones of layer 1 and 2 in each valley. It establishes that, within a given moiré valley, the two Dirac cones have the same electronic chirality, as expected in the usual continuum model [3]. This peculiar topology leads to a topological obstruction.

Quasiparticle Interferences in 30°-twisted graphene quasicrystal — •Jean-Maxime Schlachter[1], Ahmed El Alouani[2], Vincent S Renard[2], Abhishek Karn[1], Ileana Florea[2], Stéphane Vézian[2], Adrien Michon[2], Clemens B Winkelmann[1], and Vincent T Renard[1] — [1]Univ. Grenoble Alpes, CEA, Grenoble INP, IRIG, PHELIQS, 38000 Grenoble, France — [2]CNRS-CRHEA, Université Côte d'Azur, rue B. Grégory, 06560 Valbonne, France

Quasicrystals are materials that have clean diffraction pattern but no translational symmetry. The advent of van der Waals stacking has opened the possibility to engineer quasicrystals. For example, the moiré pattern in 30°-twisted graphene bilayers has 12-fold rotational symmetry which is not compatible with translation symmetry in 2D, hence it is a quasicrystal (1). Studying this system gives insight into the behavior of Dirac fermions in 2D quasicrystals. ARPES experiments (2) demonstrated the existence of multiple Dirac cone replicas, originating from the incommensurate interlayer coupling. The goal of this study is to determine to what extend these Dirac cone replicas influence the electronic properties of the Dirac fermions. Our low temperature scanning tunneling microscope (STM) experiments evidence the replicated Dirac cones by specific patterns in the local density of states patterns associated with scattering between them, contrary to previous STM experiments (3).

Machine Learning for Bandstructure-Structure Relationships in Doped Graphene — •Benedict Saunders[1], Lukas Hörmann[1,2], Valdas Vitartas[1], Chen Qian[1], and Reinhard J Maurer[1,2] — [1]University of Warwick, Coventry, United Kingdom — [2]University of Vienna, Vienna, Austria

The introduction of topological defects or dopants to graphene's honeycomb lattice is a common approach to tuning the electronic and transport properties of the material to suit a specific application. Nitrogen is a widely investigated dopant, which can be introduced into the lattice in various configurations, each with a distinct effect on the material's bandstructure. However, due to the combinatorial explosion of possible dopant configurations, conventional first-principles screening of the electronic bandstructure for all possible configurations is not feasible. Here, we address this limitation by employing the recently developed MACE-H machine learning model to predict the electronic Hamiltonian of nitrogen-doped graphene configurations directly for a series of previously generated defect configurations. This allows us to rapidly generate accurate bandstructures and densities-of-states for large numbers of configurations, enabling the identification of structure-property relationships as a function of temperature and composition.

Electronic structure of intercalated epitaxial graphene: A first principles study — •Andres Unigarro[1], Florian Günther[2], and Sibylle Gemming[1] — [1]Institute of physics, TU Chemnitz, Chemnitz, Germany — [2]UNESP, Rio Claro, Brazil

Two-dimensional materials such as graphene are particularly intriguing due to their exceptional mechanical and electronic properties. A natural next step involves combining different 2D materials to form heterostructures with enhanced functionalities. In epitaxial graphene on silicon carbide (SiC), intercalation provides an effective means to tune the electronic, optical, and transport properties of graphene while preserving its honeycomb lattice. Moreover, intercalation enables the synthesis of otherwise unstable 2D layers. In particular, the intercalation of heavy elements such as Pb [1] and Bi [2] is especially promising, as these can introduce strong spin-orbit coupling (SOC) effects [3] (e.g. Rashba effect, gap opening) in graphene. In this work, we use first-principles calculations to investigate the electronic properties of heterostructures formed by Pb and Bi intercalation.

Domain-resolved electronic structure of AgTe-intercalated graphene on SiC(0001): From semiconducting Te-rich interlayer bands to metallic AgTe alloy states — •Vibha Reddy[1], Sawani Datta[1], Bharti Matta[1], Philipp Rosenzweig[2], Ulrich Starke[1], and Kathrin Küster[1] — [1]Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, — [2]Universität Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart

Intercalation at the graphene/SiC(0001) interface provides a powerful route towards engineering the electronic properties of both the graphene and the intercalant. Here, we present the first realization of a transition-metal chalcogen alloy intercalated into the graphene/SiC(0001) interface via AgTe intercalation. The nominally AgTe-intercalated system segregates into multiple microscale intercalation phases, namely, Te-rich, Ag-rich and AgTe alloyed domains. Spatially-resolved and angle-resolved photemission spectroscopy (ARPES) reveals that each domain exhibits distinct graphene doping levels and interlayer band dispersions, highlighting the strong interplay between local intercalation chemistry investigated by X-ray photoelectron spectroscopy (XPS) and electronic band structure. Given the intrinsic spin-orbit coupling and topologically non-trivial states associated with Te- and Ag-based 2D materials, the AgTe alloy-intercalated graphene represents a promising platform for realizing domain-specific emergent quantum phenomena, underscoring the chemical versatility and tunability of alloy-based heterostructures in interface engineering.

O 62.7 Wed 16:30 HSZ/0204

Proximity-induced electronic states in epitaxial graphene/SiC (0001) via Sn intercalation — •Huu Thoai Ngo[1], Zamin Mamiyev[1], Niklas Witt[2,3], Tim Wehling[2], and Christoph Tegenkamp[1] — [1]Solid Surface Analysis, Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — [2]Institute of Theoretical Physics & Centre for Ultrafast Imaging, University of Hamburg, Hamburg, Germany — [3]Institute for Theoretical Physics and Astrophysics, University of Würzburg, Würzburg, Germany

Intercalation of heavy elements at the buffer layer/SiC interface is an effective route to decouple it from the substrate while tailoring its electronic properties, for example, energy gap opening [1] and Mott insulating states [2]. In this work, we investigate the Sn-intercalated buffer layer using low-temperature STM/STS, supplemented by SPA-LEED, and DFT calculations. By precisely controlling the intercalation process, we obtain two distinct Sn phases beneath graphene: Sn(1x1) that induces Kekulé-O distortion, and honeycomb-Sn structure that gives rise to Moiré patterns. Remarkably, our STS results reveal a gap opening in Kekulé-O graphene due to Sn-induced sublattice symmetry breaking. In contrast, the honeycomb-Sn phase exhibits Mott insulating states. These findings demonstrate how Sn intercalants modify the structural and electronic properties of graphene at both nano- and microscale. [1] Ghosal, Tegenkamp, C. et al. Phys. Rev. Lett. 129, 116802 (2022). [2] Ghosal, Tegenkamp, C. et al. Phys. Rev. B 111, 235426 (2025).

O 62.8 Wed 16:45 HSZ/0204

Doping monolayer graphene to the Van Hove singularity — •Guangyao Miao[1], Daniel Jansen[1], Bilal Hawashin[2], Julian Kleeschulte[2], Katharina Offermann[1], Christian Krämer[1], Affan Safeer[1], Abdallah Karaka[1], Jeison Fischer[1], Thomas Michely[1], Michael M. Scherer[2], and Wouter Jolie[1] — [1]II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, 50937 Cologne, Germany — [2]Theoretische Physik III, Ruhr-Universität Bochum, D-44801 Bochum, Germany

Tuning correlated states in graphene is an intriguing topic, particularly since the experimental realization of superconductivity, correlated insulator states, and magnetic states in twisted-angle bilayer graphene near the magic angle, along with Van Hove singularities (VHSs) tuned to the Fermi level. Such correlated phenomena have also been predicted in monolayer graphene doped to its van Hove singularity. Motivated by this, we study the effect of Cs doping on a graphene monolayer on Ir(111) using MBE. A $\sqrt{3}\times\sqrt{3}$ superstructure is observed due to the Cs intercalations between graphene and Ir(111). Further deposition of Cs on top of graphene leads to the formation of several surface structures with varying Cs concentrations, including adatoms, stripes, and compact islands. Their morphology and electronic structures are revealed by scanning tunneling microscopy and spectroscopy at low temperature. By optimizing the dosage, we successfully tune the VHS to the vicinity of the Fermi level and observe a $2\sqrt{3}\times2\sqrt{3}$ superstructure with respect to the graphene lattice. Possible origins of the superstructure related to many-body interactions will be discussed.

O 62.9 Wed 17:00 HSZ/0204

Optimizing quantum transport in multi-barrier graphene systems using differential evolution — •Leon Browne and Stephen R. Power — School of Physical Sciences, Dublin City University, Ireland

Potential and mass barriers in graphene introduce electron scattering, modulating transmission probabilities. Complex multi-barrier setups allow electron transmission to be controlled with high precision, but have a huge design space of possible barrier geometries. This work presents a framework to optimize electronic transport in such systems using differential evolution algorithms. First, transfer matrix methods are employed to efficiently compute quantum transport through multi-barrier structures, before optimization is applied to find barrier configurations whose transmission profiles closely match a predefined target profile. To address the trade-off between the accuracy and complexity of resulting barrier configurations, regularization techniques are incorporated into the optimization process. Our approach demonstrates the potential for highly tunable electronic transport in graphene-based systems by exploiting evolution-inspired optimization techniques.

O 62.10 Wed 17:15 HSZ/0204

Comparative study of plasmons in half-filled graphene via Quantum Monte Carlo and kinetic theory — Maksim Ulybyshev[1], •Adrien Reingruber[1], and Kitinan Pongsangangan[2] — [1]Institut für Theoretische Physik und Astrophysik, Universität Würzburg — [2]Department of Physics, Faculty of Science, Mahidol University, Bangkok

A quantitative description of hydrodynamic electronic transport in strongly correlated materials requires accurate knowledge of collective excitations such as plasmons, which can notably influence viscosity. In free-standing graphene, where long-range interactions are important, standard Dirac-cone perturbation theory misses important finite Brillouin-zone and strong-coupling effects. We investigate plasmons in half-filled free-standing graphene using unbiased Quantum Monte Carlo simulations. Our results reveal well-defined plasmon peaks near the Gamma-point, map their dispersion, and extract the momentum dependence of their quasiparticle residue. Comparing to perturbative predictions, we find substantial deviations arising from the interaction and lattice effects captured only beyond the Dirac approximation. These results underscore the need to incorporate such corrections in analytical theories of electronic transport in graphene.

NanoARPES Facility in Shanghai Synchrotron Radiation Facility and Investigation of the Moiré bands in Graphene Devices — •Zhongkai Liu — Shanghaitech University

Spatially resolved angle-resolved photoemission spectroscopy (NanoARPES) is an indispensable tool for probing the electronic structure of exfoliated sample flakes, fabricated devices, and more. In this presentation, we describe the construction, specifications, capabilities, and operation of BL07U-the NanoARPES endstation at the Shanghai Synchrotron Radiation Facility (SSRF) [1]. We will showcase our research on the electronic structure of emerging graphene devices, with a focus on moiré and flat bands. For example, our ARPES studies on magic-angle twisted trilayer graphene clearly reveal the coexistence of moiré flat bands and Dirac bands [2]. In aligned bilayer graphene/hBN heterostructures, we demonstrate that in-situ back gating enables precise tuning of the moiré electronic structure [3]. We directly observe the characteristic topological electronic structures of rhombohedral multilayer graphene, from a 3D generalization of the 1D Su-Schrieffer-Heeger (SSH) chain in thin layers to a topological Dirac nodal spiral semimetal in bulk rhombohedral graphite [4]. Finally, we present our work on the moiré band in bulk alternating twist graphene, which becomes flat at "magic momenta".

Majorana or Not? An Insight from Atomic-Scale Shot-Noise — •Abhishek Maiti[1], Genda Gu[2], and Freek Massee[1] — [1]Université Paris-Saclay, CNRS, Laboratoire de Physique des Solides, 91405, Orsay, France — [2]Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, NY, USA

The search for non-abelian states of matter has become a central theme of modern quantum material research. Notably, Majorana zero modes are of special interest, as they can serve as the foundation for topological qubits. A robust zero-bias conductance peak, observed in scanning tunneling spectra, is often regarded as the primary signature of a Majorana zero mode. Yet similar features can also arise from trivial bound states, raising a long-standing challenge of how to distinguish a genuine Majorana from imposters. In my talk, I will address this problem with a new approach, atomic-scale shot-noise spectroscopy, that goes beyond conductance measurements. Through a detailed investigation on multiple defect- and vortex-bound zero-bias states in the widely studied (putative) topological superconductor Fe(Se,Te), I will show that while differential conductance measurements might sometimes fail to detect an imposter Majorana state locally, noise measurements consistently provide a conclusive diagnostic, offering a powerful complementary probe. Looking ahead, this technique can be applied to other reported platforms to verify whether their Majorana-like signature in tunneling conductance can pass the shot-noise test.

O 63.2 Wed 15:15 HSZ/0401

Intrinsic topological superconductivity revealed by surface-extended Andreev bound states in $PtBi_2$ — •Xiaochun Huang[1], Lingxiao Zhao[2], Sebastian Schimmel[3,4], Julia Besproswanny[3,4], Patrick Härtl[1], Christian Hess[3,4], Bernd Büchner[4,5], and Matthias Bode[1] — [1]Experimentelle Physik 2, Physikalisches Institut, Universität Würzburg, Germany — [2]Quantum Science Center of Guangdong, Shenzhen, China — [3]Fakultät für Mathematik und Naturwissenschaften, Bergische Universität Wuppertal, Germany — [4]Leibniz-Institute for Solid State and Materials Research, Dresden, Germany — [5]Technische Universität Dresden, Germany

Intrinsic topological superconductivity remains a central question in condensed-matter physics. The three-dimensional Weyl semimetal $PtBi_2$ was recently shown by angle-resolved photoemission spectroscopy to host a superconducting gap that opens exclusively on its Fermi-arc surface states with a nodal structure, establishing it as a prime candidate for intrinsic topological superconductivity [1]. Using scanning tunneling microscopy and spectroscopy, we directly visualize surface-extended Andreev bound states (ABSs) across atomically pristine terraces within a sizable superconducting gap ($\Delta > 10$ meV) in $PtBi_2$. Quantitative analysis of the tunneling spectra within an anisotropic chiral pairing framework identifies these ABSs as signatures of an emergent Majorana-cone dispersion. Our findings provide a definitive real-space spectroscopic fingerprint of intrinsic topological superconductivity in $PtBi_2$.

Probing chiral symmetry with a topological domain wall sensor — •Artem Odobesko[1], Glenn Wagner[2], Titus Neupert[2], Ronny Thomale[1], and Matthias Bode[1] — [1]Physikalisches Institut, Universität Würzburg, Würzburg, Germany — [2]Department of Physics, University of Zurich, Zürich, Switzerland

Chiral symmetry is a fundamental property with profound implications for the properties of elementary particles, that implies a spectral symmetry (i.e. E -> -E) in their dispersion relation. In condensed matter physics, chiral symmetry is frequently associated with superconductors or materials hosting Dirac fermions such as graphene or topological insulators. There, chiral symmetry is an emergent low-energy property, accompanied by an emergent spectral symmetry. While the chiral symmetry can be broken by crystal distortion or external perturbations, the spectral symmetry frequently survives. As the presence of spectral symmetry does not necessarily imply chiral symmetry, the question arises how these two properties can be experimentally differentiated. Here, we demonstrate how a system with preserved spectral symmetry can reveal underlying broken chiral symmetry using topological defects. Our study shows that these defects induce a spectral imbalance in the Landau level spectrum, providing direct evidence of symmetry alteration at topological domain walls. Using high-resolution STM/STS we demonstrate the intricate interplay between chiral and translational symmetry which is broken at step edges in topological crystalline insulator $Pb_{1-x}Sn_xSe$.

O 63.4 Wed 15:45 HSZ/0401

Quantifying quasiparticle chirality in a chiral topological semimetal — •Jiaju Wang[1], Amit Kumar[1], Markel Pardo-Almanza[1], Jaime Sanchez-Barriga[2], Jorge Cardenas-Gamboa[3], Maia Vergniory[3], Vladimir Strokov[4], Moritz Hoesch[5], Chandra Shekhar[6], Claudia Felser[6], Stuart Parkin[1], and Niels Schröter[1] — [1]Max Planck Institute of Microstructure Physics, Halle (Saale), Germany — [2]Helmholtz-Zentrum Berlin, Berlin, Germany — [3]Donostia International Physics Center, San Sebastián, Spain — [4]Paul Scherrer Institute, Villigen, Switzerland — [5]Deutsches Elektronen-Synchrotron, Hamburg, Germany — [6]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

Recently, electron chirality has been proposed as an order parameter to quantify chirality. In chiral topological semimetals with the B20 structure, electron chirality is linked to parallel spin-momentum locking (SML) and spin deviations from SML, which affects numerous physical properties. However, experimental quantification of spin deviation still remains a big challenge. To achieve this, we have used spin and angle-resolved photoemission spectroscopy to directly probe the spin texture of Weyl cones in RhSi, a chiral topological semimetal with strong spin-orbit coupling (SOC). The spin-resolved spectra at different azimuthal angles are intricately fitted to extract numerical values of spin deviation for Weyl cones, allowing us to calculate the normalized electron chirality density (NECD). It was found that deviations can decrease the NECD from 1 down to 0.8. This observation may help interpret physical phenomena in chiral topological semimetals.

O 63.5 Wed 16:00 HSZ/0401

Topology and Real-Space Obstruction: The Phase Diagram of the Triangular p-Orbital Lattice — •Jonas Erhardt[1,2], Sven Schemmelmann[3], Fabian Schöttke[3], Jörg Schäfer[1,2], Giorgio Sangiovanni[2,4], Markus Donath[3], and Ralph Claessen[1,2] — [1]Physikalisches Institut, Universität Würzburg — [2]Würzburg-Dresden Cluster of Excellence ctd.qmat — [3]Physikalisches Institut, Universität Münster — [4]Institut für Theoretische Physik und Astrophysik, Universität Würzburg

Triangular *p*-orbital monolayers (MLs) host a rich topological phase diagram governed by the competition between spin-orbit coupling (SOC) and substrate-induced inversion-symmetry breaking (ISB). The SOC-dominated quantum spin Hall insulator (QSHI) phase arises from a band inversion in the $p_\pm$ manifold and was first realized in indenene, a triangular ML of In atoms on SiC [1]. Real-space interference shifts the associated Wannier centers away from the atoms to interstitial sites A/B, which for the QSHI phase produces an alternating ABAB energy sequence in the charge localization, as demonstrated by scanning tunneling microscopy (STM) [1]. Using the same STM approach, we identify the complementary ISB-dominated regime in a Tl ML on Si(111), where strong adsorption-induced ISB exceeds Tl's SOC. The charge likewise shifts off the atoms but evidences a non-alternating AABB sequence, characterizing Tl/Si(111) as a trivial obstructed atomic insulator. These results complete the experimental validation of the topological phase diagram for triangular *p*-orbital MLs.

O 63.6 Wed 16:15 HSZ/0401

Majorana-metal transition in a disordered superconductor: percolation in a landscape of topological domain walls — Vladimir A Zakharov[1], Ion Cosma Fulga[2,3], •Gal Lemut[4], Jakub Tworzydło[5], and Carlo W. J. Beenakker[1] — [1]Instituut-Lorentz, Universiteit Leiden, PO Box 9506, 2300 RA Leiden, The Netherlands — [2]Institute for Theoretical Solid State Physics, IFW Dresden, Germany — [3]Würzburg-Dresden Cluster of Excellence ct.qmat, Dresden, Germany — [4]Dahlem Center for Complex Quantum Systems and Physics Department, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany — [5]Faculty of Physics, University of Warsaw, ul. Pasteura 5, 02-093 Warszawa, Poland

Most superconductors are thermal insulators. A disordered chiral p-wave superconductor, however, can make a transition to a thermal metal phase. Because heat is then transported by Majorana fermions, this phase is referred to as a Majorana metal. Here we present numerical evidence that the mechanism for the phase transition with increasing electrostatic disorder is the percolation of boundaries separating domains of different Chern number. We construct the network of domain walls using the spectral localizer as a "topological landscape function", and obtain the thermal metal-insulator phase diagram from the percolation transition.

O 63.7 Wed 16:30 HSZ/0401

fabrication and characterization of the Moiré surface state on a topological insulator — •yi zhang — Shanghai Jiao Tong University, Shanghai, China

A Moire* superlattice on the topological insulator surface is predicted to exhibit many novel properties but has not been experimentally realized. Here, we developed a two-step growth method to successfully fabricate a topological insulator Sb2Te3 thin film with a Moire* superlattice, which is generated by a twist of the topmost layer via molecular beam epitaxy. The established Moire* topological surface state is characterized by scanning tunneling microscopy and spectroscopy. By application of a magnetic field, new features in Landau levels arise on the Moire* region compared to the pristine surface of Sb2Te3, which makes the system a promising platform for pursuing next-generation electronics. Notably, the growth method, which circumvents contamination and the induced interface defects in the manual fabrication method, can be widely applied to other van der Waals materials for fabricating Moire* superlattices.

O 63.8 Wed 16:45 HSZ/0401

Backscattering in topological edge states despite time-reversal symmetry — Jonas Erhardt[1,2], •Mattia Iannetti[3,4], Fernando Dominguez[2,5], Ewelina M. Hankiewicz[2,5], Björn Trauzettel[2,5], Gianni Profeta[3,4], Domenico Di Sante[6], Giorgio Sangiovanni[2,5], Simon Moser[1,2], and Ralph Claessen[1,2] — [1]Physikalisches Institut, Universität Würzburg — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg — [3]Dipartimento di Scienze Fisiche e Chimiche, Università degli Studi dell'Aquila — [4]CNR-SPIN C/o Dipartimento di Scienze Fisiche e Chimiche, Università degli Studi dell'Aquila — [5]Institut für Theoretische Physik und Astrophysik, Universität Würzburg — [6]Department of Physics and Astronomy, University of Bologna

Quantum Spin Hall Insulators (QSHI) are promising materials for many applications based on Dirac fermions and topologically-protected edge states. Indium adatoms on a silicon carbide surface, the so-called Indenene, was the first material in which a topological classification solely based on an inspection of the bulk wave functions has been demonstrated. In this work, we present a combined experimental and theoretical study of finite-sized Indenene systems, using STM/STS measurements and a quantitative tight-binding model revealing the rich physics of edge states. We find that a strongly non-linear edge dispersion leads to inter-Kramers pair backscattering, thereby extending the conventional understanding of backscattering protection in topological edge states.

O 63.9 Wed 17:00 HSZ/0401

Quantized Subband Tunneling from Topological Insulator Nanowire Scanning Probe Tips — •Abhisek Kole[1,2], Felix Münning[3,4], Xiaosheng Yang[1,5], Jia G. Lu[6], Oliver Breunig[4], F. Stefan Tautz[1,2], Yoichi Ando[4], and Felix Lüpke[1,4] — [1]Peter Grünberg Institute (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Institute for Experimental Physics IV A, RWTH Aachen University, Otto-Blumenthal-Straße, 52074 Aachen, Germany — [3]Institute of Physics I, Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany — [4]Institute of Physics II, Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany — [5]School of Optical and Electronic Information, Huazhong University of Science and Technology, Wuhan 430074, China — [6]Department of Physics/Electrophysics, University of Southern California, Los Angeles, CA 90089, USA

In topological insulator nanowires, the interplay between size quantization and the surface states wrapping the nanowire circumference gives rise to a magnetic-flux-tunable band structure. We demonstrate the controlled fabrication of (Bi_(1-x) Sb_x)_2 Te_3 (BST) topological insulator nanowires into scanning tunneling microscopy tips. Tunneling spectroscopy reveals a series of distinct peak-like features that exhibit a characteristic 1D DOS, indicating tunneling into the quantized 1D subbands of the BST nanowire tips. Furthermore, a magnetic-field-induced gap-closing and reopening transition is observed, consistent with the Dirac-like gap-closing transition expected for such wires. Moreover, we find indications of spin-selective helical tunneling between the nanowire tip and the Rashba surface states of Au(111).

O 63.10 Wed 17:15 HSZ/0401

Simultaneous Characterization of Dispersion and Orbital Character of the Topological Surface State on the Topological Insulator Bi_2Te_3 — •Christoph Stephen Setescak, Adrian Weindl, and Franz Josef Giessibl — Universität Regensburg, D-93053 Regensburg

Scanning probe microscopy (STM and AFM) allows one to locally probe properties of topological insulators (TIs). On the compound Bi_2Te_3, atomic-scale electronic standing waves can be observed at crystalline step edges, which are associated with the hexagonal warping of the Dirac cone. These real-space oscillations provide a direct means to study the dispersion relation of the topological boundary mode. The interpretation relies on comparing the experimental data to calculations including not only the properties of the TI but also of the tip. In this framework, the tunneling current and differential conductance is modelled using Chen's derivative rule. Bending of the CO molecule at the tip apex due to lateral tip-sample forces is also included in the model. The relevant Bloch functions of the sample are obtained from Wannier-interpolated tight-binding Hamiltonians using maximally localized Wannier functions derived from first-principles DFT + *GW* computations. In combination with the high spatial resolution obtained with CO-terminated tips, not only the dispersion, but also the orbital character of the band structure can be probed.

O 63.11 Wed 17:30 HSZ/0401

Defect-induced displacement of topological surface state in magnetic topological insulator $MnBi_2Te_4$ — •Felix Lüpke[1,2], Marek Kolmer[3,4], Hengxin Tan[5], Adam Kaminski[3,4], and Binghai Yan[5,6] — [1]Peter Grünberg Institute (PGI-3) and JARA-FIT, Forschungszentrum Jülich, 52425 Jülich, Germany — [2]Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany — [3]Ames National Laboratory, Ames, Iowa 50011, USA — [4]Iowa State University, Ames, Iowa 50011, USA — [5]Weizmann Institute of Science, Rehovot 7610001, Israel — [6]The Pennsylvania State University, University Park, Pennsylvania 16802, USA

The gapped topological surface states of $MnBi_2Te_4$ (MBT) are an attractive platform for the realization of quantum anomalous Hall and Axion insulator states. However, experimentally observed surface state gaps fail to meet theoretical predictions, with the exact mechanism behind the gap suppression still being debated. We report on the effect of intrinsic anti-site defects on the MBT surface states, which we study using scanning tunneling microscopy (STM), angle-

resolved photoemission (ARPES), and density functional theory (DFT). Our results show that high defect concentrations lead to a displacement of the surface states into the interior of the MBT crystal, consistent with theoretical predicitons [PRL 130, 126702 (2023)].

Cantilever based Scanning Force Microscopy: Ultimate Sensitivity and Quantitative Imaging of Nanoscale Spin Textures — •Hans J. Hug — Empa, Ueberlandstrasse 129, 8600 Dübendorf, Switzerland — Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel

Cantilever-based scanning force microscopy operated under vacuum or ultra-high-vacuum (UHV) conditions is a powerful and versatile technique for surface characterization with atomic resolution. Beyond topographic imaging, multimodal and multifrequency approaches enable the simultaneous mapping of Kelvin potential differences and magnetic stray fields with exceptional sensitivity. These advanced methodologies have been applied to quantitatively determine skyrmion diameters in both ferromagnetic and synthetic antiferromagnetic multilayers, revealing skyrmions with diameters down to 25 nm. Furthermore, local tip sample distance control allows MFM imaging on curved substrates, uncovering curvature-induced modifications of the Dzyaloshinskii*Moriya interaction. Finally, we demonstrate the capabilities of UHV multimodal scanning force microscopy by resolving the atomic-scale structure, local Kelvin potential, and magnetic stray fields of NiBr* monolayers grown on Au substrates, highlighting the potential of these techniques for exploring emergent magnetic phenomena in low-dimensional materials.

O 64.2 Wed 15:30 HSZ/0403

Intra-atomic s-f correlation in a single Sm atom probed by ESR-STM — Masahiro Haze[1], Saba Taherpour[2,3], Christoph Wolf[2,3], Jaehyun Lee[2,3], Yaowu Liu[2,3], Andreas Heinrich[2,3], Fabio Donati[2,3], •Yasuo Yoshida[4], and Soo-hyon Phark[2,3] — [1]ISSP Univ. Tokyo, Kashiwa, Japan — [2]Center for Quantum Nanoscience, Seoul, Korea — [3]Ewha Womans University, Seoul, Korea — [4]Kanazawa Univ, Kanazawa, Japan

Correlations between s- and f-electrons are a fundamental topic in condensed matter physics, as they can give rise to exotic phases such as heavy-fermion or non-Fermi-liquid states. Recent work has shown that isolated Sm atoms adsorbed on MgO adopt a monovalent configuration with an S=1/2 spin originating from the 6s orbital, making a single Sm atom an ideal platform for studying s-f correlations at the atomic level. Here, we performed ESR-STM measurements on individual Sm atoms adsorbed on MgO films grown on an Ag(100) substrate. We find that the excitation energy varies strongly with the orientation of the external magnetic field, even though STM probes an S=1/2 spin, which is in principle free from single-ion magnetic anisotropy. The extracted g-values from the ESR measurements range from 1.3 to 6.4. This pronounced anisotropy indicates strong coupling between the s- and f-electrons within a single Sm atom, suggesting that surface-adsorbed Sm atoms may serve as promising building blocks for artificial Kondo lattices.

O 64.3 Wed 15:45 HSZ/0403

Elliptical skyrmions in a hydrogenated Fe double-layer on Ir(110) — Timo Knispel[1], Vasily Tseplyaev[2,3], •Gustav Bihlmayer[2], Stefan Blügel[2,3], Thomas Michely[1], and Jeison Fischer[1] — [1]II. Physikalisches Institut, Universität zu Köln, D-50937 Köln — [2]Peter Grünberg Institute (PGI-1), Forschungszentrum Jülich, D-52425 Jülich — [3]Institut für Theoretische Physik, RWTH Aachen University, D-52074 Aachen

Spin-polarized scanning tunneling microscopy (SP-STM) experiments demonstrate that the magnetic ground state of two pseudomorphic Fe layers on Ir(110) is a Néel-type spin spiral with a unique sense of rotation. Employing density functional theory (DFT) calculations, we show that this spin-spiral is stabilized by frustrated exchange interactions, but the rotation direction is fixed by the Dzyaloshinskii-Moriya interaction [1]. Hydrogen adsorption on the 2Fe/Ir(110) surface significantly modifies the spin-spiral minimum, shifting it to a longer wavelength and causing it to flatten energetically out with increasing H coverage. Using DFT calculations, we can trace back this behavior to electron doping of the surface and atomistic spin-dynamics simulations show that it is possible to induce elliptic skyrmions with an external magnetic field. These spin-textures can also be observed using SP-STM with a perpendicular B-field [2].

We acknowledge funding from the CRC 1238 of the Deutsche Forschungsgemeinschaft.

O 64.4 Wed 16:00 HSZ/0403

Light-driven modulation of proximity-enhanced functionalities in hybrid nano-scale systems — •Mattia Benini[1,2], Umut Parlak[3], Jaka Strohsack[4], Andrea Droghetti[5], Tomaz Mertelj[4], Valentin Alek Dediu[2], and Mirko Cinchetti[1] — [1]Department of Physics, TU-Dortmund, Dortmund, Germany — [2]ISMN-CNR, Bologna, Italy — [3]Department of Physics, Univesity of Konstanz, Konstanz, Germany — [4]Jozef Stefan Institute, Ljubljana, Slovenia — [5]Universitá Ca' Foscari, Venezia, Italy

Recent research on Co thin films surface-hybridized with π-conjugated organic molecules demonstrated that interfacial *p-d* hybridization[1] leads to the establishment of an exotic magnetic configuration, called *Correlated Ferromagnetic Glass* (CFG). It features a glassy-like arrangement of the magnetization and vortex topological defects[2], a strongly enhanced coercivity, and an unexpected complex magnetization dynamics[3]. In this work, we demonstrate that the interface-driven magnetic properties can be actively controlled by optical means, using Co/C_{60} heterostructures as a prototypical system. By generating excitons in the molecular layer with resonant ultrashort light pulses, we achieve up to a 60% reduction of the magnetization precession frequency, ultimately due to a quenching of the interface-induced magnetic anisotropy[4]. O 64.5 Wed 16:15 HSZ/0403

Layer-dependent magnetic and electronic properties of 2D vdW magnet $FeCl_2$ on Bi(111) — •Shigemi Terakawa[1], Jianqiang Liu[1], Hikaru Ishikawa[1], Ryota Inoue[1], Isamu Yamamoto[2], Amilcar Bedoya-Pinto[3], Niels B. M. Schröter[4], and Kazuyuki Sakamoto[1] — [1]Department of Applied Physics, The University of Osaka, Osaka, Japan — [2]Synchrotron Light Application Center, Saga University, Saga, Japan — [3]Institute of Molecular Science, University of Valencia, Paterna, Spain — [4]Max Planck Institute of Microstructure Physics, Halle, Germany

Two-dimensional (2D) van der Waals (vdW) magnets are promising for future spintronic applications. Recently, transition metal dihalides (TMDHs) have received increasing attention as a new class of 2D vdW magnets. In this study, we report the layer dependence of the magnetic and electronic properties of ultrathin $FeCl_2$, a layered antiferromagnetic insulator, films on Bi(111) from monolayer to four layers. X-ray magnetic circular dichroism (XMCD) measurements revealed that the monolayer film exhibits an in-plane easy axis, while the thicker films have an out-of-plane easy axis with a spin-flip transition, which is consistent with the antiferromagnetic order of bulk $FeCl_2$. The transition field increases with increasing thickness. Angle-resolved photoelectron spectroscopy (ARPES) revealed insulating electronic structure irrespective of the thickness. Layer-dependent change is found as the increase in the width of the bands with large Cl 3p contributions. These results show that both the magnetic and electronic coupling through the vdW interfaces become stronger as the thickness increases.

Invited Talk O 64.6 Wed 16:30 HSZ/0403

Single-spin sensing: A molecule-on-tip approach — •Laurent Limot — Université de Strasbourg, CNRS, IPCMS, UMR 7504, F-67000 Strasbourg, France

Magnetometry plays a pivotal role in advancing ultra-dense data-storage technologies and addressing the challenges that arise as spin qubits are downscaled. A promising route toward atomic-scale single-spin sensing is the use of a magnetic molecule as a spin sensor, although practical implementations of this concept remain at an early stage. To demonstrate its feasibility and potential, we combine a nickelocene molecule with scanning tunneling microscopy to achieve versatile, spin-sensitive imaging of magnetic surfaces.

We investigate model Co islands of varying thickness on Cu(111), which exhibit distinct magnetic properties. Our approach proves robust and reproducible, offering atomic-scale sensitivity to both spin polarization and magnetization orientation through the direct exchange coupling between the nickelocene-terminated tip and the Co surface. This capability enables the acquisition of magnetic exchange maps, whose characteristic magnetic corrugation patterns show excellent agreement with computed spin-density distributions. Building on this foundation, we will apply the method to probe the influence of hydrogen on magnetization, a topic of significant relevance in spintronics. Collectively, these advances substantially enhance our ability to probe and visualize magnetism at the atomic scale.

O 64.7 Wed 17:00 HSZ/0403

Tailoring Robust 1D Atomic and Electronic Textures in Mn Ultrathin Films on Fe(110) via Antiferromagnet-Ferromagnet Interfaces — •Toyo Kazu Yamada[1,2], Eiichi Inami[3], and Peter Krueger[1,2] — [1]Dept. Materials Science, Chiba Univ., Chiba, Japan — [2]Molecular Chirality Res. Centre, Chiba Univ., Chiba, Japan — [3]School of Systems Engineering, Kochi Univ. Tech., Kochi, Japan

Controlling the dimensionality of electronic states on two-dimensional (2D) surfaces has remained a significant challenge over decades. In particular, achieving one-dimensional (1D) electronic ordering on 2D surface could enable anisotropic quantum transport and support quantum-confined functional units for nanoscale device integration. In this study, we demonstrate that even conventional 3d transition metals, ferromagnetic (FM) Fe and antiferromagnetic (AFM) Mn, can give rise to 1D atomic stripe patterns in the local density of states (LDOS) on a 2D surface. This study investigates the emergence of one-dimensional (1D) atomic and electronic ordering in ultrathin manganese (Mn) films grown on atomically flat Fe(110) substrates. By combining scanning tunneling microscopy/spectroscopy (STM/STS) and density functional theory (DFT), we demonstrate that the interplay between antiferromagnetic and ferromagnetic interactions at the interface leads to robust 1D stripe electronic textures that remain stable even at room temperature, persisting in the presence of atomic-scale defects.

O 64.8 Wed 17:15 HSZ/0403

Influence of the light polarization on magnetic dichroism in threshold photoemission — •Frank O. Schumann[1] and Jürgen Henk[2] — [1]Max-Planck Institut für Mikrostrukturphysik, Halle, Germany — [2]Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, Germany

Incoming normal incidence light which is neither purely s- or p-polarized will become in general elliptically polarized inside a metallic surface. We ask how the magnetic dichroism is affected if the incoming light is changed from circularly to linearly polarized, with equally large s- and p-components. This is further compared if the incoming elliptically polarized light is tuned such that it becomes circularly polarized inside the surface. Initial theoretical work on normal emission demonstrated for in-plane magnetized samples a sizeable difference in the dichroism spectra for different light polarizations.[1]

We performed an one-step photoemission calculation for threshold photoemission from a Fe(100) and capture the emission into the full half sphere. The photon energy was 5.2 eV and the angle of incidence was set to 65° as realized in PEEM instruments. We are interested in domain imaging and we determine the relevant asymmetry for magnetic domains.[2] The spectra for a given magnetization direction and polarization state are very different whereas the magnetic dichroism signal displays a weak dependence.

[1] J. Henk and R. Feder, Phys. Rev. B **55**, 11476 (1997) [2] M. Paleschke et al., Phys. Rev. B **112**, 054411 (2025).

O 64.9 Wed 17:30 HSZ/0403

Triple-Q state in magnetic breathing kagome lattice — Hangyu Zhou[1,2], Manuel dos Santos Dias[3], Weisheng Zhao[1], and •Samir Lounis[4,2] — [1]Fert Beijing Institute, Beihang University, Beijing, China — [2]Peter Grünberg Institut, Forschungszentrum Jülich & JARA, Jülich, Germany — [3]Scienti c Computing Department, STFC Daresbury Laboratory, Warrington, United Kingdom — [4]Institute of Physics, Martin-Luther-University Halle-Wittenberg, Halle, Germany

Magnetic frustration in two-dimensional triangular spin lattices produces a variety of exotic states, from multi-Q configurations to disordered spin glasses. The antiferromagnetic kagome lattice, built from corner-sharing triangles, is a paradigmatic frustrated system with macroscopic degeneracy. Building on the kagomerization mechanism we recently introduced [1], we examine the magnetic breathing kagome lattice formed by an Mn monolayer on a heavy-metal substrate capped with h-BN [2]. The Mn kagome geometry induces strong frustration, reflected in the nearly flat bands obtained from spin-spiral energy calculations. Including further-neighbor interactions yields a spin-spiral energy minimum along Γ-K and a triple-Q state with nonzero topological charge, potentially causing highly nonlinear Hall responses. The flat-band character can also stabilize more complex spin textures featuring multiple Q-pockets in the spin structure factor. These findings provide a fertile platform for studying multi-Q states and emergent topological phenomena.

O 65.1 Wed 15:00 TRE/PHYS

Effect of Organic Additives in Aqueous Dye-Sensitized Solar Cells with $TEMPO^{+/0}$ Radicals as Redox Mediator Studied by Perturbation Techniques — •Daniel Holzhacker and Derck Schlettwein — Justus-Liebig-Universität Gießen, Institut für Angewandte Physik, Heinrich-Buff-Ring 16, D-35392 Gießen

Understanding the complex interactions among the electrolyte, dye, and semiconductor (TiO_2) in dye-sensitized solar cells (DSSCs) is crucial to uncover and optimize the individual roles of each component. Organic electrolyte additives, such as 1-methylbenzimidazole (1MBI), are commonly used to enhance cell performance. In aqueous $TEMPO^+$ solutions, a distinctive color change was observed upon addition of 1MBI. Cyclic voltammetry revealed that the redox potential of the electrolyte shifted systematically to higher potentials with increasing 1MBI concentration. Photoelectrochemical analysis of DSSCs demonstrated a clear effect of 1MBI on the conduction band edge, which shifted in parallel to the redox potential of the electrolyte. It was shown that reduced recombination losses, i.e., a shift of the electron Fermi level in the TiO_2 closer to the conduction band edge, were responsible for an increased open-circuit voltage. Additionally, the shifts of both the conduction band edge and the redox level of the electrolyte may facilitate electron injection from the dye into TiO_2 and/or the regeneration of the oxidized dye by the redox mediator, thereby explaining the higher photocurrents, also observed at increased 1MBI concentrations.

O 65.2 Wed 15:15 TRE/PHYS

Laser-treated activated carbon derived from date stone for energy storage and environmental remediation applications — •Ahmad Jabr[1], Iyad Sadeddin[1], Amer El Hamouz[1], Hyun Jungb[2], and JeongWon Parkb[2] — [1]An-Najah National university, Nablus, Palestine — [2]Dongguk University, Seoul-Campus, Korea

In this study, Activated Carbon (AC) was synthesized via traditional ZnCl* and KOH routes followed by surface modification process using pulsed Nd:YAG laser (1064 nm) under aqueous conditions to produce laser-modified activated carbon (LAC).

Structural and surface analyses revealed that laser introduced new surface functionalities, increased surface roughness, promoted additional micropores and mesopores formation, resulting in 17% enhancement in SSA. Nitrogen adsorption isotherms indicated higher monolayer adsorption and more developed pore volume distribution in LAC compared with AC. Also, LAC exhibited improved surface chemistry with newly developed OCFGs, attributed to laser bombardment effects.

Electrochemical characterizations showed that AC and LAC exhibit typical EDLC behavior, with LAC achieving 70% higher specific capacitance, enhanced energy and power densities, reduced ESR, and better stability after 10000 cycles compared to AC. Furthermore, adsorption studies showed that LAC overcame AC with 400% enhancement in maximum adsorption capacity and initial rate adsorption, signifying improved surface heterogeneity and multilayer adsorption features.

O 65.3 Wed 15:30 TRE/PHYS

rationalizing capacitance differences across metal/water interfaces within a unified quantum electric double layer model — •Lang Li, Nicolas Hörmann, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin

Electrochemical routes to hydrogen and synthetic fuels promise sustainable energy storage, yet their advancement is limited by an incomplete microscopic picture of the electric double layer (EDL) that governs electrode behavior. Using extensive density-functional theory-based *ab initio* molecular dynamics simulations, we examine a series of noble-metal surfaces and capture the experimental capacitance trend Pt(111) > Cu(111) > Ag(111) ≈ Au(111). Subsequent data analysis rationalizes this trend within a unified EDL picture that rests upon a universal four-state interfacial water structure and material-dependent electron spillover [1]. We probe the generality of this understanding by performing alloy- or strain-mimicking "cross-geometry" simulations at interchanged lattice constants, and obtain capacitance variations in full accordance with the model predictions. This suggests applicability of the model for the rational design of next-generation electrode materials.

O 65.4 Wed 15:45 TRE/PHYS

Formic Acid Oxidation on Gold Electrodes — •Johannes M. Hermann[1], Areeg Abdelrahman[1], Heiko Müller[1], Ludwig A. Kibler[1], and Timo Jacob[1,2,3] — [1]Institute of Electrochemistry, Ulm University, Ulm, Germany — [2]Helmholtz-Institute-Ulm (HIU), Ulm, Germany — [3]Karlsruhe Institute of Technology, Karlsruhe, Germany

Adsorption processes are an integral part of electrocatalysis. The use of extensively studied and structurally well-defined Au(111) single crystal electrodes allows for a better understanding of such processes. Formally, the formic acid oxidation (FAOR) is a relatively simple reaction as only one proton and two electrons have to be released to obtain CO_2. However, the reaction exhibits a self-inhibition on Au(111) electrodes due to the blocking of active sites by strongly adsorbed formate indicated by a bell-shaped current density-potential curve [1]. Similarly, the addition of specifically adsorbing anions typically lowers the catalytic activity [2]. In contrast, certain adsorbates enhance the reaction by orders of magnitude. An intersting example is irreversibly adsorbed 4-mercaptopyridine forming a self-assembled monolayer (SAM) on Au(111) with the enhancement being related to the highly ordered SAM structure [3]. Several aspects of FAOR on gold single crystals will be discussed.

O 65.5 Wed 16:00 TRE/PHYS

Improving Carbon Dioxide Reduction Reactivity and Stability of Ultra-High Vacuum Prepared Cu(111) Surfaces by Crystalline Ultrathin Oxide Films — •Patrick Giesbrecht[1], Mauricio Prieto[1], Mikhail Belozertsev[1], Sergio Tosoni[2], Markus Heyde[1], Thomas Schmidt[1], Beatriz Roldan Cuenya[1], and Juan Navarro[1] — [1]Department of Interface Science, Fritz-Haber Institute of the Max-Planck Society, Berlin, Germany — [2]Dipartimento di Scienza dei Materiali, Università di Milano-Bicocca, Milano, Italy

Electrocatalytic carbon dioxide reduction reactions (CO2RR) to hydrocarbons at copper cathodes is one promising but complex route towards carbon capture and reutilization, where ultra-high vacuum (UHV) prepared single crystal electrodes can provide precise pre-catalyst structures to inform reactivity trends.[1,2] This work develops ultrathin crystalline Cu oxide phases and silica on Cu(111) electrodes under UHV conditions that activate Cu(111) toward hydrocarbon production and alter corrosion pathways under CO2RR conditions.[3] Ex situ and quasi-in situ UHV surface characterization as well as DFT computational analyses are presented that relate this altered reactivity and surface reconstruction to the pre-catalyst oxide structure, highlighting how atomic scale modifications of the surface can lead to macroscopic changes in electrocatalyst reactivity.

O 65.6 Wed 16:15 TRE/PHYS

Mechanistic insights into liquid phase photocatalysis by studying the photoconversion of tertiary alcohols on titania — •Lucia Mengel, Elena Dietz, Martin Tschurl, and Ueli Heiz — Chair of Physical Chemistry, Technical University of Munich, Lichtenbergstr. 4, 85748 Garching, Germany

Titania loaded with a metal co-catalyst represents a well-studied model photocatalyst, e.g. for investigating hydrogen evolution. For the reaction of most alcohols, the use of a co-catalyst is vital to enable hydrogen evolution and thus a fully catalytic reaction. Tertiary alcohols, however, can be employed as probe for the intrinsic photoactivity of bare titania, as they are catalytically converted in a surface photoreaction discovered by us on single crystals in UHV. In this work, we focus on the applicability of these findings to a liquid phase environment by performing photoconversion of 2-methyl-2-butanol on titania nanopowder. We investigate the catalytic activity under water- and oxygen-free conditions and discuss the reaction behavior under consideration of the catalyst's properties.

O 65.7 Wed 16:30 TRE/PHYS

Simulation of catalytic and corrosive processes via Thermopotentiostat Molecular Dynamics — •Andreas Kretschmer[1], Samuel H. Mattoso[2], Jing Yang[2], Ahmed Abdelkawy[2], Mira Todorova[2], Jörg Neugebauer[2], and Markus Valtiner[1] — [1]Institute of Applied Physics, TU Wien, 1040 Wien, Austria — [2]Max-Planck-Insitute of Sustainable Materials GmbH, Max-Planck-Straße 1, 40237 Düsseldorf, Germany

Ab Initio Molecular Dynamics (MD) provides valuable insights in dynamic processes at solid liquid interfaces on the electronic level. However, electrified interfaces have been inaccessible due to the interaction of charged systems with the periodic images. The recently developed thermopotentiostat enables the use of electric fields across a solid/liquid interface by a computational electrode. This electrode consists of a fixed layer of Ne atoms, which confines the water, and provides a compensating charge to keep the cell charge-neutral. The thermopotentiostat updates the charge of the Ne atoms after every MD step to drive the potential difference towards a desired value on average. The electronic minimization then distributes the charge, leading to a corresponding counter charge on the electrode surface, allowing the study of dynamic processes under the influence of electric fields. We apply this method to 2 model systems, one is a single Pt atom supported on two layers of graphene to study catalytic processes with water, the second is a Zn surface to study corrosion processes under H evolution at the interface in anodic and cathodic conditions.

O 65.8 Wed 16:45 TRE/PHYS

First Steps Matter Most: Free Energy Barriers of the Volmer Step in Hydrogen Evolution at Pt(111) — •Barbara Sumić, Karsten Reuter, and Nicolas G. Hörmann — Fritz-Haber-Institut der MPG, Berlin

The Hydrogen Evolution Reaction (HER) plays a central role in hydrogen-based energy conversion. The initial Volmer step, involving proton adsorption at the electrode interface, is key to understanding reaction kinetics and the influence of pH. Conventional approaches to estimating barrier heights based on density-functional theory are limited by the need for reduced system sizes and short simulation times, which restrict statistical sampling and hinder fully converged free-energy calculations, particularly when solvent reorganisation is involved.

Here, we explore machine-learned interatomic potentials (MLIPs) combined with enhanced sampling techniques to gain more comprehensive insight into the reaction mechanism and barrier for the Volmer step at Pt(111) in dynamically described interfacial water. Using data-driven collective variables, we aim to capture dynamic environmental and solvent effects that are difficult to access with standard sampling. We also investigate the applicability of the RAZOR (Response Analysis in z-ORientation) framework [1] for barrier calculations at applied bias to probe potential-dependent behavior.

Together, these approaches provide a pathway toward more consistent and physically grounded modelling of HER across different pH conditions.

O 65.9 Wed 17:00 TRE/PHYS

Modeling chemical trends of Hydrogen adsorption and reactivity on Pt (111) surface alloyed with transition metals — •Bingxin Li, Jing Yang, Mira Todorova, and Jörg Neugebauer — MPI for Sustainable Materials, Düsseldorf, Germany

Platinum's near-optimal hydrogen binding energy, as dictated by the Sabatier principle, makes it the benchmark electrocatalyst for the hydrogen evolution reaction (HER). Alloying Pt with transition metals (TMs) is known to enhance catalytic activity, though the underlying mechanisms vary substantially across alloying elements. Here, we employ ab initio molecular dynamics to investigate hydrogen adsorption on Pt (111) surfaces whose top layer is alloyed with different TMs at varying concentrations. By generating lateral free-energy maps of chemisorbed hydrogen and combining them with nudged-elastic-band calculations, we determine the Tafel-step barriers of HER. We find that Tafel-step kinetics improves as on-top-site hydrogen binding is weakened on alloyed Pt surfaces. Electronic-structure analyses, coupled with a machine-learning model, reveal that on-top-site hydrogen binding energy (key HER activity descriptor) can be quantitatively predicted from d-band centre characteristics. These results link compositional tuning of Pt-based alloys to predictable changes in HER-activity, offering a rational design route for next-generation hydrogen evolution catalysts.

O 65.10 Wed 17:15 TRE/PHYS

Atomic-scale insights into enhanced oxygen reduction on Au(100) in alkaline solutions from ab initio molecular dynamics simulations — •Alexander von Rueden[1,2], Mal-Soon Lee[1], Vassiliki-Alexandra Glezakou[3], Roger Rousseau[3], and Manos Mavrikakis[2] — [1]Pacific Northwest National Laboratory, Richland, WA, USA — [2]University of Wisconsin-Madison, Madison, WI, USA — [3]Oak Ridge National Laboratory, Oak Ridge, TN, USA

The unusually high $4e^-$ oxygen reduction reaction (ORR) activity of the Au(100) surface in alkaline environments has motivated numerous experimental and theoretical studies. Even so, atomic-scale insights into the origin of its high activity remain elusive, with static density functional theory (DFT) calculations under vacuum typically proving insufficient. Here, we instead developed atomistic models of Au(100)-water interfaces featuring fully explicit neutral or alkaline solvent environments. Using these models, we performed DFT-based ab initio molecular dynamics (AIMD) simulations to probe the dynamic atomic structures of ORR intermediates adsorbed on Au(100) in different solvent environments. Additionally combining the Blue moon ensemble enhanced sampling technique with AIMD, we demonstrated a low free energy barrier for O_2 dissociation and hydrogenation by water molecules to yield OH* on Au(100), which is consistent with its high experimental activity. Further, our alkaline simulations revealed these OH* products can form complexes with near-surface Na^+ cations, possibly leading to a more downhill reaction free energy.

O 65.11 Wed 17:30 TRE/PHYS

When Charged Intermediates Escape the Surface: Mass Transport Effects on the Electrocatalytic Selectivity of NO_3 Reduction — •Hemanth S. Pillai, Karsten Reuter, and Vanessa J. Bukas — Fritz-Haber-Institut der MPG, Berlin

Electrocatalytic selectivity is often discussed at the atomic level on the basis of the active site, while ignoring effects of mesoscopic mass transport. And yet, transport can critically shape selectivity through the exchange of surface-bound intermediates between the electrode and bulk electrolyte. We recently explored this mechanism, originally coined "desorption–re-adsorption–reaction" [1], by developing a simple model that couples the surface reaction kinetics with diffusion [2]. Here, we advance and extend our approach to describe charged inter-

mediates such as nitrite (NO_2^-) during the electrochemical NO_3 reduction reaction. Ion transport augments a mean-field microkinetic model and is treated at varying levels of sophistication to capture different double layer characteristics. Our simulations show that both the applied potential and catalyst morphology uniquely shape NO_2^- selectivity within the desorption–re-adsorption–reaction mechanism. The emerging trends are in qualitative agreement with experiments, while distinctly different from those obtained for analogous charge-neutral intermediates during e.g. CO_2 reduction. This comparison shows how the double layer affects selectivity due to transport and allows to gauge the level of detail that is required in corresponding reaction models.

O 65.12 Wed 17:45 TRE/PHYS

Electroreduction of Acetone on PtRu Model Catalysts — •Robert Hübsch[1], Daniel Schauermann[1], Pankaj Kumar Samal[2], Jan Škvára[2], Frederike Jäschke[1], Lesia Piliai[2], Tomáš Skála[2], Nataliya Tsud[2], Josef Mysliveček[2], Olaf Brummel[1], Yaroslava Lykhach[1], and Jörg Libuda[1] — [1]Interface Research and Catalysis, ECRC, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstraße 3, 91058 Erlangen, Germany — [2]Charles University, Faculty of Mathematics and Physics, Department of Surface and Plasma Science, V Holešovičkách 2, Prague, 18000, Czech Republic

The isopropanol/acetone system functions as an electrochemically active liquid organic hydrogen carrier (EC-LOHC). In this context, direct electrochemical charging is particularly attractive but requires highly active and selective catalysts. In this study, we investigated acetone reduction on well-defined PtRu model surface alloys. Our approach combined cyclic voltammetry (CV), ex-situ emersion synchrotron radiation photoelectron spectroscopy (SRPES), electrochemical infrared reflection absorption spectroscopy (EC-IRRAS), and differential electrochemical mass spectrometry (DEMS). The PtRu/Ru(0001) surface exhibits low intrinsic catalytic activity; but can be activated through a dealloying procedure. This treatment produces small Pt aggregates on a rough Ru support. In contrast, the PtRu/Ru(10 10) surface, characterized by a lower coordination number, does not require dealloying. Unlike Pt(110), which predominantly produces propane, the PtRu model catalysts selectively yield the target product isopropanol.

Ultrafast exciton dynamics in 2D semiconductors and electric field gated devices — •Jan Philipp Bange — Georg-August-Universität Göttingen, I. Physikalisches Institut, Germany

Two-dimensional (2D) semiconductors and moiré materials, formed by stacking and twisting atomically thin layers, provide an exciting platform to discover and engineer new quantum states. Precise and reversible control of carrier density and many-body effects is readily achieved through in-situ electric field gating. In combination with angle-resolved photoemission spectroscopy this has been a powerful probe of the static electronic band structure. However, capturing the ultrafast dynamics of excited states in gated 2D materials, including hybrid excitons [1], interlayer excitons [2], and trions [3], remains a fundamental challenge due to the limited real-space resolution of ultrafast time- and momentum-resolved spectroscopy techniques. In this talk, I will present how time-resolved momentum microscopy provides direct access to both the energy landscape and femtosecond dynamics of bright and dark excitons at nanometer length scales. This methodology enables the disentanglement of electron and hole transfer pathways across twisted transition metal dichalcogenide interfaces and reveals the ultrafast formation of quasiparticles as a function of gate voltage.

Ultrafast signatures of Dirac - flat-band hybrid states from time-resolved ARPES — •Maria-Elisabeth Federl[1], Johannes Gradl[1], Franziska Bergmeier[1], Zamin Mamiyev[2], Niclas Tilgner[2], Thomas Seyller[2], Christoph Tegenkamp[2], and Isabella Gierz[1] — [1]University of Regensburg — [2]Chemnitz University of Technology

Hybridization of highly itinerant Dirac electrons with localized flat-band states is predicted to yield emergent phenomena such as exotic heavy-fermion behaviour. Epitaxial graphene resting on a flat-band system at the graphene-SiC(0001) interface offers a promising platform, yet direct spectroscopic signatures - such as avoided crossings in equilibrium ARPES - have remained unresolved. We solved this problem using time-resolved ARPES where evidence of hybridization manifested in three key observations: (1) accelerated Dirac-carrier relaxation due to an increased scattering phase space, (2) transient charging of the Dirac cone enabled by direct optical excitation from the flat bands, and (3) ultrafast charge transfer back into the flat bands on timescales set by the interlayer coupling strength. Our results thus provide a clear dynamical fingerprint of hybridization in a system where equilibrium probes have proven inconclusive.

O 66.3 Wed 15:45 TRE/MATH

Probing topological Floquet states in graphene with ultrafast STM — •Nils Jacobsen[1,2], Melanie Müller[3], Michael Schüler[4,5], Martin Wolf[3], and Angel Rubio[2,6] — [1]University of Bremen — [2]MPSD Hamburg — [3]FHI Berlin — [4]PSI Villingen Switzerland — [5]University of Fribourg Switzerland — [6]CCQ The Flatiron Institute New York USA

The light-induced anomalous Hall effect in graphene driven by circularly polarized light is a hallmark example of Floquet band engineering [1]. It has been observed in ultrafast transport experiments [2] and Floquet Bloch bands in graphene have recently been resolved by time- and angle-resolved photoemission spectroscopy [3]. Here, we propose ultrafast scanning tunnelling microscopy (USTM) as a complementary probe of topological Floquet states in graphene [4]. In our simulations, dynamical band gaps and topological edge states are directly reflected in the local density of states and the ultrafast tunnelling currents. The chirality of the edge states is revealed by the suppression of backscattering at impurities, which could be probed by ultrafast STM. These results establish ultrafast STM as a promising tool to access light-induced topological states in quantum materials. [1] Oka PRB 79, 081406(R) (2009) [2] McIver Nat. O 66.4 Wed 16:00 TRE/MATH

Ultrafast Band-Gap Renormalization in Bilayer Graphene — •Eduard Moos[1], ZhiYuan Deng[1], Hauke Beyer[1], Arpit Jain[4], Chengye Dong[4], Joshua A. Robinson[4], Kai Rossnagel[1,2,3], and Michael Bauer[1,2] — [1]Kiel University, Germany — [2]Kiel Nano, Surface and Interface Science KiNSIS, Germany — [3]Electron Synchrotron DESY, Germany — [4]Pennsylvania State University, United States

We demonstrate, by femtosecond time- and angle-resolved photoemission spectroscopy, that photoinduced interlayer charge transfer in a heterostructure consisting of Bernal-stacked bilayer graphen and a single atomic layer of silver on 6H-SiC(0001) transiently modulates the intrinsic potential landscape across the silver-graphene interface. Acting as an ultrafast electronic gate, this drives momentum-dependent band renormalizations, resulting in a transient band-gap opening on femtosecond timescales. Simultaneously, the photogenerated hot-carrier population enhances electronic screening, leading to a subsequent closing of the band-gap beyond the thermal equilibrium value. These findings reveal two different mechanisms for a photoinduced, reversible control of the electronic band structure in bilayer graphen — interlayer charge transfer and hot-carrier enhanced screening — providing a general framework for the ultrafast control of electronic properties in graphene-based heterostructures. They further open novel pathways for the realization of ultrafast optoelectronic devices and the exploration of correlated quantum phases in bilayer graphene under nonequilibrium conditions.

O 66.5 Wed 16:15 TRE/MATH

Attosecond spin-orbit delays in solid-state photoemission — •Andreas Gebauer[1], Walter Enns[1], Sergej Neb[2], Tillmann Schabbehard[1], Luis Maschmann[1], J. Hugo Dil[3], Ulrich Heinzmann[1], Stephan Fritzsche[4,5,6], Nikolay M. Kabachnik[7,8], Eugene E. Krasovskii[8,9,10], and Walter Pfeiffer[1] — [1]Bielefeld University — [2]ETH Zurich — [3]EPFL, Lausanne — [4]Helmholtz Institute Jena — [5]GSI Helmholtzzentrum für Schwerionenforschung GmbH — [6]Friedrich-Schiller-University Jena — [7]European XFEL GmbH, Schenefeld — [8]DIPC, San Sebastián — [9]Universidad del País Vasco, San Sebastián — [10]IKERBASQUE, Bilbao

Attosecond time-resolved photoelectron spectroscopy allows observation of photoemission dynamics in solids on its natural time scale. Photoelectrons typically need tens to hundreds of attoseconds to be released into the vacuum while various competing effects determine the emission dynamics. We report the first observation of unexpectedly large spin-orbit delays, i.e. relative photoemission delays between spin-orbit split core levels in Bi_2Te_3 and Bi_2Se_3. The observed delays can neither be attributed to intra-atomic delays nor to ballistic photoelectron transport. Instead, calculations based on one-step photoemission theory reveal that strong variations of the final state wave function on the energy scale of the spin-orbit splitting are responsible for the experimental observation. These vari-

ations reflect the complex interplay of propagating and evanescent waves in the photoelectron emission, exhibiting qualitatively different emission dynamics.

O 66.6 Wed 16:30 TRE/MATH

Electron Correlations in Ultrafast Transmission Electron Microscopy — •Nico Stumpp[1], Andreas Wendeln[1], Alexander Schröder[1], and Sascha Schäfer[1,2] — [1]Department of Physics, University of Regensburg, Regensburg, Germany — [2]Regensburg Center for Ultrafast Nanoscopy (RUN), Regensburg, Germany

Ultrafast transmission electron microscopy (UTEM) strives to combine an atomic spatial resolution with a femtosecond temporal resolution, yet its performance is inherently limited by Coulomb repulsion within electron pulses. Research in free-electron quantum optics suggests that, rather than avoiding these dynamic interactions, exploiting their induced inter-electron correlations offers a pathway toward quantum-limited imaging performance [1,2].

Utilizing an event-based electron detector with nanosecond temporal resolution, we observe pronounced energy anti-correlations in few-electron states emitted from a high-coherence, laser-driven cold field-emission electron source [3]. Crucially, we demonstrate the ability to actively modify the magnitude and visibility of the induced energy separation depending on angular post-selection. We complement our experimental results with numerical multi-particle simulations of electron pulse dynamics within the electrostatic gun environment, focussing on the interplay between strongly interacting correlated electron pairs and the surrounding electron ensemble of the emitted photoelectron bunch.

O 66.7 Wed 16:45 TRE/MATH

Ultrafast Investigation of Competing CDW Orders in $LaTe_3$ — •Francesco Sammartino[1], Wibke Bronsch[2], Fulvio Parmigiani[1,2], and Federico Cilento[2] — [1]Università degli Studi di Trieste — [2]Elettra - Sinctrotrone Trieste

The RTe_3 family hosts a rich landscape of charge-density-wave (CDW) phases. All members display a unidirectional CDW aligned along the *c*-axis, while only the heavier rare-earth compounds develop an additional equilibrium CDW along the *a*-axis at lower temperature. Intriguingly, recent ultrafast experiments have shown that $LaTe_3$, whose equilibrium state features only the *c*-axis CDW, can transiently exhibit a rotated CDW component oriented along the *a*-axis.

Building on time-resolved optical studies that first revealed the emergence of this orthogonal order, we investigated $LaTe_3$ through time-resolved ARPES (TR-ARPES) to track, with momentum resolution, the ultrafast evolution of its electronic structure.

We monitored the melting of the equilibrium *c*-axis CDW gap and searched for transient modifications of the electronic dispersions along the *a*-axis that could be linked to the emergence of the rotated order. This study provides direct insight into the nonequilibrium CDW dynamics of $LaTe_3$ and may help clarify the microscopic pathways that enable the formation of the rotated CDW state.

O 66.8 Wed 17:00 TRE/MATH

Electron and exciton dynamics in large-angle twisted bilayer graphene — •Gianmarco Gatti[1], Anders Mortensen[1], Gesa Siemann[1], Zhihao Jiang[1], Alfred Jones[1], Chakradhar Sahoo[1], Thomas Nielsen[1], Naina Kushwaha[2], Jennifer Ridgen[2], Søren Ulstrup[1], Bruce Weaver[2], Yu Zhang[2], Charlotte Sanders[2], Emma Springate[2], Vibha Reddy[3], Ulrich Starke[3], and Philip Hofmann[1] — [1]Department of Physics and Astronomy, Aarhus University, 8000 Aarhus C, Denmark — [2]Central Laser Facility, STFC Rutherford Appleton Laboratory, Didcot, Oxfordshire OX11 0QX, UK — [3]Max Planck Institute for Solid State Research, Heisenbergstr. 1, 70569, Stuttgart, Germany

Tunable moiré superlattices naturally form in artificially stacked monolayers through control of their rotational misalignment (twist angle). In large-angle twisted bilayer graphene (TBG), orbital hybridization between the monolayer-derived π/π^* bands leads to avoided crossings and the emergence of pairs of occupied and unoccupied van Hove singularities at fixed wave vectors k*. We investigate the out-of-equilibrium electron dynamics near these points in 10°-TBG using IR-pump XUV-probe time-resolved ARPES experiments. Our measurements resolve the hot electron dynamics in TBG and reveal an additional, unexpected spectral weight within the local electronic band gap at k*. This observation is consistent with the signature of a strongly bound exciton in TBG, whose formation has been attributed by recent theoretical models to a unique destructive coherence between two energy-degenerate subband resonant transitions.

O 66.9 Wed 17:15 TRE/MATH

Hybrid Frenkel-Wannier excitons facilitate ultrafast energy transfer at a 2D-organic interface — •Wiebke Bennecke[1], Ignacio Gonzalez Oliva[2], Jan Philipp Bange[1], Paul Werner[1], David Schmitt[1], Marco Merboldt[1], Anna M. Seiler[1], Daniel Steil[1], R. Thomas Weitz[1], Peter Puschnig[3], Claudia Draxl[2], G. S. Matthijs Jansen[1], Marcel Reutzel[1], and Stefan Mathias[1] — [1]I. Physikalisches Institut, Georg-August-Universität Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — [2]Physics Department and CSMB, Humboldt-Universität zu Berlin, 12489 Berlin, Germany — [3]Institute of Physics, NAWI Graz, University of Graz, 8010 Graz, Austria

The combination of two-dimensional transition metal dichalcogenides (TMDs) and organic semiconductors (OSCs) is a highly promising material platform for the realization of future optoelectronic devices. While the excitonic properties of their individual components have been intensively studied, much less is known about excitons at the hybrid interface. Here, we use ultrafast momentum microscopy and many-body perturbation theory to investigate the exciton landscape at the PTCDA/WSe_2 interface [1]. In particular, we find an exciton state formed via Förster resonant energy transfer, which is of hybrid nature: Concomitant intra- and interlayer electron-hole transitions within the OSC layer and across the TMD/OSC interface, respectively, give rise to an exciton wavefunction with mixed Frenkel-Wannier character.

O 66.10 Wed 17:30 TRE/MATH

Electronic friction simulations of laser-driven hydrogen evolution from copper. Does surface coverage matter? — •Alexander Spears[1], Wojciech G Stark[2], and Reinhard J. Maurer[1,3] — [1]University of Vienna, AT — [2]Imperial College London, UK — [3]University of Warwick, UK

Plasmonic catalysts such as metal nanoparticles harness the energy transfer between light, electrons and phonons at interfaces to drive chemical reactivity at interfaces. However, even on clean metal surfaces with a regular structure, it is unclear whether these dynamics are the result of mode-selective energy transfer or photothermal heating effects. Molecular dynamics simulations with electronic friction (MDEF) offer a quantum-classical description of electron-phonon coupling and have previously been used to model ultrafast dynamics on metal surfaces. Using machine learning surrogate models to accelerate MDEF simulations, we show that mode-selective energy transfer has a negligible influence on light-driven hydrogen evolution from copper surfaces. By comparing energy partitioning in desorbed molecules, we conclude the choice of electronic friction approximation only determines the rate of energy transfer, while the energy distributions of desorbing molecules are governed by the potential energy surface. This suggests that thermal and laser-driven desorption may yield similar outcomes at low coverage. However, we expect mode-selective energy transfer to play a stronger role at higher coverage, and show preliminary results for surface coverage dependence in laser-driven desorption.

O 67: Focus Session: Unoccupied States by Inverse Photoemission II

The Other Half of the Picture: 50 Years of Direct Access to Unoccupied States by Inverse Photoemission

In 1981, J. Pendry evaluated the experimental access to electron states in solids: "Currently only half of the picture can be seen with photoemission. Inverse photoemission provides the other half." A complete picture of electron states needs both occupied and unoccupied states in order to describe, understand, and finally tailor macroscopic material properties. In 1976, V. Dose had submitted a first paper on Bremsstrahlung Isochromat Spectroscopy in the VUV range: "The physics involved may be most simply described as an inverse photoelectric effect." The first experiments provided surface-sensitive information on the density of unoccupied states. Later, momentum and spin resolution were added to investigate the spin-dependent E(k) dispersion of unoccupied electron states. During five decades, the technique was further developed by several groups worldwide to enhance the intensity and improve the resolution in energy, momentum, and spin. A wealth of information was gained about metals, semiconductors, ultrathin films as well as adsorbate systems. The experimental studies were accompanied by several theoretical approaches, which are able to accurately describe the unoccupied electronic structure and model the inverse photoemission process. In 2012, H. Yoshida extended the energy range to the near-UV range (low-energy inverse photoemission), which is especially suited to study organic samples due to a lower damage risk caused by the exciting electron beam.

Current research fields for inverse photoemission are, e.g., spin textures of exchange- and/or spin-orbit-induced influenced systems and topological insulators, gap structures in transition metal dichalcogenides, LUMO levels in semiconductors for photovoltaic applications, electronic structure of atomic-layer and quantum materials. This focus session will highlight recent advances obtained by inverse photoemission in different fields and material systems. Also, it will bring together researchers from different areas for addressing current trends and future applications of inverse photoemission from experimental as well as theoretical perspective.

Organized by Markus Donath, Fabian Schöttke and Peter Krüger (U Münster).

New frontiers of one step model of photoemission for quantum materials — •Jan Minar — New Technologies Research Center, University of West Bohemia in Pilsen, Pilsen, Czechia

Quantum materials feature intertwined electronic correlations, topology, and magnetism, requiring realistic treatments of spin-orbit coupling, interactions, and spin fluctuations. Spin- and time-resolved ARPES (STARPES) is a key probe of their electronic and spin structures, but its quantitative interpretation demands advanced theory. I will present a fully relativistic multiple-scattering Green function (KKR) [1] framework for spin-dependent photoemission that incorporates correlations via DMFT, spin fluctuations via the alloy-analogy model, and light-induced electronic excitations [2,3]. Applications include a one-step photoemission description of altermagnets such as RuO* and MnTe, where spin-ARPES reveals lifted Kramers degeneracy relevant for spintronics, and kagome magnets such as FeSn thin films, where persistent flat-band splitting and selective band renormalization expose strong correlation and topological effects. This framework provides a unified route to unravel spin dynamics in complex quantum materials [4,5,6].

Surface-orientation-dependent unoccupied electronic states of Fe_3O_4 — •Jan Bieling and Markus Donath — Universität Münster, Germany

Experimental studies of the occupied electronic states of magnetite (Fe_3O_4) have revealed that the observed properties, such as band dispersions, are strongly surface-orientation-dependent [1,2]. However, comparable systematic studies of the unoccupied electronic states of different Fe_3O_4 surfaces are still lacking.

We report on the unoccupied electronic states of a well-characterized $Fe_3O_4(111)$ surface using angle-resolved inverse photoemission and compare the results with our previous study of $Fe_3O_4(100)$ [3]. This direct comparison allows for (re)interpreting the spectral features observed for both surfaces.

Finally, we discuss our findings in the context of recent theoretical studies [4,5]. We report a very good agreement between our inverse photoemission spectra of $Fe_3O_4(100)$ and the theoretical results obtained from DFT+U+V for this surface.

O 67.3 Wed 15:45 WILL/A317

Beyond the surface: Probing electronic structure with IPES in Valparaíso-Chile — Patricia Martínez[1], Rolando. Esparza[1], Jonathan Correa-Puerta[1], Valeria del Campo[1], Ricardo Henríquez[1], •Patricio Häberle[1], Sanber Viscaya[1], Eric Suárez-Morell[1], Patricio Vargas[1], Jean F. Veyan[2], Marcos Flores[3], and Samuel Hevia[4] — [1]Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile — [2]Department of Materials Science and Engineering, The University of Texas at Dallas, Richardson, Texas 75080, USA — [3]Physics Department, Facultad de Ciencias Físicas y Matemáticas, Universidad de Chile, Santiago, Chile — [4]Instituto de Física and CIEN-UC, Pontificia Universidad Católica de Chile, Av. Vicuña Mackenna 1860, Macul, Chile

Over the past few years, we have employed angle-resolved inverse photoemission spectroscopy (IPES) at the Valparaíso facility, utilizing both the isochromat mode and photon energy-resolving capabilities. This technique has enabled us to investigate systems exhibiting electronic structures modified by various forms of quantum confinement. We have characterized metallic thin films, carbon nanotubes, self-assembled monolayers (SAMs), and two-dimensional semiconductors. Whenever feasible, we have mapped unoccupied energy bands; however, in many instances, we have relied on simulations and inventive averaging to extract meaningful information from these low-symmetry nanoscale systems. A comprehensive overview of our experimental findings and future directions will be presented.

Inverse photoemission studies of unoccupied electronic states of various Si(111)-based surfaces and interfaces — Younal Ksari, Hela Mrezguia, and •Jean-Marc Themlin — CNRS, Aix-Marseille Univ. University of Toulon, Marseille, France

We operate in Marseille an angle-resolved inverse photoemission (ARIPES) setup working in the isochromat mode. To illustrate the potential of this highly surface-sensitive technique, we give a comparative overview of the unoccupied part of the electronic structure of several Si(111)-based interfaces as revealed by ARIPES, from the hydrogenated H:Si(111) to 2D silicene monolayers grown on passivated Si(111) substrates.

The H-saturated (1x1) termination of Si(111) solely reveals bulk conduction band states. Upon segregation (B) or adsorption (H, As, Au) of foreign atoms on Si(111), specific surface states appear, leading to insulating (H, As, B) or metallic (Au) interfaces.

According to LEED, the adsorption of 1 ML of Si on the $\sqrt{3}\times\sqrt{3})R30^\circ$ reconstructed Au- and B- substrates leads to the formation of a non-covalently bound Si bilayer, alias silicene, which adopts the symmetry of the passivated substrates. Specific unoccupied electronic states appear on each substrate, with dispersions profiles which do not exhibit a $\sqrt{3}\times\sqrt{3})R30^\circ$ symmetry, small overall bandwidths and large bandgaps (resp. > 2 eV and > 1 eV), suggesting important correlation effects.

Layer-Dependent Electronic Signatures of Tl on Ag(111) Revealed by Inverse Photoemission — •Sarah Laufer[1], Sven Schemmelmann[1], Yuichiro Toichi[2], Kazuyuki Sakamoto[2], and Markus Donath[1] — [1]Physikalisches Institut, Universität Münster — [2]Department of Applied Physics, The University of Osaka

The Tl/Ag(111) system is characterised by pronounced changes in its spatial and electronic structure when transitioning from sub-monolayer coverage to the monolayer [1,2] and further to the bilayer [3], making an accurate determination of the layer thickness essential. While low-energy electron diffraction and Auger electron spectroscopy provide valuable information on domain orientations and Tl coverage trends, neither technique allows an unambiguous identification of the bilayer. In contrast, inverse photoemission (IPE) gives direct access to unoccupied electronic states, which are highly sensitive to the Tl film thickness. We show that Tl/Ag(111) exhibits distinct layer-dependent unoccupied states whose characteristic intensity evolution with increasing Tl coverage enables a clear identification of the bilayer. These results highlight the particular strength of IPE as a layer-specific probe for ultrathin metallic films.

O 67.6 Wed 16:30 WILL/A317

Modeling a transient Dirac-like surface state in Floquet-driven SnTe — •Aki Pulkkinen[1], Frédéric Chassot[2], Hugo Dil[3], Claude Monney[2], and Ján Minár[1] — [1]New Technologies-Research Centre, University of West Bohemia in Pilsen, Czechia — [2]Department of Physics and Fribourg Center for Nanomaterials, Université de Fribourg, Switzerland — [3]Institute of Physics, Ecole Polytechnique Fédérale de Lausanne, Switzerland

We present a theoretical analysis of the ultrafast transient cone-like dispersion observed in pump-probe photoemission experiments on SnTe[1]. A semi-infinite (111) surface Hamiltonian is constructed from a Wannier tight-binding model, and the surface Green's function is obtained using the recursive López-Sancho method[2] in extended Hilbert space. The effect of the pump pulse is introduced through a time-periodic Peierls substitution and a Jacobi-Anger expansion of the driven Hamiltonian into Floquet sectors. The Floquet-Green's-function calculations show that photoexcitation induces a transient hybridization between the Floquet replica of the valence band and the conduction band, producing a momentary band inversion at the surface. The inversion generates a short-lived Dirac-cone-like surface state, reproducing the main experimental feature. The results indicate that the transient cone originates from Floquet-induced reconstruction rather than structural or thermal effects, and demonstrate the role of strong periodic driving in reshaping surface electronic structure in SnTe. [1] F Chassot et al. 2025 arXiv:2502.11967 [2] M. P. Lopez Sancho et al. 1985 J. Phys. F: Met. Phys. 15 851

O 67.7 Wed 16:45 WILL/A317

Peak separation analysis for inverse photoelectron spectra: Comparing second derivative, curve fitting, and deconvolution — •ryotaro nakazawa[1,2], haruki sato[2], and hiroyuki yoshida[2] — [1]Institute for Molecular Science, Aichi, Japan — [2]Chiba University, Chiba, Japan

Inverse photoelectron spectroscopy (IPES) is a powerful technique for probing the unoccupied electronic states of materials. Recently developed low-energy inverse photoelectron spectroscopy (LEIPS) can significantly advance the study of unoccupied states, owing to minimal sample damage and suppressed dark counts compared to conventional IPES. However, the instrumental resolution remains at around 0.2 eV, which is one order of magnitude lower than that of photoelectron spectroscopy. Spectral broadening caused by the low instrumental resolution often results in overlapping peaks. Peak separation is therefore crucial in the analysis of LEIPS spectra. In this study, we compared three peak separation methods: second derivative, curve fitting, and deconvolution. These methods were applied to modeled and experimental LEIPS spectra of the lowest unoccupied molecular orbital-derived band of pentacene, which consists of two splitting peaks due to the two inequivalent molecules in the unit cell. We systematically and quantitatively evaluated the performance of each method in terms of analysis parameters and discussed its robustness to noise as well as its peak separation and detection capabilities. This work offers a practical framework for peak separation in LEIPS, with extensions to PES and a wide range of spectroscopies.

O 67.8 Wed 17:00 WILL/A317

The role of light polarization in inverse photoemission — •Marcel Holtmann, Pascal J. Grenz, and Markus Donath — Physikalisches Institut, Münster University, Germany

In inverse photoemission (IPE), electrons are directed onto a surface and the light emitted during radiative transitions into unoccupied states is detected. By detecting the emitted photons as a function of the kinetic energy of the electrons impinging at a defined angle of incidence, the dispersion of conduction-band states can be traced. We focus on the role of light polarization in IPE and how the simultaneous detection of photons with multiple detectors provides additional symmetry information.

In the spirit of "50 years of IPE", this talk aims to give an overview of this aspect of IPE analysis. Building on early work from the 1980s [1,2], we will present measurements of the AgTe/Ag(111) surface alloy. The polarization contrast allows us to identify the orbital character of spin-dependent unoccupied states. We will also discuss the recent improvement of our setup, in which a polarizing mirror was added to the photon detector [3], enabling us to select the detected light polarization.

O 67.9 Wed 17:15 WILL/A317

Sub-100 meV low-energy inverse photoelectron spectroscopy using an electrostatic monochromator — •Tomoko Onishi[1], Taichi Suruga[1], Daichi Honma[1], Masaya Kai[1], Issei Ishimori[1], François C. Bocquet[2], F. Stefan Tautz[2], Harald Ibach[2], and Hiroyuki Yoshida[1] — [1]Chiba University, Chiba, Japan — [2]Forschungszentrum Jülich, Jülich, Germany

Inverse photoelectron spectroscopy (IPES) is the optimal experimental method for probing unoccupied electronic states but its applicability has been limited by modest energy resolution. This resolution is determined by the convolution of the electron energy spread and photon-detector bandwidth. The best reported resolution to date is 165 meV, limited by the photon detector [1]. Low-energy IPES (LEIPS) [2], using an optical bandpass filter, achieves a photon-detection resolution of 38 meV. However, the total resolution remains limited to 250 meV due to electron-beam thermal broadening [3]. In this work, we report a LEIPS system with an electron source consisting of a LaB6 cathode, electrostatic monochromator, and deceleration lens system. This design is based on high resolution electron energy loss spectroscopy (HREELS). We modified it to deliver several hundred nA with a capability of energy scan for LEIPS [4]. An electron energy spread of 90 meV is obtained, resulting in a total LEIPS energy resolution of 98 meV. [1] M. Budke et al., Rev. Sci. Instrum. 78, 083903 (2007). [2] H. Yoshida, Chem. Phys. Lett. 539*540, 180 (2012). [3] H. Yoshida, J. Electron Spectrosc. Relat. Phenom. 204, 116 (2015). [4] H. Ibach et al., Rev. Sci. Instrum. 94, 043908 (2023).

O 67.10 Wed 17:30 WILL/A317

Towards high resolution IPES in the VUV range — Giacomo Merzoni[1], Samuele Comizzoli[1], Giacomo Panzera[1], Lucio Braicovich[1,2], and •Giacomo Ghiringhelli[1,3] — [1]Politecnico di Milano, Italy — [2]ESRF, Grenoble, France — [3]CNR/SPIN, Politecnico di Milano, Italy

Since its concept was introduced and its feasibility was demonstrated, the conceptual interest of angle-resolved inverse photoemission (ARIPES) has not declined. Unfortunately, for decades technical challenges have kept ARIPES in a niche. At the same time direct photoemission, ARPES, has become a popular and unmissable technique for the determination of the electronic structure of solids. ARPES spectra are commonly measured with energy resolution better than 30 meV, a figure still unachieved in ARIPES. Which explains the different popularity of the two complementary techniques.

Is it possible to design today an ARIPES instrument that better exploits the technological progress undergone over the years by detectors and optical elements for VUV radiation, and by monocromatized electron-beam sources?

We present some ideas guiding the realization of an ARIPES apparatus working in the 20-100 eV energy range. Aiming at a combined instrumental bandwidth smaller than 50 meV, it is based on a high-luminosity grating spectrometer and a 2D position sensitive semiconductor detector.

O 67.11 Wed 17:45 WILL/A317

2D IPES intensity maps of MoS_2 — •Patricia Martínez-Rojas, Sanber Vizcaya, Rolando Esparza, and Patricio Häberle — Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile

Inverse photoemission spectroscopy (IPES) offers direct access to the unoccupied electronic structure of solids and is particularly well suited for investigating layered transition-metal dichalcogenides such as MoS_2. We present momentum-resolved IPES measurements on a bulk 2H-MoS_2 single crystal, performed with a normal-incidence grating spectrometer operated at a fixed electron kinetic energy of 25.6 eV. The sample was prepared by ex-situ exfoliation and subsequently annealed, in UHV, up to 400°C to remove surface contaminants. By recording the photon intensity as a function of emission energy and incidence angle, we constructed two-dimensional maps of the unoccupied states along the ΓK and ΓM directions of the Brillouin zone. The data reveal several dispersive features whose energy-momentum dependence closely matches density-functional theory (DFT) band-structure calculations. In particular, the conduction-band minimum is experimentally found away from high-symmetry points, consistent with theoretical predictions. These results highlight the capability of momentum-resolved IPES to characterize the unoccupied band structure of MoS_2 and provide a benchmark for future studies of two-dimensional materials.

O 68: Nanostructured surfaces and thin films – Poster

Time: Wednesday 18:00–20:00 Location: P2

O 68.1 Wed 18:00 P2

Electrospray Ion-Beam Deposition of Organic Molecules — •Grigori Pasko, Florian Münster, Lukas Heuplick, Jan Herritsch, and J. Michael Gottfried — Fachbereich Chemie, Philipps-Universität Marburg, Germany

The preparation of molecular adsorbates on surfaces is often constrained by limitations of conventional deposition methods. While small molecules can typically be thermally evaporated from a Knudsen cell, this approach becomes unsuitable for larger or non-volatile species. Electrospray ion-beam deposition (ESIBD) provides a powerful alternative, enabling the transfer of intact, non-volatile molecules from solution into ultrahigh vacuum. Although its use is increasing, ESIBD remains an emerging technique, and the chemical state of the molecules after deposition is often insufficiently understood. Determining the oxidation state and overall chemical composition of the deposited species therefore represents a central challenge. In this study, meso-tetraphenylporphyrin (TPP) serves as a model system for evaluating the chemical integrity of ESIBD-prepared films. By combining X-ray photoelectron spectroscopy (XPS), scanning tunneling microscopy (STM), and density functional theory (DFT) calculations, we demonstrate that the porphyrins preserve the protonation state acquired during the electrospray process and remain intact upon deposition.

O 68.2 Wed 18:00 P2

Nitrogen plasma induced surface modification of nickel electrodes for enhanced electrochemical performance — •Karla Siecker[1], Christina Meinert[1], Christian Marcks[2], Timo Wagner[1], Nicolas Wöhrl[1], and Axel Lorke[1] — [1]Faculty of Physics, University Duisburg-Essen — [2]Electrochemical Reaction Engineering, RWTH Aachen University

Nickel sheets are widely used as electrode materials for electrolyzers due to their low cost and ease of handling. Here, we report on the use of a microwave-induced remote nitrogen plasma to modify the sample surface, adjusting both the electrochemical and mechanical properties of the nickel electrode. The plasma treatment leads to the formation of coral-like nanostructures on the nickel surface and promotes measurable surface nitridation. As a result, the surface roughness and wettability increase, directly affecting the electrochemical activity. For this purpose, contact angle measurements, 3D optical profilometry and electrochemical measurements were conducted to evaluate the catalytic activity of the modified electrodes.

O 68.3 Wed 18:00 P2

Nanostructured TiO_2 surfaces by low-energy ion erosion — •Berk Yildirim and Jens Bauer — Leibniz-Institut für Oberflächenmodifizierung, Permoserstraße 15, D-04318 Leipzig, Germany

Ripple nanostructures on titanium surfaces are explored as a means to enhance protein adsorption and potentially introduce directionality for implant applications. We aim to produce large areas of consistent nanostructuring on titanium surfaces. Firstly, titanium/titanium oxide thin films are deposited using argon ion beam sputtering (IBS), followed by low-energy oxygen ion etching at an angle to create the ripple structures. Four main parameters are used for control. 1) thin-film composition, adjusted by supplying a background oxygen during deposition to produce fully TiO_2 films, or by depositing without oxygen to obtain titanium films, 2) etching time, 3) etching ion beam energy, where we applied 1.4 kV and 800 V, and 4) etching ion beam incidence angle. The morphology was analysed using AFM, SEM, Thin-film Reflectometry and the composition using XPS, ToF-SIMS. At 80°, the shadowing effect dominates and produces ripples or nanoneedles aligned in the same direction as the beam, which we consistently observe across a 5 cm radius sample. Roughnesses of the unetched films were $Sq = 1$ nm (Ti) and $Sq = 4.8$ nm (TiOx). We obtain much rougher and larger structures on the titanium oxide thin films with $Sq \approx 15$ nm, and smoother ripple structures on the titanium thin films with $Sq \approx 3$ nm. Controlling etching time and beam voltage allows fine-tuning of roughness and topography.

O 68.4 Wed 18:00 P2

Anomalous morphologies in ion-beam induced surface nanopatterning — •Denise J. Erb and Stefan Facsko — Ion Beam Center, Helmholtz-Zentrum Dresden-Rossendorf, Germany

Irradiating solid surfaces with broad beams of low-energy ions often results in nanaoscale patterning, emerging from a combination of erosive, ballistic and diffusive processes between ions and surface atoms. Typical pattern morphologies comprise ripples, dots, or pits and mounds. The patterning outcome was typically explained as being dominated by either adjustable properties of the ion beam such as incident angle or ion energy, or by inherent properties of the solid material such as elemental composition or crystal symmetry. However, under appropriate experimental conditions, unexpected pattern morphologies can be formed and their understanding requires considering a more complex interplay between ion beam and solid surface. We present such anomalous surface patternings as well as the current state of understanding and modeling these morphologies.

[2] D.J. Erb and S. Facsko, Tuning the Morphology of Self-Assembled Nanopatterns on MgO(001) Surfaces by Sequential Broad-Beam Ion Irradiation, Phys. Status Solidi RRL (2025) 2500117

O 68.5 Wed 18:00 P2

Fabrication of Self-Assembled Carbon Nanodot Patterns on Quartz Glass Surfaces by Means of Ion Beam Processing — •Jamal Ghaith and Jens Bauer — Leibniz-Institut für Oberflächenmodifizierung, Permoserstraße 15, D-04318 Leipzig, Germany

Graphite Nanodot patterns can be used as a negative mask for subsequent etching of quartz glass surface to bring about anti-reflective properties required in high-power laser applications. This requires uniformity in size and distribution of the nanodots over large areas. Silicon wafers with a $\sim 200\,nm$ thick thermal oxide layer are used as silica test sample material. A carbon layer is initially deposited using Ion Beam Sputtering (IBS), followed by 800 eV Argon ion etching at an angle, with sample rotation. The parameters used to control the nanodot formation are incidence angle of the ion beam, etch time, and carbon layer thickness. We found that an incidence angle of 70 degrees produces the most uniform nanodot distribution. Interestingly, increasing etch time does not necessarily lead to larger (or higher amplitude) dots. Instead of an increased size coalescence of the dots is observed, at least as long as the carbon layer thickness is high enough. The morphology was analysed using AFM and SEM, and the composition using ToF-SIMS.

O 68.6 Wed 18:00 P2

Reversible and persistent changes in nanofilms of the ionic liquid BMP DCA after application of an electric current — •Mirco Wendt[1,2], Anton Schün[2], Regina Lange[2], Jens Berdermann[1], Ingo Barke[2], and Sylvia Speller[2] — [1]Deutsches Zentrum für Luft-und Raumfahrt, Institut für Solar-terrestrische Physik, Neustrlitz — [2]Universität Rostock, Institut für Physik

1-Butyl-1-methylpyrrolidinium dicyanamide (BMP DCA) layers with a thickness of 10 to 20 nm were shown to be effective as charge mitigation layer in the context of spacecraft charging [1]. While at moderate exposures to electrons in a scanning electron microscope (10^12 e/m^2), no changes were observed, intense electron exposure led to irreversible damage with reversible alterations occurring at intermediate conditions. To better understand the conductive mechanism and how these layers react to the presence of excess electrons, ionic liquid nano-films on interdigitated electrodes were prepared and a voltage applied between them. The monitored currents indicated that charges were permanently transferred into the sample. Atomic force microscopy revealed changes to the film*s morphology as well as shifts in dynamic mode phase, indicating trapping of charges. These findings are compatible with theoretical studies, suggesting additional electrons in this particular ionic liquid do neither pair with cations nor form cation shells, but further reduce anions into a doubly negative charge state [2]. [1] Wendt et al., J. Space Weather Space Clim. 2024, 14, 18 [2] Xu et al., J. Phys. Chem. B 2015, 119, 2, 532-542

O 69: Nanostructures at surfaces:1D, 2D, networks – Poster

Time: Wednesday 18:00–20:00 Location: P2

O 69.1 Wed 18:00 P2

Study of different structural phases of Ni-DCA networks on graphene/Ir(111) — •Ayesha Jabeen[1], Dominik Hrůza[1], Zdeněk Jakub[1], Jakub Planer[1], Anna Kurowska[1], Pavel Procházka[1], and Jan Čechal[1,2] — [1]CEITEC - Central European Institute of Technology, Brno University of Technology, Czech Republic — [2]Faculty of Mechanical Engineering, Brno University of Technology, Czech Republic

2D metal-organic frameworks (MOFs) represent a promising class of two-dimensional nanomaterials with tunable electronic and magnetic properties, which could have potential applications in catalysis and spintronics. In this

study, we investigate the structural phases and thermal stability of Ni-DCA (9,10-dicyanoanthracene) networks supported on graphene/Ir(111). Employing Low-Energy Electron Microscopy (LEEM), Scanning Tunnelling Microscopy (STM), and X-ray Photoemission Spectroscopy (XPS), we identified three distinct structural phases: two phases composed of isolated $Ni_1(DCA)_3$ coordination complexes coexisting with hydrogen-bonded DCA molecules, and one extended metal-organic framework with $Ni_2(DCA)_3$ stoichiometry. Despite their different long-range order, all three phases have the same local Ni coordination environment. Thermal annealing reveals that the $Ni_2(DCA)_3$ network is the least stable of the three, dissociating into the individual complex phases upon mild annealing around 80 °C. These findings elucidate the polymorphic nature and thermal limitations of Ni-DCA networks supported on graphene/Ir(111), contributing to the understanding of DCA-based MOFs.

O 69.2 Wed 18:00 P2

Examining the character of coordination bonding in two-dimensional MOFs by photoemission tomography — •Dominik Brandstetter[1], Simone Mearini[2], Andreas Windischbacher[1], Yan Yan Grisan Qiu[2], Daniel Baranowski[2,3], Vitaliy Feyer[2,4], Claus Micheal Schneider[2,4,5], and Peter Puschnig[1] — [1]University of Graz, Graz, Austria — [2]Jülich Research Centre, Jülich, Germany — [3]Present address: Pacific Northwest National Laboratory, Richland WA, USA — [4]University of Duisburg-Essen, Duisburg, Germany — [5]UC Davis, Davis CA, USA

We investigate the nature of the coordination bonds in 2D MOFs by examining a well-ordered nickel tetracyanoquinodimethane (Ni-TCNQ) monolayer on a Ag(100) substrate. Notably, photoemission data shows a splitting of the valence band into bonding and anti-bonding states, resulting from the interaction between the Ni d-states and the ligand orbitals. By making use of the energy-resolved photoemission momentum maps, we are able unambiguously reveal signatures of covalent bonding between the organic ligands and the transition metal d-states by identifying fingerprints of the involved orbitals in momentum space. These hybridized states are crucial in understanding the MOF's electronic structure, which is a determining factor for their electronic and magnetic properties. Our results are concrete evidence of the covalent character within 2D MOFs, offering a deeper understanding of their fundamental electronic properties.

O 69.3 Wed 18:00 P2

Superconducting quantum corrals — •Divya Jyoti[1] and Nicolás Lorente[2] — [1]Christian-Albrechts-Universität zu Kiel, Kiel, Germany — [2]Centro de Fisica de Materiales (CFM), Donostia - San Sebastian, Spain

Quantum corrals enable atomically precise control of electronic confinement on surfaces, and their extension to superconductors opens new possibilities for manipulating in-gap Bogoliubov quasiparticles. In this work, we develop a microscopic Bogoliubov-de-Gennes Green-function framework [1-2] for multiple δ-like impurities on 2D superconducting lattices. As a benchmark, the method reproduces the superconducting mirage associated with Yu-Shiba-Rusinov states in elliptical corrals. By tuning the corral geometry, and material parameters, the spatial structure and spectral evolution of in-gap quasiparticle states is determined. We further explore the effect of confinement on engineered topological phases by placing a Majorana-hosting ferromagnetic spin chain inside an elliptical corral and showing that geometric confinement strongly hybridizes its zero-energy modes, redistributing their spin texture and shifting spectral weight to finite energies. These confined in-gap states offer a new route to engineer topological features, linking atomically crafted quantum matter to emerging platforms for topological quantum computation. [1] Morr et al., Phys. Rev. Lett. 92, 107006 (2004) [2] Flatté et al., Phys. Rev. B 56, 11213 (1997)

O 69.4 Wed 18:00 P2

Cooperative Rotation and Spin Switching of Molecules in Artificial Arrays — •Niklas Ide, Arnab Banerjee, Richard Berndt, and Alexander Weismann — IEAP, Kiel, Germany

Artificial arrays of tin phthalocyanine (SnPc) molecules on Pb(100) substrate are investigated using a low-temperature scanning tunneling microscope. Switching the central SnPc molecule between its two out-of-plane configurations (SnPc↑ → SnPc↓) triggers a collective rotation of all surrounding molecules in the array. This correlated structural response is accompanied by a change of the molecular spin states. A model of the intermolecular and molecular substrate interactions reproduces the experimental observations.

O 69.5 Wed 18:00 P2

Nonalternant Carbon Nanoribbon with 4-5-6-8 Topology via Indenofluorene Polymer Fusion — •Dong Han[1], Tim Naumann[1], Faming Kang[1], Alexandr Oshchepkov[2], Mikhail Kalinin[2], Ye Liu[1], Zilin Ruan[1], Konstantin Y. Amsharov[2], and J. Michael Gottfried[1] — [1]Philipps-Universität Marburg, Fachbereich Chemie, Hans-Meerwein-Str. 4, 35032 Marburg, Germany — [2]Martin-Luther-Universität Halle-Wittenberg, Institut für Chemie, Organische Chemie, 06120 Halle (Saale), Germany

Carbon nanoribbons (CNRs) with nonhexagonal rings constitute a fascinating class of low-dimensional carbon materials exhibiting tunable chemical and physical properties distinct from those of conventional graphene nanoribbons (GNRs). Here, we report the on-surface synthesis and characterization of a nonalternant 4-5-6-8 CNR. This nanoribbon is obtained via lateral fusion of cis-linked indeno[2,1-a]fluorene (IF) polymer chains, formed by sequential debrominative and dehydrogenative C-C coupling reactions of a halogenated arene. Bond-resolved scanning tunneling microscopy (BR-STM) confirms the atomic structure of the resulting CNR. Scanning tunneling spectroscopy (STS) and density functional theory (DFT) calculations reveal its distinct electronic properties arising from the nonhexagonal rings. Notably, the 4-5-6-8 CNR exhibits a bandgap of 1.13 eV, highlighting the critical role of ring topology in modulating quantum confinement. X-ray photoelectron spectroscopy (XPS) further elucidates reaction pathways and intermediate species. This study establishes a controlled on-surface synthetic route towards structurally complex CNRs.

O 69.6 Wed 18:00 P2

Tuning electronic properties in 2D Covalent Organic Frameworks via on-surface chemistry — •Mira Sophie Arndt[1], Christoph Wachter[2], Roman Pallach[3], Yan Yan Grisan Qiu[4], Simone Mearini[4], Vitaliy Feyer[4], Sebastian Henke[3], Oliver T. Hofmann[2], Mirko Cinchetti[1], and Giovanni Zamborlini[5] — [1]Departement of Physics, TU Dortmund, Otto-Hahn-Straße 4, 44227 Dortmund, Germany — [2]Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Petersgasse 16, 8010 Graz, Austria — [3]Department of Chemistry, TU Dortmund, Otto-Hahn-Straße 6, 44227 Dortmund, Germany — [4]Peter Grünberg Institute (PGI-6), Forschungszentrum Jülich GmbH, 52428 Jülich, Germany — [5]Institute of Physics, NAWI Graz, University of Graz, Universitätsplatz 5, 8010 Graz, Austria

Two-dimensional covalent organic frameworks (2D COFs) arranging in a Kagome lattice exhibit intriguing electronic properties, like flat bands and Dirac cones. We investigate the carbonyl-bridged aza-triangulene (P^2TANGO), which assembles into a Kagome lattice on Au(111). Inspired by reports that deoxygenation of the precursor induces an open-shell triplet ground state, we explore hydrogen-assisted deoxygenation to tune the COF's electronic properties. Our angle-resolved photoemission measurements reveal changes in the electronic structure upon oxygen removal, including energy shifts of the dispersive valence band features. DFT confirms that the shift grows with the deoxygenation, and that, in case of a complete deoxygenation, the degeneracy between the flat bands and the Dirac-dispersing bands is lifted.

O 69.7 Wed 18:00 P2

On-surface Synthesis of Aza-Coronoids — •Tim Naumann[1], Zilin Ruan[1], Olaf A. Kleykamp[1], Linus Pohl[2], Anton Nizovtsev[2,3,4], Alix Kaczmarek[2], Eugen Sharikow[1], Jörg Sundermeyer[1], Doreen Mollenhauer[2,3,4], and J. Michael Gottfried[1] — [1]Marburg University, Hans-Meerwein-Str. 4, 35032 Marburg, Germany — [2]Justus Liebig University Giessen, Heinrich-Buff-Ring 17, 35392 Giessen, Germany — [3]Helmholtz Institute for Polymers in Energy Applications Jena, Lessingstr. 12-14, 07743 Jena, Germany — [4]Institute for Technical and Environmental Chemistry, Friedrich-Schiller-Universität Jena, Philosophenweg 7a, 07743 Jena, Germany

Chemical reactivity and electronic properties of nanographenes are tailored by functionalization, edge topology and doping. A versatile sub-class within the nanographenes are coronoids, defined as benzenoids featuring a cavity. π-extended coronoids possess low solubility and are challenging target molecules for in-solution chemistry. However, reliable access via on-surface synthesis was demonstrated. Here, we combined in-solution and on-surface techniques to gain access to various aza-coronoids. Besides planar armchair-edge and zigzag-edge terminated coronoids, a curved coronoid was synthesized. Nitrogen functionalization of the inner cavity allows for hosting a metal atom and yields coronoid-metal complexes. In contrast, nitrogen core-doping significantly alters the electronic properties. Low-temperature scanning tunneling microscopy/spectroscopy (STM/STS), non-contact atomic force microscopy (nc-AFM) and DFT calculations were performed.

O 69.8 Wed 18:00 P2

Bottom-up fabrication of molecular islands utilizing an SPM-based manipulation approach — •Mong-Wen Gu[1,2], Ruslan Temirov[1,2,3], F. Stefan Tautz[1,2,4], and Christian Wagner[1,2] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Jülich, Germany — [2]Jülich Aachen Research Alliance, Fundamentals of Future Information Technology, Germany — [3]II. Physikalisches Institut, Universität zu Köln, Cologne, Germany — [4]Institut für Experimentalphysik IV A, RWTH Aachen, Aachen, Germany

The scanning probe microscope (SPM) allows single molecules to be manipulated with very high precision. SPM-based manipulation provides an opportunity for the fabrication of nanostructures through bottom-up construction. One critical challenge is using molecules other than conventional CO molecules as building blocks. Here, we explore the parameter space of the manipulation process in which a single PTCDA (3,4,9,10-perylene tetracarboxylic dianhydride) molecule bridges the SPM junction. We demonstrate the bottom-up construction of artificial PTCDA islands on Ag(111). These islands reproduce the native monolayer lattice structure, can be customized in size and shape and thus allow studying their electronic properties in a systematic way.

O 69.9 Wed 18:00 P2

Effect of the catalytic-substrate and graphene-films on the growth and physical properties of non-stoichiometric silicon-oxide nanoparticles — •Mehmet Selim Imamoglu, Cem Kincal, and Oguzhan Gürlü — Istanbul Technical University, Istanbul, Turkey

It is well known that silicon-oxide particles form during the growth of graphene by chemical vapor deposition (CVD) in a quartz furnace. Our studies showed that the creation and structure of these particles is mostly governed by the hydrogen flow rate during growth. Moreover, we have proven that they can be covered by graphene films depending on their morphology; showing that graphene growth during CVD process can continue over a non-catalytic substrate. In this work we have further investigated the formation and physical properties of such nanoparticles. Our results indicated that CVD grown silicon-oxide nanoparticles have non-stoichiometric nature leading to photoluminescent behavior. In this presentation their structure and physical properties as a function of the growth substrate (Ni and Cu foils) and the existence or in-existence of graphene films will be discussed. We will also present the methodology to transfer these nanoparticles on to random substrates.

O 69.10 Wed 18:00 P2

Towards on-surface synthesis of helicene chains — •Jung-Ching Liu[1], Miguel Gavara[1], Kévin Martin[2], Narcis Avarvari[2], Karl-Heinz Ernst[3,4,5], and Johannes Barth[1] — [1]Department of Physics, Technical University of Munich, James-Franck-Str. 1, 85748 Garching, Germany — [2]University of Angers, CNRS, MOLTECH-Anjou, SFR MATRIX, 49000 Angers, France — [3]Empa, Swiss Federal Laboratories for Materials Science and Technology, Überlandstrasse 129, 8600 Dübendorf, Switzerland — [4]Institute of Physics, Czech Academy of Sciences, Cukrovarnická 10, 16200 Prague 6, Czech Republic — [5]Department of Chemistry, University of Zurich, Winterthurerstrasse 190, 8057 Zürich, Switzerland

Helicenes are polycyclic aromatic helical compounds which have been investigated at surfaces regarding their spin selectivity due to their chirality and potential use in organic spintronics. To enhance chirality-induced spin selectivity, extended helicene chains are of interest. However, fabrication of such helicene chains has not yet been reported. Here, we present atomically precise dibromohexahelicene chain formations on Au(111). Investigated by STM and bond-resolving nc-AFM at 4K, we found self-assembled supramolecular clusters at low coverage. Coupling reactions occur as the annealing temperature reaches 330C. By further annealing to 380C, short segments of planar structures are found along with 3D chains. The findings indicate potential nanographenes formation, tentatively ascribed to a Diels-Alder pathway. Our study provides insights into extended on-surface synthesis using non-planar molecular precursors.

O 69.11 Wed 18:00 P2

Orthogonally oriented molecular motors assembled on the surface: from liquid-solid to ultrahigh vacuum — •Robby Reynaerts[1], Cosima Stähler[2], Steven De Feyter[3], Ben L. Feringa[2], and Leonhard Grill[1] — [1]Department of Chemistry, Division of Physical and Theoretical Chemistry, University of Graz, Heinrichstraße 28, 8010 Graz, Austria — [2]Stratingh Institute for Chemistry, University of Groningen, 9747 AG Groningen, The Netherlands — [3]Department of Chemistry, Division of Molecular Imaging and Photonics, KU Leuven, Celestijnenlaan 200F, B-3001 Leuven, Belgium

Molecular motors continue to attract wide interest, due to their capability to convert energy into uni-directional rotary motion at the nanoscale. Immobilization of molecular motors on a solid surface through molecular self-assembly could amplify their nanoscale motion. Applying specific molecular design such controlled assembly of molecular motors was achieved at the liquid-solid (LS) interface under ambient conditions and studied using scanning tunnelling microscopy (STM). However, the dynamics inherent to ambient conditions were inseparable from the response of the molecular motors to external stimuli. Bringing the system over to low temperature and ultra-high vacuum (LT-UHV) conditions would rid any inherent dynamics from those ambient conditions. In this contribution I will discuss the controlled self-assembly of molecular motors on a solid surface achieved through molecular design under ambient and LT-UHV conditions and the experimental transition between these conditions. References: Chem. Rev. 2005, 105, 1281; Chem. Eur. J. 2024, e202303994.

O 69.12 Wed 18:00 P2

Manipulation of Atomically Precise Nanostructures from Single Atoms and Molecules — •Nikita Osipov, Christophe Nacci, Grant J. Simpson, and Leonhard Grill — Physical Chemistry Department, University of Graz, Heinrichstrasse 28, 8010 Graz, Austria

Quantum corrals are of particular interest in surface science as they can be used to investigate quantum phenomena, such as quantum mirage [1] or function as quantum simulators that mirror the electronic properties of real atoms or molecules [2]. Currently, investigating these prominent structures requires researchers to manually assemble the objects on a surface using atomic manipulation techniques, a process that is extremely time-consuming. Our work aims to solve this critical bottleneck and save valuable research time. A primary goal of our project is to create an instrument for automatic and autonomous atomic manipulation. We are developing this system using machine learning algorithms to enable the careful, precise positioning of atoms or molecules [3]. This novel instrument will facilitate the assembly of large-scale objects or complex compositions of multiple smaller ones with high precision, thereby enabling the collection of significantly more data. In this work, we present our current status of assembled quantum corrals on noble metal surfaces. First results of manually assembled nanostructures will be presented together with the computational algorithm in the automated construction. [1] Li, Q. et al., Nat. Commun. 11 (2020) 1400. [2] E. Sierda et al., Science 380 (2023) 1048-1052. [3] B. Ramsauer et al., J. Phys. Chem. A 127 (2023) 2041.

O 69.13 Wed 18:00 P2

Atomic-Scale Sequencing of Biomolecules with nc-AFM — •Benjamin Mallada[1], Alejandro Lynch-Gonzalez[1], Marko Grabarics[1], Pavel Jelinek[2], Bruno de la Torre[3], and Stephan Rauschenbach[1] — [1]Department of Chemistry, University of Oxford, Oxford, UK — [2]Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic — [3]Nanomaterials and Nanotechnology Research Center (CINN-CSIC) , Mieres, Spain

Glycans, peptides, and cyclodextrins present major challenges for structural analysis due to branching, heterogeneous modifications, and stereochemical diversity. Conventional tools such as MS and NMR often fail to resolve these features at the single-molecule level. Non-contact AFM, combined with STM and KPFM under cryogenic UHV conditions, has recently demonstrated chemical sensitivity sufficient to discriminate functional groups and stereochemical arrangements by probing electrostatic and non-covalent interactions. Applications include the direct visualization of glycans in protein and lipid conjugates [1], submolecular resolution of cyclodextrins [2], and progress toward sequencing of complex carbohydrates and peptides. These results underline the potential of nc-AFM to expand the scope of SPM from imaging and identification toward true atomic-scale sequencing of biomolecules.

O 70: 2D materials: Stacking and heterostructures – Poster (joint session O/TT)

Time: Wednesday 18:00–20:00 Location: P2

O 70.1 Wed 18:00 P2

Unexpected Ordered Interfaces in WSe_2-$MoSe_2$ Lateral Interfaces Observed by STEM — •Matvei Kislitsyn[1], Max Bergmann[1], Julian Picker[2], Jürgen Belz[1], Robin Günkel[1], Badrosadat Ojaghi Dogahe[1], Shamail Ahmed[1], Andrey Turchanin[2], and Kerstin Volz[1] — [1]mar.quest | Marburg Center for Quantum Materials and Sustainable Technologies, Philipps-Universität Marburg, 35032 Marburg, Germany — [2]Faculty of Chemistry and Earth Sciences, Friedrich-Schiller-Universität, 07743 Jena, Germany

Two-dimensional WSe_2-$MoSe_2$ lateral heterostructures offer a platform for engineering band alignment and excitonic behavior through atomic-scale control of composition, making this material attractive for use in 2D optoelectronic devices. In this contribution, we present a systematic scanning transmission electron microscopy (STEM) study of monolayer WSe_2-$MoSe_2$ heterostructures synthesized by chemical vapor deposition (CVD) directly on SiO_2 TEM grids. While some investigated 2D flakes show atomically sharp interfaces with minimal intermixing, we also observe a highly ordered and unexpected interface configuration consisting of alternating Mo and W atomic rows. By comparing experimental observations with STEM image simulations and theoretical predictions, we analyze the structural origins of both interface types and discuss the mechanisms that may give rise to this unusual ordering. These results provide insight into interface formation mechanisms in lateral transition-metal dichalcogenide heterostructures and their potential impact on material properties.

O 70.2 Wed 18:00 P2

Superdomains and Strain Localization in Twisted Two Dimensional Transition Metal Dichalcogenides — •Riya Patel[1], Daniel Wolf[1], Kristina Weinel[1,2], Silke Hampel[1], and Axel Lubk[1,2] — [1]IFF, IFW Dresden, 01069 Dresden — [2]Faculty of Physics, Technical University Dresden, 01069 Dresden

Bilayers of 2D transition metal dichalcogenides (TMDCs) exhibit special structural and electronic phenomena when stacked with a low-twist-angle. Particularly, they undergo lattice reconstruction, forming large triangular stacking domains, separated by domain walls that concentrate strain (soliton regime), which

was shown in simulations. However, direct experimental quantification of these strain features and their correlation with electronic properties remains limited. Here we investigate low-twist-angle TMDCs using high-resolution transmission electron microscopy to visualize the reconstructed super lattice and identify the resulting superdomains structure. We employ geometric phase analysis to quantitatively map the strain distribution at the domain walls with nanometer resolution, revealing spatial maps of different strain components. We use Electron Energy Loss Spectroscopy to further probe the electronic properties of the reconstructed system. The understanding of strain localization in superdomain structures and the related electronic properties in such systems facilitate strain-engineered electronic properties in twisted TMDCs.

O 70.3 Wed 18:00 P2

Pseudomonolayer TMDCs via organic intercalation — •Katharina Steinkirchner[1,2], Jakob Dilling[1,2], Matthias Kalläne[1,2,3], Tim Riedel[1,2], Markus Scholz[4], and Kai Rossnagel[1,2,3,4] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [3]Kiel Nano, Surface and Interface Science KiNSIS, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [4]Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany

Transition metal dichalcogenides (TMDCs) are a versatile class of layered materials with tuneable electronic properties. One approach to tailoring these properties is to manipulate the material's effective dimensionality. Specifically, intercalating cationic organic molecules with different alkane carbon chain into the van der Waals gaps between the layers increases the interlayer distance of the TMDC host material. This transforms the crystal from a bulk state to a monolayer-like state, thereby altering the electronic structure [1]. Here, we present a comprehensive study of the geometric and electronic structures of intercalated and non-intercalated TMDCs, such as $NbSe_2$, using SEM, EDS, and 11eV laser-based ARPES.

O 70.4 Wed 18:00 P2

Preparation of quasi-freestanding few-layer samples of 2D materials — •Seyedeh Helya Alaei, Hanna Shirin Pulikkal Hamza, Mashood Tariq Mir, Lukas Nöding, Ahmed Hassanien, Arne Senftleben, Jochen Mikosch, and Thomas Baumert — University of Kassel, Institute of Physics, 34132 Kassel, Germany

Two-dimensional (2D) materials have garnered significant attention in the last two decades and have been analyzed using various methods in the fields of materials science and physics. To study the dynamic behavior of 2D materials upon irradiation with femtosecond laser pulses using ultrafast electron diffraction, it is necessary to isolate few-layer structures from bulk crystals and prepare them in a quasi-freestanding manner. Due to the weak van-der-Waals forces between the layers relative to the in-plane forces of the structure, mechanical exfoliation is a commonly used method. However, the transfer is challenging, due to the thinness of the flake and the adhesive force between the flake and the surface. Our preparation involves three major steps: (1) exfoliation using adhesive tape and viscoelastic gel, (2) isolation of 2D material nanosheets with thicknesses ranging from 3 to 50 nm, and (3) transfer onto a standard sample mesh of transmission electron microscopy with a high success rate. The transfer exploits liquid-solid phase transitions of a soluble wax-like material. In this ongoing study, the 2D ferromagnetic material Fe_5GeTe_2 has been of interest. We will discuss the different steps in detail and the challenges associated with the preparation of this material, including the fragility of the crystals due to oxidation and the partially covalent out-of-plane forces.

O 70.5 Wed 18:00 P2

Ordering Phenomena in MoS_2 Nanocrystals on Graphite — •Lukas Nöding[1], Ahmed Hassanien[1], Mashood Tariq Mir[1], Hanna Shirin Pulikkal Hamza[1], Seyedeh Helya Alaei[1], Thomas Baumert[1], Jochen Mikosch[1], Florian Grassme[2], Claudia Backes[2], and Arne Senftleben[1] — [1]University of Kassel, Institute of Physics, Kassel, Germany — [2]University of Kassel, Institute of Chemistry, Kassel, Germany

Two-dimensional transition-metal dichalcogenides (TMDCs) such as MoS_2 offer a platform for tailoring electronic and optical properties through controlled stacking and orientation. Achieving ordered assemblies of MoS_2 nanocrystals on crystalline substrates is, therefore, of considerable interest. In this work, we study the crystallographic alignment of MoS_2 nanocrystals on a graphite substrate. The samples were prepared using the Langmuir-Schäfer technique, enabling the reproducible deposition of nanocrystals with controlled density. To probe the crystallographic alignment of the deposited nanocrystals with respect to the graphite lattice, we performed wide field static electron diffraction measurements at an acceleration voltage of 35 kV, complemented by selected area electron diffraction at 200 kV.

Our preliminary analysis reveals a pronounced localized and short-range ordered crystallographic alignment of the MoS_2 nanocrystals, extending over at least a few micrometers. A quantitative evaluation of the global ordering behavior, as well as its dependence on crystal size and deposition parameters, is currently underway and will be discussed.

O 70.6 Wed 18:00 P2

Multiferroic Two-Dimensional Cu(CrX2)2 (X = S, Se, and Te) as Anode Materials for Lithium-Ion Batteries: A First-Principles Study — •Muhammad Fayaz[1] and Zijing Lin[2] — [1]Department of Physics, University of Science and Technology of China, Hefei 230026, China — [2]Department of Physics, University of Science and Technology of China, Hefei 230026, China

Identifying two-dimensional (2D) materials with the desired electrochemical performance for lithium-ion batteries is of great interest in developing next-generation energy devices. Motivated by the successful synthesis of multiferroic 2D materials, Cu(CrX2)2 (X = S, Se, and Te), which exhibit simultaneous ferroelectricity and ferromagnetism, we performed first-principles calculations to investigate their potential as anodes for lithium-ion batteries. We comprehensively investigate the electrochemical properties of the predicted systems and demonstrate that lithium exhibits sufficient mobility on their surface, with appreciable stability. For instance, the binding energy (Eb) of the lithium adatom on Cu(CrS2)2 is -4.034 eV, with a diffusion barrier as low as 0.212 eV. As a consequence, the maximum theoretical specific capacity for lithium adatoms reaches as high as 1089 and 666 mAhg-1, respectively, for Cu(CrS2)2 and Cu(CrSe2)2, which can be attributed to a much higher storage capacity of lithium adatoms compared to previously identified 2D anode materials. All of these remarkable properties, including high binding energy (Eb), low diffusion barrier, high specific capacity, and good electrical conductivity.

O 70.7 Wed 18:00 P2

Valence-Band Renormalization and Spin Splitting in a Monolayer WTe2/WSe2 Heterostructure — •Daiyu Geng, Natalie Lehmann, Jiabao Yang, and Niels Schröter — Max Planck Institute of Microstructure Physics, Weinberg 2, Halle (Saale), Germany

Monolayer WTe2 (1L-WTe2) hosts a variety of broken-symmetry phases, including a quantum spin Hall insulator, a topological excitonic insulator, and several intriguing spin-ordered states. The dielectric environment and charge-carrier density play crucial roles in the competition among these electronic phases. In this work, we investigate the band structure of 1L-WTe2 interfaced with semiconducting WSe2 using laser- and synchrotron-based micro-ARPES. We observe strong valence-band renormalization accompanied by pronounced spin splitting in 1L-WTe2. Additionally, multiple replica pockets emerging in the Fermi surface indicate a substantial moiré effect in this heterostructure.

O 71: 2D Materials: Electronic structure, excitations, etc. – Poster (joint session O/TT)

Time: Wednesday 18:00–20:00 Location: P2

O 71.1 Wed 18:00 P2

Observation of many-body-localization in substituted $1T$-TaS_2 — •Jesumony Jayabalan[1], Gael Reecht[1], Ricards Kristers Knipšis[2], Florian K Diekmann[3], Friedemann Queisser[2], Walter Schnelle[4], Ping Zhou[1], Kai Rossnagel[3], Ralf Schützhold[2], Manuel Gruber[1], and Uwe Bovensiepen[1] — [1]Uni. of Duisburg-Essen, Fakultät für Physik and CENIDE — [2]HZ Dresden-Rossendorf, — [3]CAU of Kiel and DESY — [4]MPI for Chemical Physics of Solids, Dresden

Random modulations in the potential landscape are known to localize a single quantum particle, the Anderson localization leads, to stable non-thermalizing states. Adding interaction is expected to cause delocalization and a quick thermalization of such single particles, but in a strongly disordered system, the many-body quantum state itself becomes localized, known as the Many-Body Localization (MBL). Using time-resolved photoelectron spectroscopic measurements, we show that it is possible to realize MBL states in a Tungsten substituted $1T$-TaS_2 material. Electrons are excited by using a 1.51 eV, 50 fs pulses and a 6 eV probe pulse was used to photoemit electrons. In contrast to ultrafast (<20 fs) decay of doublons in pristine $1T$-TaS_2 [1], we observe that some of the doublons decay in hundreds of femtosecond time scale, while the rest lasts for more than few microseconds. This observation is supported by scanning tunneling micro-

scopic measurements and Fermi-Hubbard model calculations. Funding by DFG through QUAST-FOR5249 and SFB 1242 is acknowledged. [1] M. Ligges et al., Phys. Rev. Lett., 120, 166401 (2018).

O 71.2 Wed 18:00 P2

Exciton Transport in Monolayer TMDs — •Lifeng Ou, Alejandro Molina-Sánchez, and Alberto García-Cristóbal — ICMUV, University of Valencia, Valencia, Spain

Atomically thin transition metal dichalcogenides semiconductor emerges as promising candidates for novel optoelectronic application, displaying weak dielectric screening due to its truly two-dimension character. The optical properties are mostly related to inter-band transitions between valence and conduction bands, also called the strongly binding electron hole pair, exciton. Strain is expected to impact spatiotemporal distribution of excitons, e.g. spatially inhomogeneous strain acts as a driving force for exciton/carrier funneling, similarly to bias fields for charged particles. In this work we demonstrate the capability to manipulate exciton motion via spatially modulated strain fields, where excitonic energy especially its bandgap is largely tunable and the effective mass of electronic valleys is modified resulting in a qualitative change of the excitonic landscape and efficiency of exciton-phonon scattering channels. These transport properties are represented by the coupled two equations, continuity equation and drift-diffusion equation, which derive from zero-order and first-order moment of Boltzmann equation, respectively. In addition, the simulation diffusion coefficient and mobility in latter equation are evaluated by first-principle and experiment qualitatively, as the function of strain fields.

O 71.3 Wed 18:00 P2

trARPES investigation electron-phonon coupling in CrSBr — •Maurits Houmes, Karl Schiller, Lasse Sternemann, Jonah Nitschke, and Mirko Cinchetti — Departement of Physics, TU Dortmund University, 44227 Dortmund, Germany

CrSBr is a magnetic, semiconducting van der Waals material that has recently attracted significant interest. It hosts both localized Frenkel excitons and delocalized Wannier-Mott-like excitons, and its excitonic properties are strongly influenced by magnetic ordering and lattice distortions. [1,2,3] These features make CrSBr a compelling platform for exploring correlated phenomena in condensed matter systems.

To advance our understanding of the interplay between excitons, magnetism, and lattice dynamics in this material, a more complete characterization is essential. In this work, we present time- and angle-resolved photoemission spectroscopy (trARPES) measurements performed on CrSBr, with particular emphasis on quantifying the electron-phonon coupling. Aiming to provide a previously missing component needed to build a comprehensive picture of the interactions in CrSBr, offering a foundation for future studies and potential technological applications of this promising material.

O 71.4 Wed 18:00 P2

Probing defect-induced wave patterns and superconductivity in $2H$-NbS_2 — Werner M.J. van Weerdenburg, •Margarete Huisinga, Constantin Flommersfeld, Lisa M. Rütten, and Katharina J. Franke — Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany

Transition metal dichalcogenides (TMDCs) host a variety of electronic phases, including superconductivity and charge-density-wave (CDW) order. Recent reports on $2H$-NbS_2 have added a coexisting pair-density-wave (PDW) order to this set, inspiring new questions about the coexistence and driving mechanisms of these phases [1]. In contrast, the closely-related superconducting compound $2H$-NbS_2 lacks a CDW phase, but has been suggested to be close to a CDW instability and sensitive to the presence of defects [2,3].

Using low-temperature scanning tunneling microscopy and spectroscopy, we probe the electronic, phononic and superconducting properties of $2H$-NbS_2. We observe wave-like modulations around intrinsic defects in differential-conductance maps and compare them to band-structure calculations. To assess the nature of these modulations, we probe the modulated regions and characterize the superconductivity spatially. These observations add to the ongoing exploration of superconducting, CDW, and PDW phases in TMDC materials.

O 71.5 Wed 18:00 P2

Theory of few- and many-body excitations in carbon nanotubes — •Maurice Beringuier[1,2] and Richard Schmidt[1,2] — [1]Institut für Theoretische Physik, Philosophenweg 16, 69120 Heidelberg — [2]Universität Heidelberg, Grabengasse 1, 69117 Heidelberg

Even decades after their discovery, some properties of Carbon Nanotubes (CNTs) are still not fully understood. One of the phenomena still lacking a satisfying explanation is the behaviour of the absorption spectrum of semiconducting CNTs under doping. A resonance in these spectra appears only in the presence of additional charge carriers.

This has in the past been described with phenomenological models or few body physics (using trions and excitons), but experimental data (e.g. time resolved measurements of the spectra) hint at potential signatures of many-body physics. Inspired by their abundance in 2D or 3D semiconductors and cold quantum gases, we investigate whether quasiparticles like Fermi polarons could be responsible for the observations in CNTs, which due to their interesting geometry exhibit aspects of both 1D and 2D materials.

We tackle these questions by modeling charge carriers and excitons on CNTs interacting using a combination of exact diagonalization and variational techniques to gain insight into the interplay of few- and many-body physics in these systems.

O 71.6 Wed 18:00 P2

Spin-orbit coupling in non-van der Waals 2D materials — •Mani Lokamani[1], Gustav Bihlmayer[2], Gregor Michalicek[2], Daniel Wortmann[2], Stefan Blügel[2], and Rico Friedrich[1,3] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden — [2]Forschungszentrum Jülich — [3]TU Dresden

In recent years, the rising class of non-van der Waals 2D materials [1] has garnered substantial attention for their distinctive electronic and magnetic properties. In this contribution, we explore the impact of spin-orbit coupling (SOC) on the properties of these non-van der Waals 2D systems and its potential to induce topological properties. Given the presence of heavy elements like Bi and Tl in several 2D candidates, SOC effects notably influence the electronic structure. In our approach, we utilize AFLOW's standardized workflows [2] for initial screening. Subsequently, we extract metadata using AFLOW and tailor the parameters with an AiiDA-plugin [3] for precise electronic structure calculations employing the full-potential all-electron program FLEUR [4] within AiiDA. We analyze the influence of SOC on band structures and densities of states, with a particular focus on topologically protected 1D conduction edge channels.

O 71.7 Wed 18:00 P2

Strain Engineering Single Photon Emission in hBN and MoS2 Monolayers using First Principles — •Paulina Chodyra, Chengcheng Xiao, Johannes Lischner, and Arash Mostofi — Departments of Physics and Materials and the Thomas Young Center for Theory and Simulation of Materials, Imperial College London, London SW7 2AZ, U.K

Point defects in monolayer hexagonal boron nitride (hBN) and molybdenum disulphide (MoS_2) are promising single-photon emitters (SPEs) for quantum technologies due to their potential for room-temperature operation and high photon emission efficiency. In this work we use density-functional theory calculations to investigate the nitrogen antisite-vacancy complex (N_BV_N) and boron vacancy (V_B) in hBN, and the sulphur vacancy (V_S) in MoS_2. We calculate the defect formation energy of different charge states of these defects as a function of biaxial strain and electronic chemical potential. For the charge states that are likely candidates for SPE, we find that their stability can be enhanced via application of biaxial strain. Furthermore, the range of electronic chemical potential over which these charge states are stable can also be increased. These findings can provide predictive design rules for strain-engineered SPEs with improved resilience against electrostatic fluctuations. It also establishes our first steps toward an accelerated discovery of stable SPEs across 2D materials, where DFT-derived stability criteria combined with optical absorption and emission spectra could enable a deeper understanding of SPE operation under realistic conditions.

O 71.8 Wed 18:00 P2

Beyond the Gamma point: Scanning tunneling spectroscopy on MoS_2/graphene/Ir(111) — Borna Pielić[1,2], Dino Novko[2], Nina Girotto Erhardt[2], Vito Despoja[2], Alice Bremerich[1], Sumanasa Begur Prakash[1], •Robin Ohmann[1], and Carsten Busse[1] — [1]Universität Siegen, Walter-Flex-Str. 3, 57068 Siegen, Germany — [2]Institute of Physics, Bijenička cesta 46, 10000 Zagreb, Croatia

Scanning tunneling spectroscopy (STS) reveals information about the band structure of surfaces by measuring the local density of states, and it also allows detection of quasiparticles. For semiconducting transition-metal dichalcogenides the conduction- and valence-band edges have been readily explored with this method. However, STS studies at higher energies than the Γ-point are limited. Here, we investigate epitaxially grown monolayer islands of MoS_2 on graphene/Ir(111) using STS at low-temperature (T=10 K). Specifically, we employ the constant-current STS method, which enables easier access to spectroscopic features with higher energies, than the more commonly used constant-height STS. We find several peaks a few hundred meV above the Γ-point. We do not see them on graphene, allowing us to exclude substrate- or tip-related effects. When measured near the step edge of an island, these peaks bend closer to the Fermi level, similar to the peak at the Γ-point. Their appearance also varies

depending on tip condition and intercalation. Our observations cannot be explained in a single-particle picture. Possible many-body models, such as phonon assisted inelastic tunneling or plasmarons are discussed.

O 71.9 Wed 18:00 P2

Band structure and Work Function in Ultrathin HfSe2 — •Young Jun Chang — University of Seoul, Seoul, Republic of Korea

Two-dimensional (2D) transition metal dichalcogenides (TMDs) exhibit significant modifications in their electronic structures when reduced from bulk to monolayer thickness. In this study, we investigated the thickness-dependent electronic properties of epitaxial 1T-HfSe2 thin films. The films were grown via molecular beam epitaxy (MBE) and monitored in situ by reflection high-energy electron diffraction (RHEED). Scanning tunneling microscopy (STM) revealed atomically flat surfaces with well-defined 1T hexagonal lattices, while scanning tunneling spectroscopy (STS) measured a bandgap of ~1.1 eV for the monolayer. Angle-resolved photoemission spectroscopy (ARPES) revealed thickness-induced band splitting in the valence band, while the valence band maximum (VBM) remained pinned regardless of thickness. In contrast, the work function increased monotonically with film thickness. Density functional theory (DFT) calculations reproduced the observed band structures and attributed the thickness-dependent work function to the screening effect of the underlying graphene substrate. These findings provide key insights into band alignment and interface engineering in 2D semiconductor-based electronic and optoelectronic devices. (RS-2023-00220471, RS-2023-00284081, RS-2024-00334854)

O 71.10 Wed 18:00 P2

Exciton and trion dynamics of 2D transition metal dichalcogenides — •Seawoo Moon[1], Alessandro De Vita[1], Lawson T. Lloyd[2], Tania Mukherjee[1], Anh T. Nguyen[3], Dong-Wook Kim[3], Martin Wolf[2], Ralph Ernstorfer[1,2], and Tommaso Pincelli[1] — [1]Institute for Physics and Astronomy, TU Berlin, Germany — [2]Fritz Haber Institute of the Max Planck Society, Germany — [3]Department of Physics, Ewha Womans University, South Korea

Key functionalities of transition metal dichalcogenides (TMDs) are determined by excitons whose behaviour can be tweaked by interface–induced external perturbation such as proximity effects, charge transfer and local electromagnetic fields. Excitonic behaviors and band alignment of TMDs with interfacing materials are explored. We studied the band alignment of monolayer WS_2 on nanostructured Ag by Kelvin probe force microscope, a tool that can map electrical potential of sample surface. By this method, the exciton–to–trion conversion mechanisms in WS_2 could be explained, including the role of the localized surface plasmons. For a more direct approach, time and angle–resolved photoemission spectroscopy (TrARPES) with pump–probe technique is employed to directly map the equilibrium and non–equilibrium electronic structure of TMD–metal and TMD/TMD interfaces. In–situ and ex–situ techniques are required to achieve pristine TMD surfaces and interfaces, since TrARPES is a highly surface sensitive technique.

O 71.11 Wed 18:00 P2

Ultrafast Photocarrier-Induced Ionic Rearrangement in Monolayer ReS_2 Probed with Femtosecond Electron Diffraction — •Victoria C. A. Taylor[1], Yoav W. Windsor[1,2], Samuel Lai[3], Hyein Jung[1,2], Martin Wolf[1], Fang Lui[3], and Ralph Ernstorfer[1,2] — [1]Fritz-Haber-Institut der Max-Planck-Gesellschaft, 14195 Berlin, Germany — [2]Technische Universität Berlin, 10623 Berlin, Germany — [3]Stanford University, Stanford, CA 94305, USA

Rhenium disulphide (ReS_2) exhibits a distorted crystal structure compared to prototypical hexagonal transition metal dichalcogenides. This Peierls-like distortion results in quasi-1D chains of Re ions running in plane through each layer of ReS_2, which give rise to prominent anisotropic properties, such as polarization dependent optical absorption and anisotropic effective carrier masses.

We investigate the ultrafast lattice dynamics of monolayer ReS_2 with femtosecond electron diffraction (FED). Leveraging the strength of FED as a direct and quantitative measurement of the crystal lattice, we fit the intensities of many hundreds of Bragg peaks at each time delay to extract time resolved crystallographic information.

With this method, we not only resolve the increase in the incoherent phonon population (Debye-Waller), but also reveal a concerted atomic rearrangement within the lattice, with the ions rapidly (< 1 ps) moving away from their equilibrium atomic coordinates and returning on timescales of a few picoseconds. We associate this response with the aforementioned distortion, and discuss the physical origin.

O 71.12 Wed 18:00 P2

Exploring Zincblende (100) Semiconductor Surfaces as Platforms for Correlated Adatom Lattices — •Olga Kashirina, Niklas Enderlein, and Philipp Hansmann — Friedrich-Alexander-Universität Erlangen-Nürnberg

Adatom lattices on (111) surfaces of zincblende structured semiconductors have proven to be versatile, experimentally realizable platforms for hosting strong electronic correlations and associated emergent behavior near the Fermi energy (see [1] and references therein). Our recent study [2] reveals transition metals adatom lattices on 3C-SiC(111) surfaces to be intriguing candidates for strongly correlated material design. In the present contribution we continue this strategy by leaving the hexagonal/triangular lattices. Specifically, we explore the (100) surfaces of silicon, diamond, and 3C-SiC which in the infinite bulk exhibit a fourfold rotoinversion symmetry enabling square/rectangular adatom lattices. As the (100) surface is prone to dimerization, an additional complication arises from dimer-derived electronic states inside the bulk gap, which - depending on the chosen adatom and substrate combination - may or may not hybridize with the adatom states. In this context, the adatom coverage is another crucial parameter as it directly influences the nature of surface reconstructions and dimerizations. To assess the structural stability of our candidate systems, we employ phonon calculations based on density-functional perturbation theory as well as molecular-dynamics simulations. [1] X. Cao, et al., PRB 97, 155145 (2018). [2] H. Menke, N. Enderlein, et al., arXiv:2410.17165.

O 71.13 Wed 18:00 P2

Engineering correlated electrons in adatom lattices on semiconductors — •Tim Kullick[1], Niklas Enderlein[1], Henri Menke[1,2], Giorgio Sangiovanni[3], and Philipp Hansmann[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg — [2]Max Planck Institute for Solid State Research, Stuttgart — [3]Julius-Maximilian-Universität of Würzburg

Adatom lattices on (111) surfaces of zinc-blende structured semiconductors have proven to be versatile, experimentally realizable platforms for hosting flat bands with strong electronic correlations near the Fermi energy. A recent study [1] revealed transition metals on 3C-SiC(111) surfaces to be intriguing adatom systems, showcasing the diverse nature of strongly correlated systems. Together with earlier theoretical and experimental studies on adatom lattices on the Si(111) surfaces, this recent work underlines the great potential of this material family. In the present project, we explore promising adatom lattices on semiconducting/insulating substrates such as SiC and cubic BN in order to realize one-, two-, and three-band Hubbard models at different fillings. Combined with estimates of the quasiparticle interaction via cRPA, we point out new material directions in this increasingly vivid field. [1] H.Menke, N.Enderlein, *et al.*, arXiv:2410.17165.

O 71.14 Wed 18:00 P2

Investigation of the atomic and electronic structures of WSe2-xTex — •Ganbat Duvjir[1], Nguyen-Hoang Dang[2], Younghun Hwang[1], and Jungdae Kim[1] — [1]Department of Semiconductor Physics and Engineering, University of Ulsan, Ulsan 44610, Republic of Korea — [2]Electricity and Electronics and Semiconductor Applications, Ulsan College, Ulsan 44610, Republic of Korea

Ternary transition metal dichalcogenides (TMDs) exhibit diverse crystal structures and electronic properties depending on their composition. In this study, we systematically investigate the atomic and electronic structure of ternary WSe2-xTex as a function of Te concentration using scanning tunneling microscopy/spectroscopy (STM/S). Notably, STM topography indicates that increasing the Te content induces structural deformation of the hexagonal lattice of WSe2-xTex. This deformation manifests as the stretching of 2H structure along the zigzag direction and compression along the armchair direction. STS measurements reveal a significant reduction in the band gap of WSe2-xTex with increasing Te concentration. While the valence band maximum shifts toward the Fermi level, the conduction band minimum remains relatively unchanged.

O 71.15 Wed 18:00 P2

STM study on tuning the Fermi level of transition metal dichalcogenides — •Nguyen-Hoang Dang[1], Mincheol Kim[2], Ganbat Duvjir[1], Young Jun Chang[2,3], and Jungdae Kim[1] — [1]Department of Semiconductor Physics and Engineering, University of Ulsan, Ulsan 44610, Republic of Korea — [2]Department of Physics, University of Seoul, Seoul 02504, Republic of Korea — [3]Department of Smart Cities, University of Seoul, Seoul 02504, Republic of Korea

Controlling the Fermi level is essential for tailoring the electronic properties of semiconductors. Here, we investigate two routes of chemical doping and defect control using scanning tunneling microscopy and spectroscopy. For V-doped $MoSe_2$, we study how substitutional V atoms influence its electronic structure. Although STM primarily probes the top Se layer and the dopants are not directly imaged, the topography exhibits defect-like features whose contrast reverses with the bias polarity: dark at positive sample bias and bright at negative bias. This is characteristic of negatively charged acceptor states, consistent with V substituting Mo. STS spectra show a Fermi-level shift toward the valence band, indicating that V doping drives $MoSe_2$ from intrinsic n-type toward p-type. For $HfSe_2$, we study defect control via thermal annealing. STS measurements under different annealing conditions show Fermi level shifts toward the conduction band, suggesting that prolonged annealing enhances Se-vacancy formation, which acts as an electron donor. These results highlight how STM/STS links local defects with electronic properties, offering microscopic insight into Fermi level tuning through doping and defect engineering.

O 71.16 Wed 18:00 P2

Impact of Mo doping on the charge density wave in 1*T*-TaS_2 studied by laser-ARPES and LEED — •Adina Timm[1,2], Finja Schillmöller[1,2], Florian K. Diekmann[1,2], Jana Kähler[1,2], Matthias Kalläne[1,2,3], Tim Riedel[1,2], and Kai Rossnagel[1,2,3] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [3]Kiel Nano, Surface and Interface Science KiNSIS, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

Controlling charge density waves (CDWs) in quantum materials enables the fine-tuning of their electronic properties, paving the way for future electronic and optoelectronic devices. The layered compound 1*T*-TaS_2 exhibits various temperature-dependent CDW phases that we aim to modify through doping. We introduced the dopant molybdenum during crystal growth via the chemical vapor transport method. Using 11-eV laser-based angle-resolved photoelectron spectroscopy (ARPES), we comparatively measured the electronic band structures of pristine and Mo-doped 1*T*-TaS_2 crystals. Complementary low-energy electron diffraction (LEED) measurements revealed the structural rearrangements during the CDW transitions and partial CDW suppression at specific doping levels. Our results suggest that modest Mo doping allows for subtle adjustments to the CDW landscape of 1*T*-TaS_2, yielding different transition temperatures while preserving the underlying electronic-structural order.

O 71.17 Wed 18:00 P2

Probing Electronic Structure Modulation in WSe_2 and $MoTe_2$ under Out-of-Plane Electric Fields via ARPES and XPS — •Sonja Reinheimer[1,2], Lukas Bruckmeier[1,2], Jakob Dilling[1,2], Jens Buck[1,2], Matthias Kalläne[1,2,3], Chithra Sharma[1,2,4], Markus Scholz[5], and Kai Rossnagel[1,2,3] — [1]IEAP, CAU Kiel, 24098 Kiel, Germany — [2]RHL, DESY, 22607 Hamburg, Germany — [3]KiNSIS, CAU Kiel, 24098 Kiel, Germany — [4]Universität Hamburg, 22761 Hamburg, Germany — [5]DESY, 22607 Hamburg, Germany

Transition metal dichalcogenides (TMDCs) are quantum materials that exhibit a broad spectrum of emergent electronic phenomena, arising from layer-dependent band structures. Owing to their tunable (opto-)electronic properties, TMDCs are promising candidates for next-generation photovoltaic devices and highly integrated electronic components. A key challenge is to systematically control charge transport and band alignment in these layered systems. Here, we investigate vertically stacked 2*H*-WSe_2/2*H*-$MoTe_2$ heterostructures using angle-resolved photoemission spectroscopy (ARPES) and X-ray photoelectron spectroscopy. By performing in-operando ARPES on a sample with an applied out-of-plane electric field during the measurements, we can directly probe field-induced modifications to the electronic band structure and the density of states. This approach enables us to identify electric-field-driven changes in the electronic and lattice structure and contribute to a deeper understanding of electric control mechanisms in TMDC heterostructures.

O 71.18 Wed 18:00 P2

Many-body localisation in the Fermi-Hubbard model? — •Ričards Kristers Knipšis[1], Jesumony Jayabalan[2], Gael Reecht[2], Vivek Mondal[2], Florian Konstantin Diekmann[3], Friedemann Queisser[1], Ping Zhou[2], Walter Schnelle[4], Kai Rossnagel[3,5], Ralf Schützhold[1,6], Manuel Gruber[2], and Uwe Bovensiepen[2] — [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — [2]Faculty of Physics and CENIDE, University of Duisburg-Essen, Duisburg, Germany — [3]Institute of Experimental and Applied Physics, Christian-Albrechts-University of Kiel, Kiel, Germany — [4]MPI for Chemical Physics of Solids, Dresden, Germany — [5]Ruprecht-Haensel-Laboratory, DESY, Hamburg, Germany — [6]Institute of Theoretical Physics, Dresden University of Technology, Dresden, Germany

Motivated by recent experimental results, we study the 2D Fermi-Hubbard model in the Mott insulator state under the influence of a disorder potential. Special emphasis is placed on signatures of many-body localisation.

Using the hierarchy of correlations, we find that the disorder potential can localise the effective quasi-particle wavefunctions, resulting in their spatial separation. This, in turn, can be used to explain the drastic increase in the quasi-particle lifetimes observed in experiment.

Funding by the DFG through the SFB 1242 is gratefully acknowledged.

O 71.19 Wed 18:00 P2

Magnetic properties of V-doped WSe2 — •Jules M. Knebusch[1,2], Jana Kähler[1,2], Matthias Kalläne[1,2,3], Robert Zierold[4], Tim Riedel[1,2], Adina Timm[1,2], Robert H. Blick[4], and Kai Rossnagel[1,2,3] — [1]IEAP, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]RHL, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [3]KiNSIS, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [4]CHyN, Universität Hamburg, 22761 Hamburg, Germany

Spintronics holds promise for highly efficient classical and quantum computing and is therefore considered a key technology for future innovation. Pristine tungsten diselenide (WSe_2), known as a semiconductor with a quasi-two-dimensional hexagonal 2*H* structure, is expected to transform into a room-temperature dilute ferromagnetic semiconductor upon vanadium doping. This makes it a highly attractive candidate for spintronic applications. Density functional theory calculations and scanning transmission electron microscopy studies support this assumption, and RKKY interactions are predicted to be the driving mechanism. Pristine WSe_2 and vanadium-doped WSe_2 crystals were synthesized in separate in-house batches using the chemical vapor transport (CVT) method. The doped samples were grown with varying nominal concentrations of V intended to induce substitutional doping at the tungsten sites. The samples were investigated using a vibrating-sample magnetometer (VSM). The results provide insight into the magnetic characteristics of the doped material compared to the pristine reference crystal.

O 71.20 Wed 18:00 P2

Coexistence of a fully metallic antiphase boundary and the semiconducting charge density wave phase in 1T-TaS_2 — •Georg A. Traeger[1], Kai Rossnagel[2,3], and Martin Wenderoth[1] — [1]IV. Institute of Physics, University of Göttingen, Göttingen, Germany — [2]Institute of Experimental and Applied Physics, Kiel University, Kiel, Germany — [3]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

Transition metal dichalcogenides are an ideal platform for studying the interplay between charge density waves (CDWs), electronic correlations, and defect states. Using scanning tunneling microscopy and spectroscopy, we investigate a new type of intrinsic antiphase boundary (APB) in the commensurate CDW phase of 1T-TaS_2. In contrast to previous studies, we find a metallic APB extending laterally across several nanometers. We observe evanescent states spilling out from the defect into the metallic region and find that the fingerprint of the semiconducting system gradually disappears within the APB, without signs of strong interactions, suggesting the orthogonality of the two systems wave functions. Our findings highlight the crucial role of domain boundaries in the interpretation of other, especially conductivity-based, measurements. Furthermore, we propose this new type of metallic APB as a model system to study interlayer coupling in correlated layered materials.

O 71.21 Wed 18:00 P2

Temperature-dependent VUV-ARPES of 1*T*-$Mo_xTa_{1-x}S_2$ — •Torben Petersen[1,2], Matthias Kalläne[1,2,3], Adina Timm[1,2], Tim Riedel[1,2], and Kai Rossnagel[1,2,3] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [2]Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — [3]Kiel Nano, Surface and Interface Science KiNSIS, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

Examining the charge density wave (CDW) phase transitions of transition metal-substituted transition metal dichalcogenides (TMDCs) provides insight into tuning transition behavior by doping. To this end, we use the 1*T*-$Mo_xTa_{1-x}S_2$ reference system, comparing the pristine sample with two doped samples (x = 0.5% and x = 1%) using 11 eV laser-based VUV-ARPES. We investigate work function changes alongside doping-induced band structure changes in the temperature range of 60 K to 370 K. This allows us to observe the high- and low-temperature CDW phase transitions known from the pristine material and determine how the CDW-induced band structure changes vary with doping.

O 71.22 Wed 18:00 P2

STM/STS Studies of Single-Atom Fe Inclusions in MBE-grown Monolayer MoS_2/Gr/Ir(111) — •Alina Drechsler, Marta Przychodnia, Maciej Bazarnik, and Anika Schlenhoff — Institute of Physics, University of Münster, Germany

Transition metal dichalcogenides (TMDs) exhibit thickness-dependent electronic properties and are highly sensitive to structural defects, which can strongly modify their density of states even at low concentrations. Defect engineering has therefore become an important route to tailor their electronic, magnetic, optical, and catalytic behaviour. While most of the current research focuses on naturally occurring defects in chemical vapour-deposited TMDs, we focus on intentional single-atom inclusions in TMDs grown by molecular beam epitaxy (MBE) to improve control in defect engineering.

We present scanning tunneling microscopy and spectroscopy (STM/STS) studies of Fe-doped monolayer MoS_2 on Gr/Ir(111), achieved by co-evaporation Fe during MBE growth. By comparing to undoped MoS_2 grown under identical UHV conditions, we identify the Fe-related defects and measure their electronic signatures. STS reveals in-gap states associated with single-atom Fe inclusions, whose spatial distributions are resolved via differential conductance mapping. Additionally, resonant tunneling spectroscopy shows that Fe inclusions modify the image potential states by locally shifting their energetic positions. Our work demonstrates the potential of single-atom substitutions for tailoring the electronic properties of two-dimensional TMDs.

O 71.23 Wed 18:00 P2

Layer thickness dependent band gap of MBE grown single- to few-layer MoS_2 — •Maciej Bazarnik[1], Marta Przychodnia[1,2], Thorsten Deilmann[3], and Anika Schlenhoff[1] — [1]Institute of Physics, University of Münster, Germany — [2]Institute of Physics, Poznan University of Technology, Poland — [3]Institute of Solid State Theory, University of Münster, Germany

In light of the rise of transition metal dichalcogenides as 2D semiconductors for device applications, band engineering becomes very important from an application point of view. In many of these materials, such as the canonical example of MoS_2, the semiconductor band gap depends on the layer number. There is a transition from an indirect band gap semiconductor in bulk to a direct band gap for a monolayer. Interestingly, it was predicted and experimentally confirmed that, by thinning the material from bulk to a bilayer, the indirect transition blue-shifts.

Here, we present the results of scanning tunnelling spectroscopy measurements on MoS_2 that has been grown in situ via molecular beam epitaxy (MBE) on graphene on Ir(111) at thicknesses ranging from 1 to 6 layers. We observe a decrease in the band gap with increasing layer number. We also find a pinning of the conduction band, which vanishes for layer thicknesses beyond 4 layers. Comparing our experimental data with DFT and GW calculations indicates that a screening in addition to that of the substrate needs to be introduced to explain the experimentally obtained relation. We discuss possible sources of this additional screening in light of our findings.

O 72: 2D Materials beyond graphene: Growth, structure and substrate interaction – Poster (joint session O/TT)

O 72.1 Wed 18:00 P2

In-Situ CVD growth of vertical Heterostructures of Borophene and Hexagonal Boron Nitride — •Niels Ganser[1], Marko Kriegel[1], Smruti Ranjan Mohanty[1], Karim Omambac[1], Marin Petrovic[2], Christian Brand[1], Steffen Franzka[3], Birk Finke[1], Tobias Hartl[4], Thomas Michely[4], Frank-Joachim Meyer zu Heringdorf[1,3], and Michael Horn-von Hoegen[1] — [1]Universität Duisburg-Essen — [2]Institute of Physics, Zagreb — [3]ICAN, Duisburg — [4]Universität zu Köln

Intrinsic segregation provides a promising and scalable route for the in situ fabrication of 2D heterostructures. Using UHV chemical vapor deposition (CVD) of a single borazine ($B_3N_3H_6$) precursor [1], we demonstrate the growth of an hBN/borophene heterostructure on Ir(111). At high temperatures and low precursor pressures, boron dissolves into the Ir subsurface region, creating a boron reservoir below the surface [2]. Largely increasing the precursor dosing pressure shifts the chemical potential toward the formation of a complete hBN layer. Upon cooldown, the decreasing boron solubility of the Ir substrate drives segregation to the surface, where a borophene layer forms underneath the hBN overlayer and thus completing the heterostructure. The resulting structure and its growth kinetics were investigated using a combined low energy electron diffraction (SPA-LEED) and microscopy (LEEM) approach.

O 72.2 Wed 18:00 P2

Growth of 2D molecular networks on graphene — •Haruto Shibahara and Toyo Kazu Yamada — Dept. Materials Science, Chiba Univ., Chiba, Japan

We demonstrate the engineering of qubits on solid surfaces using organic molecules and transition-metal magnetic atoms. Atomically flat and clean graphene (Gr) grown on an Ir(111) substrate was selected as the platform. Scanning tunneling microscopy (STM) and low-energy electron diffraction (LEED) revealed the characteristic moiré pattern, while scanning tunneling spectroscopy (STS) and angle-resolved photoemission spectroscopy (ARPES) confirmed the presence of Dirac bands. Although single atoms can in principle serve as qubits, they tend to thermally diffuse on surfaces and their energy levels may remain degenerate. To overcome these issues, it is necessary to coordinate the atoms with organic ligands, whose ligand fields can lift the degeneracy. As a first approach, we attempted to employ 1,3,5-tris(4-bromophenyl)benzene (TBB) molecules to form a two-dimensional (2D) covalent organic framework. However, on the Gr surface we found that thermal activation desorbed the TBB molecules before they could undergo Ullmann coupling. As a second approach, we attempted to grow a 2D metal organic framework (MOF) on Gr. The details of this effort will be discussed.

O 72.3 Wed 18:00 P2

Probing the Electrostatic Potential of hBN by AFM with Oxygen-Terminated Copper Tips — •Jan ter Glane[1,2], Philipp Wiesener[1,2], Thorsten Deilmann[3], Milena Merkel[1,2], Maciej Bazarnik[2], Anika Schlenhoff[2], and Harry Mönig[1,2] — [1]Center for Nanotechnology, University of Münster, Germany — [2]Institute of Physics, University of Münster, Germany — [3]Institute of Solid State Theory, University of Münster, Germany

Monolayer hexagonal boron nitride (hBN) hosts point defects with promising optoelectronic properties, yet their atomic structure remains unclear [1]. Conventional scanning tunneling (STM) and atomic force microscopy (AFM) lack elemental contrast, making it difficult to reliably distinguish B and N sites. Non-contact AFM with oxygen-terminated copper tips (CuOx-tips) has previously enabled elemental discrimination and defect identification on metal oxides [2].

Using CuOx-tip AFM, we demonstrate elemental contrast on NaCl thin films, suggesting its broad applicability to polarized surfaces. Leveraging this capability, we investigate its application to monolayer hBN. DFT-optimized electrostatic potential calculations predict clear B-N contrast. To realize these measurements, we employ in-situ chemical vapor deposition growth procedures for high-quality hBN on single-crystalline substrates. We outline the benefits of CuOx-tip AFM and present initial results towards correlating STM/STS measurements, aiming to enable atom-specific defect identification in hBN.

O 72.4 Wed 18:00 P2

Pt-doped borane nanomembranes — •Martha Frey[1], Julian Picker[1], Christof Neuman[1], Jan Macháček[2], Tomáš Baše[2], and Andrey Turchanin[1] — [1]Friedrich Schiller University Jena, Institute of Physical Chemistry, Lessingstraße 10, 07743 Jena, Germany — [2]The Czech Academy of Sciences, Institute of Inorganic Chemistry, 250 68 Husinec Rez, 1001, Czech Republic

Boranes are clusters of boron and hydrogen atoms that form three-dimensional, cage-like molecules. We have recently employed them as convenient starting precursors for synthesising two-dimensional (2D) carbon-free nanomembranes. In this study, we present the preparation and characterisation of the self-assembled monolayers (SAMs) of two thiolated *syn*-$B_{18}H_{22}$ clusters on silver substrates. Subsequently, these SAMs were cross-linked laterally to form boron nanomembranes (BNMs) via low-energy electron irradiation under ultra-high vacuum (UHV) conditions. We investigated the structural and chemical properties of these 2D nanomembranes using surface-sensitive techniques such as X-ray photoelectron spectroscopy (XPS) and scanning tunnelling microscopy (STM). Both the starting SAMs and the resulting boron nanomembranes exhibited reactivity toward Pt-containing complexes. While such reactivity was expected for the SAMs, it was particularly noteworthy that the BNMs also enabled the insertion of Pt atoms. This Pt-doping positions borane-derived SAMs and BNMs as a promising 2D platform for nanoscale catalytic studies.

Defects and Initial Approaches to TMDC Heterostructure Growth on Pt_xTe_y films — •Isabella Stollberg, Andreas Raabgrund, and M. Alexander Schneider — Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

Transition-metal dichalcogenides (TMDCs) can generally be synthesised either by co-evaporating the metal and chalcogen onto a suitable substrate [1] or by depositing only the chalcogen onto the desired metal surface. Using STM, STS, and DFT, we investigate Pt_xTe_y films on Pt(111) prepared via the latter approach. With increasing Te content, different initial growth surface telluride structures are observed, followed by the formation of Pt_2Te_2 and $PtTe_2$ layers [2]. This contribution focuses on STM and spatially resolved STS analyses of point defects in $PtTe_2$, as well as domain boundaries within a $PtTe_2$ or Pt_2Te_2 layer. Furthermore, we evaluate the suitability of these telluride films as substrates for TMDC heterostructure growth. First results on attempting to grow $TiTe_2$ and $PdTe_2$ demonstrate considerable intermixing. While $TiTe_2$ islands can be identified by their apparent height and other lattice constants, $PdTe_2$ islands cannot be distinguished from $PtTe_2$ based on topography due to their similar vertical and lateral lattice parameters.

Boosting the Efficiency of Quantum Replica-Exchange Molecular Dynamics — •Jan-Niklas Mohr, Shubham Sharma, and Mariana Rossi — MPI for the Structure and Dynamics of Matter, Hamburg, Germany

Replica exchange molecular dynamics can be combined with path-integral techniques in order to incorporate quantum statistics in the sampled ensembles [1].

However, the efficiency in swapping replicas is decreased to a point that makes simulations extremely inefficient at lower temperatures.

We propose a new acceptance criterion for path-integral replica-exchange molecular dynamics (PI-REMD) that incorporates the path-integral spring term in the Hamiltonian and rescales it consistently. As a result, the acceptance probability is only sensitive to potential-energy differences, and the efficiency of the method is thus increased. Benchmarking on several test systems, including asymmetric double wells and glassy-like potentials, shows that our method outperforms standard PI-REMD in sampling efficiency and exchange frequency. We also show improvements for realistic materials, such as monolayer 1H-TaS_2 [2], where it is paramount to obtain an accurate description of the charge-density-wave phase transition. Our acceptance criterion therefore provides an efficient and reliable tool for studying quantum phase transitions and exploring thermodynamic ensembles under challenging conditions.

Towards enhanced spin-orbit coupling in epitaxial graphene via Pb intercalation — •Markus Gruschwitz[1], Sergii Sologub[1,2], Hoyeon Jeon[3], Saban Hus[3], An-Ping Li[3], and Christoph Tegenkamp[1] — [1]Institut für Physik, TU Chemnitz, Germany — [2]Institute of Physics, NAS of Ukraine, Kyiv, Ukraine — [3]CNMS, ORNL, Oak Ridge, USA

The design of noval quantum phases by combining low dimensional materials poses the next evolution step of electronics. Intercalated epitaxial graphene on SiC embodys a van-der-Waals heterostack with well defined lattice arrangement. Stabilizing monolayers of heavy elements in proximity to graphene, potentially enhances the spin-orbit interaction (SOI) in graphene. Using Pb as intercalant, we reliably decouple and neutralize graphene by minimizing the substrate influence. At the interface coexisting striped and hexagonal superstructures emerge from local strain and density variations in the Pb monolayer. [1] Multi-probe transport measurements, assisted by finite element simulations, revealed a temperature dependent resistance. This emergent behavior was attributed to a gap opening in graphene in the order of 3-5 meV. [2] Tip–sample spacing dependent spectroscopy supports this finding by a clearly reduced density of states at the Dirac point. The desired enhanced intrinsic SOI competes with Rashba-SOI and modulations of the sublattice potential by the Pb superstructure. Although the nature of this gap was not revealed yet, it has potential to stabilize a quantum spin Hall state.

O 73.2 Wed 18:00 P2

Graphene-Based Coatings on Titanium Alloy for Implants — •Franziska Gladitz[1], Christof Neumann[1], Guobin Jia[2], Jonathan Plentz[2], and Andrey Turchanin[1] — [1]Friedrich-Schiller-University Jena, Institute of Physical Chemistry, Jena, Germany — [2]Leibniz-Institut of Photonic Technology (Leibniz-IPHT), Jena, Germany

Titanium alloy implants are essential for bone replacement surgeries; however, they are susceptible to infection. To improve their antimicrobial properties, we develop graphene-based coatings on the implant substrates (alloy Ti6Al4V), taking advantage of the antibacterial and biocompatible properties of graphene (G) or graphene oxide (GO). For this purpose, the titanium alloy is coated with G or GO nanosheets using different coating techniques like double self-assembly procedure and electrochemical deposition. The coatings are characterized using complementary characterization techniques including scanning electron microscopy (SEM), X-ray photoelectron spectroscopy (XPS), Raman spectroscopy, atomic force microscopy (AFM) and optical microscopy. The morphological and chemical properties of the obtained graphene coatings are analyzed in respect to their growth conditions to elucidate influences on the quality, uniformity, and possible biofunctional performance.

O 73.3 Wed 18:00 P2

Graphene on 4H-SiC and 6H-SiC: The Influence of the SiC-Polytype onto the Local Transport Properties of Graphene — •Simeon Bode[1], Benno Harling[1], Klaus Pierz[2], Teresa Tschirner[2], and Martin Wenderoth[1] — [1]IV. Physikalisches Institut, Georg-August-Universität Göttingen — [2]Physikalisch-Technische Bundesanstalt (PTB), Braunschweig

Studies of Graphene on silicon carbide have shown a strong dependence of the surface termination of the SiC substrate on the local transport properties. In this study, we investigate the influence of the polytype of the substrate SiC onto the local properties of Polymer Assisted Sublimation Growth (PASG) graphene. It is known that graphene on 6H-SiC displays two distinct surface terminations [1], while on 4H-SiC it is only one dominant surface termination. Here, local characterization is done by AFM and STM, while the local electronic properties are investigated by STS. Graphene on both polytypes present a similar characteristic in multibias topographies. To gain access to local transport properties, we utilized Scanning Tunneling Potentiometry (STP), which revealed two distinct sheet resistances attributed to the different surface terminations. Although PASG graphene on 4H-SiC shows only one surface termination, the spread of the sheet resistance is much larger than the difference of the two distinct sheet resistances on 6H-SiC. This work was financially supported by the DFG through the FOR5242. [1] Sinterhauf et al., Nat Commun 11, 555, 2020

O 73.4 Wed 18:00 P2

Sn intercalation of Zero-Layer Graphene — •Jan-Lucas Hornbostel, Benno Harling, and Martin Wenderoth — IV. Physikalisches Institut, Georg-August Universität Göttingen

Graphene is a 2D material with a wide range of potential applications. Our research area is the intercalation of epitaxial graphene with tin, a system that has recently shown interesting phenomena such as Mott states [1]. To achieve such systems, zero-layer graphene (ZLG) as starting point is intercalated. Tin binds to the SiC substrate transforming the ZLG into quasi-freestanding monolayer graphene. ZLG graphene can be epitaxially grown on SiC using various methods. The intercalation of Sn on polymer assisted sublimation growth (PASG) samples has shown to be strongly influenced by substrate steps [2]. In this study, we grow ZLG samples using resistive heating under UHV conditions on 6H-SiC. Compared to PASG, AFM and KPFM reveal a weakness of UHV growth for producing high quality ZLG samples, namely a generally disorder structure and depressions within the terraces. This type of defects disappears at higher temperatures. After ZLG growth and verification, Sn is deposited. We focus specifically on the influence of sample temperature (120-1000 K) during deposition. These are analyzed using AFM and KPFM. [1] Ghosal et al, Phys. Rev. B 111, 235426, 2025 [2] Harling et al, Carbon 244, 120711, 2025

O 73.5 Wed 18:00 P2

Ca-intercalation of epitaxial monolayer graphene — Luqman Mahdi Syed[1,2], Niclas Tilgner[1,2], •Philip Schädlich[1,2], and Thomas Seyller[1,2] — [1]Institut für Physik, Technische Universität Chemnitz — [2]Research Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Technische Universität Chemnitz

Realizing proximity-induced correlation effects, such as superconductivity, in graphene is a major challenge in the field of research on two-dimensional (2D) materials. Among the graphite intercalation compounds (GICs), the Ca-GICs exhibit the highest critical temperature with T_c=11.5 K, where the electron doping from the Ca atoms may be a crucial factor. Hence, expanding this superconducting phase into the 2D limit of epitaxial monolayer graphene (EMLG) on SiC(0001) requires precise control over the arrangement of the intercalated Ca atoms. However, several structural models have been proposed for Ca-intercalated EMLG, and in particular, the vertical position - i.e., the gallery - in which Ca resides remains unresolved (S. Ichinokura et al. 2016 ACS Nano 10 2761, J.C. Kotsakidis et al. 2020 Chem. Mater. 32 (15) 6464). Here, we investigate Ca-intercalation into EMLG grown by polymer-assisted sublimation growth. Using x-ray and angle-resolved photoemission spectroscopy, we monitor the intercalation process and quantify the doping level. Our results indicate the saturation of the SiC interface by Ca. We observe the low-energy bands of the resulting intercalated bilayer graphene, and more interstingly regarding the superconducting state, a highly doped graphene π-band, which may point towards the presence of calcium in the upper gallery.

O 73.6 Wed 18:00 P2

Porphyrin derivatives on Graphene/Cu(111) — •Asma Khizar, Christophe Nacci, and Leonhard Grill — Department of Physical Chemistry, University of Graz, Heinrichstrasse 28, 8010 Graz, Austria

Molecules as well as their assemblies and reactions have been widely investigated on single-crystal metal samples, which represent a highly defined flat support for efficient diffusion and high-resolution imaging by scanning probe microscopy (STM). However, the interaction between the metal and the molecule can alter the intrinsic properties of the molecules, making a decoupling layer essential to understand the pristine molecular properties. Graphene, with its two-dimensional structure and weak interaction with adsorbates, serves as an excellent decoupling layer for molecules. On epitaxial graphene, the reduced molecule-metal interaction allows molecules to retain their intrinsic electronic features while still sensing the underlying metal, which influences adsorption energy and selective interactions. In this study, we use Cu(111) as a substrate for

graphene growth, due to its cleanliness and minimal lattice mismatch. Our focus is on chemical reactions of porphyrin derivatives on the graphene layer, thus at a distance from the copper catalyst. Various stimuli are used to controllably dissociate side groups from the molecules and induce covalent coupling to get better insight into the chemical reactions.

Strong-Field Bloch Electron Interferometry for Band-Structure Retrieval — •Tamara Pröbster, Tobias Weitz, Christian Heide, and Peter Hommelhoff — Friedrich-Alexander-Universität Erlangen-Nürnberg, Department Physik, Staudtstr. 1, 91058 Erlangen

Strong optical fields drive electrons in solids far from equilibrium, enabling access to ultrafast quantum dynamics that directly reflect the underlying band structure. When Bloch electrons in graphene are exposed to an intense few-cycle laser field, they undergo coherent intraband motion during which they accumulate a quantum phase determined by the local band curvature. If this laser-driven trajectory encounters an avoided crossing between the valence and conduction bands, the electron wave packet can coherently split via a Landau-Zener transition. In our work, we exploit pairs of such transitions to realize strong-field Bloch electron interferometry, forming an interferometric sequence fully embedded in the electronic band structure. The resulting interference encodes band information in the phase-dependent photocurrent. We retrieve the Fermi velocity of graphene near the K points as 1.07 ± 0.04 nm·fs^{-1}, in excellent agreement with theoretical expectations. Our results establish strong-field Bloch electron interferometry as a general and versatile approach for band-structure reconstruction under ambient conditions. Because the method relies solely on ultrafast optical driving and detection, it is naturally suited for tracking light-induced modifications of electronic structure with femtosecond temporal resolution.

O 74.2 Wed 18:00 P2

Folding the electronic band structure of graphene-Bi and graphene-Pb heterobilayers — •Johanna Schurr, Alexander Korn, Andres Unigarro, Sibylle Gemming, and Nebahat Bulut — Institute of Physics, TU Chemnitz, Germany

Translational and rotational degrees of freedom in 2D material stacks open up a wealth of tunable materials properties, such as electrical conductivity, magnetism, or optical properties, in particular if heavy intercalant atoms are present. In this study, the band structure of the two hexagonal hetero-bilayer systems bismuthene-graphene and plumbene-graphene were investigated, because experiment gives evidence for a large number of structural varieties especially for plumbene.

The aim was to identify and characterise the influence of bismuthene and plumbene layers on the band structure of graphene. For this purpose a code was generated to correlate the k-path of the band structures calculated for supercells and primitive cells within their respective Brillouin zones. Subsequent folding back of the bands into the first Brillouin zone of the supercell, while maintaining the information of the original k-path in the primitive cell, provided an overview of all existing bands and the origin of their Brillouin zone.

O 74.3 Wed 18:00 P2

A tool for folding and unfolding of electronic band structures applying it to graphene and the gold(111)-surface — •Alexander Korn, Nebahat Bulut, and Sibylle Gemming — Institute of Physics, TU Chemnitz, Germany

The electronic band structure is an important property of materials. For comparison with experiments and other studies, as well as for better readability, it is useful to display and analyse the band structure of the primitive cell rather than a supercell. Studying more complex materials with dopants or adatoms is only possible using a supercell instead. Therefore, one must unfold the band structure of the supercell into the primitive cell.

For this purpose, we offer a tool for abinit (www.abinit.org) that can be used to unfold all possible supercells. The unit vectors of the supercell can be stretched and also rotated relative to the unit vectors of the primitive cell. We also offer an additional qualitative tool for band folding that also tracks the origin of the Brillouin zone of each band at each k-point. We provide a practical example of folding and unfolding using the gold(111) surface with sulfur as an adatom.

O 74.4 Wed 18:00 P2

Enhanced Screening in Indium Intercalated Graphene Enabled by 2D Nearly Free Electron States — •Lukas Gehrig[1,2], Cedric Schmitt[1,2], Kilian Strauss[1,2], Jonas Erhardt[1,2], Stefan Enzner[2,3], Martin Kamp[1,4], Timur Kim[5], Giorgio Sangiovanni[2,3], Jörg Schäfer[1,2], Simon Moser[6], and Ralph Claessen[1,2] — [1]Physikalisches Institut, Universität Würzburg, Germany — [2]Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Germany — [3]Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Germany — [4]Röntgen Center for Complex Material Systems, Würzburg, Germany — [5]Diamond Light Source, Harwell Science and Innovation Campus, Didcot, United Kingdom — [6]Experimentalphysik IV - AG Oberflächen, Ruhr-Universität Bochum, Germany

Intercalation of epitaxial graphene on SiC has been intensively explored to modify graphene's electronic properties, but previous intercalants provide only weak screening, leading to pronounced electron-plasmon coupling and the appearance of plasmaron bands in ARPES [1]. Here, we demonstrate that intercalated bilayer indium exhibits strongly Rashba-split bands, which acquire nearly free-electron-like character at the Fermi level. This induces exceptionally strong screening in graphene, significantly reducing many-body renormalization effects in the graphene bands, which arise from plasmaron coupling. This approach opens new opportunities to explore and control many-body interactions in graphene-based heterostructures.

Terbium intercalation as a route to n-doping of graphene past the van Hove singularity — •Bharti Matta[1], Philipp Rosenzweig[1], Craig Polley[2], Kathrin Küster[1], and Ulrich Starke[1] — [1]Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany — [2]MAX IV Laboratory, Lund, Sweden

Exotic ground states driven by many-body interactions, such as unconventional chiral superconductivity and spin-density waves, were theoretically predicted more than a decade ago for heavily n-doped graphene near the van Hove singularity (VHS). In recent years, achieving such high doping levels in epitaxial graphene on SiC via intercalation has attracted considerable interest. Intercalation of rare-earth elements such as Gd, Yb, and Er has already proven promising in reaching these regimes. Here, we demonstrate that intercalation of Tb atoms at the graphene/SiC interface provides access to extreme n-doping levels beyond the π^* VHS, without requiring any adsorbates on the graphene surface. The extended VHS is shifted by 0.07 eV below the Fermi level (E_F) as seen in angle-resolved photoemission spectroscopy. From the area enclosed by the giant hole pocket around Γ, we extract an electron density of $\approx 5{\times}10^{14}$ cm^{-2}. Strong renormalization of the graphene bands leads to a Dirac point about 1.55 eV below E_F, indicating that the doping cannot be described by a rigid single-particle band shift. Based on these experimental parameters, theoretical calculations predict the emergence of topological superconductivity with a critical temperature up to 600 mK (S. A. Herrera *et al.*, *ACS Nano 18* (51), 34842–34857 (2024)).

O 74.6 Wed 18:00 P2

Vanishing Fermi velocity in Periodically Strained Graphene — •Leo-Malik Benneka[1], Taher Rhouma[2], Guy Trambly de Laissardière[2], Clemens Winkelmann[1], Mark Zelsmann[3], and Vincent Renard[1] — [1]Université Grenoble Alpes, CEA-IRIG-PHELIQS, 38000 Grenoble, France — [2]CNRS-LPTM, CY Cergy Paris Université, 95302 Cergy-Pontoise, France — [3]CNRS-LTM, 38000 Grenoble, France

Intense research has been made in engineering flat bands in twisted bilayer graphene, leading to various correlated phases [1]. An alternative route to realizing similar flat bands involves a monolayer graphene strained by a periodic triangular superlattice induced by a corrugated substrate. The height modulation h and the superlattice periodicity L serve as tuning parameters for controlling band flattening and the Fermi velocity v_F near the Dirac cones [2, 3]. Tight-binding calculations were performed by explicitly accounting for relative rotations between the graphene lattice and the superlattice, as would occur in an experimental device. These calculations not only reproduce the known decrease of the Fermi velocity with increasing h [4], but also reveal a renormalization of v_F that depends on the specific ratio $\sqrt{a_C C\ L}/h$ and on the relative lattice orientation. Remarkably, this behavior is universal for any superlattice size L. These predictions may assist in the design of experimental devices aimed at engineering flat bands. B, 24 (2020) 245427.

O 74.7 Wed 18:00 P2

Optimizing the excitation cross section for graphene phonons in inelastic electron tunnelling via intercalation. — Karl Rothe[1], •Nicolas Néel[1], Mads Brandbyge[2], and Jörg Kröger[1] — [1]Institut für Physik, Technische Universität Ilmenau, D-98693 Ilmenau, Germany — [2]Center of Nanostructured Graphene, Department of Physics, Technical University of Denmark, DK-2800 Kongens Lyngby, Denmark

Platinum-intercalated graphene on a (111)-oriented iridium surface gives rise to a variety of rotational domains, which exhibit characteristic moiré patterns. Independent of the twist angle subtended by the graphene and substrate lattice, inelastic electron tunnelling spectroscopy reveals elevated graphene phonon excitation only on the intercalated phases. Combining spatially resolved spectroscopy of the electronic structure with non-equilibrium Green's function simulations highlights the relevance for effective phonon creation of the balance between elastic and inelastic electron transport. The intercalation-induced shift of electron density of states from the Brillouin zone centre to its boundary enhances the inelastic channel at the expense of the elastic channel and thereby increases the phonon excitation cross section. Financial support by the Deutsche Forschungsgemeinschaft through KR 2912/18-1 is acknowledged.

O 74.8 Wed 18:00 P2

Se-intercalation of graphene on SiC(0001) — •Susanne Wolff[1,2] and Thomas Seyller[1,2] — [1]Institut für Physik, Technische Universität Chemnitz — [2]Research Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Technische Universität Chemnitz

The epitaxial growth of graphene on SiC in an argon atmosphere is a well-established method to produce homogeneous, high quality carbon layers. The first-grown carbon layer exhibits a $\left(6\sqrt{3}\times 6\sqrt{3}\right)R30^{\circ}$ periodicity and is partially covalently bound to the SiC substrate. Therefore, this so-called buffer layer lacks the typical electronic properties of graphene. One pathway to decouple the buffer layer from the substrate and obtain graphene-like electronic properties is intercalation, which involves introducing a certain element at the buffer layer/SiC interface. Furthermore, the choice of intercalant influences the electronic properties of the decoupled graphene.

In this study, we investigated the intercalation of a buffer layer with selenium (Se). This process was carried out in a two-zone tube furnace, with the selenium precursor $SnSe_2$ and the buffer layer positioned in different temperature zones. The samples were characterized using X-ray photoelectron spectroscopy (XPS) and angle-resolved photoelectron spectroscopy (ARPES). XPS revealed successful decoupling of the buffer layer with intercalated Se at the interface and not-intercalated Se on the surface. ARPES measurements in the vicinity of the Dirac point of graphene showed a p-type doping of the decoupled carbon layer.

O 74.9 Wed 18:00 P2

Mesoscopic Lateral Intercalation Dynamics of Indium Between the Epitaxial Zero-Layer of Graphene and SiC — •Benno Harling[1], Zamin Mamiyev[2], Narmina Balayeva[2], Dietrich R.T. Zahn[2], Christoph Tegenkamp[2], and Martin Wenderoth[1] — [1]IV. Physikalisches Institut, Georg-August-Universität, Friedrich-Hund-Platz 1, 37077, Göttingen, Germany — [2]Institut für Physik, Technische Universität Chemnitz, Reichenhainer Str. 70, 09126, Chemnitz, Germany

Intercalation, the process of diffusing a material species in-between layered materials, can be utilized for both bulk and 2D systems to achieve tailored electronic properties. [1] For the 2D limit, this work investigates the lateral diffusion dynamics of indium intercalation into the epitaxial zero-layer of graphene on SiC using Kelvin Probe Force Microscopy (KPFM). For tin, material transfer across surface substrate steps is observed at local sites at the mesoscopic scale. [2] With the used experimental parameters, we find that this is not the case for indium intercalation. Instead, only terrace transport is observed. The KPFM measurements were complemented by micro-Raman spectroscopy, assessing the extent and uniformity of In intercalation. Remarkably, intercalation through the carbon layer seems to be dependent on the graphene or substrate properties that still need to be further resolved. This leads to a situation where just some of the terraces are observed to be intercalated. Financial support by the DFG within Research Unit FOR5242 is acknowledged. [1] Stark et al., Adv. Mater. 2019, 31, 1808213 [2] Harling et al., Carbon 244 (2025) 120711

Oxide interfaces as platforms for emergent quantum phenomena — •Manuel Bibes — Laboratoire Albert Fert, CNRS, Thales, U. Paris-Saclay, Palaiseau (France)

Oxide surfaces and heterointerfaces host electronic phases that emerge from the combined effects of broken inversion symmetry, orbital reconstruction, and electrostatic boundary conditions. In this overview, I will discuss how two-dimensional electron gases (2DEGs) formed at oxide surfaces and interfaces give rise to large and tunable spin-orbit interactions, interfacial magnetism, and ferroic control of transport properties.

The focus will be on Rashba-type spin-orbit coupling in oxide 2DEGs and its interplay with ferromagnetism and ferroelectricity, leading to effects such as electrically tunable Anomalous Hall effect, spin and orbital Edelstein effects, and spontaneous non-reciprocal charge transport. Angle-resolved photoemission spectroscopy (ARPES) and X-ray photoelectron spectroscopy (XPS) play a central role in elucidating the electronic structure, orbital character, and electrostatic landscape underlying these phenomena, and in establishing clear links between interface chemistry, symmetry breaking, and transport behavior.

Finally, I will discuss how these engineering 2DEGs enables new routes toward low-power spin-orbitronic and ferroelectric device concepts compatible with silicon technology. The talk will highlight open challenges and opportunities at the interface between surface science, correlated electron physics, and oxide electronics.

Angle-resolved photoemission spectroscopy study on AgTe/Ag/Au(111) heterostructures. — •Muthu P. T. Masilamani, Sophia Munne, Begmuhammet Geldiyev, Maximilian Ünzelmann, and Friedrich Reinert — Experimental Physics VII and Würzburg-Dresden Cluster of Excellence ctd.qmat, Universität Würzburg, Germany

We report a comprehensive angle-resolved photoemission spectroscopy (ARPES) study on the electronic band structure of AgTe/Ag/Au(111) heterostructures. We systematically explore the interplay between Rashba-like spin-split surface states (SS) of AgTe [1] and quantum well states (QWS) of Ag/Au(111) [2] by epitaxially varying the Te coverage and the Ag spacer-layer thickness. This allows us to address the influence of epitaxial composition on the electronic structure. Our measurements reveal decoupling of the Rashba-like SS and QWS, with no observable hybridisation, attributed to their distinct orbital symmetries. Furthermore, we investigate the emergence of moiré reconstruction in the AgTe/Ag/Au(111) heterosystem.

O 76.2 Thu 10:45 HSZ/0201

One-step investigation of the electronic tapestry of 2H-WSe2 — •Ridha Eddhib[1], Samuel Beaulieu[2], Aki Pulkkinen[1], and Jan Minar[1] — [1]New Technologies Research Centre, University of West Bohemia, 301 00 Pilsen, Czechia — [2]Université de Bordeaux-CNRS-CEA, CELIA, UMR5107, F33405 Talence, France.

Angle-resolved photoemission spectroscopy (ARPES) is a powerful tool for unraveling the electronic band structure of crystalline solids. However, the intricate and multifaceted electronic structures of complex materials often require complementary measurement strategies and careful experimental design. In our research, we employed the one-step model of photoemission, as implemented in the SPRKKR code[1], supported by experimental studies. We combined circular dichroism in photoelectron angular distributions (CDAD) with the layer-dependent symmetry properties of 2H-WSe2, which enables a time-reversal operation (TRCDAD)[2]. This approach quantifies the modulation of photoemission intensity across a wide energy range, providing detailed insight into the material's fine electronic structure while suppressing extrinsic contributions to the photoemission cross section to some extent. We present the monolayer, bilayer, and trilayer contributions to the photocurrent alongside the bulk response, while accounting for final-state effects using both time-reversed low-energy electron diffraction and a free-electron-gas final-state. O 76.3 Thu 11:00 HSZ/0201

Spin-orbital signatures and topological evolution in the $Mo_xW_{1-x}Te_2$ alloy — •Sarath Sasi[1], Aki Pulkkinen[1], Raphaël Salazar[1], Jakub Schusser[1], Laurent Nicolaï[1], Christine Ritcher[2,3], and Karol Hricovini[2,3] — [1]New Technologies Research Centre, University of West Bohemia, Pilsen, Czech Republic — [2]LPMS, CY Cergy Paris Université, Neuville-sur-Oise, France — [3]Université Paris-Saclay, CEA, CNRS, LIDYL, Gif-sur-Yvette, France

We examine how compositional disorder modifies the electronic structure of the transition-metal dichalcogenide alloy $Mo_xW_{1-x}Te_2$[1], with particular attention to the evolution of band topology and the persistence of Type-II Weyl features. Using high-resolution spin-polarized ARPES and circular-dichroism ARPES provides complementary insights into the spin and orbital character of the electronic states. These measurements give insight into its intrinsic spin-orbital properties compared to WTe_2[2], and for identifying how alloying is affecting its properties, like Berry curvature. Together with fully relativistic one-step photoemission calculations within the SPR-KKR[3] framework, we yield a detailed picture of how alloying tunes the electronic structure and topological responses in this family of quantum materials.

O 76.4 Thu 11:15 HSZ/0201

electronic properties observation of kagome lattice Nb3X8 by angle-resolved photoemission spectroscopy — •Xiaojing Liu[1], Antonija Grubisic-cabo[1], Joost aretz Aretz[2], Sergii Grytsiuk[2], Marco Bianchi[3], Malte Rosner[2,4], Mazhar Ali[5], Philip Hofmann[3], Zhiying Dan[1], Giovanna Feraco[1], Chrystalla Knekna[1,6], Muhammad Waseem[1], and Mikhail Katsnelson[2,7] — [1]University of Groningen, Groningen, The Netherlands — [2]Radboud University, Nijmegen, The Netherlands — [3]Aarhus University, Aarhus, Denmark — [4]Bielefeld University, Bielefeld, Germany — [5]Delft University of Technology, Delft, the Netherlands — [6]University of Amsterdam, Amsterdam, The Netherlands — [7]Constructor University, Bremen, Germany

The Nb3X8 family (X=Cl, Br, I) is a novel group of breathing kagome materials. Despite interest in these materials, their electronic properties are still unclear and are likely to differ among the family members. For instance, they could exhibit characteristics of either a strongly correlated Mott insulator or a weakly correlated obstructed atomic insulator. Moreover, the kagome lattice can naturally host flat bands, which give rise to exotic properties such as spin-liquids and high-temperature superconductivity. Here, I will present our recent experimental investigation of the band structure in bulk Nb3X8 kagome materials by means of angle-resolved photoemission spectroscopy (ARPES). With ARPES we directly image the flat bands in the Nb3X8 systems, and are able to verify their strong correlation character with the support of theoretical calculations.

O 76.5 Thu 11:30 HSZ/0201

Studying the polar surfaces of MAX and MAB phases using μ-ARPES — •Gesa Siemann[1], Gianmarco Gatti[1], Amalie Svaneborg[5], Wu Bing[4], Anders S. Mortensen[1], Charlotte Sanders[2], Naina Kushwaha[2,6], Jenny Rigden[2], Yu Zhang[2], Matthew D. Watson[3], Kristian Thygesen[5], Zdeněk Sofer[4], and Philip Hofmann[1] — [1]Department of Physics and Astronomy, Aarhus University, DK — [2]Central Laser Facility, Harwell, UK — [3]Diamond Light Source, UK — [4]University of Chemistry and Technology Prague, CZE — [5]Department of Physics, Technical University of Denmark, Lyngby, DK — [6]School of Physics and Astronomy, St Andrews University, UK

Natural heterostructures with interlayer charge transfer in the bulk can exhibit distinctive surface effects when this transfer is interrupted, such as Rashba splitting and itinerant ferromagnetism, both absent in the bulk. These layered systems therefore provide a platform to study how charge redistribution and symmetry breaking shape the emerging surface electronic structure. Here, we introduce MAX and MAB phases as a promising material family to host similar effects due to their alternating MX and A layers. After cleaving the samples, we used photoemission experiments with a micrometer-scale light spot (μ-ARPES), allowing us to reliably distinguish different surface terminations and their electronic structures. This work furthermore explores how covalency and metallicity govern charge transfer, and thus the surface electronic properties, in layered compounds.

O 76.6 Thu 11:45 HSZ/0201

Spin-resolved momentum microscopy of BiX_2 surface alloys on Cu(111) and Ag(111) using a 2D imaging spin-filter — •Fabian Göhler, Stefanie Suzanne Brinkman, Xin Liang Tan, Anders Christian Mathisen, Chul-Hee Min, and Hendrik Bentmann — Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, 7491 Trondheim, Norway

Despite the rapid development of angle-resolved photoelectron spectroscopy (ARPES), measurements of the electron spin over wide regions in momentum space remain challenging with single-channel spin detectors. In this contribution, we present spin-resolved ARPES measurements from a momentum microscope, which gives the photoelectron momentum distribution over the full half-sphere above the sample surface. When combined with a 2D imaging spin filter [1], this allows parallel measurement of the in-plane spin polarization for full constant energy cuts $E(k_x, k_y)$. We acquired data on BiX_2/X(111) surface alloys - formed by 1/3 monolayer of Bi atoms arranged in a $(\sqrt{3}\times\sqrt{3})R30^\circ$ periodicity on Cu(111) or Ag(111) - which are well established model systems for spin-orbit effects and (spin-dependent) photoemission from surfaces [2-4]. Using linearly polarized ($h\nu$ = 6.0 eV) and unpolarized ($h\nu$ = 21.2 eV) light sources, we probe the spin polarization in these systems for varying experimental conditions.

O 76.7 Thu 12:00 HSZ/0201

Distinguishing bulk vs surface states from designed cleaving planes in ruthenium dioxide with ARPES — •Maria Visscher[1,2], Lea Richter[1], Sebastian Buchberger[2], Shu Mo[2], Bruno Saika[2], Mats Leandersson[3], Craig Polley[3], Andrew Mackenzie[1,2], and Phil King[2] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]University of St Andrews, St Andrews, UK — [3]Max IV, Lund, Sweden

Ruthenium dioxide has a rich band structure, giving rise to phenomena like superconductivity under strain and hosting a Dirac nodal line network. Recent studies also found that the material hosts flat band surface states and unusual spin-polarisations. These phenomena motivate the need for more detailed studies into its electronic structure. ARPES would be an ideal probe for this, and there have been several pioneering studies to date. However, the material's strongly three-dimensional structure makes these experiments challenging because of difficulties both in preparing the required atomically flat and clean surfaces, and in disentangling bulk from surface states in the electronic structure. Here, we exploit a fabrication method based on Focused Ion Beam (FIB) structuring to stimulate cleaving along desired crystallographic planes. With this method, we obtained high quality surfaces in two distinct orientations, allowing high-resolution ARPES experiments. From this, and supporting density-functional calculations, we identify a rich hierarchy of bulk and surface states in this system and uncover a strong influence of structural relaxations and surface stoichiometry on the electronic states that form.

O 77: Nanostructures at surfaces:1D, 2D, networks II

Interplay of flexibility, coverage, and host-guest interaction in the self-assembly of Tris(4-carboxyphenyl)amine (TCA) on Au(111) — Vishakya Jayalatharachchi[1], •Paul Philip Schmidt[1], Roberto Robles[2], Nicolas Lorente[2], Meike Stöhr[1,3], and Sabine Maier[1] — [1]Department Physik, FAU Erlangen-Nürnberg, Erlangen, Germany — [2]CFM/MPC (CSIC-UPV/EHU), Donostia-San Sebastián, Spain — [3]University of Applied Sciences of the Grisons, Switzerland

Triphenylamine derivatives are attractive building blocks for molecular architectures owing to their strong electron-donating properties, structural versatility, and ability to form highly ordered structures. Here, we explore how the non-planar and conformationally flexible arms of the unbridged threefold-symmetric TCA influence its self-assembly on Au(111), with particular emphasis on the formation and stability of porous networks. Using a combination of STM, LEED, and DFT, we show that RT deposition of TCA on Au(111) produces a coexistence of hexagonal porous domains and close-packed structures. Upon subsequent annealing, well-ordered porous networks emerge, stabilized by the dimeric carboxylic acid bonding motif. At higher coverage, this motif persists but instead directs the formation of close-packed assemblies. These findings provide insights into the interplay between molecular flexibility, intermolecular interactions, and coverage in directing supramolecular architectures of unbridged triphenylamines on metal surfaces. In addition, we show on the example of molecular rotors the hosting properties of the porous TCA network.

O 77.2 Thu 10:45 HSZ/0204

Revealing and manipulating correlated protons in one-dimensional hydrogen-bonded chains at the atomic scale — •Yiqi Zhang — Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China

Hydrogen-bonded systems such as water and ice exemplify highly cooperative proton dynamics, where covalent bonds are broken and formed in a concerted fashion. Yet directly probing and controlling many-body proton configurations at the atomic scale remains challenging. Here, using bond-resolved atomic force microscopy and spectroscopy, we reveal multistate proton ordering in self-assembled one-dimensional chains of an imidazole derivative on a noble metal surface. In as-grown chains of varying length, we consistently identify an interior species bonded to an extra proton, forming a localized imidazolium cation (state 1). Selective removal of a single proton from either chain end triggers a collective rearrangement of protons, yielding unidirectional hydrogen-bonding along the entire chain (states 2 or 3). Further deprotonation creates a proton vacancy, enabling reversible switching of hydrogen-bonding directionality (states 4 and 5) via collective proton hopping above a threshold bias voltage. In conjunction with density functional theory calculations, we elucidate the microscopic origin of complex proton ordering in hydrogen-bonded chains and the correlated motion of multiple protons.

O 77.3 Thu 11:00 HSZ/0204

On-Surface Synthesis of a Janus Polyazaacene — •Faming Kang, Tim Naumann, Zilin Ruan, Ye Liu, and J. Michael Gottfried — Fachbereich Chemie, Philipps-Universität Marburg, Hans-Meerwein-Str. 4, 35032 Marburg, Germany

Acenes are a fascinating class of polycyclic aromatic hydrocarbons that have gained considerable research interest due to their potential application in organic electronics as well as their role in advancing fundamental knowledge about conjugated aromatic systems. Isosteric exchange of CH units of the acenes by nitrogen atoms formally gives azaacenes. The nitrogen substitution pattern, i.e., the number, position, and type of nitrogen atoms enables topological design of azaacenes, which facilitates precise tuning of frontier orbital energy level alignment and radical characters. Guided by topological considerations, introducing distinct edge structures on either side further creates Janus azaacenes. Here, we successfully synthesized a Janus polyazaacene on the Au(111) surface, in which one edge was decorated by nitrogen atoms while the other edge keeping unchanged. The length of such a polymer chain can reach up to 50 rings. Using scanning tunneling microscopy, we characterized its geometric structure and electronic property on Au(111), as well as its stability in air.

O 77.4 Thu 11:15 HSZ/0204

Modeling the Registry of Molecular Adsorbates on Solid Surfaces — •David Ari Hofmeister[1], Christian Erik Selzer[2], Laura zur Horst[1], Simon Christian Rickert[1], Julia Kohn[2], Andreas Hansen[2], Stefan-Sven Jester[1], and Sigurd Höger[1] — [1]Kekulé-Institut für Organische Chemie und Biochemie, Rheinische Friedrich-Wilhelms-Universität Bonn, Bonn (Germany) — [2]Mulliken Center for Theoretical Chemistry, Rheinische Friedrich-Wilhelms-Universität Bonn, Bonn (Germany)

Rationalizing the adsorption behavior of large organic molecules on crystalline substrates is crucial for the design of functional surfaces in supramolecular chemistry, catalysis, and electronics. Conventional quantum-chemical approaches often fail for large π-conjugated systems due to their size and conformational flexibility. Here, we present a physically intuitive and generalizable method that overcomes these limitations by optimizing the molecular registry through a geometry-based strategy: maximizing the overlap between surface-oriented hydrogen atoms ("spikes") and the periodic "pockets" defined by the hexagon centers of HOPG. Inspired by the Groszek alkane-on-graphite model, our approach extends to structurally complex architectures and assigns adsorption geometries with high resolution without costly computations. Combining registry scoring with STM data allows the determination of absolute atropisomer conformations, demonstrating that geometric registry is a broadly applicable metric for predicting the surface arrangements of large molecules.

O 77.5 Thu 11:30 HSZ/0204

Low Dimensional Assemblies of Endohedral Fullerenes on Surfaces — •Lukas Emanuel Spree[1,2], Caroline Hommel[1,2], Pierre Josse[1,2], Justyna Piwowar[1,2], Robert Ranecki[1,2], and Andreas Heinrich[1,3] — [1]IBS Center for Quantum Nanoscience, Seoul, South Korea — [2]Ewha Womans University, Seoul, Republic of Korea — [3]Department of Physics, Ewha Womans University, Seoul, Republic of Korea

Scanning probe microscopy techniques like STM and AFM facilitate the characterization of atoms and molecules on flat substrates with nearly unrivaled spatial resolution. Utilizing the strengths of these techniques, our team is looking to build custom molecular structures in a bottom-up manner and characterize their physical properties.

The main focus of this work is on endohedral fullerenes, a class of compounds that facilitate the stabilization of exotic configurations of few-atom structures within a carbon cage. Among them are some of the best single molecule magnets discovered to date, as well as promising candidates for spin-qubits. These desirable traits are combined with very high chemical stability. Utilizing the physical properties of these fascinating compounds is limited by two main issues: synthetic yield and, to a lesser degree, crystalline order. Both can be addressed elegantly by focusing on their properties in low dimensional arrangements, like monolayers or single molecules on ultraflat surfaces.

In this presentation we will detail our ongoing efforts of utilizing a broad range of deposition techniques, molecule manipulation on the surface, and chemical self-assembly approaches.

O 77.6 Thu 11:45 HSZ/0204

Electronic Modulation by the Sc3N Cluster in Endohedral Fullerene Sc3N@C80 — •Seong-Hyun Hong[1,4], Dmitriy Borodin[1,2], Lukas Spree[1,2], Andrés Pinar Solé[1,2], Caroline Hommel[1,2], Merve Ercelik[1,2], Shinjae Nam[1,2], Robert Ranecki[1,2], Fabio Donati[1,3], Se-Jong Kahng[4], and Andreas Heinrich[1,3] — [1]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS) — [2]Ewha Womans University — [3]Department of Physics, Ewha Womans University — [4]Department of Physics, Korea University

Endohedral fullerenes such as Sc3N@C80 present a unique platform to study confined molecular systems, where the behavior of an enclosed cluster can strongly influence the properties of the surrounding cage. Understanding how the Sc3N cluster interacts with the carbon framework at the submolecular level is essential, but direct observation of these interactions remains challenging due to existence of carbon cage.

Here, we combine low-temperature scanning tunneling microscopy (STM) and atomic force microscopy (AFM) with a CO-functionalized tip to investigate Sc3N@C80. Using scanning tunneling spectroscopy (STS) and Kelvin probe force microscopy (KPFM), we map the charge distribution across the fullerene with submolecular resolution, revealing how the Sc3N cluster modulates the electronic structure of the cage. This approach provides significant insight into the interplay between core position and molecular charge distribution, uncovering details of the inner cluster that were previously unclear.

O 77.7 Thu 12:00 HSZ/0204

Ferroelectric vortices in elemental Bismuth square islands — •Shasha Xue and Hao Zheng — Tsung-Dao Lee Institute, Shanghai Jiao Tong University, Shanghai, China

Ferroelectric vortices, with their unique topological polarization patterns, show great potential for next-generation electronics. Although they have been observed in compounds, their realization in single-element materials has remained elusive. Here, we experimentally prepare three-bilayer Bi(110) square-shaped islands on high-T_C superconductor ($Bi_2Sr_2CaCu_2O_{8+\delta}$) substrates by molecular beam epitaxy. Scanning tunneling microscopy/spectroscopy combined with first-principal calculations verify in-plane polarization and a ferroelectric vortex state in our islands, as well as reveals exceptional vortex stability against electric-field-driven switching. This work pioneers single-element ferroelectric vortices, advances topological ferroelectrics design and expands the understanding in related fundamental physics.

The Wendelstein 7-X plasma vessel vacuum system from a scientific perspective — •Georg Schlisio[1], Torsten Bräuer[1], Stylianos Varoutis[1], Paul McNeely[1], Dirk Hartmann[1], Chandra Prakash Dhard[1], Dirk Naujoks[1], Victoria Hak[1], and the W7-X team[2] — [1]Max-Planck-Institut für Plasmaphysik, Teilinstitut Greifswald — [2]See author list of O. Grulke et al. Nuclear Fusion, 64(11), 112002 (2024)

Wendelstein 7-X (W7-X) is the world's most advanced stellarator, a long-overlooked concept for magnetic confinement fusion. Fusion devices require excellent vacuum conditions to minimize impurity influx and charge-exchange losses during high-temperature plasma operation. The W7-X plasma vessel vacuum system comprises the main vessel, 254 vacuum ports, and several auxiliary diagnostic vacuum systems, the largest of which is the Neutral Beam Injection (NBI) system.

We describe the W7-X plasma vessel vacuum system and its instrumentation for total and partial pressure measurements. A key parameter for valve and gauge calibration, as well as for exhaust quantifi- cation, is the effective plasma-vessel volume; we outline an approach for determining this volume with sufficient pre-

cision. We also report experimentally derived pumping speeds of the turbomolecular pumps (TMPs) and cryo vacuum pumps (CVPs), which are essential inputs for modelling and exhaust analysis.

As an application of these capabilities, a recent study of gas-species transport in the sub-divertor region is shown, comparing experimental measurements with modelling results.

O 78.2 Thu 11:00 HSZ/0401

Pulsed Molecular Beam Reactive Scattering for Investigation of Surface Chemical Reactions — •Oleksandr Arsatiants, Tobias Hinke, Kevin Bertrang, and Ueli Heiz — Chair of Physical Chemistry, Technical University of Munich, Lichtenbergstr. 4, 85748 Garching, Germany

Molecular beam reactive scattering (MBRS) is a powerful technique for investigating surface reactions on defined surfaces in UHV, providing complementary results to single-cycle experiments like thermal desorption spectroscopy (TDS) [1]. Pulsed MBRS is especially promising, as it can be used to investigate surface reaction kinetics under quasi steady-state conditions [2-5]. For molecules with complex MS fragmentation patterns, however, the short time scales present a challenge due to mass switching delays. Ongoing work on automation of p-MBRS measurements for rapid mass switching will be presented.

O 78.3 Thu 11:15 HSZ/0401

Advancing Ultra-Clean Deposition of Fragile Molecular Building Blocks via Electrospray-Based Controlled Ion Beam Deposition — •Andreas Walz[1,2], Annette Huettig[1,2], Michael Walz[1,2], Hartmut Schlichtung[1,2], Patrick Lawes[2], and Johannes V. Barth[2] — [1]pureions GmbH, Gilching, Germany — [2]Technical University of Munich, Physics E20, Garching, Germany

The fabrication of functional nanostructures from organic, inorganic, or biorelevant molecular building blocks regularly requires clean and gentle deposition in vacuum. Conventional approaches such as thermal evaporation (MBE, OMBE) are restricted to volatile species, while solution-based deposition techniques offer versatility but frequently suffer from impurities.

Controlled Ion Beam Deposition (CIBD) in UHV, equipped with an electrospray ionization (ESI) source overcomes these limitations by granting access to a broad class of large, reactive, and fragile species including functionalized organic molecules, graphene nanoribbons, proteins, and DNA. Efficient ion transfer and mass selection is ensured through fully digitally driven ion guides and a digital quadrupole mass filter (dQMF) with "virtually unlimited" mass range. Control over kinetic energy and dose allow for soft-landing or, when desired, reactive landing of the building blocks.

We present advances in ES-CIBD instrumentation and exemplary STM/AFM characterization of depositions. The technology provides a high degree of control during depositions, clean layers of mass selected molecules and access to otherwise low processability material.

O 78.4 Thu 11:30 HSZ/0401

Temperature-Programmed Spectroscopy: A Novel Tool for Kinetic and Mechanistic Studies for Processes on Surfaces — •Robert Bavisotto and Wilfred Tysoe — Department of Chemistry and Biochemistry, University of Wisconsin-Milwaukee, Milwaukee, WI 53211, USA

Advances in computational chemistry have facilitated the integration of theoretical calculations to complement experimental findings. However, since computational methods depend on many approximations and variables, they require careful validation, which in the case of experimental validation can be challenging or unfeasible. For example, activation barriers are often predicted using climbing nudged elastic band calculations, whose benchmarking has traditionally relied on temperature-programmed desorption, a technique inherently sensitive only to processes that produce gas-phase products. To establish a surface-selective experimental approach capable of probing kinetic processes directly on surfaces without requiring gas-phase products, a suite of innovative spectroscopic techniques is introduced. These methods, collectively referred to as temperature-programmed spectroscopy (TPS), rely on precise control of sample conditions, enabling surface spectroscopic data to be collected quasi-continuously. These novel analytical tools can be easily combined with existing spectroscopic methods, such as IR or XPS, without the need for new capital equipment. This capability enables the detection of subtle changes over short time intervals, thereby facilitating kinetic measurements of surface-based processes that were previously unverifiable.

O 78.5 Thu 11:45 HSZ/0401

Traceable outgassing rate measurements of sticky gases — •Matthias Bernien[1], Annas bin Ali[1], Janez Šetina[2], and Karl Jousten[1] — [1]Physikalisch-Technische Bundesanstalt (PTB), Berlin, Germany — [2]Inštitut za kovinske materiale in tehnologije (IMT), Ljubljana, Slovenia

In the semiconductor industry, the outgassing of components in vacuum must be well controlled. These contaminants are monitored using quadrupole mass spectrometry. However, quantitative measurements of the amount of contamination are challenging as quadrupole mass spectrometers (QMSs) inherently lack stability of their sensitivity. To provide comparability and traceability of outgassing rate measurements, processes and transfer standards must be established. PTB together with IMT and industrial partners have developed and characterized outgassing reference samples for dodecane and water. These reference samples consist of a reservoir sealed with an elastomer through which the liquids permeate into vacuum. The reference samples provide well-defined outgassing rates that are used to calibrate QMSs in situ for water and hydrocarbon contaminants. When using sticky gases like water and dodecane, a significant amount of gas molecules adsorbs on the inner surfaces of the vacuum chamber. A numerical model is utilized to simulate the dynamics of the adsorbed phase and the gas phase.

O 78.6 Thu 12:00 HSZ/0401

A dynamic analysis of the static friction in microscopic Hertzian contacts: Size effects and 2D-material assisted superlubricity — •Ahmed Uluca[1,2], Pierce Sinnott[1,2], and Graham Cross[1,2] — [1]School of Physics, Trinity College Dublin, Dublin, Ireland — [2]CRANN, Trinity College Dublin, Dublin, Ireland

Friction governs how objects start to move, yet our understanding still relies on empirical laws that vary across materials and length scales. To build a more fundamental picture, we focus on the interfacial shear strength (ISS)-a concept adapted from fracture mechanics that describes friction in terms of shear stress over the contact area.

We developed a mesoscale dynamic analysis method capable of probing contact radii from tens of nanometers to micrometers with sub-nanometer displacement and 10-nanonewton force resolution. Starting from static contact, we gradually increase lateral oscillation amplitude while tracking contact radius and laterally stuck zone radius. This enables us to monitor the transition from sticking to sliding in real time while simultaneously measuring contact radius.

Using diamond-fused silica pairs, we map ISS across pressures from tens of MPa to several GPa and compare the results with theoretical models spanning from the Peierls (lattice) stress to the upper bound of a perfectly commensurate interface. Our findings reveal a pressure and scale dependent shear strength that is consistent with the dislocation emission models, extended to include the effects of deformation mode, nanoroughness, junction growth and interfacial modification by graphene layers.

Time: Thursday 10:30–12:15 Location: HSZ/0403

O 79.1 Thu 10:30 HSZ/0403

Cavity control of multiferroic order in the single-layer NiI_2 — •Chongxiao Fan[1,2], Emil Viñas Boström[1], Xinle Cheng[1], Lukas Grunwald[1], Dante Kennes[2], and Angel Rubio[1,3] — [1]Max Planck Institute for the Structure and Dynamics of Matter — [2]Institute for Theory of Statistical Physics, RWTH Aachen University — [3]Initiative for Computational Catalysis, Flatiron Institute

Controlling materials in thermal equilibrium, through their interactions with quantum fluctuations of the electromagnetic field, is a promising new frontier in material engineering. Although recent experiments have demonstrated cavity effects in charge density wave, quantum Hall systems and superconducting systems, a smoking gun experiment is lacking for magnetic systems. To a large extent this comes from the focus on discontinuous phase transitions (e.g. from antiferro- to ferromagnetic), where a large light-matter coupling is required for cavity modifications to be observable. Here, we instead propose spiral magnets as a promising platform to explore cavity effects, where even a small cavity-mediated change in magnetic interactions is directly reflected in a change of the spiral wavelength. For concreteness we focus on the single-layer multiferroics NiI_2 and $NiBr_2$, with the surface phonon polaritons of the paraelectric substrate $SrTiO_3$ acting as the cavity. We show that the surface cavity suppresses the ratio J_3/J_1 of the third nearest and next nearest neighbor exchange interactions,

leading to a increase of the spiral wavelength and the eventual transition into a ferromagnetic state. Our work proposes a realistic platform to observe cavity renormalization effects in magnetic systems.

O 79.2 Thu 10:45 HSZ/0403

Compressing few-cycle optical near fields in the tip-sample junction of a scanning probe microscope — •Sam S. Nochowitz, Tom Jehle, Juanmei Duan, and Christoph Lienau — Institute of Physics, University of Oldenburg, 26129 Germany

Plasmonic nanogaps confine light to dimensions in the nanometer or even subnanometer range while simultaneously enhancing the local electromagnetic field strength. This spatial confinement of light led to dramatic advances in nanosensing (1) and tip-enhanced Raman Spectroscopy. So far, the time dynamics of the fields emitted from such nanocavities have achieved little attention. Here, we introduce a broadband interferometric scattering-type SNOM technique to reconstruct amplitude and phase of light scattered from a sharp gold taper acting as a near-field probe. We isolate the near-field that is scattered from the apex and quantitatively measure its time structure (2). The apex field decays within 6 fs, a decay time mainly given by the radiative damping of the apex mode. Upon approaching the tip to a gold surface, the coupling of the apex field to its image dipole results in 2-fold reduction in the decay time to less than 2.7 fs, caused by phase shifts in the apex response, predicted in FDTD simulations (3). Our results pave the way towards linear and nonlinear ultrafast oscilloscopy with nm/fs resolution. (1) R. J. Chikkardy et al., Nature 535, 127 (2016); (2) T. Jehle, submitted (2025). (3) S. Thomas et al. New J. Phys. 17 (2015).

O 79.3 Thu 11:00 HSZ/0403

Symmetry Guidelines of Vacuum Cavity Material Engineering — •Jingkai Quan[1], Chongxiao Fan[1], Benshu Fan[1], I-Te Lu[1], and Angel Rubio[1,2] — [1]Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761, Hamburg, Germany — [2]Center for Computational Quantum Physics, Flatiron Institute, Simons Foundation, New York City, New York, 10010, USA

Cavity material engineering, which manipulates material properties by exploiting vacuum-fluctuating photon modes in dark cavities, is a rapidly advancing field. Despite significant progress, most studies focus on isolated combinations of materials and cavity modes. In this study, based on a comprehensive group theory analysis, we develop a general framework for cavity material engineering with linearly polarized vacuum photon modes. We analyze the symmetry of the effective photon-free Hamiltonian inside dark cavities and establish a complete symmetry-breaking characterization induced by cavity photon modes across all 32 crystalline point groups. Building on this analysis, we predict phenomena such as the degeneracy lifting and emergence of new infrared and Raman spectral features induced by cavity modes. More intriguingly, we reveal a previously overlooked effect: cavity-induced polarization in non-polar crystals, and derive the corresponding tensor forms. These predictions are validated through advanced quantum-electrodynamical density-functional theory (QEDFT) calculations. Our work uncovers the fundamental symmetry principles governing light-matter interactions in the dark cavity and provides a systematic roadmap for future researches in cavity material engineering.

O 79.4 Thu 11:15 HSZ/0403

Low temperature near-field fingerprint spectroscopy of 2D electron systems in oxide heterostructures and beyond — Julian Barnett[1], Konstantin Wirth[1], Richard Hentrich[2], Yasin C. Durmaz[2], Felix Gunkel[3], Marc-Andre Rose[3], and •Thomas Taubner[1] — [1]I. Institute of Physics (IA), RWTH Aachen University — [2]Attocube Systems AG, Munich — [3]PGI-7, Forschungszentrum Jülich

Scattering-type scanning near-field optical microscopy (s-SNOM) is a useful tool for the non-destructive investigation of buried confined electron systems with nanoscale resolution, however, a clear separation of carrier concentration and mobility was often not possible. Here, we predict a characteristic fingerprint response of the LaAlO3/SrTiO3 2DEG in the mid-infrared spectral range, which was not experimentally accessible in the past, and verify this using a state-of-the-art tunable narrow-band laser in cryo-s-SNOM at 8 K [1]. Our modeling allows us to separate the influence of carrier concentration and mobility on fingerprint spectra and to characterize 2DEG inhomogeneities on the nanoscale. We show that our fingerprint spectra are a universal feature and generally applicable to confined electron systems, like topological insulators or stacked van-der-Waals materials.

O 79.5 Thu 11:30 HSZ/0403

Tunable skyrmion, meron, and skyrmion bag topologies in surface phonon polariton lattices — •Julian Schwab[1], Florian Mangold[1], Bettina Frank[1], Timothy J. Davis[1,2], and Harald Giessen[1] — [1]4th Physics Institute, Research Center SCoPE, and Integrated Quantum Science and Technology Center, University of Stuttgart, Germany — [2]School of Physics, University of Melbourne; Parkville Victoria 3010, Australia

Surface phonon polaritons (SPhPs) enable nanoscale manipulation of mid-infrared light via deeply subwavelength topological vector textures, such as skyrmions. Achieving dynamic, real-time control over these topological features remains challenging. Here, we theoretically propose and numerically demonstrate an actively tunable platform on a silicon carbide membrane that creates diverse topological lattices, including skyrmions, merons, and skyrmion bags. By exploiting the sublinear SPhP dispersion, we dynamically adjust the excitation wavelength to tune the topological character of the lattices. This allows for the tunability between bubble-type and Néel-type configurations in the electric field and the spin angular momentum. Furthermore, we identify a novel singularity-type meron arising from the interplay of electric and magnetic spin components. This texture exhibits topological charge conservation in moiré superlattices and a spatially confined spin reversal with tunable lateral sizes as low as $\lambda_{SPhP}/29$. These findings provide a versatile framework for on-chip, reconfigurable topological photonic devices with potential applications in high-resolution imaging and precision metrology.

Raman Studies of Proximity Effects in Epitaxial Graphene: Emphasis on Strong Light-Matter Coupling — •Zamin Mamiyev, Narmina O.Balayeva, Dietrich R.T. Zahn, and Christoph Tegenkamp — Institut für Physik, Technische Universität Chemnitz

Proximity engineering provides a route to tailor the electronic and vibrational properties of epitaxial graphene without introducing structural disorder. Because phonons and electronic states in graphene are strongly coupled, Raman spectroscopy provides a reliable approach to studying the quasiparticle dynamics and their modification in graphene.

In this work, we investigate how Sn and In intercalation, their nanoscale distributions, and the resulting interfacial reconstructions modify the phonon dynamics of quasi-free monolayer graphene on SiC(0001), particularly focusing on the plasmonically enhanced light-matter interaction regimes, such as in surface- (SERS) and tip- (TERS) enhanced Raman spectroscopies. Using resonance μ-Raman and TERS, we map the charge doping, electron-phonon coupling, and anharmonicities with high spectral and spatial resolution. Combined with electron diffraction, scanning tunneling microscopy (STM), and atomic force microscopy (AFM), our measurements allow us to study the optical fingerprints of strain, charge transfer, and symmetry-breaking that originate from distinct metal-intercalated interfaces and confined 2D metallic layers [1-2]. Inelastic electron-light interaction probed by holographic scanning transmission electron microscopy — •Tim Dauwe[1,2], Nora Bach[1,2], Murat Sivis[1,2], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, University of Göttingen, Germany

Ultrafast Transmission Electron Microscopy (UTEM) is a unique tool to study inelastic electron-light scattering (IELS). Photon-Induced Near-Field Electron Microscopy (PINEM) can now routinely image optical fields at laser-excited nanostructures in magnitude. Phase-resolved imaging is enabled by sequential interactions [1,2]. However, this requires an elaborate geometry with multiple optical interaction stages and offers only limited variability in tailoring the interaction. In this work, we combine IELS with a STEM holography approach, using two spatially separated, coherent electron probes [3]. By recording the interference pattern in the far field behind an electron spectrometer, we get simultaneous access to the energy of the electrons and the phase imprinted during the inelastic interaction. Our results from two interfering quantum walks reveal exotic electron states governed by interaction strengths and relative phase differences. Our approach further enhances the UTEM near field imaging capabilites and enables tailoring of electron states by multiple parallel electron-light interactions.

Surface chemistry of silicate minerals at the atomic scale — Luca Lezuo[1], Andrea Conti[1], Alexander Hoheneder[1], Elena Vaníčková[2], Domitilla Aloi[1], Rainer Abart[3], Florian Mittendorfer[1], Michael Schmid[1], Ulrike Diebold[1], and •Giada Franceschi[1] — [1]Inst. Appl. Phys., TU Wien, Austria — [2]CEITEC, Brno, Czechia — [3]Dept. Lithospheric Res., Uni Wien, Austria

Silicate minerals underpin key processes in geochemistry, atmospheric science, and materials technology, yet their atomic-scale surface chemistry remains insufficiently understood. Their intrinsic heterogeneity and electrical insulation have limited experimental characterization, leaving most mechanistic insight to simulations. Here, we extend the capabilities of noncontact atomic force microscopy (ncAFM) in ultrahigh vacuum to achieve atomic and chemical resolution on natural silicates such as muscovite mica,[1,2] feldspar microcline[3] and wollastonite.[4] Our measurements provide direct evidence for processes central to mineral reactivity, such as ion hydration, ice nucleation, and carbonation reactions. They demonstrate that ncAFM affords fundamental insights previously restricted to theory and offer benchmark data to guide and challenge emerging computational models of mineral-gas interactions.

O 80.2 Thu 11:00 TRE/PHYS

First Principles Investigations of Energy Dissipation Processes during Atom-Surface Collisions — •Nils Hertl[1,2] and Reinhard J. Maurer[1,2,3] — [1]Department of Chemistry, University of Warwick, Coventry, UK — [2]Department of Physics, University of Warwick, Coventry, UK — [3]Department of Physics, University of Vienna, Vienna, Austria

H atom scattering experiments have emerged as a powerful tool for selectively probing the energy transfer mechanisms between adsorbate and surface, which are relevant for adsorption—the first elementary step in heterogeneous catalysis. This typically includes both phonon and electron excitation in the substrate. Yet, the latter is challenging to model with molecular dynamics because it requires simulation techniques that go beyond the Born-Oppenheimer approximation. In this talk, I will demonstrate how combining electronic structure theory, machine learning, and non-adiabatic molecular dynamics enables a quantitative study of energy transfer between H atoms and surfaces across diverse material classes. I will show that the computed energy loss spectra agree well with experimental findings, enabling detailed characterisation of individual energy transfer channels as well as processes that are experimentally inaccessible, such as adsorption. Based on these findings, I will present a conceptual framework that links adsorbate and surface electronic structure to the probability for non-adiabatic effects to occur in gas-surface collisions.

O 80.3 Thu 11:30 TRE/PHYS

Exchange-driven magnetoelastic coupling in a correlated itinerant ferromagnet — •Carolina A. Marques[1], Luke C. Rhodes[1], Weronika Osmolska[1], Harry Lane[1], Izidor Benedičič[1], Masahiro Naritsuka[1], Siri A. Berge[1], Rosalba Fittipaldi[2], Mariateresa Lettieri[2], Antonio Vecchione[2], and Peter Wahl[1,3] — [1]SUPA, School of Physics and Astronomy, University of St Andrews, UK — [2]CNR-SPIN, c/o Università di Salerno, Italy — [3]Physikalisches Institut, Universität Bonn, Germany

The electronic properties of materials are the result of the complex relationship between lattice and electronic degrees of freedom. In magnetic materials, exchange interactions leads to magnetoelastic coupling, whose effect can be enhanced by the presence of electronic correlations. In the itinerant ferromagnet $Sr_4Ru_3O_{10}$, its magnetic and electronic properties are strongly influenced by electron correlations driven by Van Hove singularities close to the Fermi level. Here, we detect changes to the electronic structure, magnetic ground state and lattice in $Sr_4Ru_3O_{10}$ using scanning tunneling microscopy and spectroscopy (STM/STS). By switching between ferromagnetic and anti-ferromagnetic alignment of the magnetization of the surface and subsurface layers, we study the impact of exchange interaction on the electronic structure and detect jumps in the interlayer spacing, revealing giant exchange magnetostriction in $Sr_4Ru_3O_{10}$. Our measurements reveal a direct link between exchange interaction, electronic and crystal structures, providing a platform to test theoretical descriptions of strongly correlated electron materials.

O 80.4 Thu 12:00 TRE/PHYS

Effect of atomic-scale defects on light-matter interaction in transition-metal dichalcogenides — •Vibhuti N. Rai, Junyoung Sim, Florian Faaber, Sergey Trishin, Nils Bogdanoff, Paul Wiechers, Caroline Firschke, Tom S. Seifert, Tobias Kampfrath, Christian Lotze, and Katharina J. Franke — Freie Universität Berlin, Department of Physics, Arnimallee 14,14195 Berlin, Germany

Defects crucially affect the physical properties of (quasi-) two-dimensional materials, such as transition metal dichalcogenides (TMDCs). Here, by using THz scanning tunneling microscopy [1], we excite and detect long-range coherent in-plane shear and out-of-plane breathing modes on the surface of 2H-$MoTe_2$. We find that atomic-scale intrinsic defects influence their relative excitation efficiency. We attribute this response to local tip-induced band bending [2].

In the monolayer limit, where quantum confinement enhances defect sensitivity, we further show ultrafast charge modulation in defect sites of quasi-freestanding nanopatches of a monolayer MoS_2 on Au(111) driven by THz pulses. These insights into defect-mediated phonon excitation and charge transfer provide a pathway toward future ultrafast electronics.

Topological Dirac Quasiparticles Tailored by Moiré Engineering — •Maximilian Ünzelmann, Romana Ganser, Muthu Masilamani, Begmuhammet Geldiyev, and Friedrich Reinert — Exp. Physik VII and Würzburg-Dresden Cluster of Excellence ctd.qmat, Universität Würzburg, Germany

Moiré heterostructures have become a promising platform for tailoring electronic states in a highly controllable manner. The emergent superlattice potential gives rise to band gaps in the folded moiré band structure, which lead to a quenching of kinetic energy and thus increase of electron-electron interactions. Emergent flat bands have been observed in nano-focused angle-resolved photoemission spectroscopy (ARPES) experiments and demonstrated to trigger correlation-driven phenomena. Here, we go beyond the mere creation of flat bands and demonstrate that surface moiré engineering allows transforming a 'simple' epitaxial monolayer-substrate heterostructure into topological Dirac matter. In particular, using ARPES experiments, we will (i) prove the existence of one-dimensional Dirac fermions in the moiré-driven band structure, (ii) show that those are robustly protected by the emergent superlattice symmetry, and (iii) demonstrate how the entire mini-band structure can be controlled by epitaxial manners and sample temperature. Overall, this expands the potential of moiré materials by shifting the focus from almost exclusively flat bands to the creation of new, highly controllable Dirac quasiparticles.

Pd/Cu single atom alloys for selective alcohol dehydrogenation: from single crystalline to nanostructured model catalysts — •Philipp Alexander Fredersdorff[1], Jan Smyczek[1], Carsten Schroeder[1], Paul Froehlich[1], Paul Kohlmorgen[1], Stephan Appelfeller[2], Konstantin Neyman[3], and Swetlana Schauermann[1] — [1]Institute of Physical Chemistry, University Kiel, 24118 Kiel, Germany — [2]MAX IV Laboratory, Lund University, 22100 Lund, Sweden — [3]Departament de Ciència de Materials i Química Física & Institut de Química Teòrica i Computacional (IQTC-UB), Universitat de Barcelona, Barcelona 08028, Spain

Single-atom alloy (SAA) catalysts offer atomic-level control of selectivity, yet structure reactivity relationships in realistic systems remain insufficiently understood. Here, we report the first preparation of well-defined Pd/Cu single-atom alloy nanoparticles under UHV on Al2O3/NiAl(110) and investigate their properties using IRAS CO titration, STM, and TPD. Temperature-dependent Pd de-aggregation shows the same behaviour as on Pd/Cu(111), with optimal incorporation at 550 K. Both de-aggregated materials catalyze the non-oxidative dehydrogenation of butanol, but only the nanostructured Pd/Cu-NP SAA achieves 100 percent selectivity, completely suppressing CO formation. A Pd-coverage-dependent analysis reveals that cluster formation rapidly decreases aldehyde selectivity on single-crystal Pd/Cu(111), whereas the newly developed nanostructured SAA catalysts maintain full selectivity across a wide Pd range.

O 81.2 Thu 10:45 TRE/MATH

Acetylene Cyclotrimerization to Aromatic Products on Coinage Metal Surfaces — Nipun T. S. K. Dewage[1], •Dennis Meier[1], Santu Biswas[2], Matthew M. Montemore[2], and E. Charles H. Sykes[1] — [1]Department of Chemistry, Tufts University, Medford, Massachusetts 02155, USA. — [2]Department of Chemical and Biomolecular Engineering, Tulane University, New Orleans, Louisiana 70118, USA.

Benzene and toluene are indispensable chemical feedstocks used in products ranging from pharmaceuticals to building materials. They are primarily produced through petroleum cracking and reforming, which require high energy input, severe operating conditions, and lack 100% selectivity. As the chemical industry transitions from oil to shale gas as its primary hydrocarbon feedstock, interest is growing in alternative routes to synthesize aromatics. One promising approach is the cyclotrimerization of acetylene, which uniquely yields benzene with 100% selectivity on Ag(111) in ultra-high vacuum. However, this reaction requires more than a monolayer of acetylene to initiate benzene formation, necessitating high pressures that may limit industrial viability. In this work, we investigate strategies to enhance the activity of this reaction on coinage metal surfaces.

Automated Workflow for Kinetic Modeling in Heterogeneous Catalysis: A Case Study of the Ammonia Oxidation Reaction — •Emanuel Colombi Manzi, Hyunwook Jung, Hendrik H. Heenen, Vanessa J. Bukas, and Karsten Reuter — Fritz-Haber-Institut der MPG, Berlin

Developing reliable kinetic models in computational catalysis is a big challenge, especially when involving large reaction networks with complex intermediates. Atomistic models built upon first-principles energetics, typically density-functional theory (DFT), are widely used today for elucidating catalytic mechanisms and trends. The cost of DFT calculations, however, makes these models far too expensive to thoroughly sample the many structural configurations that are possible for all relevant surface-bound intermediates. As a result, assumptions on the preferred geometry or surface binding site are commonly adopted based on chemical intuition. Here, we present a fully automated workflow that derives an entire microkinetic model without any *a priori* knowledge or heuristics about the preferred binding configurations. The approach is demonstrated on the kinetics of NH_3 oxidation over selected metal surfaces and alloys. Enabled by an efficient DFT-trained machine learned interatomic potential, an ensemble of low-energy adsorbate structures is identified through global optimization and all process barriers between them are systematically computed. Our simulations provide chemical insight beyond the limitations of standard DFT models and open the road for large-scale screening studies without the need of simplifying assumptions like scaling relations.

O 81.4 Thu 11:15 TRE/MATH

Adsorption of CO and CO_2 on MgO(100) single-crystal surfaces investigated by polarization-resolved IRRAS — •Wangtao Li, Zairan Yu, Alexei Nefedov, Christof Wöll, and Yuemin Wang — Institue of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), 76344 Eggenstein-Leopoldshafen, Germany

MgO, a low-cost alkaline metal oxide material, is widely used in heterogeneous catalysis. Comprehensive understanding of MgO-based catalysts requires reliable reference data from surface science studies on MgO model systems. Here, we present polarization-resolved reflection absorption spectroscopy (IRRAS) data obtained for CO and CO_2 adsorption on MgO(100) single-crystal surfaces using a sophisticated UHV apparatus (THEO). The low-temperature (67 K) and temperature-dependent IRRAS results provide deep insights into the interaction of CO and CO_2 with MgO(100). The p- and s-polarized IRRAS data enable detailed analysis of vibrational frequencies, adsorption configurations, and binding energies of different species bound to distinct surface sites including defects. This work was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) - Project-ID 426888090 - SFB 1441.

O 81.5 Thu 11:30 TRE/MATH

Experimental Modelling of Ti-based (Photo-)Catalysts for the Activation of Greenhouse Gasses — •Lars Mohrhusen — Carl von Ossietzky Universität Oldenburg, Germany

Sustainable catalysts are key materials for future energy technologies and the activation of greenhouse gasses via thermal and photo-catalysis. To replace critical raw materials such as (noble) metals in (photo-)catalysts, we combine low-dimensional (semi-)metallic structures such as point defects or 2D materials with oxides to hybrid materials. Combined insights from spectroscopy, microscopy and reactivity studies on well-defined model systems under UHV or so-called operando conditions gains a comprehensive atomistic picture.[1–3]

Selected examples for such Ti-based materials relevant for solar photocatalysis will be presented. Therein, the activation of greenhouse gas molecules (esp. N_2O and CO_2) on Ti^{3+} and Ti^{2+} defects will be illuminated.[3,4] While such gases interact weakly with defective rutile TiO_2 in UHV, higher pressures of CO_2 combined with the presence of water as an H donor were found to enable a rich reduction chemistry along multiple parallel pathways in operando-XPS.[4] In addition to oxides, nanostructured 2D titanium disulphide (TiS_2) as well as conjugated organic polymers on metal and oxide surfaces represent potential candidates for photocatalytic applications.[5]

O 81.6 Thu 11:45 TRE/MATH

Studying low surface area photocatalysts at ambient pressure in a microreactor — •Paula Neumann[1], Clara Aletsee[2], Martin Tschurl[1], and Ueli Heiz[1] — [1]Chair of Physical Chemistry, School of Natural Sciences & Catalysis Research Center, Technische Universität München, Lichtenbergstr. 4, 85748 Garching, Germany — [2]SurfCat Section for Surface Physics and Catalysis, Department of Physics, Technical University of Denmark, 2800 Kgs Lyngby, Denmark

While driving reactions with solar light is an ambitiously pursued goal, current approaches often suffer from low efficiencies due to missing knowledge about reaction dynamics on the catalysts surface. Here, the application of highly defined photocatalysts may allow deeper mechanistic insight but their low surface area imposes high demands on detection sensitivity for studying reactions at ambient conditions. Our gas-phase microreactor enables time-resolved investigation of planar photocatalysts by mass spectrometry in a well-defined reaction environment. Using the photo-oxidation of alcohols on a titania photocatalyst as a model system we show how reaction mechanisms first established in the ultra-high vacuum transfer to conditions of 1000 mbar. Disentangling the mechanistics of alcohol photochemistry might be a crucial step towards improving hydrogen formation as an important energy carrier as well as opening up pathways for the production of higher-value chemicals.

O 81.7 Thu 12:00 TRE/MATH

Model-Free Reconstruction of Local Kinetic Information on Catalytic Surfaces from Operando Profile Measurements — •Jinyi Zhou[1], Mishai Avila[2], Daniel Runge[3], Lukas Thum[4], Heinz Junkes[1], Michael Geske[2], Christian Merdon[3], Frank Rosowski[2,5], Karsten Reuter[1], Christoph Scheurer[1], and Sebastian Matera[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]BasCat - UniCat BASF JointLab, TU Berlin — [3]Weierstraß-Institut, Berlin — [4]Helmholtz-Zentrum Berlin — [5]BASF SE, Catalysis Research, Ludwigshafen, Germany

Operando characterization experiments are typically strongly affected by transport effects, which can cause strong local variations of reactivity and concentration on the catalytic surface. We present a framework that allows one to obtain this local kinetic information from a measured concentration profile away from the active surface, without assuming any specific kinetic model. Utilizing Green's functions of the transport operator and a function space formulation of the inverse problem, the approach allows robust reconstruction from finite, noisy data. We apply this approach to a compact profile reactor, where concentration is measured along the axis of a channel flow with catalyst deposited on the channel walls. Using synthetic data, we demonstrate that the approach has the potential to resolve sub-millimeter variations in surface reactivity with modest computational and experimental footprints. Additional challenges that need to be overcome in order to fully exploit this potential for high accuracy when using experimental data will be discussed.

O 82: Focus Session: Unoccupied States by Inverse Photoemission III

The Other Half of the Picture: 50 Years of Direct Access to Unoccupied States by Inverse Photoemission

In 1981, J. Pendry evaluated the experimental access to electron states in solids: "Currently only half of the picture can be seen with photoemission. Inverse photoemission provides the other half." A complete picture of electron states needs both occupied and unoccupied states in order to describe, understand, and finally tailor macroscopic material properties. In 1976, V. Dose had submitted a first paper on Bremsstrahlung Isochromat Spectroscopy in the VUV range: "The physics involved may be most simply described as an inverse photoelectric effect." The first experiments provided surface-sensitive information on the density of unoccupied states. Later, momentum and spin resolution were added to investigate the spin-dependent E(k) dispersion of unoccupied electron states. During five decades, the technique was further developed by several groups worldwide to enhance the intensity and improve the resolution in energy, momentum, and spin. A wealth of information was gained about metals, semiconductors, ultrathin films as well as adsorbate systems. The experimental studies were accompanied by several theoretical approaches, which are able to accurately describe the unoccupied electronic structure and model the inverse photoemission process. In 2012, H. Yoshida extended the energy range to the near-UV range (low-energy inverse photoemission), which is especially suited to study organic samples due to a lower damage risk caused by the exciting electron beam.

Current research fields for inverse photoemission are, e.g., spin textures of exchange- and/or spin-orbit-induced influenced systems and topological insulators, gap structures in transition metal dichalcogenides, LUMO levels in semiconductors for photovoltaic applications, electronic structure of atomic-layer and quantum materials. This focus session will highlight recent advances obtained by inverse photoemission in different fields and material systems. Also, it will bring together researchers from different areas for addressing current trends and future applications of inverse photoemission from experimental as well as theoretical perspective.

Organized by Markus Donath, Fabian Schöttke and Peter Krüger (U Münster).

Low-energy inverse photoelectron spectroscopy (LEIPS): probing unoccupied states and conduction band structure in functional materials — •Hiroyuki Yoshida — Chiba University, Chiba, Japan

We developed low-energy inverse photoelectron spectroscopy (LEIPS) in 2012 [1] to enable damage-free probing of functional materials such as organic semiconductors, polymers and hybrid perovskites. By reducing the incident electron energy below the damage threshold (about 5 eV), LEIPS allows damage-free measurements while simplifying operation and improving energy resolution. By incorporating an electron energy analyzer [2], we achieved an energy resolution of 98 meV. LEIPS enables determination of electron affinity with an uncertainty of 0.1 eV. These precise values provide access to key parameters including band gaps, exciton binding energies, polarization energies, and electron injection barriers. The technique has been commercialized, and more than 100 systems are now in operation worldwide. We further developed angle-resolved LEIPS (AR-LEIPS) [3], enabling for the first time direct observation of conduction band structure in organic semiconductors [4]. The measured band structures yield insight into electron-phonon coupling and polaron formation relevant to carrier transport. [1] Chem. Phys. Lett. 539-540, 180 (2012). [2] Rev. Sci. Instrum. 94, 043908 (2023). [3] Rev. Sci. Instrum. 94, 063903 (2023). [4] Nat. Mater. 21, 910 (2022).

Invited Talk O 82.2 Thu 11:00 WILL/A317

Enhanced Sensitivity in Low-Energy Inverse Photoemission Spectroscopy with an Off-Axis Parabolic Mirror for Efficient Light Collection — •Yongsup Park[1,2], Jong-Am Hong[1], Kyu-Myung Lee[1], and Min-Jae Maeng[1] — [1]Dept. of Physics, Kyung Hee University, Seoul, Republic of Korea — [2]Dept. of Information Display, Kyung Hee University, Seoul, Republic of Korea

Inverse photoemission spectroscopy (IPES) is a powerful tool for studying unoccupied electronic states but suffers from low sensitivity due to the low photon emission probability during free electron transitions. To improve sensitivity via better photon collection, an off-axis parabolic (OAP) mirror was designed and built for low-energy IPES (LEIPS). Optical simulations showed the OAP mirror raised photon collection efficiency from 3.06% to 63.3%, confirmed experimentally through LUMO spectra of C60 thin films. The OAP mirror-LEIPS system was applied to study energy level alignment (ELA) of pentacene films on substrates with different work functions (WF). By measuring HOMO and LUMO levels, the changes in transport gaps and the ELA with respect to the Fermi level were analyzed. Pentacene showed n-type behavior on low WF substrate (Cs2CO3) and p-type on high WF substrate (ITO). This OAP mirror-enhanced LEIPS system significantly shortened experiment times, enabling efficient and reliable measurements.

O 82.3 Thu 11:30 WILL/A317

Development of angle resolved low energy inverse photoelectron spectroscopy for conduction band structure measurements of functional materials — •yuki kashimoto[1], satoshi ideta[1], haruki sato[1], keita kawamura[1], hibiki orio[1], and hiroyuki yoshida[1,2] — [1]chiba university, chiba, japan — [2]chiba university MCRC, chiba, japan

Understanding the energy band structure is essential for clarifying charge-transport behavior in solids. Although angle-resolved inverse photoelectron spectroscopy (ARIPES) can measure conduction bands, it is unsuitable for emerging materials such as organic semiconductors due to their narrow bandwidths and electron irradiation damage. Low-energy inverse photoelectron spectroscopy (LEIPS)[1] overcame these issues by reducing the electron kinetic energy. In this study, we advanced LEIPS and enabled band-structure measurements by introducing angle-resolved detection. Stray electric and magnetic fields were suppressed, and a dedicated low angular spread, energy-scannable electron source was implemented. This enabled angle-resolved LEIPS (AR-LEIPS) with 0.23 eV energy resolution and 0.94 nm^{-1} momentum resolution[2]. Using AR-LEIPS, we determined the conduction band structure of pentacene, the first such measurement for an organic semiconductor[3] and revealed the conduction-band dispersion of the photovoltaic perovskite $CH_3NH_3PbI_3$. [1] H.Yoshida, Chem. Phys. Lett. 539-540, 180 (2012). [2]Y.Kashimoto, H.Yoshida et al, Rev. Sci. Instrum. 94, 063903 (2023) [3] H. Sato, H. Yoshida et al, Nature Mat. 21,910 (2022).

O 82.4 Thu 11:45 WILL/A317

Observation of conduction band structure of conductive polymer PBTTT — •Taichi Suruga[1], Shunichiro Ito[2], Taishi Takenobu[2], and Hiroyuki Yoshida[1,3] — [1]Chiba University, Chiba, Japan — [2]Nagoya University, Nagoya, Japan — [3]Chiba University MCRC, Chiba, Japan

The most fundamental information regarding the electron transport mechanism of these polymers is the conduction-band structure. However, until now, we did not have the appropriate methods to measure it. In 2020, we developed angle-resolved low-energy inverse photoelectron spectroscopy (ARLEIPS) [1] and successfully measured the conduction band structure of small-molecule organic semiconductors for the first time [2]. In this study, we applied ARLEIPS to a conductive polymer. Fabricating crystalline thin films with well-aligned molecular orientation is essential for the ARLEIPS measurement. We fabricated thin films using the blade-coating method [3]. Using ARLEIPS, we observed the conduction-band structure of a conductive polymer, PBTTT-C14 [4,5], in oriented films. As predicted by the DFT calculations, the bands split into two and exhibited large dispersion along the Γ-Z direction. These results demonstrate the first observation of conduction-band in a conductive polymer. [1] Y. Kashimoto, H. Yoshida et al., Rev. Sci. Instrum, 94, 043908 (2023) [2] H. Sato, H. Ishii, H. Yoshida et al., Nat. Mater. 21, 910 (2022). [3] D. Delongchamp et al., ACS Nano. 3, 780 (2009). [4] H. Tanaka, K. Kanahashi, T. Takenobu et al., Sci. Adv., 6,

O 82.5 Thu 12:00 WILL/A317

Effects of Crystallization on the Electronic Structure of Discrete Oligomers — •Alexander Ehm[1], Rukiya Matsidik[2], Michael Sommer[2], and Dietrich R. T. Zahn[1] — [1]Semiconductor Physics and Research Center for Materials, Architectures and Integration of Nanomembranes (MAIN), TU Chemnitz, Chemnitz, Germany — [2]Polymer Chemistry, TU Chemnitz, Chemnitz, Germany

Recently, organic photovoltaic cell efficiency surpassed the 20 % landmark, thanks to the development and improved crystallinity of non-fullerene acceptor (NFA) molecules and suitable polymer donors [1]. Low exciton binding energies (EBE), measured by the difference of the transport gap and the optical bandgap, were attributed as key factors in such improvements [2].

Photoemission and low-energy inverse photoemission spectroscopy (PES and LEIPES) in combination directly measure the transport gap. However, challenges are posed by their surface sensitivity in conjunction with the solution processing, low conductivity and radiation sensitivity of thin films of large organic molecules.

Here, we address strategies to avoid surface contamination and charging effects, while investigating the interfacial electronic structure of conjugated discrete oligomer films [3] spin-coated on Ag substrates. Their thermal crystallization reduced their bulk EBE to < 0.1 eV.

O 82.6 Thu 12:15 WILL/A317

Development of near-ambient-pressure low-energy inverse photoelectron spectroscopy enabling measurement under the water vapor pressure — •Mihiro Kubo[1], Gaku Yokogawa[1], Hitoshi Tomizuka[2], and Hiroyuki Yoshida[1] — [1]Chiba University, Chiba, Japan — [2]TOYAMA Co., Ltd., Kanagawa, Japan

Inverse photoemission spectroscopy has evolved over fifty years, providing essential insight into the unoccupied electronic structure. In 2012, Dr. Yoshida developed low-energy inverse photoelectron spectroscopy (LEIPS[1]). This technique enables the measurement of organic materials without damaging the sample by reducing the kinetic energy below 5 eV, their typical damage threshold. To further extend the applicability of LEIPS, we are developing near-ambient-pressure LEIPS (NAP-LEIPS) capable of measurement under the vapor pressure of water (10^3 Pa). NAP-LEIPS will allow measurements of volatile samples, biomaterials, and catalysis with the introduction of reactive gases. To realize NAP-LEIPS, we use an electron gun with a yttria-coated disc cathode and an electrostatic energy analyzer. Because the electron source operates at pressures better than 10^{-5} Pa, a differential pumping system is installed between the electron source chamber and the main chamber (10^3 Pa). Electrons travel about 300 mm through the differential pumping section using an electrostatic transfer lens. Photons emitted from the sample are focused by a mirror, passed through a band-pass optical filter, and detected with a photomultiplier tube. The apparatus has been constructed and is currently in the start-up phase. [1] H. Yoshida, Chem. Phys. Lett. 539-540, 180 (2012).

O 83: Organic molecules on inorganic substrates: electronic, optical and other properties III

Spin-Crossover and Structural Correlation in Surface Confined Indigo-Based Fe-Coordination Polymers — •Mohammad Salehi[1], Aliki Soufla[2], Hongxiang Xu[1,5], Fulden Eratam[3], David A. Duncan[3,4], Tien-Lin Lee[3], Joachim Reichert[1], Johannes V. Barth[1], and Anthoula C. Papageorgiou[2] — [1]Technical University of Munich, DE — [2]National and Kapodistrian University of Athens, GR — [3]Diamond Light Source, UK — [4]University of Nottingham, UK — [5]Peking University, CN

Surface confined coordination polymers (CPs) exhibiting spin-crossover (SCO) behavior hold promise for molecular spintronics. By harnessing the natural dye indigo as a molecular building block, we investigated $[\text{Fe-indigo}]_n$ CPs on Ag(111). Sub-molecular resolution scanning tunnelling microscopy (STM) and atomic force microscopy (AFM) confirmed well-defined CPs. We employed Fe *L*-edge X-ray absorption near-edge spectroscopy and high-resolution Fe 2*p* soft X-ray photoelectron spectroscopy to probe the spin states of Fe-indigo CPs at different temperatures. The data analysis supports thermally activated spin-crossover behavior, as predicted by density functional theory calculations. Normal incidence X-ray standing wave analysis yielded varying adsorption heights of Fe centers. We correlate the spin state with structural variations, revealing the interplay between ligand fields and magnetic properties.

O 83.2 Thu 15:15 HSZ/0201

Probing pi-conjugation in functionalized pentacene via photoemission orbital tomography — Felix Otto[1], Andrei Matestskii[2], Maximilian Schaal[1], Elise Fürch[1], Jonas Brandhoff[1], Roman Forker[1], François C. Bocquet[2], Michael G. Ramsey[3], Serguei Soubatch[2], •Peter Puschnig[3], Frank Stefan Tautz[2], and Torsten Fritz[1] — [1]Institute of Solid State Physics, Friedrich Schiller University Jena, Germany — [2]PGI-3, FZ Jülich & RWTH Aachen University, Germany — [3]Institute of Phyics, University of Graz, Austria

Tuning the electronic structure of polycyclic aromatic hydrocarbons is an effective route to control their physical and chemical properties. Here, we present an experimental approach that enables direct assessment of how chemical functionalization modifies the conjugation length of adsorbed molecules. We demonstrate the method using pentacenequinone (P2O), a functionalized pentacene derivative that forms a self-assembled monolayer on Ag(110), as confirmed by low-energy electron diffraction and scanning tunneling microscopy. Employing photoemission orbital tomography, we combine experimental photoelectron momentum maps with density-functional-theory simulations to elucidate the character of the frontier molecular orbitals. Our results provide direct experimental evidence that the functional group in P2O disrupts the conjugation of the parent pentacene backbone, causing the electronic structure of P2O to resemble two electronically decoupled naphthalene units. This interpretation is further supported by the observed increase in the band gap upon functionalization.

O 83.3 Thu 15:30 HSZ/0201

Stochastic spin-state transitions in an Fe(II) spin-crossover complex on Cu(111) — •Jasmeen Jasmeen[1], Sujoy Karan[1], Karl Ridier[2], Reecht Gaël[1], and Manuel Gruber[1] — [1]Faculty of Physics and CENIDE, University of Duisburg-Essen, 47057 Duisburg, Germany — [2]2LCC, CNRS and Université de Toulouse, UPS, INP, 31077 Toulouse, France

Spin-crossover molecules can be switched between a low- (S = 0) and a high-spin (S = 1) state using external stimuli. Although the switching properties of crystalline powder were shown to strongly depend on the molecules environment, a full microscopic description is lacking. The switching of individual molecules in contact with a surface, evidenced in recent years, open new routes to further understand the impact of the local environment in the switching properties.

Using scanning tunneling microscopy at 4.5 K, we investigated the [Fe(HB(1,2,4-triazolyl)3)2] complex in direct contact with Cu(111) surface, focusing on the dynamics of its spin-state switching and the factors controlling switching behavior. The switching is triggered by injecting current at voltages above 0.5 V and monitored by the induced change in conductance.

We observe a drastic change of the switching yield with the local molecular environment, showing a clear dependence on both the number and the spin-state of neighboring molecules. These observations suggest that intermolecular interactions influence the switching efficiency.

Funding from the CRC 1242 is gratefully acknowledged.

O 83.4 Thu 15:45 HSZ/0201

Coordination and Molecular Band Dispersion of a 2D Metal-Organic Network — •Martin Anstett[1], Lu Lyu[2], Jannis Lessmeister[1], Alexander Schmid[2], Ralf Hemm[1], Vitaliy Feyer[3], Yan Yan Grisan Qiu[3], Simone Mearini[3], Martin Aeschlimann[1], and Benjamin Stadtmüller[2] — [1]Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, 67663 Kaiserslautern, Germany — [2]Experimentalphysik II, Institute of Physics, University of Augsburg, 86135 Augsburg, Germany — [3]Peter Grünberg Institute (PGI-6), Jülich Research Centre, 52428 Jülich, Germany

Two-dimensional metal-organic porous networks (2D-MOPNs) provide a versatile platform exploring emergent electronic and magnetic phenomena at designed surface nanoarchitectures. Here, we prepare a cobalt-coordinated hexaaza-triphenylene-hexacarbonitrile (HATCN) network on Ag(111) to fingerprint the role of metal centers in mediating electronic behaviour. Scanning tunnelling microscopy (STM) reveals an ordered network structure. Photoelectron momentum microscopy identifies a distinct hybrid interface state arising from the Co-mediated coupling with the molecules. These results reveal the microscopic mechanism underlying the role of metal centers in tailoring the electronic structures of 2D-MOPN systems.

O 83.5 Thu 16:00 HSZ/0201

Phthalocyanine-based bipartite lattices: Towards a molecular Lieb lattice — •Tzu-Chao Hung[1], Luis M. Mateo[2], Leo Gross[3], Diego Peña[2], and Jascha Repp[1] — [1]University of Regensburg, Germany. — [2]Universidade de Santiago de Compostela, Spain. — [3]IBM Research Europe - Zurich, Switzerland.

The Lieb lattice is a text-book example of topology governing material properties: Its sublattice imbalance gives rise to extended degenerate states resulting in a flat band. Here, we realize several different covalently bonded phthalocyanine (Pc)-based Lieb-lattice prototypical structures by means of on-surface synthesis. Bond-resolved atomic force microscopy images reveal planar structures with extended π-conjugation. Differential conductance maps, combined with density-functional theory calculations and tight-binding models, confirm strong intersite electronic coupling and quantum states with symmetry-enforced nodes and symmetry-protected degeneracy. Structures of increasing complexity allow exploring the evolu-tion of these symmetry-derived features.

O 83.6 Thu 16:15 HSZ/0201

Correlation-driven d-band modifications promote chemical bonding at 3d-ferromagnetic surfaces — •David Janas[1], Andreas Windischbacher[2], Alessandro Sala[3], Manuel Gruber[4], Mehdi Bouatou[4], Vitaliy Feyer[5], Iulia Cojocariu[5], Andrea Droghetti[6], Peter Puschnig[1,2], Giovanni Zamborlini[1], and Mirko Cinchetti[1] — [1]TU Dortmund University — [2]Karl-Franzens-University Graz — [3]CNR-Istituto Officina dei Materiali (IOM), Trieste — [4]University of Duisburg-Essen — [5]Elettra Sincrotrone Trieste — [6]Ca' Foscari University of Venice

Many-body effects at adsorbate-metal interfaces play a crucial but often overlooked role in designing spintronic and electrocatalytic materials. We recently showed that a chemisorbed oxygen layer on ferromagnetic (FM) Fe enhances electron correlation, causing narrowing of the Fe d-bands near the Fermi level, and a reduced exchange splitting, with direct implications for surface reactivity [1]. Here, we study a pentacene monolayer on oxygen-passivated Fe using momentum-resolved photoemission, scanning tunneling microscopy/spectroscopy, and Hubbard-corrected density functional theory (DFT+U) guided by dynamical mean-field theory (DMFT). Non-standard U values reproduce unexpectedly strong molecule-substrate interactions on a nominally passivated surface, highlighting the decisive role of electron correlation at organic/FM interfaces [2].

[2] Janas, D.M., et al. accepted in Small.

O 83.7 Thu 16:30 HSZ/0201

A quantum dot-functionalized scanning tunnelling microscope tip: Sensing through electron-vibron coupling — •Stefan Schulte[1,2,3], Emilio Scontrino[1,4], Taner Esat[1,3], F. Stefan Tautz[1,3,4], and Ruslan Temirov[1,2,3] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — [2]II. Physikalisches Institut, Universität zu Köln, Germany — [3]Fundamentals of Future Information Technology, Jülich Aachen Research Alliance (JARA), Germany — [4]RWTH Aachen University, Germany

Scanning tunnelling microscope (STM) tips functionalized with a single-molecule quantum dot (QD) have been used for quantitative measurements of electrostatic surface potentials through a technique known as scanning quantum dot microscopy (SQDM) [1]. The functionalization of STM tips with large organic molecules has further enabled measurements of electrostatic and magnetic fields at the atomic scale [2, 3]. Here, we attach a naphthalene tetracarboxylic dianhydride (NTCDA) molecule, acting as a QD, to the tip of an STM and investigate charge transport through the resulting junction. In the resonant regime, the transport through the NTCDA QD exhibits signatures of electron-vibron coupling. We propose that this electron-vibron coupling can be leveraged to map surface polarizability with sub-nanometre resolution.

O 83.8 Thu 16:45 HSZ/0201

Spatial Mapping of Vibronic Excitations in a Single Organometallic Complex — Xiangzhi Meng[1], Kai Uwe Clausen[2], Marie-Laure Bocquet[3], •Alexander Weismann[1], Niklas Ide[1], Felix Tuczek[2], and Richard Berndt[1] — [1]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, D-24098 Kiel, Germany — [2]Institut für Anorganische Chemie, Christian-Albrechts-Universität zu Kiel, D-24098 Kiel, Germany — [3]Laboratoire de Physique de l'École normale supérieure, ENS, Université PSL, CNRS, Sorbonne Université, Université Paris Cité, 75005 Paris, France

Vibronic excitations in single molecules at nanoscale interfaces are central to molecular electronics and are usually modeled with a double-barrier tunneling junction that assumes a homogeneous electric field and ignores atomic details of the contacts. Using STM measurements of a nonplanar organometallic complex on Ag(111), we obtain spatially resolved vibronic maps that reveal shifts in excitation energies caused by reordering of occupied molecular orbitals under the rapidly decaying tip potential. These shifts vary strongly with tip position. Combined with modeling, our results show that tip-induced, atomically varying electric fields can actively control molecular orbitals and must be considered in studies of nonplanar molecules.

O 83.9 Thu 17:00 HSZ/0201

Exciton Dynamics and Charge Transfer at Prototype Organic/Organic Interfaces Studied with LEEM and 2P-PEEM — Franz Niklas Knoop, •Klaus Stallberg, and Winfried Daum — Institute of Energy Research and Physical Technologies, TU Clausthal, Germany

Organic semiconductor (OSC) films deposited on weakly interacting substrates, such as natively oxidized silicon, often suffer from poor structural order. Using low-energy electron microscopy (LEEM), we show that para-sexiphenyl (*p*-6P) molecules on SiO_2 serve as a wetting layer, promoting the growth of microcrystalline phthalocyanine (Pc) thin films, which renders Pc/*p*-6P/SiO_2 a structurally well-defined model for an organic heterojunction. Using two-photon photoemission (2PPE), we study the exciton dynamics in both CuPc and F_{16}CuPc films on *p*-6P/SiO_2. For F_{16}CuPc/SiO_2, i.e., in absence of *p*-6P, the S_1 exciton is observed with a lifetime of 50 ps, indicating negligible influence of the substrate on the exciton dynamics. In contrast, for F_{16}CuPc/*p*-6P/SiO_2, the S_1 exciton is quenched. Moreover, laser-induced changes in electron reflectivity reveal a surface potential shift for F_{16}CuPc/*p*-6P/SiO_2, which points to the formation of surface dipoles upon optical excitation of F_{16}CuPc. Accordingly, we attribute the S_1 exciton quenching to formation of charge transfer (CT) excitons, which is compatible with the type II energy level alignment at the F_{16}CuPc / *p*-6P interface. In contrast, at the CuPc/*p*-6P type I heterojunction no charge transfer takes place. Accordingly, neither exciton quenching nor significant surface potential shifts are observed.

O 83.10 Thu 17:15 HSZ/0201

Magnetic Excitations in on-surface metallacrown complexes — •Robert Ranecki[1,2], Stefan Lach[2], Anne Lüpke[3], Angeliki Athanasopoulou[3], Eva Rentschler[3], and Christiane Ziegler[2] — [1]QNS, Seoul, Korea — [2]RPTU Kaiserslautern-Landau and OPTIMAS, Kaiserslautern, Germany — [3]Inst. of Inorganic and Analytical Chemistry, JGU Mainz

The implementation of quantum information processing demands achieving electrical control over spin-qubits that can be integrated into scalable architectures. Addressing this challenge, multi-spin-carrying molecules on surfaces offer a route to surface-integrable qubits: chemically diverse with tunable spin properties. However, the interaction with the supporting substrate can dramatically modify the electronic and magnetic properties of such complexes. Here, we present spin-flip inelastic tunneling spectroscopy studies of pentanuclear metallacrown complexes, CuCu4 and CuFe4, under adsorption onto Au(111) surface. By comparing the experimental results with perturbative electron transport model simulations[1], we extract quantitative values of the exchange coupling constants and determine the ground spin states of the metallacrown complexes[2]. These findings advance our understanding of the spin interactions in complex molecular systems adsorbed on surfaces, paving the way towards future quantum technologies.

Linearized augmented plane waves for low-dimensional materials — •Andris Gulans, Ernests Jansons, and Janis Uzulis — University of Latvia, Riga, Latvia

We address the challenge of efficient yet highly precise density-functional theory calculations of low-dimensional materials and present a set of tools and algorithms specific to linearized augmented plane waves (LAPW) that is implemented in the electronic-structure code `exciting`. First, we discuss our iterative eigensolver compatible with local and hybrid functionals. It is an extension of Davidson*s algorithm and does not require explicit Hamiltonian construction while overcoming difficulties associated with high condition numbers. The second important ingredient is the adaptively compressed exchange that represents

the non-local (screened) Fock exchange via a low-rank approximation. This approach enables computational complexity as low as $O(N^3 \log N)$ floating-point operations (FLOPs) with N being the number of atoms. It is a novel feature in hybrid functional calculations using LAPW as the standard approaches require $O(N^4)$ FLOPs. Finally, we introduce a cylindrical cutoff for the Coulomb interaction for handling the $q = 0$ singularity.

O 84.2 Thu 15:15 HSZ/0204

Graphene-Enabled Mott–Metal Transition in Silicon Dangling Bonds — •Niclas Tilgner[1], Siheon Ryee[2], Zamin Mamiyev[1], Philip Schädlich[1], Christoph Tegenkamp[1], Tim O. Wehling[2], and Thomas Seyller[1] — [1]Institute of Physics, Chemnitz University of Technology, Germany — [2]I. Institute of Theoretical Physics, University of Hamburg, Germany

Controlling emergent electronic phases in materials with strong Coulomb interactions remains a central challenge in condensed matter physics. Adatom lattices on semiconducting surfaces provide prototypical platforms for exploring such correlated phenomena. Recent advances have facilitated the synthesis of 2D Mott insulators in proximity to graphene (N. Tilgner et al 2025 2D Mater. 12 045022). Here, we demonstrate that alkali adsorption on a graphene/Si/SiC(0001) heterostructure – where the Si layer hosts correlated dangling bonds – enables controlled charge transfer to the Mott insulator. Beyond a critical carrier concentration, we observe a sudden collapse of the Mott gap, indicating a transition to a correlated metallic phase. Our results point to a finite proximity coupling between the Mott layer and graphene, as recently suggested by a theoretical study (N. Witt et al 2025 arXiv:2503.03700), which gives rise to nonlocal dynamical screening beyond simple electrostatics and provides a natural pathway for the observed phase transition.

O 84.3 Thu 15:30 HSZ/0204

From self-consistent DFT+DMFT to the two-particle level: Magnetic phase diagram of X:SiC(111) — •Lukas Bongardt[1,2], Niklas Enderlein[3], Giorgio Sangiovanni[4], Philipp Hansmann[3,5], and Henri Menke[1] — [1]Max Planck Computing and Data Facility — [2]Technical University of Munich — [3]FAU Erlangen — [4]Universität Würzburg — [5]University of Iceland, Reykjavík

Recently we have proposed a novel and versatile platform to realize a two-band Hubbard model with massless Dirac fermions and flat bands hosting strong correlations by depositing three different species of transition-metal adatoms on semiconductor surfaces (arXiv:2410.17165). Using state-of-the-art DFT+DMFT calculations we investigated the spectral properties of X:3C-SiC(111) (X = Ti, V, Cr). Due to the presence of well-defined Dirac cones and flat bands, indicating the potential for realizing topological and correlated phases, we identify transition-metal adatoms on SiC as a possible platform for exploring the interplay of correlations, topology, and magnetism in two-dimensional materials.

In this work, we explore the magnetic phase diagram of these systems within DMFT by calculating the generalized two-particle vertex and using it to solve the Bethe-Salpeter equation for the generalized susceptibility. This gives us a fully orbital-, spin-, and most importantly momentum-dependent susceptibility which carries the information about the ordering wave vector and is experimentally accessible through various techniques.

O 84.4 Thu 15:45 HSZ/0204

Cr 3*d* Orbital Hybridization and Electronic Structure in the Layered Magnetic Semiconductor $CrPS_4$ — •Lasse Sternemann[1], David Maximilian Janas[1], Richard Leven[1], Eshan Banerjee[2], Jonah Elias Nitschke[1], Marco Marino[1], Leon Becker[3], Ahmet Can Ademoglu[1], Frithjof Anders[1], Stefan Tappertzhofen[3], and Mirko Cinchetti[1] — [1]TU Dortmund University, Department of Physics, 44227 Dortmund, Germany — [2]Department of Materials, Imperial College London, London, SW7 2AZ, United Kingdom — [3]TU Dortmund University, Department of Electrical Engineering and Information Technology, 44227 Dortmund, Germany

Despite its promising spintronic and magneto-optical characteristics, the electronic band structure of the van der Waals magnetic semiconductor $CrPS_4$ is still unknown. Here, we report angle-resolved photoemission spectroscopy measurements of its band structure in the para- and antiferromagnetic phase, complemented by DFT+U calculations. Theoretical results reveal dominating Cr 3*d* and S 3*p* contributions to the valence band and a ligand-to-metal charge-transfer band gap. Crystal field split Cr 3*d* orbitals display distinct hybridization regimes with S 3*p* orbitals: t_{2g} orbitals are only weakly affected by hybridization, while e_g states experience a 4 eV anti-bonding/bonding splitting with S-mixing relaxing dipole selection rules, otherwise darkening optical *d*-*d* transitions. These findings establish the ground state electronic and orbital structure of $CrPS_4$ and provide essential benchmarks for understanding its optical and magnetic responses.

O 84.5 Thu 16:00 HSZ/0204

Spectroscopic Investigation of the Ni Valence States in $NiTe_2$ — •Tassaphon Tirasutt[1], Sheng-Huai Chen[1], Alexander C. Komarek[1], Chun-Fu Chang[1], Yu-Chieh Ku[2], Po-Yu Cho[3], Chun Sum Brian Pang[4], Mizuki Furo[5], Naoki Ito[5], Ulrich Burkhardt[1], Simone G. Altendorf[1], Atsushi Hariki[5], and Liu Hao Tjeng[1] — [1]Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — [2]National Yang Ming Chiao Tung University, Hsinchu, Taiwan — [3]National Synchrotron Radiation Research Center, Hsinchu, Taiwan — [4]The University of British Columbia, Vancouver, Canada — [5]Osaka Metropolitan University, Osaka, Japan

Nickel-based transition metal compounds exhibit a wide range of properties arising from the strongly correlated *d* electrons. In this study, we investigate $NiTe_2$, a layered transition-metal dichalcogenide with reported type-II Dirac semimetallic properties. While its topological nature has been the focus of interest, the fundamental question of the properties of the Ni ions in $NiTe_2$ has rarely been discussed. We address this issue using soft X-ray core-level and valence-band photoelectron spectroscopy, as well as Ni-$L_{2,3}$ absorption spectroscopy, combined with a theoretical approach using LDA+DMFT. Our findings provide insights into the Ni 3*d* occupation and degree of correlation of the Ni in a metallic ligand bath of the $NiTe_2$ system.

O 84.6 Thu 16:15 HSZ/0204

TMDC surfaces as scattering targets in spin-polarization detectors: A case study of MoS_2 — •Christoph Angrick[1], Annika Henriksen[1], Nicole Edossa[1], Andre Reimann[1], Moritz Ewert[2,3], Lars Buss[2,3], Jens Falta[3], Jan Ingo Flege[2,3], and Markus Donath[1] — [1]University of Münster, Germany — [2]Brandenburg University of Technology Cottbus-Senftenberg, Germany — [3]University of Bremen, Germany

Spin-polarization detectors are employed in photoemission experiments to reveal the spin texture of electronic states. One well-proven approach is based on the VLEED process, where the spin-dependent electron reflection from targets influenced by exchange and/or spin-orbit interaction is used. The suitability of a target must be investigated beforehand [1,2]. In this talk, a first impression of TMDC-based detectors is given [3]. The spin-dependent electron reflectivity of spin-orbit-influenced MoS_2 is measured over a wide range of incident energies and angles for the following samples: a single layer of MoS_2 on Au(111) and cleaved MoS_2 single-crystal surfaces. On the basis of the resulting maps for the electron reflectivity, Sherman function, and figure of merit, promising features of MoS_2 for use in spin-polarization detection are discussed.

O 84.7 Thu 16:30 HSZ/0204

Efficient GW calculations for metals from an accurate ab initio polarizability: the case of doped MoS2 monolayer — •Giacomo Sesti[1], Pino D'Amico[1], Alberto Guandalini[2], Claudia Cardoso[1], Andrea Ferretti[1], and Daniele Varsano[1] — [1]CNR-NANO, Modena, Italy — [2]Università di Roma La Sapienza, Roma, Italy

Many-body perturbation theory in the GW approximation has proved very successful for the calculation of quasiparticle (QP) band structures of semiconductors. QP corrections are less significant in metals and are typically disregarded for the computational cost involved. Also, GW calculations of metals suffer of specific methodological challenges to properly treat the screening. This is typically solved under the addiction of a Drude term, that however is inadequate at low dimensionalities[1]. Furtherly, even for metals, QP corrections become more relevant at lower dimensionalites.

Here, we present GW calculations of QPs for doped MoS_2 monolayer showing excellent agreement with experimental ARPES measurements[2]. Such an unprecedented agreement has been possible thanks to the W-av method, which combines a Monte Carlo integration with interpolation approaches. This technique originally developed for 2D semiconductors[3] is here extended to the metallic case.

O 84.8 Thu 16:45 HSZ/0204

Ultrafast Momentum Dependent Relaxation Dynamics in $TbTe_3$ — •Florian Denizer[1], Noah Meyer[2,3], Anisha Singh[3], Ian R. Fisher[3], Uwe Bovensiepen[1], Zhi-Xun Shen[2,3], and Patrick S. Kirchmann[2] — [1]Fakultät für Physik, Universität Duisburg-Essen — [2]Department of Physics, Applied Physics and Stanford Synchrotron Radiation Laboratory, Stanford University — [3]Geballe Laboratory for Advanced Materials, Departments of Physics and Applied Physics, Stanford University

Rare-earth tritellurides (RTe_3) form charge density waves (CDW) due to electronic instabilities at the Fermi-surface, because of an anisotropy of the crystal lattice between the two major in-plane crystal axes *a* and *c*. Unoccupied electronic states can be populated by ultrafast laser excitation. Electronic relaxation

and coherent vibrational modes including the amplitude mode have been investigated by time and angle resolved photoelectron spectroscopy (*tr*-ARPES). Among the manifold of laser-driven processes, the one that is responsible for the electronic instability has not yet been identified. With this objective in mind we perform a *tr*-ARPES experiment on $TbTe_3$ and investigate the momentum transfer along the a- and the c-axis as a function of excitation strength. At sufficiently low pump fluence below $F = 0.3$ mJ/cm^2 we identify (quasi-)elastic scattering in the vicinity of the Fermi surface. In the talk we will discuss isotropic defect-induced elastic scattering and directed quasi-elastic scattering determined by the nesting vector. Funding through the DFG within SFB 1242 and through the DOE is gratefully acknowledged.

O 84.9 Thu 17:00 HSZ/0204

Unconventional Topological Superconductivity in CrCl3/NbSe2 heterostructures — •Souvik Das[1], Benjamin Zhou[2,3], Anshuman Padhi[1], Jing-Rong Ji[1], Niclas Heinsdorf[2,3], Prajwal Rigvedi[1], Tianzhe Chen[1], Weibin Li[4], Pierluigi Gargiani[4], Manuel Valvidares[4], Marcel Franz[2,3], Banabir Pal[1], and Stuart S.P. Parkin[1] — [1]Max Planck Institute of Microstructure Physics, Halle, Germany — [2]Quantum Matter Institute, University of British Columbia, Vancouver, Canada — [3]Department of Physics and Astronomy, University of British Columbia, Vancouver, Canada — [4]ALBA Synchrotron Light Source, Barcelona, Spain

Topological p-wave superconductors can host non-Abelian particles useful for fault-tolerant quantum computing. Here we report experimental evidence of unconventional topological superconductivity in a heterostructure of monolayer, in-plane ferromagnetic CrCl3 islands on superconducting NbSe2. STM measurements show that, despite CrCl3 being ferromagnetic, the interfacial superconducting gap is more robust against out-of-plane magnetic fields than the s-wave gap of NbSe2, indicating unconventional pairing. We also find enhanced zero-energy states along CrCl3 island edges, consistent with the presence of edge modes. Theory suggests these features arise from an intrinsic helical p-wave state stabilized by interfacial Rashba spin-orbit coupling. This demonstrates a new route to create topological superconductivity via interface engineering.

O 84.10 Thu 17:15 HSZ/0204

Structural and Electronic Properties of CrSBr Nanoribbons: Insights from First-Principles Calculations — •Daniil Kruklinskii, Mahdi Ghorbani-Asl, and Arkady Krasheninnikov — Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

Experiments show that exfoliated CrSBr flakes naturally form nanoribbons along a specific crystallographic direction, and similar structures can be fabricated using an electron beam in the TEM as a cutting tool. Here, we employ density functional theory calculations to systematically investigate the stability as well as electronic and magnetic properties of CrSBr nanoribbons. Our results indicate that nanoribbons oriented along one of the two major crystallographic directions are the most stable under typical growth and exfoliation conditions and remain semiconducting, exhibiting pronounced electron-hole separation between the VBM and CBM. In contrast, nanoribbons in the perpendicular direction display a substantially reduced band gap due to strongly localized edge states. Both orientations retain strongly spin-polarized band-edge states near the Fermi level and show only a weak dependence of the band gap on ribbon width. Using *ab initio* molecular dynamics simulations, we further demonstrate that electron-beam irradiation with energies of at least 200 keV can facilitate the fabrication of nanoribbons directly from pristine monolayer CrSBr, favouring the formation of diagonal nanoribbons. These diagonal ribbons are metallic, in contrast to the monolayer, and host a high density of majority-spin edge states, giving rise to pseudo-half-metallic transport.

O 84.11 Thu 17:30 HSZ/0204

Band-selective coherent phonon-driven band renormalization in 1T-$MoTe_2$ — •Carl Jensen[1], Christopher Emeis[2], Stephan Jauernik[1], Petra Hein[1], Fabio Caruso[2], and Michael Bauer[1,3] — [1]nstitute of Experimental and Applied Physics, Kiel University, 24098 Kiel, Germany — [2]Institute of Theoretical Physics and Astrophysics, Kiel University, 24098 Kiel, Germany — [3]Kiel Nano, Surface and Interface Science KiNSIS, Kiel University, 24118 Kiel, Germany

Understanding the coupling between coherent phonons and the electronic system is crucial for controlling nonequilibrium properties in solids. Here, we investigate mode- and band-selective electron-phonon coupling in centrosymmetric 1T-$MoTe_2$ using time- and angle-resolved photoemission spectroscopy combined with frequency-domain analysis (FDARPES). Femtosecond near-infrared pulses excite coherent Ag-symmetric phonon modes at 2.34 THz, 3.34 THz, and 3.86 THz, which manifest as oscillatory modulations in photoemission intensity and binding energy across the valence bands. Pixel-wise Fourier analysis, based on a recently developed methodology [1], reveals pronounced band selectivity with distinct coupling strengths for different electronic states and phonon modes, enabling the evaluation of band-renormalization amplitudes in the few-meV range. Ab initio calculations using DFT/DFPT qualitatively reproduce the experimentally observed coupling patterns and relative trends, demonstrating the capability of combined experimental and theoretical approaches to resolve ultrafast electron-phonon interactions in quantum materials.

From light to pressure: Laser-based quantum technologies for the realization of high-precision pressure and vaccum standards — •Tom Rubin — Physikalisch-Technische Bundesanstalt (PTB), Berlin

The new realization of the pascal in the range between 1 Pa and 100 kPa is achieved by means of photonic pressure measurement. This not only enables significantly lower measurement uncertainties, but also more robust and faster-operating systems that can cover the entire pressure range continuously and for different gases. Gas-density-based methods open up new perspectives: from precise calibrations at the highest metrological level to non-invasive applications in vacuum technology and the development of innovative pressure sensors for the mass market.

This presentation is about key findings and highlights from the EU projects *QuantumPascal* and *MQB-Pascal*. These include overcoming major challenges, such as the need for sub-mK-level gas temperature knowledge, the advantages of the GAMOR (Gas Modulation Refractometry) method, and the latest results from validation and comparison measurements.

O 85.2 Thu 15:30 HSZ/0401

Near Ambient Pressure ARPES for Operando Surface Studies at Synchrotron SOLEIL — •L. Dudy[1], E. Auffray[1,2], J.-J. Gallet[1,3], F. Bournel[1,3], M. Bouaziz[3], B. S. Mun[4], S. Jang[4], Y. Tsujikawa[5], H. Kondoh[5], S. Moser[6], V. Jovic[10], V. Mischke[7], P. Kessler[8], and S. Maehl[9] — [1]Synchrotron SOLEIL, France — [2]U Paris-Saclay, France — [3]Sorbonne U, France — [4]GIST, South Korea — [5]Keio U, Japan — [6]U Bochum, Germany — [7]TU Dortmund, Germany — [8]U Würzburg, Germany — [9]SPECS, Germany — [10]GNS Science, New Zealand

We present a near-ambient pressure angle-resolved photoemission spectroscopy (NAP-ARPES) setup for operando studies of electronic structure under gas exposure at Synchrotron SOLEIL. This development bridges the gap between conventional UHV ARPES and realistic surface environments, enabling momentum-resolved measurements during catalytic and energy-related processes at pressures up to several millibars. The approach is demonstrated using model systems, showing that band structure evolution can be tracked in real-time during adsorption and reaction. These results highlight the potential of NAP-ARPES for investigating dynamic surface phenomena. By extending ARPES into near-ambient conditions, this method opens new opportunities for studying functional materials under realistic environments for operando electronic structure analysis in surface science.

O 85.3 Thu 15:45 HSZ/0401

A new framework for analysing transport ARPES applied to the current induced insulator to metal transition in Ca_2RuO_4. — •Anders Sandermann Mortensen, Hippolyte Raymond Bourel, Katarina Ogliara Praest, Davide Curcio, and Philip Hofmann — Institute of Physics and Astronomy, Aarhus University

The advent of μm-resolution spatially resolved ARPES-measurements allows for in-operando measurements of modifications to the electronic band structure of electrical devices (transport-ARPES). However, this technique poses a new set of challenges, as local biasing of the samples results in systematic shifts of the measured energy, hindering direct comparison of ARPES spectra.

Here, we propose a novel solution to this problem: Realigning the spectra by minimizing the L1-norm between them. Combined with k-means clustering, this provides an effective framework for real-time analysis and characterisation of transport-ARPES measurements.

As a proof of concept, we apply our analysis scheme to transport-ARPES measurements of the current-induced insulator to metal transition in Ca_2RuO_4, and thus provide new, high statistics measurements of the changes to the electronic band structure during the current-induced insulator to metal transition.

O 85.4 Thu 16:00 HSZ/0401

Cross-correlation measurements of a Two-Color Infrared Free-Electron Laser — •Akash Chandra Behera, América Yareth Torres Boy, Sandy Gewinner, Marco De Pas, Gert von Helden, Martin Wolf, Wieland Schöllkopf, Gerard Meijer, and Alexander Paarmann — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195 Berlin, Germany

Infrared-Free Electron Lasers (IR-FEL) uniquely provide high-power narrowband radiation for spectroscopic measurements, that is continuously tunable from the mid-IR to the terahertz spectral range.

The IR-FEL at the Fritz Haber Institute recently commissioned a two-color upgrade, enabling simultaneous lasing at two independently tunable wavelengths. This is realized by employing a high-frequency kicker cavity to feed alternating electron bunches into the two separate undulators. Within this scheme, a high intrinsic temporal synchronization between both FEL outputs is expected.

In our contribution, we present two-color optical cross correlation measurements proving this synchronization. By leveraging the independently tunable pulse durations in each FEL, we further explore the achievable time-resolution that can be expected when the two-color FEL is employed for future IR-IR pump-probe experiments

O 85.5 Thu 16:15 HSZ/0401

K-Means Clustering of Time-Resolved Diffraction: Dynamics of Laser-Excited Si(111)-(7x7) — •Jonas D. Fortmann[1,2], Alexander Neuhaus[1], Pascal Dreher[1,3], Birk Finke[1], Christian Brand[1], and Michael Horn-von Hoegen[1] — [1]Uni Duisburg-Essen, Duisburg, Germany — [2]MAX IV, Lund, Sweden — [3]Uni Würzburg, Würzburg, Germany

We present an unsupervised analysis workflow that leverages k-means clustering to extract characteristic dynamics from time-resolved diffraction data, using ultrafast reflective high energy electron diffraction (URHEED) measurements of laser-excited Si(111)-(7x7) as a case study. Delay-dependent intensity profiles of diffraction features are clustered by trajectory shape to reveal characteristic dynamics without prior model assumptions. When combined with a simple population model, relative integral-intensity changes of clusters yield lifetimes of coupled phonon systems and trace the excitation pathway to surface electronic states. The method is robust to practical limitations (e.g., camera light sensitivity), scales to large datasets, and is directly transferable to other diffraction modalities (ULEED, UTEM, and pump-probe X-ray diffraction), where clustering of intensity evolutions can provide an objective map of structural dynamics.

O 85.6 Thu 16:30 HSZ/0401

ESEM Automation - Agent-Oriented Autonomous Microscopy — •Maurits Vuijk[1], Johannes Zeininger[2], Karsten Reuter[1], Thomas Lunkenbein[3], and Christoph Scheurer[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]TU Wien — [3]Universität Bayreuth

Are the datasets captured in usual Environmental Scanning Electron Microscopy (ESEM) experiments truly representative? While focusing on a single view or feature, critical events may occur elsewhere on the accessible surface. In addition, effects such as beam damage and inhomogeneous gas concentration introduce further need for more representative surface sampling. Starting from an automation interface to the ESEM, we have built an agent-oriented framework that enables fully autonomous ESEM experiments. To achieve this, the actions normally carried out by the human operator are instead performed by various agents. To this end, a set of agents keep up image quality by controlling brightness and contrast, focus and astigmatism without interrupting the imaging flow. A set of computer vision agents analyze captured images on the fly for interesting features and activity. Using a dynamic priority queue system, high-resolution frames are automatically taken of identified active zones. Each overview image is processed and scored based on activity, feature presence, or other desired qualities. The queue system then assigns an acquisition frequency based on the score, giving priority to more active zones. This gives a full set of overview images and multiple smaller image sets of dynamically identified active areas.

O 85.7 Thu 16:45 HSZ/0401

Image Stacking: A Simple Method to Enhance SNOM Measurements — •Florian Mangold[1], Farid Aghashirinov[1], Enrico Baù[2], Julian Schwab[1], Bettina Frank[1], Andreas Tittl[2], and Harald Giessen[1] — [1]4th Physics Institute, Research Center SCoPE, and Integrated Quantum Science and Technology Center, University of Stuttgart, Germany — [2]Nano-Institute Munich, Department of Physics, Ludwig-Maximilians Universität München, Germany

Scanning near-field optical microscopy (SNOM) enables optical characterization with spatial resolution far beyond the diffraction limit, making it a powerful tool for studying nanoscale optical and material properties. However, achieving a high signal-to-noise ratio (SNR) in SNOM can be challenging and, depending on the experimental conditions, sometimes not feasible. We present a simple and equipment-free method to enhance SNOM performance by aligning and stacking multiple sequential measurements. This procedure effectively increases the SNR while avoiding drift-induced errors and system alterations. In addition, the stacking process suppresses outliers and isolated noise contributions, further improving data quality. We demonstrate that stacked SNOM measurements can surpass the quality of single measurements under comparable conditions. This straightforward method can be broadly applied to strengthen existing SNOM experiments and opens possibilities for measurements in challenging regimes, including low-signal materials, extended wavelength ranges, and higher-order demodulation schemes where conventional single-shot SNR would be insufficient.

Ultrafast Dynamics at Surfaces with Machine Learning Surrogates — •Reinhard Maurer — University of Vienna, AT — University of Goettingen, DE — University of Warwick, UK

Ultrafast dynamics at surfaces (driven by light, electrons, or hyperthermal scattering) involve the concerted motion of electrons and atoms at comparable energy and time scales, giving rise to nonadiabatic effects. Excited electrons drive chemical conversions, induce phase transitions, and mediate energy transfer between adsorbates and surfaces. To reliably predict such effects with scalable, state-of-the-art nonadiabatic dynamics simulations requires the use of accurate and data-efficient high-dimensional machine learning (ML) surrogate models. This includes representations of energy landscapes, but also nonadiabatic couplings or excited-state properties that are required for nonadiabatic simulations. I will present recent strategies to construct high-dimensional ML surrogate models of electronic structure, including active learning and fine-tuning of foundation models that allow us to reduce the required electronic structure data to a few hundred data points per gas-surface dynamics model and even transfer learn across density functional approximations. Electronic properties such as electron-phonon coupling tensors or electronic Hamiltonians can be efficiently represented by encoding physical equivariance properties in the model. I will showcase the utility of the introduced models with recent dynamics applications on reactive molecular scattering and light-driven structural dynamics.

O 86.2 Thu 15:30 HSZ/0403

Ultrafast Structural Dynamics of Layered Material Surfaces — •Alp Akbiyik[1,2], Felix Kurtz[1,2], Hannes Böckmann[1,2], and Claus Ropers[1,2] — [1]Department of Ultrafast Dynamics, Max Planck Institute for Multidisciplinary Sciences, D-37077 Göttingen, Germany — [2]University of Göttingen, 4th Physical Institute, D-37077 Göttingen, Germany

Layered materials are promising candidates for studying and applying correlated phenomena, and their carrier dynamics have been extensively investigated, including through ultrafast pump-probe techniques. However, the structural evolution of their surface layers remains poorly accessible. Ultrafast low-energy electron diffraction (ULEED) leverages the surface sensitivity of low-energy electron pulses, with high spatial resolution and temporal resolution down to 1-2 ps. This allows us to monitor the momentum-dependent out-of-plane phonon populations across the Brillouin zone as well as changes in diffraction peak intensities [1,2]. Here, we contrast the phonon equilibration behaviour of transition metal dichalcogenides (TMDCs), such as WTe2, with graphite following electron-phonon coupling.

O 86.3 Thu 15:45 HSZ/0403

Nonadiabatic Energy Loss in Hyperthermal Gas-Surface Scattering: Going Beyond the Mean Field Approximation — •Ash Baldwin[1] and Reinhard J. Maurer[1,2] — [1]University of Vienna, Vienna, Austria — [2]University of Warwick, Coventry, United Kingdom

Nonadiabatic energy dissipation is known to play a crucial role in hyperthermal scattering at surfaces, leading to electron-hole pair excitation and highly inelastic scattering. For projectiles with unpaired spins, such as hydrogen atoms, hybridi-

sation with the metal surface results in strong non-adiabatic effects driven by a phase transition in its spin-polarisation. It is known that traditional mean-field descriptions of the resultant nonadiabatic dynamics using methods like MDEF and Ehrenfest dynamics break down in the presence of the transition, leading to divergent energy transfer rates and unphysical stopping powers at the location of the spin transition [Box et al. *J. Phys. Chem. Lett.* 15, 51 (2024); Lindenblatt et al. *Phys. Rev. Lett.* 97 (2006)].

Here, we model H/Cu(111) and H/Ag(111) scattering in the presence of on-site correlation in the adsorbate state using the Newns-Anderson Hamiltonian. We go beyond previous works by simulating the dynamics using stochastic trajectory surface hopping methods that capture the coupling between the nuclear and electronic degrees of freedom beyond the mean-field. By systematically classifying scattering regimes, we assess the applicability of mean-field and beyond mean-field methods for predicting nonadiabatic energy loss.

O 86.4 Thu 16:00 HSZ/0403

Manipulation of charge density wave order in 1H-TaS_2 to simulate broken lattice degeneracy of misfit layered chalcogenides — •Laura Pätzold[1], Sandra Sajan[2], Clara Pfister[1,3], Haojie Guo[2], Miguel M. Ugeda[2], and Tim O. Wehling[1,3] — [1]U Hamburg — [2]DIPC San Sebastian — [3]The Hamburg Centre for Ultrafast Imaging

Misfit layer compounds, a class of van der Waals heterostructures comprised of noncommensurate layers, are ideal platforms to explore the influence of broken lattice symmetries and incommensurability on collective electronic phases, such as charge density waves (CDWs). The simulation of these symmetry-broken ground states poses a computational challenge due to large numbers of inequivalent atoms. By employing an electron-lattice downfolding scheme [1] followed by molecular dynamics (MD) simulations, we obtain the (thermo-)dynamics of these systems with the accuracy of full first-principles calculations while reducing the computational cost by several orders of magnitude. Here, we explore CDW control parameters to analyze the influence of the PbS layer in the misfit layer compound $(PbS)_{1.13}TaS_2$, where a shift in CDW order accompanied by symmetry breaking is measured in the 1H-TaS_2 layer. Simulating charge doping, interlayer hybridization effects via external potentials and frustration effects via the supercell size, we show that only a combination of these effects reproduces the characteristics of the measured structure factor while being thermodynamically stable.

O 86.5 Thu 16:15 HSZ/0403

Control and thermal evolution of commensurate charge-density wave order in 1H-$NbSe_2$ — •Clara Pfister[1,2], Alexander Bäder[3,4], Laura Pätzold[1], Tobias Wichmann[3], Felix Lüpke[3,4], Mariana Rossi[5], and Tim O. Wehling[1,2] — [1]I. Institut für Theoretische Physik, Universität Hamburg — [2]The Hamburg Centre for Ultrafast Imaging — [3]Peter-Grünberg-Institut, Forschungszentrum Jülich — [4]II. Physikalisches Institut, Universität zu Köln — [5]MPI für Struktur und Dynamik der Materie, Hamburg

Charge-density waves (CDWs) are symmetry-broken ground states arising from electron-lattice interactions and offer a platform to study tunable ordered phases in quasi two-dimensional materials. Using *ab initio* calculations and a downfolding approach [1], we investigate how biaxial tensile strain and electron doping affect CDW order in 1H-$NbSe_2$. In both cases, a transition from the native 3×3 to a competing 2×2 CDW ground state is induced. The strain-induced 2×2 CDW is supported by experimental data of monolayer 1H-$NbSe_2$ flakes that are rotated with respect to the underlying bulk $NbSe_2$. By constructing phase diagrams, we are able to identify the strain- and doping-induced boundaries between the competing CDW ground states. Moreover, by performing molecular dynamics (MD) simulations, we find that strain-induced 2×2 order persists up to $T_{CDW} \approx 10$ K, whereas the doping-induced 2×2 CDW is thermally much less stable. Our MD results furthermore suggest that nuclear entropy is the driving mechanism in the melting process of the CDW.

O 86.6 Thu 16:30 HSZ/0403

Surface Resonant Raman Scattering of Ag(110) surfaces — Sandhya Chandola[1,2], •Norbert Esser[1], Mohamed Yassine Fatihi[3], and Simone Sanna[3] — [1]Institut für Festkörperphysik,TU Berlin, Hardenbergstr. 36, 10623 Berlin, Germany — [2]Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Schwarzschildstr. 8, 12489 Berlin, Germany — [3]Institut für Theoretische Physik, Heinrich-Buff-Ring 16, 35392 Gießen, Germany

The phonon and electron scattering mechanism on Ag(110) surfaces is investigated using Surface Resonant Raman scattering (SRRS) and Reflectance Anisotropy Spectroscopy (RAS) in ultra-high vacuum (UHV). The surface electronic transition is clearly visible with RAS, with Raman spectra showing surface phonons near the resonant excitation. A low energy peak is also seen, which should be related to the Rayleigh mode at the Brillouin zone edge. This shows that the surface is rough, and that the intensity of this mode depends on the sample treatment. Consequently, RAS together with Raman spectroscopy allows optimization of surface reconstruction and control of surface morphology. By means of first-principles calculations within density functional theory, we demonstrate that the dominant Raman signature is coupled to an electronic transition between localized surface-states (calculated at 1.6 eV). The corresponding surface-localized phonon mode enhances the distance between the topmost surface layers. The combined experimental and theoretical approach to resonant surface Raman spectroscopy establishes a powerful tool for investigating surface vibrational dynamics and electron-phonon interactions.

O 86.7 Thu 16:45 HSZ/0403

Spatiotemporal control of Peierls heterostructures by valley-selective photoswitching — •Hannes Böckmann[1], Jan Gerrit Horstmann[3], Felix Kurtz[1], Manuel Buriks[4], Karun Gadge[4], Salvatore Manmana[4], Stefan Wippermann[5], and Claus Ropers[1,2] — [1]Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany — [2]4th Physical Institute, Solids and Nanostructures, University of Göttingen, Germany — [3]Department of Materials, ETH Zurich, Zürich, Switzerland — [4]Institute for Theoretical Physics, University of Göttingen, Germany — [5]Faculty of Physics, Philipps University of Marburg, Germany

Phase competition and coexistence are hallmarks of strongly-correlated materials, promising tunable functionality on the nanoscale. Light allows for tilting the balance between distinct correlated states and phases with a prominent example given by the optical switching of an insulator to a metal. However, optical excitation generally lacks the specificity to select sub-wavelength domains. In this work, we employ valley-selective photodoping of correlated electronic states to drive the domain-specific quench of a textured Peierls insulator. Specifically, we exploit the anisotropic absorption of nanowire domains by tuning both the photon energy and the polarization to the transition matrix elements most strongly coupled to the structural transformation. We find that averting dissipation facilitates domain-specific carrier confinement, control over nanotextured phases, and a prolonged lifetime of the metastable metallic state.

O 86.8 Thu 17:00 HSZ/0403

Surface resonant Raman scattering from coinage metal surfaces — •Mohamed Yassine Fatihi[1], Sandhya Chandola[2,3], Norbert Esser[2,3], and Simone Sanna[1] — [1]Institut für Theoretische Physik and Center for Materials Research (LaMa), Justus-Liebig-Universität Gießen, 35392 Gießen, Germany — [2]Helmholtz Zentrum Berlin für Materialien und Energie GmbH, 12489 Berlin, Germany — [3]Institut für Festkörperphysik, TU Berlin, 10623 Berlin, Germany

The vibrational characterization of clean metal surfaces has remained largely inaccessible to optical spectroscopy, as Raman scattering from pristine metals is extremely weak and dominated by bulk phonon backgrounds. However, the first direct Raman observation of surface phonons on a Cu(110) single crystal has been recently reported[1]. We explain this Raman activity and predict it for the related Ag(110) surface from first principles, demonstrating by means of atomistic models how tuning the incident photon energy to the surface-state transition induces a striking resonant enhancement of the surface phonon signal. This mechanism selectively amplifies the surface response with respect to the bulk contribution. Our resonant surface phonon Raman approach establishes a powerful probe for investigating surface vibrational dynamics and electron-phonon interactions, creating new opportunities for real-time studies of metallic surfaces under diverse conditions, from ultra-high vacuum to catalytic and electrochemical environments

Manipulation of Optical Phonons by Thermal Expansion Mismatch in Bi/Si(111) Heterostructures — •Fabian Thiemann, Maja Penkl, and Michael Horn-von Hoegen — University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany

We investigate how substrate-induced biaxial strain controls the temperature behaviour of the A_{1g} phonon frequency $\Omega(T)$ in epitaxial Bi(111) films on Si(111) in the time domain. Bismuth's anisotropic A7 structure, strong electron-phonon coupling and its Peierls' distortion make the out-of-plane c-axis vibrations highly sensitive to strain. Using *in situ* SPA-LEED and broadband femtosecond transient reflectivity on the same samples, we measured temperature-dependent lattice parameters and coherent-phonon frequencies. Strained Bi films on Si(111) exhibit a larger thermal redshift $\partial\Omega/\partial T$ compared to relaxed bulk or polycrystalline Bi. Applying an extended phonon-shift model reveals that the anharmonic multi-phonon term depends solely on the value of the c-axis lattice parameter. This identifies c-axis expansion as the key structural factor governing the A_{1g} phonon, enabling targeted strain-engineering of phonon properties in bismuth and related anisotropic materials.

O 86.10 Thu 17:30 HSZ/0403

Nested Sampling Simulations of Oxygen Induced Surface Reconstructions on Cu(100) — •Felix Riccius[1,2], Hendrik H. Heenen[1], Jutta Rogal[2], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG , Berlin — [2]Flatiron Institute, New York

Under operating conditions, catalysts can undergo structural, compositional, and morphological changes, which ultimately dictate their activity and stabil-

ity. However, extensive sampling of surface configurations at finite temperature and pressure is computationally expensive and non-trivial. To this end, nested sampling simulations can be used to explore the full configuration space, estimate the partition function, and directly access the desired thermodynamic ensemble averages. We here render such simulations tractable by using them in combination with a machine-learning interatomic potential, optimize the code to run efficiently on GPUs, and tailor system specific nested sampling moves. Applied to the early oxidation of Cu(100), the approach correctly captures clean surface configurations at various oxygen coverages and the relative stability of the O adsorption sites as a function of temperature. Moreover, nested sampling successfully predicts the experimentally observed and highly complex $(2\sqrt{2} \times \sqrt{2})$ R45°-O missing-row surface reconstruction and their defect states without any human bias.

Interfacial Enrichment and Reactivity of Organic Molecules in Ionic Liquids — •Alisson Ceccatto Santos[1], Luciano Sanchez Merlinsky[2,3], Luis M. Baraldo[2,3], Federico J. Williams[2,3], Florian Maier[1], and Hans-Peter Steinrück[1] — [1]Lehrstuhl für Physikalische Chemie 2, Friedrich-Alexander-Universität Erlangen-Nürnberg — [2]Departamento de Química Inorgánica, Analítica y Química Física, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires — [3]Instituto de Química Física de los Materiales, Medio Ambiente y Energía, CONICET- Universidad de Buenos Aires

Controlling the surface composition of metalloporphyrins in ionic liquids (ILs) is crucial for designing photoactive materials. Here, we investigate the interfacial behavior of zinc-didodecylporphyrin molecules (Zn-DDP) dissolved in the 1-butyl-3-methylimidazolium hexafluorophosphate [C4C1Im][PF6] IL using angle-resolved X-ray photoelectron spectroscopy (ARXPS). Upon mild heating, Zn-DDP undergoes spontaneous demetallation, evidenced by the appearance of aminic (-NH-) and iminic (=N-) nitrogen XPS signals. Our measurements reveal extremely high surface enrichment of porphyrins at the IL/vacuum interface, with the dodecyl chains oriented toward the vacuum. ARXP spectra reveal that the surface enrichment increases with increasing temperature. Our findings provide molecular-level insights to guide the design of photoactive interfaces in IL systems. How is the hydrophobic force modified by an oscillation frequency in saline conditions? — •Chiara Wagner, Paul Stöcher, Laura Mears, and Markus Valtiner — Vienna University of Technology, Vienna, Austria

There have been many investigations over the years regarding the mechanism behind the hydrophobic force and over how long a range it can be felt [1]. We present a detailed set of AFM force measurements of hydrophobic SAM modified surfaces, with varying salt concentration and oscillation frequency (0-2kHz). We observe dynamic changes in the force curve characteristics with both salt concentration and oscillation frequency. The changes lead to a reduction of the average force with increasing applied frequency, while multiple distinct characteristic curves are present and enhanced by certain conditions. We also notice changes in the range of the force away from the surface. Altogether, the results we will present bring new insight into the mechanism of hydrophobic interactions.

Interfacial non-Markovian friction determines non-linear spectral shifts at the water-graphene interface — •Johannes Schröter, Louis Lehmann, Shane Carlson, and Roland R. Netz — FU Berlin, Fachbereich Physik, Arnimallee 14 14195 Berlin

Understanding the behavior of aqueous interfaces is crucial for various applications. In particular, the graphene water interface plays a key role for energy storage and energy conversion, however, its properties remain poorly understood. Using DFT molecular dynamics simulations we show that the sum-frequency signal of non-hydrogen bonded OH bonds is significantly red-shifted at the water-graphene compared to the water-air interface, in agreement with recent experiments. The red shift is demonstrated to be caused by non-Markovian friction between the graphene surface and interfacial water, which offers a direct method to extract solid-water interfacial friction properties from non-linear spectroscopy.

O 87.4 Thu 15:45 TRE/PHYS

Structural Stability of NaCl and KCl Cleavage Surfaces in the BMIM-PF6 Ionic Liquid — •Ebru Cihan[1], Natalia Janiszewska[2], Kamil Awsiuk[2], Qingwei Gao[3], Rong An[4], Ronen Berkovich[5], and Enrico Gnecco[2] — [1]TU Dresden, Dresden, Germany — [2]Jagiellonian University, Krakow, Poland — [3]Shanghai University of Electric Power, Shanghai, China — [4]Nanjing University of Science and Technology, Nanjing, China — [5]Ben-Gurion University of the Negev, Beer-Sheva, Israel

An investigation was conducted into the evolution of freshly cleaved NaCl(100) and KCl(100) surfaces exposed to the ionic liquid (IL) 1-butyl-3-methylimidazolium hexafluorophosphate (BMIM-PF6). The surfaces were repeatedly scraped using AFM, resulting in contrasting responses from the two surfaces to the IL. In the case of NaCl, the cleavage step edges are slightly eroded, and the surface is progressively smoothed by the AFM tip. These changes are accompanied by a continuous increase in the friction force. In the case of KCl, a pronounced dissolution of the surface is evident immediately following contact with the IL. The surface is then smeared in the area scratched by the tip and even beyond. An increase in the friction force is also observed but only at the onset of the surface modification process. Crystallites (100-200 nm in size) are observed across the unscratched areas of KCl, but not of NaCl. This result was corroborated by MD simulations and Raman spectroscopy, which revealed that IL exhibits a stronger interaction with the KCl surface, ultimately forming a BMIM-PF6 adlayer. [1] E. Cihan et al., Langmuir 41, 13793 (2025)

O 87.5 Thu 16:00 TRE/PHYS

How Water Controls Ion Adsorption at Aqueous Interfaces via Entropic and Dielectric Interplay — •Florian Altmann[1], Matteo Olgiati[1], Moritz Zelenka[2], Joanna Dziadkowiec[3], Andreas Kretschmer[1], Alper T. Celebi[1], Laura L.E. Mears[1], Ellen H.G. Backus[2], and Markus Valtiner[1] — [1]Vienna University of Technology, Institute of Applied Physics, Wiedner Hauptstrasse 8-10, A-1040, Vienna, Austria — [2]University of Vienna, Faculty of Chemistry, Institute of Physical Chemistry, Währinger Straße 42, 1090 Vienna, Austria — [3]NJORD Centre, Department of Physics, University of Oslo, Oslo 0371, Norway

Ion-specific behavior at aqueous interfaces remains poorly understood. Using Li^+, Ca^{2+}, and Cs^+, we combine quantitative atomic force microscopy on muscovite mica with molecular dynamics simulations and sum-frequency generation spectroscopy to resolve interfacial thermodynamics at molecular resolution. Pair correlation functions link ion-water-surface organization to entropy and electrostatics. Small or highly charged ions compact interfacial water, creating entropic penalties and strong dielectric screening, whereas larger ions deplete interfacial water, lower screening, and promote overadsorption. This interplay between entropy and screening governs inner double-layer formation and provides a molecular framework for ion-specific adsorption in complex electrolytes.

O 87.6 Thu 16:15 TRE/PHYS

Accessing interfaces of ionic liquids in vacuum — •Florian Maier and Hans-Peter Steinrück — Lehrstuhl Physikalische Chemie II, Friedrich-Alexander-Universität Erlangen-Nürnberg

About one decade ago, the perspective "Surface science goes liquid" described possibilities of investigating surfaces and interfaces of vacuum-stable liquids with surface science tools under ultrahigh vacuum (UHV).[1]

Since then, new experimental concepts and setups have been developed considering the special requirements for handling ionic liquids (ILs) in vacuum in order to push the boundaries of surface science experiments further.

In this presentation, some of our experimental developments including key showcases will be presented demonstrating at which level molecular properties of IL interfaces can be accessed under ultra-clean and well-defined UHV conditions.

O 87.7 Thu 16:30 TRE/PHYS

Beyond the Electric Dipole Approximation: Electric and Magnetic Multipole Contributions Reveal Biaxial Water Structure from SFG Spectra at the Air-Water Interface — •Louis Lehmann[1], Maximilian R. Becker[1], Lucas Tepper[1], Alexander P. Fellows[2], Álvaro Díaz Duque[2], Martin Thämer[2], Martin Wolf[2], and Roland R. Netz[1] — [1]Department of Physics, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany — [2]Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195 Berlin, Germany

Sum-frequency generation (SFG) analysis has been hindered by the lack of quantitative predictions for higher-order multipole contributions. Magnetic dipole and electric quadrupole terms, though determined by bulk properties, appear in all SFG spectra and obscure connections to interfacial structure. We present a simulation-based framework that predicts all multipole contributions and provides depth-resolved spectra for precise localization of features. Applied to the

air-water interface, it reproduces experimental spectra across polarization combinations in both bending and stretching regions. Higher-order multipoles are essential: in the bending band, electric and magnetic dipoles are comparable, while the quadrupole dominates; in the OH-stretch region, the quadrupole accounts for the 3600/cm shoulder. Isolating the true second-order electric-dipole susceptibility reveals pronounced biaxial ordering of interfacial water and enables reliable interfacial structure determination from SFG spectra.

O 87.8 Thu 16:45 TRE/PHYS

Heat transfer across nanometre-sized water meniscus — •Oscar Mateos[1], Ruben Lopez[2], Pablo Martinez[1,3], Guilherme Vilhena[1], Nicolas Agrait[2,4], and Juan Carlos Cuevas[3,4] — [1]Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC), 28049 Madrid, Spain — [2]Departmento de Física de la Materia Condensada, Universidad Autónoma de Madrid, 28049 Madrid, Spain — [3]Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, 28049 Madrid, Spain — [4]Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, 28049 Madrid, Spain

Heat transfer in nanoscale gaps is of key relevance for a variety of technologies. Recent experiments have reported contradictory results shedding doubts about the mechanisms for heat exchange in nanometre-sized gaps. We aim at resolving this controversy by measuring the thermal conductance of gold atomic-sized contacts with a custom-designed scanning tunnelling microscope that incorporates a novel thermal probe, enabling the measurement of thermal and electrical conductance in different transport regimes. When the electrodes are separated by a nanometre-sized gap, we observe thermal signals which cannot be explained with standard heat transfer mechanisms. Through non-equilibrium molecular dynamic simulations, we elucidate that these anomalous signals are due to thermal conduction through water menisci that form between tip and sample under customary operation conditions.

O 87.9 Thu 17:00 TRE/PHYS

Charging dynamics of the electrical double-layer in nanometre sized channels — •Marco Schönig, Serge Lemay, and Marc Koper — Leiden University, Leiden, The Netherlands

Nanoporous electrodes play a crucial role in modern energy storage and conversion technologies. However, despite their ubiquitous usage, the impact of nanoscale geometrical confinement on their electrochemical properties remains poorly understood. This is particularly relevant when the pore dimensions become so confined that the double layers of opposing sides overlap. A key challenge in studying this phenomenon in a systematic manner is the necessary precise control of the experimental dimensions[1]. We aim to bridge this gap by utilizing modern nanofabrication techniques to fabricate model gold slit electrodes[2].

In this contribution, we present the charging behaviour of electrodes with 5 - 20 nm wide slits, under confined and unconfined conditions. We further explore the usage of ATR-IR spectroscopy to probe the electrolyte in the slit electrodes by using micro-grooved Si wafers as substrate[3].

Trapping ionomer for efficient proton exchange membrane fuel cells — •Fanpeng Kong — Harbin Institute of Technology, Harbin, China

Both uniformity of ionomer distribution and adsorption dynamics of side-chain sulfonates are paramount in determining the performance of low Pt-loaded membrane electrode assembly (MEA), particularly at high current densities. However, the heterogeneity of Pt/C leads to strong sulfonate anion adsorption on Pt sites and deleterious ionomer aggregation on the carbon support. Here, we synthesize atomic dipole modulated Pt/C (SCDC-Pt) electrocatalysts for low Pt-loaded MEA. Remarkably,this catalyst delivers a superior peak power density (1.4 W cm-2) and only a 15% of activity loss after 30 000 square-wave cycles. Operando characterization and computational analysis demonstrate that surface charged dipole facilitates homogenous ionomer distribution, while mitigating sulfonate poisoning of Pt. Electrochemical diagnostic technique establishes the low sulfonate coverage (~8%) and local O2 transport resistance (38.6 S m-1).This finding demonstrates the viability of rationally designed high-performance surface composition-homogenization low Pt-loaded MEA.

O 88.2 Thu 15:15 TRE/MATH

Molecular Beam Surface Scattering and PECD to Probe Chirality in Surface Reaction Products — Arved Dorst[1,2], Johannes Diedrich[1,2], Rasika Dissayanake[1,2], and •Tim Schäfer[1,2] — [1]Georg-August-University of Göttingen, Germany — [2]Max-Planck Institute for Multidisciplinary Sciences, Göttingen, Germany

The epoxidation of olefins on Ag/O systems is an important industrial heterogeneous catalytic process. However, the mechanistic details of the surface reaction remain controversial, and it has been highly challenging to reconcile findings obtained under realistic reaction conditions with the highly detailed but static studies performed under ultra-high vacuum (UHV).

An additional level of complexity and opportunity arises when using prochiral olefin molecules. Their epoxidation can yield chiral epoxide products, provided the reaction pathway can be directed toward one enantiomer. In our studies, we combine molecular-beam surface scattering with laser spectroscopy to probe this process. By detecting the photoelectron circular dichroism (PECD) of the reaction products, we are able to determine their absolute chirality.

Our overarching goal is to achieve an atomistic understanding of reaction dynamics on chiral surfaces, ultimately bridging the gap between UHV studies and catalytic behavior under operational conditions.

From Processes to Mechanisms: Machine-Learning Based Automated Lattice Mapping as Prerequisite to Microkinetic Modeling — •Aditya Kumar[1], Patricia Poths[1], King Chun Lai[2], Christoph Scheurer[1], Sebastian Matera[1], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Max Planck Computing and Data Facility, Garching

Finding the reaction mechanism of a surface reactive system from first principles is a tedious task requiring a lot of human effort and being affected by human bias. To address these points, we have developed the Automatic Process Explorer (APE), which generates a comprehensive library of elementary reaction steps [1]. With easily thousands of steps identified, their manual assembly into a reaction network as a prerequisite to subsequent microkinetic modeling becomes intractable. To this end, we develop an automated framework that infers an effective lattice onto which all APE-discovered elementary steps may be coarse-grained. In this, atomic configurations from APE are analyzed using density-based hierarchical clustering, creating a fine-to-coarse hierarchy of potential lattice sites. All processes are then mapped onto the lattice as discrete occupation changes and, exploiting symmetry, a network of unique elementary reactions on this lattice is generated. We demonstrate the approach for a large set of elementary processes within the initial oxidation of Pd(100) terrace edges, and discuss the feasibility of subsequent efficient lattice-based microkinetic simulations.

Investigating the Promotion Mechanism of Lanthanum on Cobalt Model Catalysts for Ammonia Production — •Clara C. Aletsee, Lau H. Wandall, Emanuel Biletter, and Ib Chorkendorff — DTU, Copenhagen, Denmark

Developing catalysts for ammonia synthesis under milder conditions than the Haber-Bosch process has gained significant interest. Recent studies demonstrate that usually unreactive magnetic materials, such as cobalt, can be activated for NH_3 synthesis by adding lanthanum.(1,2) According to theoretical calculations, this is attributed to not only an electrostatic, but also a beneficial spin promotion effect.(3) Herein, we examine the role of the promoter form on the catalytic performance. For this, either metallic La or La_2O_3 was deposited on a stepped Co(10-115) single crystal surface via e-beam evaporation. Additionally, mass-selected Co nanoparticles were deposited on two different magnetron-sputtered film supports: LaN and La_2O_3. All catalysts were characterized by X-ray photoelectron spectroscopy and low-energy ion scattering before and after reaction, and their activity was measured between 350-500°C at 1 bar in a UHV-compatible cell.(4) We show that Co/La_2O_3 exhibits the same activity as the LaN supported catalyst system at 350°C, but the stability decreases at higher temperatures.

Bridging the Pressure and Materials Gaps in NO Adsorption on Ceria — •Lukas Bolz[1], Ali Essa[1], Zairan Yu[1], Alexei Nefedov[1], Julia Vecchietti[2], Adrian Bonivardi[3], Yuemin Wang[1], and Christof Wöll[1] — [1]Insitute of Functional Interfaces, KIT, Eggenstein-Leopoldshafen, Germany — [2]Instituto de Desarrollo Tecnológico para la Industria Química, UNL, Santa Fe, Argentina — [3]Facultad de Ingenieria, UBA, Buenos Aires, Argentina

Nitric oxide (NO) is well known to have adverse effects on human health and the environment. One effective approach to decrease its emission is the selective catalytic reduction of NO over metal oxide surfaces. Understanding the reaction mechanisms, by tracking the structural changes of the active sites and intermediates as a function of reaction atmosphere and temperature, is crucial. Here, we present results on UHV-IRRAS and FTIRS as well as in situ/operando DRIFTS studies at atmospheric pressures and elevated temperatures to investigate the interaction between NO and ceria (CeO_2). A reliable assignment of the IR bands observed in the complex DRIFTS spectra was achieved based on accurate references obtained for NO molecules adsorbed on single crystal surfaces and nanocrystalline powders, thereby bridging the material and pressure gap for oxidic catalysts. The combined results enabled the tracking of facet-dependent surface transformations, the adsorption and reaction of NO, and the formation of intermediates such as nitrous oxide (N_2O). This work was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) - Project-ID 426888090 - SFB 1441, project B03 and A04.

O 88.6 Thu 16:15 TRE/MATH

Competing reaction pathways in decomposition of 2-propanol over V-doped Co3O4(111) model catalyst: a mechanistic study. — •Patrick Hubert[1], Jan Smyczek[1], Maximilian Galinski[1], Lina Marquardt[1], Justin Girschik[1], Philipp Fredersdorff[1], Paul Fröhlich[1], Bernd Hartke[1], Guntram Rauhut[2], and Swetlana Schauermann[1] — [1]Institute of Physical Chemistry, Christian-Albrechts-University Kiel, Max-Eyth-Str. 1, 24118 Kiel, Germany. — [2]Insitute of Theoretical Chemistry, University of Stuttgart, Pfaffenwaldring 55, 70569 Stuttgart, Germany.

This study investigated catalytic decomposition of 2-propanol over Co_3O_4(111)/Au(111) and VO_x/Co_3O_4(111)/Au(111) model catalysts to unravel competing reaction pathways toward acetone or propene. Ultra-high vacuum (UHV) surface science techniques were employed, including scanning-tunneling microscopy (STM), molecular-beam methods, infrared reflection absorption spectroscopy (IRAS), and temperature-programmed desorption (TPD). The VO_x/Co_3O_4(111)/Au(111) surface exhibits structures with V^{3+}, V^{4+} adsorption sites and vanadyl groups (V=O). TPD measurements showed propene desorption at 480 K from 2-propanol adsorbed at 100 K on surfaces exceeding 0.6 ML VO_x coverage. At 180 K, 2-propanol dissociatively adsorbs on VO_x, consuming vanadyl groups during OH deprotonation, forming tilted 2-propoxy with surface-proximal methyl groups. At 400 K, a second intermediate forms via C-O bond scission and methyl deprotonation. IR spectra suggest this intermediate is a surface-bound propene-derived species.

O 88.7 Thu 16:30 TRE/MATH

Beyond U-Ce charge transfer: stabilization of Ce^{3+} states in epitaxial $Ce_{1-x}U_xO_2$ films grown on Ru(0001) — •Carlos Morales[1], Rudi Tschammer[1], Thomas Gouder[2], Hicham Idriss[3], and Jan Ingo Flege[1] — [1]Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology, Cottbus, Germany — [2]European Commission, Joint Research Centre (JRC), Karlsruhe, Germany — [3]Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

Cerium oxide (CeO_2) stands out among reducible metal oxides for its stability and activity. Yet, promoting Ce^{3+} active states requires high energy. The conversion of Ce^{4+} to Ce^{3+} at lower temperatures for the thermochemical splitting of H_2O or CO_2 can be enhanced by doping ceria with other elements. Particularly, ceria mixing with uranium has been proven successful: substituting a fraction of Ce^{4+} by U^{4+} results in a charge transfer that promotes the formation of Ce^{3+} and U^{5+} states. We have explored the redox properties of 8 nm thick epitaxial (111)-oriented $Ce_{1-x}U_xO_2$ on Ru(0001). In line with previous studies focused on polycrystalline powders, the as-grown films exhibit a high Ce^{4+} to Ce^{3+} conversion, with a maximum reduction corresponding to approximately 20 % of U content. However, the concentration of Ce^{3+} states and oxygen is higher than predicted by density function theory (DFT) calculations for various U contents and spatial ordering. The observed behaviour could be likely related to the lattice distortion caused by the significant difference in the ionic radii of Ce^{3+} and U^{5+}. This effect has not been considered before in $Ce_{1-x}U_xO_2$ mixed oxides.

O 88.8 Thu 16:45 TRE/MATH

Product Selectivity in Fischer-Tropsch Synthesis — •Benjamin Rasmus Grimm, Luis Antonio Cipriano Marcos, Oliver Christensen, and Jens Kehlet Nørskov — DTU Physics, Kongens Lyngby, Denmark

The product selectivity and activity of Fischer-Tropsch synthesis (FTS) is important for producing synthetic fuels and chemicals from natural gas, coal, or biomass. Some catalysts generate mainly undesired methane, whereas others show higher selectivity toward longer hydrocarbons. In this study, density functional theory (DFT) is employed to calculate the activity- and selectivity-determining reaction steps and energy barriers of FTS on cobalt-based catalysts. Reaction rates and product selectivities are then evaluated using a microkinetic model that incorporates the rate- and selectivity-determining steps of the FTS mechanism. To describe the catalyst as realistically as possible, adsorbate coverage and migration effects under experimental conditions are taken into account. Finally, strategies to improve reaction rates and selectivity are discussed.

O 88.9 Thu 17:00 TRE/MATH

Low-Temperature CO2 Methanation over Ni/Ce-Sm Oxide Catalysts — •Rachow Fabian, Sichen Liu, Evgenia Charlafti, Raquel Sánchez-Barquilla, and Jan Ingo Flege — Brandenburg University of Technology, Cottbus-Senftenberg, Germany

Nickel catalysts on doped ceria are attractive for CO_2 methanation due to their redox flexibility and potential for improved efficiency and stability. In this work, we investigate Ni supported on mixed Ce–Sm oxides with Ce:Sm ratios of 3:1, 2:1, and 1:1. The catalysts are tested as powders in a fixed-bed flow reactor between 250 and 400°C and benchmarked against a conventional Ni/Al_2O_3 catalyst. Among the compositions, the Ce:Sm ratio of 2:1 shows the highest CO_2 conversion, with a pronounced enhancement in low-temperature activity compared to Ni/Al_2O_3. To relate performance to material properties, we combine X-ray diffraction (XRD), temperature-programmed reactivity (H_2-TPR), Raman spectroscopy, high-resolution transmission electron microscopy (HRTEM/EDX), as well as in-situ X-ray absorption near-edge spectroscopy (XANES) under reaction conditions, elucidating how Sm incorporation and Ce:Sm ratio influence the structural and redox characteristics of the oxide support, oxygen vacancy formation, and Ni dispersion, which together govern catalytic activity and stability. To assess practical applicability and scale-up, the optimized Ni/Ce–Sm (2:1) oxide formulation is deposited on Al_2O_3 spheres and evaluated under conditions representative of packed-bed operation with a limited amount of active material, revealing high conversion and stable, efficient operation in low-temperature CO_2 methanation.

Heteroepitaxial growth of Sm_2O_3 nanoislands on Cu(111) — •Björn Riedel[1], Raquel Sánchez-Barquilla[1], Lars Buss[1], Iulia Cojocariu[2], Tevfik Onur Mentes[2], Andrea Locatelli[2], and Jan Ingo Flege[1] — [1]Brandenburg University of Technology, Cottbus, Germany — [2]Elettra-Sincrotrone Trieste, Basovizza, Italy

Doping of CeO_2 with samarium can significantly influence its redox behavior by promoting the formation and stabilization of reduced Ce^{3+} species. Yet, studies of well-defined samaria model systems grown on single-crystal surfaces are scarce, leading to a lack of combined structural and spectroscopic studies and, hence, a gap in understanding the relationship between samaria's structure and its chemical behavior. We have investigated hexagonal and monoclinic Sm_2O_3 nanoislands grown on Cu(111) using a multi-method approach with high structural and chemical sensitivity, employing low-energy electron microscopy (LEEM), micro-spot diffraction (μLEED) and intensity-voltage LEEM in combination with X-ray absorption spectroscopy photoemission electron microscopy (XAS-PEEM). To study the influence of different structures and phases on the chemical behavior of Sm_2O_3 islands, we have examined their redox properties under reducing (H_2) and oxidizing (O_2) conditions. The results indicate a highly dynamic system that can be readily adjusted by varying the conditions during deposition, such as growth temperature and oxygen partial pressure.

O 88.11 Thu 17:30 TRE/MATH

Surface Modifications in Complex Mixed Oxide Activation for the Selective Oxidation of Hydrocarbons — •Kyeonghyeon Nam[1], L. Masliuk[1], T. Jones[1], Y. Song[1], A. Trunschke[1], R. Schlögl[1], T. Lunkenbein[1,2], K. Reuter[1], and C. Scheuer[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Universität Bayreuth

Calcination (thermal activation) is crucial for metal-oxide catalysts, enhancing activity and durability by preparing surface morphology and active sites. However, thermal treatment also induces dynamic surface changes, such as defect formation, reconstruction, and grain reorientation, complicating the continuous monitoring of a catalyst's surface. Here, identical-location STEM imaging of a ternary M1 $(Mo,V)O_x$ catalyst reveals that the (hk0) surface undergoes pronounced modification under calcination and oxidative dehydrogenation (ODH) conditions. The surface evolution is modeled using machine learning force fields. Molecular dynamics (MD) simulations reproduce the reconstruction of extended M1 regions from MoO_2-like motifs, as well as mass transport within the pentagonal motif that further activates the catalyst. Experimentally observed catalytic activity changes can be assigned to the presence of highly charged surface metal centers via DFTB Mulliken charge analysis. These surface transformations strongly influence the catalytic properties of ternary M1 catalysts, suggesting potential applications in improving catalytic performance through controlled surface modifications.

Magnetization Curves of Antiferromagnetic Spin Chains: Probing the Quantum to Classical Crossover — •Henrik Lichtl[1,2], Lukas Veldman[1,2], Nicolaj Betz[1,2], Johannes Schust[1], Laëtitia Farinacci[1,3], Fernando Delgado[4], Susanne Baumann[1], and Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies. — [2]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart. — [3]Carl-Zeiss- Stiftung Center for Quantum Photonics Jena - Stuttgart - Ulm. — [4]Instituto de Estudios Avanzados IUDEA, Departamento de Física, Universidad de La Laguna.

As the size of a magnetic structure increases it undergoes a transition from a quantum system to a classical magnet, yet the evolution of the magnetization behavior at this crossover is largely unexplored. Here we introduce an approach to record high-speed magnetization curves in a scanning tunneling microscope (STM), reaching magnetic field sweep rates of up to 40kT/s. We analyze the statistics of the transitions between the two antiferromagnetic ground states of antiferromagnetic Fe spin chains on a Cu2N surface, which allows us to distinguish between quantum and classical regimes in their magnetization curves. Quantum signatures diminish rapidly with size of the chain, where chains longer than five atoms already show characteristics of classical nanoscale magnets. Accessing such high-speed magnetization curves at the atomic scale brings concepts originally developed for bulk materials into the STM, offering insight into how quantum spins interact with their environment during the quantum-to-classical transition.

O 89.2 Thu 15:15 WILL/A317

Optimizing On-Surface Quantum Spins for Quantum Information Processing — •Denis Jankovic[1,2], Hoang-Anh Le[1,2], Saba Taherpour[1,3], and Christoph Wolf[1,2] — [1]Center for Quantum Nanoscience, Institute for Basic Science, Seoul, Republic of Korea — [2]Ewha Womans University, Seoul, Republic of Korea — [3]Departement of Physics, Ewha Womans University, Seoul, Republic of Korea

The bottom-up engineering of quantum-coherent spins on surfaces with STM enables atomically precise quantum logic in on-surface qubits, and atomic-scale multi-qubit devices.

We use optimal control on an open-system model of exchange-coupled surface spins to counter decoherence, static coupling, and imperfect initialization, identifying high-fidelity gates compatible with current ESR-STM constraints.

Finally, building on advances in electrically driven nuclear spins, we will outline ongoing experiments using lanthanides on surfaces, where ESR-STM manipulates hyperfine-coupled nuclear-spin manifolds as on-surface qudits.

O 89.3 Thu 15:30 WILL/A317

Spin Lifetime Engineering using Superconducting Surfaces — •Máté Stark, Luise Renz, Jonas Arnold, Johannes Schwenk, Christoph Sürgers, Wolfgang Wernsdorfer, and Philip Willke — Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany

Extending the spin lifetime (T_1) and decoherence time (T_2) of atomic and molecular spins is central to realizing quantum-coherent spin systems on surfaces studied by scanning tunneling microscopy (STM). For instance, previous studies have demonstrated that T_1 can be extended to nanoseconds for Fe-OEP-Cl on superconducting Pb(111) to milliseconds for Fe on MgO/Ag(001) by exploiting superconducting protection or electronic decoupling, respectively [1,2].

Building on these concepts, we aim here to combine protection by a superconducting gap and insulating decoupling layers to explore and control spin lifetimes of single FePc spins. By switching from the normal-conducting into the superconducting state we discuss how superconductivity as well as decoupling from the substrate and tip govern the lifetime and dynamics of molecular spin excitations. We show first results using all electric pump-probe spectroscopy, which are performed in a home-built dilution refrigerator scanning tunneling microscope operating at 50 mK.

O 89.4 Thu 15:45 WILL/A317

Bottom-up realization of band structure using arrays of individual Cs atoms on InSb(110) — •Niek M.M. Aarts, Kira Junghans, Roel Burgwal, Daniel Wegner, and Alexander A. Khajetoorians — Institute for Molecules and Materials, Radboud Universiteit, Nijmegen, Netherlands

The combination of atomic manipulation and scanning tunneling spectroscopy has become a powerful platform for quantum simulation of electronic structure. The approach is based on the atomically precise placement of atoms and the flexibility to realize structures with a variety of shapes and symmetry. Inherent to this approach is role of finite size effects in the tailored electronic structure. This plays an integral role in understanding the influence of various interactions, like spin-orbit interactions, or electron-electron interactions, on any potential quantum phase of matter to be simulated.

Here, we study the evolution of the electronic structure as a function of lattice size, using the recently discovered quantum simulator platform of Cs on InSb(110). Using STM, we start by studying structures that exhibit atomic like states and expand these structures into the molecular limit. We study the changes in the localized states and the symmetry of the responsible wavefunctions. We then quantify the increase of states as the number of sites in the system increases, and band structure emerges. We also discuss the role of the size of the artificial atomic sites. This extension of the Cs/InSb(110) quantum simulator to larger systems enables the study of artificial band structure in the presence of strong SOC.

O 89.5 Thu 16:00 WILL/A317

Crystal field manipulation of magnetic atoms on an insulating surface — •Julian Zeitler[1], Johannes Schust[1], Nicolaj Betz[1,2], Lara Mezger[1], Lukas Veldman[1], Laëtitia Farinacci[1,3], Fernando Delgado[4], Philip Willke[5], Sebastian Loth[1,2], and Susanne Baumann[1] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies. — [2]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart. — [3]Carl-Zeiss-Stiftung Center for Quantum Photonics Jena - Stuttgart - Ulm. — [4]Instituto de Estudios Avanzados IUDEA, Departamento de Física, Universidad de La Laguna. — [5]Karlsruhe Institute of Technology, Physikalisches Institut.

The magnetic behavior of ions in solid-state materials is predominantly driven by their immediate atomic-scale environment. The specific arrangement of surrounding charges creates a crystal field (CF), which alters and mixes the electronic states. For magnetic atoms on insulating thin films, this CF is strongly influenced by the atom's adsorption site on the underlying lattice. Using combined scanning tunneling microscopy (STM) and atomic force microscopy (AFM), we investigate the CF influence on magnetic atoms on thin-film MgO and use tip-atom forces to precisely reposition the atoms within their binding sites, thereby tuning the CF. We quantify changes of the local binding geometry by combining our measurements with multiplet calculations. Our measurements pave the way for harnessing magneto-elastic effects in individual atoms either by manipulating their magnetic properties via electric fields or local forces, such as mechanical strain.

O 89.6 Thu 16:15 WILL/A317

Topological End States of Chiral Graphene Nanoribbons on Proximitized Superconducting Au (111) — •Trisha Sai[1], Frederik Bauer[1], Stefano Trivini[1], and Jose Ignacio Pascual[1,2] — [1]CIC nanoGUNE-BRTA, 20018 Donostia-San Sebastián, Spain — [2]Ikerbasque, Basque Foundation for Science, 48013 Bilbao, Spain

Graphene nano-structures may host localized magnetic moments characterized by their geometry, heteroatom substitution, topological frustration, or bulk-boundary correspondence. However, observation of their open-shell configuration via on-surface synthesis can be inhibited due to charge transfer. This is in the case of (3, 2, 8) chiral graphene nanoribbons (chGNRs) synthesized on Au(111), whose symmetry-protected topological end states (SPTES) are quenched due to electron depopulation. In this work, we synthesize (3, 2, 8) chGNRs on thin films of Au (111) grown on a superconducting Nb (110) single crystal. Through controlled deposition of monolayers of Au, we observe a modulation in the surface state of Au (111), thereby a reduction in the work function of the resulting platform. Moreover, the substrate is also complemented with proximity induced superconductivity. Low-Temperature scanning tunneling spectroscopic (STS) measurements reveal that the SPTES of (3, 2, 8) chGNRs are retained in a mixed-valence regime where their spectral weight is distributed between an in gap Yu-Shiba-Rusinov (YSR) state and an orbital state close to Fermi energy. In case of a depopulated terminus, the YSR states are weak and suppressed while the orbital state is more pronounced.

O 89.7 Thu 16:30 WILL/A317

Confinement-modulated spin-orbit coupling tuned with atomic-scale gating fields — •Hermann Osterhage, Julian H. Strik, Anna M. H. Krieg, Ivan Ado, Mikhail Titov, Daniel Wegner, and Alexander A. Khajetoorians — Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands

In 2D, inversion symmetry breaking combined with a sizeable potential gradient leads to the well-known Rashba spin-orbit coupling (SOC), locking the spin and momentum. Using potential gradients to induce SOC is not limited to the Rashba case, but may be extended to lower dimensional structures, such as quantum dots. However, tuning SOC in these limits is challenging: it requires potential gradients that are comparable to the size of the confined structure itself.

Here, we demonstrate a new type of SOC, akin to the Rashba effect, where large potential gradients are formed within an atomically patterned quantum

dot. Using low-temperature scanning tunnelling microscopy and spectroscopy we create quantum dots of various shapes and sizes by patterning individual Cs ions on the surface of InSb(110). We find that we can tune the confinement potential, as shown by the presence of multiple localized states. In addition, by probing the resultant multiplet structure, we identify zero-field splittings within a given quantum dot that are induced by the geometry of the potential. We also discuss the magnetic field dependence of this level structure and explain the findings based on the 8-band Kane model.

O 89.8 Thu 16:45 WILL/A317

Tuning the Kondo temperature of MoS_2 mirror twin boundaries on graphene — •Tfyeche Y. Tounsi[1], Kuber Vyas[1], Camiel van Efferen[1], Affan Safeer[1], Achim Rosch[2], Jeison Fischer[1], Thomas Michely[1], Theo A. Costi[3], and Wouter Jolie[1] — [1]II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany — [2]Institut für Theoretische Physik, Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany — [3]Peter Grünberg Institut, Forschungszentrum Jülich, 52425 Jülich, Germany

In scanning tunneling spectroscopy, the dI/dV signatures of the Kondo effect in MoS_2 mirror twin boundaries (MTBs) are the zero-bias resonance peak, in addition to the impurity levels [1]. The experimental data give access to the Anderson model parameters; The splitting U of the non-degenerate states, the impurity orbital's position ϵ with respect to E_F, and the impurity level's bare width γ_0.

In this work, we compare the Kondo temperature T_K measured in MTBs of MoS_2 grown on three different substrates. In the case of MoS_2 / Graphene (Gr) / Ir (111), T_K was in the range [10^{-4} K, 10^{-10} K] [1]. By intercalating with a single layer of Eu under Gr, we have noticed a decrease of γ_0, leading to a drop in T_K. The third system, MoS_2 / Gr / Ir (110), T_K increased significantly to the range [1 K, 10 K]. This enabled us to study the Kondo effect at the boundary between the weakly screened magnetic state above T_K and the Kondo singlet state below T_K.

Statistical analysis of electron-induced switching of a spin-crossover complex — •Jonas Fussangel[1], Björn Sothmann[1], Sven Johannsen[2], Sascha Ossinger[3], Felix Tuczek[3], Richard Berndt[3], Jürgen König[1], and Manuel Gruber[1] — [1]Fakultät für Physik and CENIDE, Universität Duisburg-Essen, 47048 Duisburg, Germany — [2]Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany — [3]Institut für Anorganische Chemie, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany

Spin-crossover complexes switch between two spin states, but the microscopic pathway remains unclear. Using low-temperature STM, electron-induced switching of $[Fe(H_2B(pz)(pypz))_2]$ on Ag(111) has opened new perspectives for understanding the switching mechanisms. Current time traces show two levels matching the spin states. An analysis of waiting-time distribution yields switching rates whose voltage dependence is explained by a simple model where transient molecular charging triggers switching. Comparing experiment and theory provides previously inaccessible estimates of LUMO energies [1]. The approach offers new insights into the switching mechanism and predicts higher switching rates when the molecule is electronically decoupled from the substrate, e.g., by introducing an ultrathin insulating layer.

Decoupling strategies for YPc_2 molecular spin qubit platforms on metal surfaces — Franklin H. Cho[1,2], Soyoung Oh[1,2,3], Dan Chi Nguyen[1,2], Jinjoo Lee[1,2], We-hyo Soe[1,2], Luciano Colazzo[1,2], Jisoo Yu[1,2], Pierre Josse[1,2], Caroline Hommel[1,2], Lukas Spree[1,2], Christoph Wolf[1,2], and •Fabio Donati[1,2] — [1]IBS Center for Quantum Nanoscience, South Korea — [2]Ewha Womans University, South Korea — [3]The Clarendon Laboratory, University of Oxford, The United Kingdom

Yttrium phthalocyanine double-decker (YPc_2) is an appealing building block for surface spin-qubit architectures due to its delocalized $S = 1/2$ radical and planar structure [1]. Here, we investigated the morphology, electronic structure, and spin properties of single- and multi-layer YPc_2 on Cu(111) single crystals and on zinc phthalocyanine (ZnPc) grown on Cu(111). Low temperature scanning tunneling microscopy reveals the molecular layer structure and the variation of its electronic configuration when directly adsorbed on Cu(111) versus on a ZnPc decoupling layer [2]. X-band electron spin resonance using our custom-built surface-sensitive spectrometer [3] shows that the YPc_2 radical is preserved on ZnPc but quenched upon direct contact with Cu(111). Density functional theory attributes this quenching to the hybridization of molecular orbitals with the substrate electrons. Our study highlights the necessity of suitable decoupling layers to preserve radical spins near metallic surfaces. [1] F. Branzoli et al., Phys. Rev. B 83, 174419 (2011). [2] S. Oh et al., Nanoscale 17, 22163 (2025). [3] F. H. Cho et al., Rev. Sci. Instrum. 95, 063904 (2024).

Current-induced Electron Spin Polarization in Magnetic Molecules — •Paul Greule, Wantong Huang, Máté Stark, Kwan Ho Au-Yeung, Johannes Schwenk, Christoph Sürgers, Wolfgang Wernsdorfer, and Philip Willke — Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany

Electron spins of single molecules offer a promising platform for quantum information processing. To harness such spins as functional qubits, efficient initialization is essential. Electron spin resonance combined with scanning tunnelling microscopy (ESR-STM) has emerged as a powerful technique to probe molecular spins at the atomic scale. Using this technique, it has been shown that a spin-polarized tunnelling current can polarize the nuclear spin of a single Cu atom [1]. In this talk, we show that this concept can be transferred to the electron spin of molecules: Using Fe-FePc complexes with an electron spin of S=1/2 [2], we build molecular dimers. Here, the first complex serves as a readout and pumping system, while the energy-level occupation of the second complex is probed and manipulated. The exchange interaction between them enables remote spin-pumping, where angular momentum is transferred. Controlling the spin-polarized tunnel current via the bias voltage allows us to tune the spin polarization of the second complex remotely. Our findings establish an all-electrical technique to initialize molecular spin qubits and provide insights for enhanced control schemes. [1] K. Yang et al., Nat Nano 2018, 13, 1120-1125 [2] W. Huang et al., Nat Commun 2025, 16, 5208

Identifying Electronic Doorway States in Secondary Electron Emission — •Anna Niggas[1], Maosheng Hao[2], Peter Richter[3], Felix Blödorn[1], Florian Simperl[1], Alessandra Belissimo[4], Joachim Burgdörfer[2], Thomas Seyller[3], Wolfgang Werner[1], Florian Libisch[2], and Richard A Wilhelm[1] — [1]Institute of Applied Physics, TU Wien, Vienna, Austria — [2]Institute for Theoretical Physics, TU Wien, Vienna, Austria — [3]Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — [4]Institute of Photonics, TU Wien, Vienna, Austria

Secondary electron emission following low-energy (<200 eV) electron impact is fundamental to particle-solid interactions but remains incompletely understood. While high-energy electrons are described by reflected primaries undergoing inelastic losses, the low-energy (<20 eV) region is often considered featureless. Coincidence spectroscopy has revealed hidden structures, notably the 3.3 eV X peak in graphite arising from plasmon excitation and interlayer-state hybridisation. Following that, we have measured low-energy secondary electrons from graphite and quasi-freestanding single- and bilayer graphene, enabling a controlled transition from bulk to two-dimensional systems. We observe layer-dependent features and, supported by density functional theory, attribute them to Feshbach-type resonances of quasi-bound above-vacuum states coupling to the continuum. The strong 3.3 eV resonance appears only in systems with five or more layers [1].

O 93.2 Fri 9:45 HSZ/0201

A novel approach to depth-resolved magnetic spectoscopy: grazing-incidence XMCD — •Umut Parlak[1], Katharina Wehrstein[1], Pia Maria Düring[1], Oliver Rehm[1], Endrit Kusari[1], David Capalbo[1], Andrei Gloskovskii[2], Christoph Schlueter[2], Lutz Baumgarten[3], and Martina Müller[1] — [1]Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany — [2]Deutsches Elektronen-Synchrotron, 22607 Hamburg, Germany — [3]Peter Grünberg Institut, PGI-6, Research Centre Jülich, 52425, Jülich, Germany

Magnetic depth profiling plays a key role in understanding inter- and intralayer magnetic coupling mechanisms in multilayer thin films. We employ a synchrotron-based photoelectron spectroscopy approach (P22 beamline, DESY) to measure x-ray magnetic circular dichroism with depth-resolution taking EuO thin films grown on heavy metal (HM) underlayers as prototype sample. The presence of HM underlayer enables the near-total reflection x-ray excitation, where the incident and reflected x-rays interfere at the grazing angles forming high-intensity nodal points. The depth-resolution is achieved by probing at angles between 0.2 and 1°, i.e., tuning the position of the nodal points. Simulations of the x-ray intensity profile at these low angles allow us to optimize the MBE-grown MgO/EuO/HM trilayer structure for accessing both the upper and lower interfaces. Our results reveal the distribution of Eu^{2+} and Eu^{3+} ions throughout the EuO layer, which form ferromagnetic and paramagnetic oxides, respectively. The valency profile of the Eu ions directly aligns with the magnetic asymmetry profile.

O 93.3 Fri 10:00 HSZ/0201

Experimental Verification of the d-band Center Model in Au/Pt Systems: A Low-Energy XPS Study — •Justyna Piwowar[1,2,3] and Adam Lewera[3] — [1]Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Seoul 03760, Republic of Korea — [2]Ewha Womans University, Seoul 03760, Republic of Korea — [3]Faculty of Chemistry, University of Warsaw Pasteura 1 02-093 Warszawa

This work presents an experimental verification of the relationship between electronic structure and electrocatalytic properties in Pt-based materials, specifically critically evaluating the d-band center theory. Using Au-modified Pt as a model system, surface electronic properties were probed via X-ray Photoelectron Spectroscopy (XPS). We demonstrate that employing low-energy X-ray sources (Zr Mγ, 151 eV) provides superior surface sensitivity compared to standard sources (~1500 eV), allowing for the detection of subtle surface electronic shifts otherwise masked by bulk signals.

We observed a nonlinear evolution of electronic properties in Au/Pt thin films, specifically in core-level binding energies, which correlates with synergistic catalytic activity in formic acid oxidation. Detailed analysis of the valence band spectra reveals that significant modifications in the Density of States (DOS) near the Fermi level can occur even when the calculated shift in d-band center is negligible, due to spectral redistribution on both sides of the centroid. These findings indicate that the d-band center parameter alone may be insufficient to describe complex electronic structure modifications.

O 93.4 Fri 10:15 HSZ/0201

Spin Polarization of Photoelectrons Excited by Deep-UV Pulses with Orbital Angular Momentum — •Paul Valerian Möllers, Ruwen Quenter, and Helmut Zacharias — Center for Soft Nanoscience, Universität Münster

It is well known that circularly polarized light can excite longitudinally spin-polarized photoelectrons from centrosymmetric crystal surfaces [1]. The light carries an angular momentum of $\pm\hbar$, and the selection rules dictate that the photoexcitation occurs into final states with a specific total angular momentum. In the presence of spin–orbit interaction, states with different total angular momenta are energetically separated, and the excited electrons can exhibit a net spin imbalance. Light with helical wave fronts carries orbital angular momentum as a degree of freedom that is independent of its polarization and not limited to $\pm\hbar$ [2]. As the light always acts on the orbital electron angular momentum during photoexcitation, it appears plausible to assume that the optical orbital angular momentum could translate into a nonzero photoelectron spin polarization. This hypothesis has yet to be tested experimentally. We present preliminary results of spin-resolved photoemission measurements on Cu(111) and Au(111) surfaces that address this issue. [1] G. Borstel, M. Wöhlecke, Phys. Rev. B 26, 1148-1155 (1982) [2] S. S. R. Oemrawsingh et al., Appl. Opt. 43, 688-694 (2004)

Imaging stripe dynamics in superconducting nickelate — •Uladzislau Mikhailau[1], Luke C. Rhodes[1], Matthias Hepting[2], Masahiko Isobe[2], Pascal Puphal[2], and Peter Wahl[1,3] — [1]University of St Andrews, St Andrews, United Kingdom — [2]Max-Planck-Institute for Solid State Research, Stuttgart, Germany — [3]Physikalisches Institut, Universitat Bonn, Germany

In the Hubbard model, there is a competition between charge localization due to Coulomb repulsion and delocalization due to the energy reduction from electrons hopping between sites. When both tendencies are equally strong, a unique correlated stripe order can be stabilized [1]. Such a state is known to be realized in lightly doped high temperature superconducting cuprates and in nickelates.

Our STM investigation shows that commensurate stripe order forms in the metallic state of the recently discovered high-temperature superconductor $La_4Ni_3O_{10}$. Quasi-1D channels of delocalized charge appear as solitonic domain walls in charge density probed by STM. Interestingly, electrons tunnelling from the tip can induce local stripe fluctuations, pointing at the weak pinning of the order to the lattice.

Observation of stripe orders in normal states of high temperature cuprates and nickelates suggests shared correlated physics as a precursor to high-temperature superconductivity in both systems. Such experimental evidence is a valuable foundation for investigations into the mechanism of high-temperature superconductivity in both systems.

Surface Rashba effect influence on bulk states: test case on Au(111) — •Laurent Nicolaï[1], Ján Minár[1], Christine Richter[2,3], Olivier Heckmann[2,3], Laxman Nagi Redi[2,3], Sourour Ayari[1], Aki Pulkkinen[1], Mauro Fanciulli[2,3], and Karol Hricovini[2,3] — [1]University of West-Bohemia in Pilsen, Czeck Republic — [2]CY Cergy Paris Université, France — [3]Université Paris-Saclay, CEA, France

Au(111) crystals are commonly used in the Photo-emission Spectroscopy field to calibrate instruments. When coming to spin-resolved ARPES, one uses the well-known surface states, spin-split due to the Rashba effect [1,2], as a reference. Au(111) being a centro-symmetric material, it is commonly assumed that bulk sates are spin degenerate. However, we here present measurements attesting a spin polarisation of bulk states within the valence band. The measurements are complemented with ab-initio calculations confirming the existence of bulk states' spin polarisation on a fundamental level.

Defect-driven polarity compensation on weakly polar $BaTiO_3$ (001) and $SrTiO_3$ (001) surfaces. — •Darin Joseph[1], Llorenç Albons[4], Florian Ellinger[2], Michele Reticcioli[2,3], Martin Setvin[4], and Cesare Franchini[1,2] — [1]University of Bologna, Italy — [2]University of Vienna, Austria — [3]CNR-SPIN, L' Aquila, Italy — [4]Charles University, Prague , Czech Republic

$BaTiO_3$ (001) and $SrTiO_3$ (001), commonly classified as Tasker Type I and nonpolar, exhibit surface instability, as evidenced by A-site (Ba/Sr) adatoms and vacancies on cleaved surfaces observed in experiments. Density Functional Theory (DFT) calculations revealed the work function variation between the TiO_2 and AO terminations and an electric field in the vacuum of asymmetric slabs, which are typically associated with polar surfaces. Our study reveals that both perovskites exhibit weak polar stacking along the crystallographic axis, leading to surface charges on the pristine terminations and creating an unfavorable electrostatic environment. Our analysis shows that the experimentally observed A-site defects act as compensation mechanisms by counterbalancing these charges to restore charge equilibrium. Charge compensation occurs at 12.5% Sr adatom and 12% vacancy coverage for $SrTiO_3$ and at approximately 12-13% defect concentration for $BaTiO_3$. These theoretical values are consistent with the experimental defect concentrations.

O 93.9 Fri 11:30 HSZ/0201

3D Mapping of Photoelectron Diffraction Patterns at Very Low Energies — •O. Tkach[1], T.-P. Vo[2], D. Biswas[3], J. Liu[3], O. Fedchenko[1,4], T.-L. Lee[3], J. Minár[2], H.-J. Elmers[1], and G. Schönhense[1] — [1]Univ., Mainz — [2]Univ. of West Bohemia, Czech Republic — [3]Diamond Light Source, UK — [4]Goethe Univ. Frankfurt

The full-field recording architecture of momentum microscopes (MMs) efficiently captures the (E,k) valence band structure along with the corresponding dichroism and spin texture [1]. Here, we apply the same approach to photoelectron diffraction (PED) in the low-energy range. Capturing PED in a solid angle up to 2π, including the corresponding core-level CDAD [2] reveals a wealth of structure far beyond that of standard PED measurements. The experiments are compared with calculated three-dimensional (E,k_x,k_y) patterns obtained via one-step photoemission calculations using the PED implementation [3] within the SPRKKR package. Calculated results over a wide range of kinetic energies (106 – 1036 eV) for the Ge 3d core level reveal striking patterns that change rapidly with photon energy. The high-energy end provides insight into bulk (Kikuchi-) diffraction, while the lower end with its high surface sensitivity yields structural information about the surface. This is indicative of the transition from a localized core level to an itinerant, time reversed LEED photoemission final state. In general, these results bridge the gap between PED analysis and electronic structure investigations.

Shaping Surface States: The Art of Designing Quantum Corrals — •Nadine Egger, Simon B. Hollweger, and Oliver T. Hofmann — Institute of Solid State Physics, TU Graz, Austria

Quantum corrals enable precise control over electron behavior on surfaces and can be designed to carry out tasks such as atomic-scale logic operations. However, determining the optimal corral shape and the precise placement of the individual building blocks is a nontrivial task. To address this, we introduce a simulation-based framework that automatically designs corral geometries to achieve specific functionalities. The approach combines surface-state electron simulations with an optimization algorithm that identifies not only the number of atomic building blocks required but also their optimal arrangement on the surface. As a first application, the framework is applied to design corrals capable of performing basic logic operations, such as AND or NOT gates. Beyond these examples, this method offers a versatile path toward creating atomically precise nanostructures with customized functional properties, paving the way for future developments in quantum device engineering.

O 94: Oxides and insulators: Adsorption and reaction of small molecules

Invited Talk O 94.1 Fri 9:30 HSZ/0204

Surface Chemistry on Copper Oxides — •Dario Stacchiola — Brookhaven National Laboratory, Upton NY, 11720, USA

The chemical and electronic properties of copper combined with its large natural abundance lend this material to impact a wide range of technological applications, including heterogeneous catalysis. The reactivity of copper in its Cu1+ oxidation state makes this specific state relevant in various chemical reactions, but the facile redox properties of copper make the isolation of individual states for fundamental studies difficult. I will present our work on model systems including Cu2O/Cu(111) films, bulk Cu2O crystals and copper-based mixed-oxides used to study the interaction of Cu1+ with small molecules making use of in-situ surface science techniques. Advantages and disadvantages of each system are discussed and exemplified through case studies of chemical adsorption and reactivity studies

O 94.2 Fri 10:00 HSZ/0204

Calculating vibrational bands for formic acid on magnetite surfaces — •Gregor Vonbun-Feldbauer — Institute for Interface Physics and Engineering, TU Hamburg, Germany — Institute of Surface Science, Helmholtz-Zentrum hereon, Germany

Understanding the adsorption properties of organic molecules on oxide surfaces, such as their adsorption geometry, is crucial for optimising processes in various applications, ranging from heterogeneous catalysis to hybrid nanocomposites. In this study, the adsorption of formic acid on magnetite surfaces (001), (111) and (112) is examined using Density Functional Theory (DFT). The vibrational properties are then calculated and compared with experimental infrared spectroscopy data for single crystalline surfaces and nanoparticles. This enables adsorption geometries and modes to be identified.

O 94.3 Fri 10:15 HSZ/0204

Thermal CO_2 Activation and Carbonate Formation on Fe_2O_3(012) — •Johannes Filzmoser, Moritz Eder, Florian Kraushofer, Jiri Pavelec, and Gareth Parkinson — Vienna University of Technology, Austria

The adsorption of CO_2 on hematite α-Fe_2O_3(012) has been investigated in ultrahigh vacuum (UHV) using temperature-programmed desorption (TPD) and infrared reflection absorption spectroscopy (IRAS). CO_2 adsorption on this surface exhibits complex behavior, resulting in multiple desorption features in TPD. For coverages up to one molecule per unit cell (0.5 molecules per Fe^{2+} cation), two desorption features centered around 150 K and 220 K increase concurrently with increasing coverage. IRAS shows that this behavior originates from a thermally activated conversion of weakly bound, physisorbed CO_2 into surface carbonate (CO_3^{2-}) species at temperatures above 100 K, a process that directly competes with molecular desorption. By supplying CO_2 at temperatures just below the carbonate desorption temperature, higher carbonate coverages can be obtained. These findings contribute to our understanding of CO_2 activation on Fe_2O_3(012) and will be a prerequisite for surface reaction studies.

O 94.4 Fri 10:30 HSZ/0204

Redox dynamics of Co_3O_4(111) during H_2S adsorption and decomposition — Jonas Hauner[1], Tomáš Skála[2], Nataliya Tsud[2], Fernando Stavale[3], •Yaroslava Lykhach[1], and Jörg Libuda[1] — [1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — [2]Charles University, Prague, Czech Republic — [3]Brazilian Center for Research in Physics, Rio de Janeiro, Brazil

The redox interactions between transition metal oxides and sulfur-containing compounds play a key role in catalytic processes and gas sensing technologies. We investigated the redox dynamics of Co_3O_4(111)/Ir(100) model catalysts in response to the adsorption and decomposition of hydrogen sulfide (H_2S) using synchrotron radiation photoelectron spectroscopy (SRPES). Upon adsorption, H_2S partially dissociates to form a variety of species including sulfites, sulfides, chemisorbed H_2S, hydroxyl and sulfhydryl groups. Subsequent annealing in ultrahigh vacuum induces desorption and conversion of adsorbed species to sulfates. These transformations are accompanied by temperature-dependent redox processes which can be monitored as a function of Co^{3+}/Co^{2+} ratio. The obtained insights into H_2S–Co_3O_4 redox interactions offers a foundation for the rational design of cobalt oxide catalysts and sensors for H_2S detection and abatement.

O 94.5 Fri 10:45 HSZ/0204

Characterization of CO_2 adsorption configurations on stoichiometric, reduced and hydroxylated In_2O_3 — •Sarah Tobisch[1], Andreas Ziegler[2], Sarah Horak[1], Marco Knapp[1], Michele Riva[1], Michael Schmid[1], Ulrike Diebold[1], Bernd Meyer[2], and Margareta Wagner[1] — [1]TU Wien, Vienna, Austria — [2]FAU-Erlangen-Nürnberg, Erlangen, Germany

CO_2 reduction to methanol is a promising pathway towards a more circular economy, converting CO_2 into valuable fuels and feedstock for the chemical industry. In_2O_3-based catalysts have gained lots of attention in recent years due to their high selectivity towards methanol synthesis. Since catalytic reactions typically take place at the interface, it is important to understand how CO_2 molecules interact and adsorb on the surface on an atomic level.

In this work, the adsorption of CO_2 molecules was studied on three different $In_2O_3(111)$ surfaces: stoichiometric, reduced, and hydroxylated. We present atomically resolved non-contact AFM images which allow for the identification of the adsorption sites of all individual molecules. The CO_2-saturated, stoichiometric $In_2O_3(111)$ shows long range order, albeit breaking the threefold symmetry of the surface. Missing contrast inversion in nc-AFM combined with XPS measurements result in the identification of physisorbed and carbonate species. DFT calculations confirm adsorption sites and orientation of the individual molecules. CO_2 shows similar motifs on the reduced surface but partly displaces the In adatoms. On the hydroxylated surface, the OH groups block adsorption of CO_2 and long-range order is not observed.

O 94.6 Fri 11:00 HSZ/0204

How chirality controls catalysis: Spin-dependent effects in the catalytic OER from first-principles — •Suryansh Suryansh[1], Rafael Gutiérrez[1], Arezoo Dianat[1], and Gianaurelio Cuniberti[1,2] — [1]Institute of Materials Science and Max Bergmann Center of Biomaterials, Dresden University of Technology, Dresden 01062, Germany — [2]Dresden Center for Computational Materials Science (DCMS), TU Dresden, 01062, Dresden, Germany

The evolution of a mixture of unpolarized electrons into an ensemble of spin-polarized electrons after passing through a chiral molecule such as DNA, proteins, or peptides is a well-established phenomenon attributed to the chiral-induced spin selectivity (CISS) effect. This effect has important implications for electrochemical water-splitting. Experiments have shown that chiral molecules enhance the oxygen evolution reaction (OER) by controlling the spin of electrons at the electrode surface when the electrode is coated with a monolayer of chiral molecules, a film of chiral polymer, or a chiral inorganic oxide. This enhancement is associated with facilitating the singlet-to-triplet spin transition of oxygen at the interface. However, the microscopic origin and physical mechanisms behind CISS-based water-splitting remain unclear. In this work, we investigate the electronic and magnetic properties of ferrimagnetic surfaces functionalized with chiral and achiral molecules using first-principles calculations. We compute the reaction energy barriers of the individual OER steps and analyze the spin-polarized electronic states near the Fermi level, providing theoretical insights into the mechanisms underlying spin-assisted water-splitting.

O 94.7 Fri 11:15 HSZ/0204

Tailoring the OER activity of Co_3O_4 surfaces by Mn and V-doping: insights from DFT+U calculations — •Palani Muthu Kumar and Rossitza Pentcheva — Department of Physics, University of Duisburg-Essen

The rational design of efficient electrocatalysts for sustainable energy conversion demands an atomistic understanding of how surface modifications influence the overall activity. Here we present a detailed DFT+U investigation of Mn- and V-doping on the oxygen evolution reaction (OER) activity at Co_3O_4 surfaces. Mn-doping at the surface octahedral sites on both A- and B-terminated $Co_3O_4(001)$, reduces the OER activity. Conversely, V-doping demonstrates termination-dependent behaviour: at the B-termination, V^{5+} in a surface octahedral site reduces the overpotential at Co_{oct} from 0.48 V to 0.43 V. At the A-termination, V^{4+} in a subsurface octahedral site leads to the lowest overpotential of 0.18 V at Co_{tet} reaction site, reversing the intrinsic activity trend where pristine Co_{tet} sites (0.74 V) are less active than Co_{oct2} (0.55 V) sites. For most studied cases, the deprotonation of *OH to *O is the potential-determining step. The enhanced catalytic activity of the V-doped A-termination originates from the modification of surface Co^{3+}(IS) to Co^{2+}, weakening the *OH binding energy and lowering the PDS by 0.56 eV. These findings show that selective doping effectively tunes electrocatalyst performance. The scope of the investigation is further extended to the $Co_3O_4(111)$ surface, thereby broadening the understanding of facet-dependent effects.

O 94.8 Fri 11:30 HSZ/0204

Towards Understanding the Photoreactivity of SrTiO3 through Studies in Ultra-High Vacuum — •Anna Lemperle, Philip Petzoldt, Martin Tschurl, and Ueli Heiz — Chair of Physical Chemistry, Technical University of Munich, Lichtenbergstr. 4, 85748 Garching, Germany

Strontium titanate is renowned for its photocatalytic water splitting capabilities. However, the catalytic mechanism remains elusive. A promising approach to obtain insights into structure-reactivity relations is to investigate well-defined single crystal model catalysts under ultra-high vacuum conditions. This contribution discusses first results on the thermal and photoreactivity of water and oxygen on the bare strontium titanate (100) surface. Experiments combining temperature programmed desorption and studies under illumination point to a high importance of the dynamic behaviour of bulk and surface oxygen for the reactivity of strontium titanate (100).

O 94.9 Fri 11:45 HSZ/0204

Methanol photodecomposition on TiO_2(110) under UV illumination studied with vibrational SFG spectroscopy in ambient conditions — •Milad Salarinasab[1], Julian Andreas Hochhaus[1], Anas Akhtar[2], Kristina Tschulik[2], Carsten Westphal[1], Zhe Wang[1], and Ahmed Ghalgaoui[1] — [1]Department of Physics, TU Dortmund University, Otto-Hahn-Str. 4a, Dortmund, 44227, Germany — [2]Analytical chemistry II, Ruhr-Universität Bochum, Universitätsstrasse 150, 44801 Bochum, Germany.

Methanol is widely used as a model system for photocatalysis on TiO_2 surfaces, but many earlier investigations were performed in UHV and therefore do not reflect real catalytic conditions. To address this gap, we studied methanol photodecomposition on TiO_2(110) under realistic ambient conditions using vibrational sum frequency generation (SFG) spectroscopy. By recording spectra in the C-H stretch region, we followed CH_3, CH_2, and methoxy species during UV illumination and monitored how these surface species evolve in real time.

The SFG signals show clear differences from the reaction pathways commonly described in vacuum studies. Most importantly, we identify a new photodecomposition route that becomes active only under realistic conditions combined with UV excitation. This finding provides new insight into methanol chemistry on TiO_2(110) and helps connect surface science studies with photocatalytic behavior in practical environments.

O 94.10 Fri 12:00 HSZ/0204

Bridging the Gap: Interpreting Photocatalysis Under Ambient Conditions Based on Findings from Surface Science — •Martin Tschurl, Philip Petzoldt, Lucia Mengel, Paula Neumann, Anna Lemperle, and Ueli Heiz — Chair of Physical Chemistry, Technical University of Munich, Lichtenbergstr. 4, 85748 Garching, Germany

The interpretation of heterogenous photocatalytic reactions is usually closely linked to electrochemistry. Based on a qualitative, exclusively thermodynamic picture, it normally focuses on the properties of photon-generated charge-carriers. However, some years ago in ultra-high vacuum (UHV) studies, we discovered that for the heavily studied Pt-titania system, a fundamentally different reaction mechanism governs the photocatalytic conversion of alcohols. This mechanism underscores the critical role of surface chemistry - an aspect often neglected in the interpretation of applied photocatalysts. In this presentation, we will interpret systems operating under ambient conditions based on insights gained from UHV experiments. This way, we also demonstrate merit of surface science studies for a comprehensive understanding of photocatalysis.

O 94.11 Fri 12:15 HSZ/0204

Molecular Dynamics Simulation of Impingment of Atomic Oxygen on Alumina and Silica Surfaces — Stephen Hocker, Hansjörg Lipp, Aahmed Kassem, Ricco Isele, Leonidas Simitsis, and •Johannes Roth — Institute for Functional Matter and Quantum Technologies (FMQ), University Stuttgart, Germany

Atomic oxygen (AO) impinging on satellite surfaces in very low earth orbit (VLEO) transfers momentum and energy, leading to material degradation and drag forces. To be able to counteract these effects, we investigate the impact mechanisms of AO on alumina (Al2O3) and silica (SiO2) surfaces. In this talk we give an overview of our activities: Using molecular dynamics (MD) simulations with classical force fields, we study material stability, angular distributions of reflected particles, and adsorption rates. Our findings indicate that bare Al2O3 does not degrade under AO impacts but accumulates oxygen due to adsorption processes. The angular distribution of reflected particles is highly dependent on the surface structure and the angle of incidence, with a higher ratio of specular reflection observed on smoother surfaces and at larger incidence angles. This is confirmed by the few experimental results available. We further present first results of the impingement of AO on SiO2 surfaces obtained with the same method. Here we study especially the influence of different interactions. The talk is completed with an outlook on the role of specific interactions in general.

O 95: 2D Materials: Stacking and heterostructures (joint session O/HL/TT)

Time: Friday 9:30–12:30 Location: HSZ/0401

O 95.1 Fri 9:30 HSZ/0401

A new fabrication method for metal intercalated epitaxial graphene devices — •Marc Bothe[1], Stefan Wundrack[1,2], Marcelo Jaime[1], Klaus Pierz[1], Frank Hohls[1], Rainer Stosch[1], Hans Werner Schumacher[1], Andrey Bakin[2], and Teresa Tschirner[1] — [1]Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany — [2]Institut für Halbleitertechnik, TU Braunschweig, Hans-Sommer-Str. 66, 38106 Braunschweig, Germany

Epitaxial graphene grown on silicon carbide is a promising platform to achieve metal intercalation. It enables the creation of two-dimensional metal layers that are encapsulated and protected by graphene. However, the use of metal intercalated graphene samples for lithographic device fabrication presents two critical challenges. First, solvents used in the lithography process lead to the deintercalation of the metal atoms. Second, the presence of lattice defects in the graphene - necessary for the intercalation process - compromises the structural and electronic integrity of the device. We present a novel fabrication method that solves these problems. In our approach, the graphene devices are first pre-structured using lithography and subsequently intercalated. This is made possible by a spatial separation on the sample between the device structures and the intercalation origin and by intercalation channels that can guide the intercalation front reliably to the devices. We demonstrate this method on gallium intercalated epitaxial graphene Hall bars that exhibit superconducting behaviour.

O 95.2 Fri 9:45 HSZ/0401

Anisotropic Strain Observation in Naturally Occurring Buckling on Twisted Bilayer Graphene: A Nano-Raman Study — •Gustavo Soares[1], Rafael R. Barreto[1], Rafael Nadas[1], Kenji Watanabe[2], Takashi Taniguchi[2], Leonardo C. Campos[1], Luiz G. Cancado[1], and Angelo Malachias[1] — [1]Physics Department, Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, 31270-901, Brazil — [2]National Institute for Materials Science, Tsukuba, Ibaraki, 3050047, Japan

This work investigates naturally occurring buckling and its relation with anisotropic strain relaxation in twisted bilayer graphene (tBG). In the tBG system a twist angle is imposed to influence graphene structural and electronic properties. Such condition directly implies in the occurrence of biaxial in-plane strain, with usual observation of buckled/wrinkled localized regions where the tBG morphology is no longer planar. Using tip-enhanced Raman spectroscopy, we conducted high-resolution mapping to analyze variations in Raman bands associated with twist angle variation and strain effects. Our findings reveal that localized strain gradients, modulated by twist angle variations, induce deterministic buckling in graphene layers, evidencing distinct uniaxial and biaxial strain regions. Finite element modeling further supports these observations, showing that buckling can store elastic energy sufficient to overcome usual tBG-substrate adhesion forces.

O 95.3 Fri 10:00 HSZ/0401

Kirkendall Voids in Monolayer $Mo_xTa_yS_2$ Alloys on Au(111) — Kai Mehlich[1], Thais Chagas[1], Francis H. Davies[2,3], Alessia Bardazzi[1], Catherine Grover[1], Arkady V. Krasheninnikov[3], and •Carsten Busse[1] — [1]Department Physik, Universität Siegen, Walter-Flex-Straße 3, 57072 Siegen, Germany — [2]Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany — [3]Department of Physics and Astronomy, University of Exeter, Stocker Road, Exeter, EX4 4QL United Kingdom

During the growth of monolayer MoS_2-TaS_2 heterostructures, we observe the Kirkendall effect: Diffusing vacancies agglomerate in MoS_2, forming what are commonly termed Kirkendall voids - here manifesting as holes in the 2D layer. This phenomenon has not been previously reported in systems with reduced dimensionality.

We prepare the lateral heterostructures by reactive molecular beam epitaxy on chemically inert and weakly interacting Au(111). First, compact MoS_2 cores are grown. In a second step, TaS_2 is added in a sulfur-rich environment at elevated temperatures which promotes diffusion at the interface. The resulting heterostructures exhibit characteristic 2D Kirkendall holes surrounded by a $Mo_xTa_yS_2$ alloy region. These findings reveal defect-mediated processes in low-dimensional systems and open new avenues for designing 2D lateral heterostructures with intricate morphologies.

O 95.4 Fri 10:15 HSZ/0401

Designing 2D Non-van der Waals Heterostructures — •Anastasiia Nihei[1,2], Tom Barnowsky[1,2], and Rico Friedrich[1,2] — [1]TU Dresden — [2]Helmholtz-Zentrum Dresden-Rossendorf

Heterostructure interfaces created by stacking two-dimensional (2D) materials offer a pathway to realizing advanced electronic and magnetic functionalities at the nanoscale. In this work, we present a high-throughput screening of non-van der Waals (non-vdW) 2D heterostructures; including sandwich-like stacking. Non-van der Waals 2D materials can be obtained by both top-down exfoliation as well as bottom-up growth approaches of non-layered bulk crystals [1]. Our approach uses the AFLOW-Hetbuilder - a newly developed tool for stacking 2D systems based on the coincidence lattice algorithm [2-4].

We investigate interfacial binding effects across a wide range of heterobilayers [5] and sandwich-like systems, analyzing their structural, electronic, and magnetic characteristics such as hybrid interface bands and robust magnetic coupling. Furthermore, we compare the binding energetics of non-vdW and conventional vdW heterostructures. The tunable interfacial properties of non-vdW 2D heterostructures provide a versatile platform for advanced functionalities with potential applications in electronics, spintronics, and the energy sector [5].

O 95.5 Fri 10:30 HSZ/0401

Second-Order Nonlinear Imaging for Probing 2D van der Waals Structures — •Tao Yang[1], Ben John[1], Kyoung P. Lee[2], Nasim Mirzajani[1], Martin Wolf[1], Xiaoqin Li[2], Martin Thaemer[1], Alexandar Paarmann[1], Niclas S. Mueller[3], and Alexander P. Fellows[1] — [1]Fritz Haber Institute, Berlin, Germany — [2]University of Texas at Austin, Austin, USA — [3]Freie Universitaet Berlin, Berlin, Germany

Twisted and stacked multi-layer architectures offer new opportunities for tailoring the electronic and optical properties of two-dimensional (2D) van der Waals materials. Reliable determination of crystal structure, stacking sequence, and twist angle is therefore crucial. Second-order nonlinear optical microscopy, including second-harmonic and sum-frequency generation (SHG and SFG, respectively), provides high sensitivity to crystal symmetry and orientation in non-centrosymmetric lattices. Recently, we employed heterodyne-detected vibrational SFG microscopy to probe the local structure of hexagonal Boron Nitride (hBN) monolayers with sub-micron resolution. By employing our developed azimuthal-scanning approach, we fully resolved the crystallographic structure and edge termination in monolayer flakes. Here, we extend these measurements to multi-layer hBN structures, using the same azimuthal-scanning approach in a newly developed SHG microscope to gain insight into their different stacking configurations. Our results highlight second-order nonlinear microscopy as a powerful tool for quantitative structural analysis in 2D materials and for future studies of moiré and twisted heterostructures.

O 95.6 Fri 10:45 HSZ/0401

Moiré-Driven Electronic Modulations in Weakly Coupled h-BN/Graphite — •Fábio J. R. Costa[1,2,7], Daniel Arribas[2], Thiago G. L. Brito[2], Tin S. Cheng[3], Jonathan Bradford[3], Amelia Thompson[3], Alex Saywell[3], Christopher J. Mellor[3], Peter H. Beton[3], Sergey V. Novikov[3], Juliette Plo[4], Bernard Gil[4], Guillaume Cassabois[4,5], Luiz F. Zagonel[1], Klaus Kuhnke[2], Klaus Kern[2,6], and Anna Rosławska[2] — [1]University of Campinas, Brazil — [2]Max-Planck-Institut für Festkörperforschung, Germany — [3]University of Nottingham, UK — [4]Laboratoire Charles Coulomb, France — [5]Institut Universitaire de France, France — [6]EPFL, Lausanne, Switzerland — [7]Current address: Université de Strasbourg, CNRS, IPCMS, Strasbourg, France

Van der Waals materials and their heterostructures offer exciting opportunities for next-generation nanophotonic and electronic technologies. Their electronic and optical properties can be modulated by moiré superlattices that emerge when mismatched layers are stacked together. Hexagonal boron nitride (h-BN) is a key platform in this context, yet the influence of moiré patterns on weakly interacting h-BN interfaces remains underexplored. Here[1], we use scanning tunneling microscopy to resolve large moiré superlattices in h-BN/graphite and uncover pronounced nanoscale modulations of the electronic landscape, despite their weak interlayer interactions. These findings position moiré engineering in h-BN as a powerful tool to tailor local functionalities in van der Waals heterostructures.

O 95.7 Fri 11:00 HSZ/0401

μ-ARPES study on the fine electronic structure of misfit layer compound (PbSe)1.16(TiSe2)2 — •haruki muramatsu[1], natsuki mitsuishi[2,3], teppei ueno[4], kenichi ozawa[5], kaya kobayashi[4,6], and kyoko ishizaka[1,2] — [1]Dept. of Appl. Phys. & QPEC, Univ. of Tokyo — [2]CEMS, RIKEN — [3]Grad. Sch. Sci., Nagoya Univ. — [4]Dept. of Physics, Okayama Univ. — [5]KEK-PF — [6]RIES, Hokkaido Univ.

Misfit layered compounds have been attracting significant attention due to their lattice mismatches and resultant two-dimensional electronic structures reminiscent of van der Waals heterostructures. One such compound, (PbSe)1.16(TiSe2)2, consists of alternating stacking of PbSe monolayers (NaCl-

type, four-fold symmetry) and TiSe2 bilayers (CdI2-type, three-fold symmetry). To elucidate its electronic structure, we performed μ-ARPES measurements by carefully distinguishing the cleavage surface terminations. In the presentation, we will discuss the novel electronic states reflecting the natural incommensurate heterostructure as well as charge density wave in the buried TiSe2 bilayer.

O 95.8 Fri 11:15 HSZ/0401

Twisted $NbSe_2$ heterostructures — •Alexander Bäder[1,2], Clara Pfister[3,4], Tobias Wichmann[1,5], Laura Pätzold[3,4], Tim O. Wehling[3,4], and Felix Lüpke[1,2] — [1]Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich — [2]II. Physikalisches Institut, Universität zu Köln — [3]I. Institute of Theoretical Physics, U Hamburg — [4]The Hamburg Centre for Ultrafast Imaging — [5]Institut für Experimentalphysik IV A, RWTH Aachen

We fabricated monolayers (MLs) of the van der Waals material $NbSe_2$ that are rotated with respect to the underlying bulk $NbSe_2$ using our developed ultra-high vacuum (UHV) stacking technique. These heterostructures were characterized through the use of scanning tunneling microscopy and spectroscopy at a base temperature of 1.4 K. The MLs realize a variety of twist angles relative to the underlying bulk lattice, with the lowest observed twist angle being 10°. The MLs display the coexistence of charge density waves (CDW) and moiré effects: In the absence of strain, the MLs develop a 3×3 CDW, however the application of strain through interfacial disorder results in a 2×2 CDW state, supported by theoretical calculations. Compared to isolated MLs the superconducting order parameter is enhanced due to the proximity effect from the underlying bulk.

O 95.9 Fri 11:30 HSZ/0401

band structure and charge density wave in a natural van der Waals heterostructure 4Hb-TaSe2 — •fumihiko kimura[1], tomoki maeda[2], natsuki mitsuishi[3,4], kazuki okada[2], takuya nomoto[5], kenichi ozawa[6], masahiro naritsuka[3], tetsuo hanaguri[3], shunsuke kitou[7], yuiga nakamura[8], taka-hisa arima[3,7], takao sasagawa[2], and kyoko ishizaka[1,3] — [1]Quantum-Phase Electronics Center & Department of Applied Physics, The University of Tokyo — [2]Laboratory for Materials and Structures, Science Tokyo — [3]RIKEN CEMS — [4]Graduate School of Science, Nagoya University — [5]Department of Physics, Tokyo Metropolitan University — [6]Institute of Materials Structure Science, High energy Accelerator Research Organization (KEK) — [7]Department of Advanced Materials Science, The University of Tokyo — [8]Japan Synchrotron Radiation Research Institute (JASRI), SPring-8

4Hb-TaSe2 is a natural van der Waals heterostructure charge density wave (CDW) material consisting of alternative stacking of monolayer 1T-TaSe2 (Mott insulator with Star-of-David CDW) and monolayer 2H-TaSe2 (superconductor with 3 by 3 CDW). Although transport measurements have suggested the existence of multiple CDWs, the details of the CDW and electronic structures remain unclear. In this study, we directly observed the electronic structure of 4Hb-TaSe2 by micro-focused angle-resolved photoemission spectroscopy with careful selection of the surface terminations. We discuss the temperature dependent electronic structure with comparison to the CDW structures obtained by scanning tunneling microscopy and X-ray diffraction.

Coexisting charge density waves in twisted NbSe2 bilayers — •Christopher Tat Shun Cheung[1], Zachary A. H. Goodwin[2], Yixuan Han[3], Jiong Lu[3], Arash A. Mostofi[1], and Johannes Lischner[1] — [1]Departments of Physics and Materials and the Thomas Young Center for Theory and Simulation of Materials, Imperial College London, London SW7 2AZ, U.K. — [2]Institute for Functional Intelligent Materials, National University of Singapore, Singapore 117544, Singapore — [3]Department of Materials, University of Oxford, Parks Road, Oxford OX1 3PH, United Kingdom

Twisted bilayers of semiconducting transition metal dichalcogenide (TMD) monolayers have been studied extensively. In contrast, twisted bilayers composed of metallic monolayers, such as NbSe2, remain less understood.

Monolayer NbSe2 can host different types of charge density waves (CDWs), in which the Nb atoms move away from their high-symmetry positions. In twisted bilayer NbSe2, identifying CDWs in relaxed structures is challenging because atomic relaxations occur both because of CDW formation and also because of the moiré pattern.

We have carried out large-scale first-principles calculations using density functional theory to study the moiré relaxations and CDWs in twisted bilayer NbSe2. We have developed methods for revealing the CDWs, and for locally classifying the type of CDW. We find that different types of CDWs coexist in the moiré unit cell due to the interactions with strain induced by moiré relaxations [1].

O 95.11 Fri 12:00 HSZ/0401

MicroARPES studies of contact doping of monolayer transition metal dichalcogenides by RuCl3 — •Thomas Nielsen[1], Edvard Solbrekken[1], Alfred J. H. Jones[1], Zhihao Zhiang[1], Chakradar Sahoo[1], Kenji Watanabe[2], Takashi Taniguchi[2], Jill A. Miwa[1], Søren Ulstrup[1], Christian Overby[1], and Christian V-B. Fokdal[1] — [1]Aarhus University, Denmark — [2]National Institute for Materials Science, Japan

Placing van der Waals materials into contact with α-$RuCl_3$ has recently emerged as a method of modulating their electronic structures. The proximity to α-$RuCl_3$ has been observed to produce strong hole doping in the van der Waals material, and this has been established as a method to create better electrical contacts in transistor devices based on monolayer transition metal dichalcogenides (TMDs). Here, we use the microARPES endstation at the ASTRID2 synchrotron light source at Aarhus University in Denmark to study the valence bands and core levels of semiconducting monolayer TMDs in proximity to α-$RuCl_3$. We observe a large valence-band shift of 0.7 – 0.8eV indicating strong hole doping. α-$RuCl_3$ is highly sensitive to the temperatures and chemicals typically used in the dry-transfer fabrication procedures of van der Waals heterostructures. How the degradation of α-$RuCl_3$ affects the proximity-induced doping of the TMD is discussed based on the ARPES measurements.

O 95.12 Fri 12:15 HSZ/0401

STEM Investigation of Entropy Forbidden Ordering in CVD Grown WSe_2-$MoSe_2$ Alloys — •Max Bergmann[1], Matvei Kislitsyn[1], Julian Picker[2], Jürgen Belz[1], Robin Günkel[1], Badrosadat Ojaghi Dogahe[1], Shamail Ahmed[1], Andrey Turchanin[2], and Kerstin Volz[1] — [1]mar.quest | Marburg Center for Quantum Materials and Sustainable Technologies, Philipps-Universität Marburg, 35032 Marburg, Germany — [2]Faculty of Chemistry and Earth Sciences, Friedrich-Schiller-Universität, 07743 Jena, Germany

2D transition metal dichalcogenides have gained significant interest due to their optoelectronic properties, which can be tailored by structural variation. However, controllable production, namely growth, of such tailored structures still remains a key challenge towards large-scale production. In this study, we show lateral heterostructures of 2D $MoSe_2$ and WSe_2, grown on a SiO_2 TEM grid by chemical vapor deposition, that at the interface show a highly ordered structure of W and Mo atoms at the TMD positions, as observed by scanning transmission electron microscopy. This is in contrast to *ab initio* calculations, which ascribe unordered alloys as the preferred configuration, since entropy is the main driving force compared to formation enthalpy. We link this unexpected phenomenon to the initial nucleation of the material on a clean $MoSe_2$ crystal edge, present before the alloy growth, together with special precursor chemistry. Furthermore, we show *ab initio* results in conjunction with the special quasirandom structure method on the bandstructure and optical properties of this structure.

O 96: Plasmonics and nanooptics: Fabrication, characterization and applications

How to fix silver for plasmonics ? — •Jonas Graf[1], Björn Ewald[1], Leo Siebigs[1], Cheng Zhang[2], Achyut Tiwari[3], Max Rödel[1], Sebastian Hammer[1], Vladimir Stepanenko[4], Frank Würthner[4], Bruno Gompf[3], Bert Hecht[2], and Jens Pflaum[1] — [1]Experimental Physics 6, Univ. Würzburg, 97074 Würzburg — [2]Experimental Physics 5, Univ. Würzburg, 97074 Würzburg — [3]1. Physikalisches Institut, Univ. Stuttgart, 70569 Stuttgart — [4]Institute for Organic Chemistry, Univ. Würzburg, 97074 Würzburg

Silver (Ag) is an ideal plasmonic material for applications in the visible regime, but its use is hindered by poor chemical stability and structural quality of thermally evaporated thin films and nanostructures. Here, we present a simple approach to overcome these limitations by alloying Ag thin films with small amounts of gold (Au) through thermal co-evaporation. We analyzed $Ag_{100-x}Au_x$ thin films with Au contents ranging from 5 to 20 at.% with respect to their surface and bulk crystal quality, optical properties and chemical stability. Remarkably, already $Ag_{95}Au_5$ thin films exhibit a drastically enhanced chemical stability and excellent plasmonic properties outperforming pure Ag. This is related to the high film quality achieved without metallic wetting layers, epitaxial substrates or template stripping. As a proof of concept, we fabricate $Ag_{95}Au_5$ plasmonic nanoantennas demonstrating excellent long-term durability over one month under ambient conditions. Our approach thus demonstrates a simple and effective strategy to overcome the general limitations of Ag in plasmonic applications. B. Ewald et al., ACS Photonics 2025, DOI: 10.1021/acsphotonics.5c01659

O 96.2 Fri 9:45 HSZ/0403

Topological quasiparticles in a bucket: water waves as an experimental platform for emulating optical nearfields — •Alexander Neuhaus, Pascal Dreher, Philipp Gessler, Michael Horn-von Hoegen, Karin Everschor-Sitte, and Frank Meyer zu Heringdorf — Faculty of Physics and Center for Nanointegration, Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47048 Duisburg, Germany

Optical near fields can host a variety of topological quasiparticles, including merons, skyrmions, skyrmion bags and optical vortices, but their nanometric spatial scales and femtosecond time dynamics make them difficult to access experimentally. Modern techniques, such as time resolved photoemission microscopy or nearfield scanning optical microscopy can image these field configurations, but they are both experimentally challenging. Here, we demonstrate a much simpler 3d printed experiment that can be used as a model system to emulate the behavior of optical nearfields with capillary-gravity water waves. Although water waves and surface polaritons are vastly different wave phenomena, the displacement vector field in the water can be described by surface wave equations that are similar to the equations used to describe surface polaritons. We reconstruct the displacement field of the water wave by fast checkerboard decomposition of videos of the water wave propagation. Water-wave experiments yield the same topological quasiparticles as observed in optical nearfields, yet they do so in seconds instead of hours of experimental time.

O 96.3 Fri 10:00 HSZ/0403

Layer-Resolved Optical Metrology of MoS_2 Using Surface Plasmon Resonance Imaging — •Priyanka Thawany[1,2], Hesam Amiri[1], Lina Jäckering[2], Andrei Vescan[3], Thomas Taubner[2], Sven Ingebrandt[1], and Vivek Pachauri[1] — [1]Institute of Materials in Electrical Engineering 1 (IWE1), RWTH Aachen University — [2]I. Institute of Physics (IA), RWTH Aachen University — [3]Compound Semiconductor Technology, RWTH Aachen University

Conventional techniques such as scanning probe microscopy, Raman spectroscopy [1], ellipsometry [2], and terahertz microscopy [3] provide crucial information on optical and electronic parameters of 2D materials. However, they remain limited in measurement speed and spatial coverage for large-area characterization. To address these limitations, we demonstrate the use of surface plasmon resonance imaging (SPRi) as a complementary wide-field technique for mapping few-layer MoS_2 stacks. Thickness-dependent shifts in the SPR resonance angle and corresponding reflectance contrast allow clear discrimination of atomic-layer regions, consistent with theoretical predictions for MoS_2 optical permittivity changes. SPRi therefore offers a rapid, scan-free approach for real-time metrology of few-layer MoS_2, and similar measurements on other 2D materials show the same suitability for rapid optical characterization.

Launching and confining In-Plane Hyperbolic Phonon Polaritons in α-MoO_3 with In_3SbTe_2 nanostructures — •Umberto Saldarelli[1], Lina Jäckering[1], Lukas Conrads[1], Matthias Wuttig[1], Pablo Alonso-González[2,3], and Thomas Taubner[1] — [1]I. Institute of Physics (IA), RWTH Aachen University — [2]Department of Physics, University of Oviedo — [3]Center of Research on Nanomaterials and Nanotechnology, CINN (CSIC-Universidad de Oviedo)

Alpha-phase molybdenum trioxide (α-MoO_3), a van der Waals material, supports in-plane hyperbolic phonon polaritons (HPPs) with high confinement, low losses, and extremely directional propagation [1]. Rapid prototyping of nanostructures for tailoring polaritons can be achieved with the plasmonic phase-change material In_3SbTe_2 (IST) [2], switchable between amorphous and crystalline phases via laser-induced heating. This has been already shown for programmable resonator structures within hBN [3]. Here we combine α-MoO_3 with IST. We use scattering-type scanning near-field optical microscopy (s-SNOM) to explore HPP launching by antennas of different orientations. Next, we optically program a circular launching structure to focus polaritons. Finally, adding a second focusing disk and reconfiguring the disk distance, we tailor field enhancement and confinement. Our results enable rapid design of reconfigurable structures and provide an all-optical material platform for controlling in-plane HPPs.

O 96.5 Fri 10:30 HSZ/0403

Nanoscale Optical Readout of Antiferromagnetic Order by Photocurrent Nanoscopy — •Dario Siebenkotten[1], Anna Schmid[2], Dinghe Dai[1], Joao Godinho[2], Sam Fairman[1], Arne Hoehl[1], Tomas Janda[2], Tomas Ostatnicky[3], Bernd Kästner[1], and Jörg Wunderlich[2] — [1]Physikalisch-Technische Bundesanstalt, Berlin, Germany — [2]Institute of Experimental and Applied Physics, University of Regensburg, Regensburg, Germany — [3]Charles University, Faculty of Mathematics and Physics, Prague, Czech Republic

Antiferromagnets are prime candidates for next-generation spintronic technologies as they allow for rapid switching and miniaturization compared to ferromagnets. However, readout of their magnetic state remains an open challenge, as their vanishing net magnetisation suppresses conventional magnetic readout schemes. Therefore, new mechanisms are required to measure the state of antiferromagnetic domains, which are often confined to the nanoscale. Here, we report on the experimental observation of a previously only theoretically predicted light-induced, Néel-order-dependent transverse photocurrent that we refer to as the optical nonlinear anomalous Hall effect. We demonstrate the effect by nanoscale imaging of the photocurrent generated in PT-symmetric CuMnAs cross-bar devices by mid-infrared near fields at the apex of a sharp metal tip. We exclude purely thermal mechanisms by showing that the photocurrent reverses sign when the Néel vector is rotated by 180° via current-induced switching of nanoscale antiferromagnetic domains of a few hundred nanometers in size, consistent with a time-reversal-odd nonlinear anomalous Hall photocurrent.

O 96.6 Fri 10:45 HSZ/0403

Plasmonic Effects in a honeycomb metasurface of Ag Nanotriangles and Nanoholes — •Paul-G. Nitsch[1], Paul Oleynik[1], Markus Ratzke[1], David Stolarek[2], Jon Schlipf[2], Oliver Skibitzki[2], Rudi Tschammer[3], Carlos Morales[3], Jan I. Flege[3], Christian Wenger[2], and Inga A. Fischer[1] — [1]Experimentalphysik und funktionale Materialien, BTU-CS, Cottbus, Germany — [2]IHP - Leibniz- Institut für innovative Mikroelektronik, Frankfurt (Oder), Germany — [3]Angewandte Physik und Halbleiterspektroskopie, BTU-CS, Cottbus, Germany

Coupled lattices of metal nanoparticle and nanohole arrays can support spectrally narrow plasmonic resonances with potential applications, e.g., in biosensing. In nanohole arrays, the interplay of surface plasmon polaritons at metal-dielectric interfaces and Rayleigh anomalies can lead to Fano resonances, whose spectral positions are well described by Bragg coupling conditions. For nanoparticle arrays with small interparticle distances, the coupling of neighboring particles via their overlapping evanescent fields leads to resonances, whose dispersion relation has been described by tight-binding models. Here, we investigate resonances in coupled nanoparticle and nanohole lattices both experimentally and in simulation. We show that a variation in angle of incidence can be used to tune mode coupling and present results on the detection of near-surface refractive index changes with high sensitivities and figures-of-merit in our samples.

Hybrid Gold–Vanadium-Dioxide Tunable Plasmonic Devices — Rostislav Řepa, Jiří Kabát, Jiří Liška, Peter Kepič, Michal Horák, Tomáš Šikola, and •Vlastimil Křápek — Brno University of Technology, Brno, Czechia

Vanadium dioxide (VO_2) exhibits a metal-insulator transition near room temperature, which can be exploited in tunable plasmonic devices with compelling functions. However, devices based solely on VO_2 suffer from a large optical absorption and low chemical stability of VO_2 [1].

We present a hybrid material platform that combines high-quality crystalline self-assembled VO_2 nanoparticles [2] with lithographically defined gold nanostructures in a lateral arrangement In this way, we benefit from both the tunability of VO_2 and the high conductivity of gold. The lateral arrangement minimizes the amount of VO_2 and thus contributes to the high quality of the devices.

We demonstrate two tunable plasmonic devices based on the above-mentioned material platform: (1) Electric-magnetic switches, in which either an electric or magnetic hot spot is formed, following a design from Ref. [3]. (2) Resonance-energy switches, in which the spectral profile of the scattering or absorption is controlled, with possible applications in selectively-enhanced photoluminescence.

Phonon Polariton Materials Discovery from First Principles — Elena Gelzinyte[1], Giulia Carini[1], Niclas S. Mueller[1], Martin Wolf[1], Karsten Reuter[1], •Johannes T. Margraf[2], Alexander Paarmann[1], and Christian Carbogno[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Universität Bayreuth

Phonon Polaritons (PhPs), quasi-particles that arise from strong coupling between infrared photons and optical lattice vibrations, are promising in nanophotonic applications for highly directional and confined light propagation with low optical loss [1]. So far, PhP studies have been mostly focused on a few canonical materials, and the trends in the material space that influence the emergence and properties of PhPs remain largely unexplored. To consider the suitability of various polar crystals for the formation of PhPs, we compute the infrared permittivity functions [2] of 3,000 materials in the JARVIS-DFT database [3]. We then categorize these compounds by their normalized light-matter coupling strength and Reststrahlen band width, whereby we also decompose these in terms of individual phonon mode contributions. A broad range of materials emerges with comparable or better properties than those of typically studied PhP compounds. Using orthorhombic PbO, monoclinic TiO_2, and trigonal $CdCN_2$ as represen-

tative examples, we validate our approach and discuss the PhP property trends that allow to identify and design promising PhP candidates.

Infrared beam-shaping via geometric phase metasurfaces with the plasmonic phase-change material In_3SbTe_2 — •Lukas Conrads, Florian Bontke, Matthias Wuttig, and Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University

Conventional optical elements are bulky and limited to specific functionalities, contradicting the increasing demand of miniaturization and multifunctionalities. Optical metasurfaces enable tailoring light-matter interaction at will, especially important for the infrared spectral range which lacks commercially available beam-shaping elements. While the fabrication of those metasurfaces usually requires cumbersome lithography techniques, direct laser writing promises a simple and convenient alternative. Here, we exploit the non-volatile laser-induced insulator-to-metal transition of the plasmonic phase-change material In_3SbTe_2 (IST) [1,2] for optical programming of large-area metasurfaces for infrared beam-shaping. We tailor the geometric phase of metasurfaces with rotated crystalline IST rod antennas to achieve beam steering, lensing, and beams carrying orbital angular momenta. Finally, we investigate multi-functional and cascaded metasurfaces exploiting enlarged holography, and design a single metasurface creating two different holograms along the optical axis. Our approach facilitates fabrication of large-area metasurfaces within hours, enabling rapid-prototyping of customized infrared meta-optics for sensing, imaging and quantum information.[3] [1] Heßler et al. *Nat. Com.* **12**, 924 (2021) [2] Conrads et al. *Opt. Mat. Ex.* **15**, 2664-2687 (2025) [3] Conrads et al. *Nat. Com.* **16**, 3698 (2025)

O 96.10 Fri 11:45 HSZ/0403

Ab Initio Theory of Chemical Interface Damping of Surface Plasmons — •Jordan Edwards[1], Johannes Lischner[1], Andrei Stefancu[2], Wenxuan Tang[3], Ming Fu[3], Ross Schofield[3], Toby Millard[3], Rupert Oulton[3], Pilar Carro[4], Naomi Halas[5], Peter Nordlander[5], and Emiliano Cortes[2] — [1]Imperial College London, London, United Kingdom — [2]Ludwig-Maximilians-Universität (LMU), Munich, Germany — [3]Imperial College London, London, United Kingdom — [4]University of Laguna, La Laguna, Spain — [5]Rice University, Houston, United States

Metallic nanostructures support surface plasmons, collective electron oscillations that give rise to unique optical properties. Molecular adsorption can strongly modify plasmon behaviour; for example, experiments showing that functionalisation reduces their propagation length, a phenomenon is known as chemical interface damping (CID). However, the origin behind CID remains debated, with two proposed mechanisms being: (1) excitation of electron-hole pairs involving the adsorbate orbitals, and (2) electronic scattering by adsorbate-induced dipoles.

To investigate the physical origin of CID, we perform first-principles density-functional theory calculations for different molecules adsorbed on Au(111) surfaces. We calculate the density of states projected onto the adsorbate orbitals to analyse surface-plasmon decay channels associated with mechanism (1). We also use cluster models of the surface to investigate mechanism (2). These results are compared to experimental measurements, offering insights into the origin of CID.

O 96.11 Fri 12:00 HSZ/0403

Tailoring hyperbolic phonon polaritons in hexagonal boron nitride with the phase-change material In_3SbTe_2 — •Lina Jäckering, Aaron Moos, Lukas Conrads, Matthias Wuttig, and Thomas Taubner — I. Institute of Physics (IA), RWTH Aachen University

Polaritons in van-der-Waals materials (vdWM)[1] promise high confinement and multiple tailoring options by resonators and launching structures which conventionally require cumbersome lithography techniques. Optical programming of phase-change materials (PCMs) offers fast and reconfigurable fabrication of these structures. As the plasmonic PCM In_3SbTe_2 (IST) can be switched between a dielectric and metallic phase, IST is promising for nanophotonics[2], especially for optical programming of metallic launching structures to tailor and confine polaritons in vdWM. Here, we combine the vdWM hexagonal boron nitride (hBN) with IST.[3] We optically program circular resonators for hBN's phonon polaritons into IST through the hBN flake. We investigate the polariton resonators with near-field optical microscopy. Demonstrating the reconfigurability, we decrease the resonator diameter to increase the confinement up to $\lambda/39$ and achieve a quality factor of 72. Finally, we fabricate a focusing structure for hBN's polaritons whose focal point we reconfigure. We promote IST as a versatile platform for rapid prototyping of polariton optics in various vdWM such as α-MoO_3, β-Ga_2O_3 and $MoOCl_2$. [1] Basov et al. Science **354**, 6309 (2025) [2] Conrads et al. Opt. Mater. Express **15**, 2664 (2025). [3] Jäckering et al. Nano Letters **25**, 15809 (2025).

O 96.12 Fri 12:15 HSZ/0403

Self-assembled dielectric network metamaterials based on vanadium oxide — •Marcello Pozzi[1], Jeremi Setz[1], Noel von Wattenwyl[1], Georg Haberfehlner[2], Arnold Müller[3], Ralph Spolenak[1], and Henning Galinski[1] — [1]Laboratory for Nanometallurgy, ETH Zürich, Switzerland — [2]FELMI-ZFE, TU Graz, Austria — [3]Laboratory of Ion Beam Physics, ETH Zürich, Switzerland

Among scalable optical nanomaterials, network metamaterials stand out because of their large-area compatibility, versatility and low footprint. These systems are created by self-assembly in a reaction-diffusion process called "chemical dealloying", resulting in complex network structures with broadband optical response driven by plasmonic mode equipartition [1]. Typical network metamaterials consist of noble metallic elements and show plasmonic behavior. Here we propose a material system that extends the design space of network metamaterials to dielectrics. Using magnetron co-sputtering of aluminum-vanadium followed by chemical dealloying, we fabricate network metamaterials based on vanadium oxide. Through the combination of Rutherford backscattering spectroscopy (RBS) and focused ion beam (FIB) tomography we analyze the dynamics of pattern formation, while the light-matter interaction is studied combining full-wave simulations and various spectroscopy techniques. Finally, we determine the degree of hyperuniformity of the dielectric networks by measuring the scaling behavior of the volume fraction variance of the systems.

Invited Talk O 97.1 Fri 9:30 TRE/PHYS

Questions of Selectivity in Electrocatalysis — •Vanessa J. Bukas — Fritz-Haber-Institut der MPG, Berlin

Heterogeneous electrocatalysis is at the heart of developing sustainable energy technologies. The rational design of suitable electrocatalysts, however, depends on a deeper understanding of the underlying reaction mechanisms. Product selectivity, in particular, remains poorly understood and cannot be rationalized by popular thermodynamic models that currently define the state-of-the-art in computational electrocatalysis. In this talk, I will address a number of possible scenarios as to why this may be while challenging prevalent mechanistic assumptions. Atomistic models, based mainly on density-functional theory, will explore microscopic reaction mechanisms to demonstrate effects due to the local field at the electrical double layer, the delicate kinetic competition between electrochemical and non-electrochemical reaction steps, as well as the key role of mesoscopic mass transport. The emerging insight adds to our fundamental understanding of electrocatalysis and supports ongoing efforts toward optimal process design.

O 97.2 Fri 10:00 TRE/PHYS

Mechanism of Fe(II) Chemisorption on Hematite(001) Revealed by Machine Learning Molecular Dynamics — •Kit Joll[1], Philipp Schienbein[1,2], Kevin Rosso[3], and Jochen Blumberger[1] — [1]Department of Physics and Astronomy and Thomas Young Centre, University College London, London WC1E 6BT, United Kingdom; — [2]Ruhr-Universität Bochum, 44780 Bochum, Germany; Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, 44780 Bochum, Germany — [3]Pacific Northwest National Laboratory, Richland, Washington 99354, United States;

Understanding ion adsorption at mineral-water interfaces is key to explaining geochemical processes such as redox cycling, dissolution, and crystal growth. However, probing these reactions experimentally at atomic resolution remains challenging. Here, we employ reactive neural network potential molecular dynamics (NNP-MD) with umbrella sampling and reactive flux transition state theory to simulate the chemisorption of aqueous Fe^{2+} on hematite(001) at density-functional theory (DFT) accuracy and nanosecond time scales. We identify a dissociative mechanism for Fe^{2+} water-ligand exchange and multiple stable surface complexes, nonadsorbed, physisorbed, monodentate, and tridentate chemisorbed species, along the adsorption pathway. The overall process is exergonic, in contrast to previous classical force-field predictions. These results

demonstrate how machine-learning potentials bridge the accuracy of ab-initio methods with the sampling efficiency of classical molecular dynamics, providing new atomistic insight into reactive processes at oxide-water interfaces.

O 97.3 Fri 10:15 TRE/PHYS

How to Best Achieve a Steady State: Comparison of Different Methods to Acquire Tafel Plots — •Maren-Kathrin Heubach and Gregory Jerkiewicz — Department of Chemistry, Queen's University, Kingston, Canada.

The performance of an electrocatalyst is typically characterized by Tafel plots, which show a natural logarithm of the current density of a reaction as a function of the overpotential. Hereby, the exchange current density and the Tafel slope can be determined, giving insights into the mechanism of the electrocatalytic reaction. Even though Tafel plots are widely used, there is a large variety in performing the measurements to create Tafel plots.

In this contribution, we will discuss and compare several approaches to achieve the closest approximation to the desired steady state. These approaches will be showcased with the benchmark system of a polycrystalline Pt sample in an aqueous sulphuric acid solution.

O 97.4 Fri 10:30 TRE/PHYS

Exploring the Surface Structure of Ni Anodes and the Role of pH for Alkaline Oxygen Evolution Using SERS — •Justus Leist, Annika Neufischer, Roman Jocher, Benjamin Schilling, Timo Jacob, and Albert Engstfeld — Ulm University, Institute of Electrochemistry, Ulm, Germany

Sustainable hydrogen can be generated by electrochemical water splitting, but the process is typically limited by the sluggish kinetics of the oxygen evolution reaction (OER) at the anode. To avoid reliance on noble-metal catalysts such as Ir and Ru, Ni-based catalysts have attracted considerable interest due to their abundance and efficiency. Under OER conditions, where the Ni anode surface is accepted to be NiOOH, Raman spectroscopy enables *in situ* monitoring of both the surface structure and possible OER intermediates. In this work, using Surface-enhanced Raman spectroscopy (SERS) combined with DFT, we challenge the assumed presence of NiOOH under OER conditions.[1]

To probe the atomic composition of the oxidized Ni anodes, isotope-labelled Raman experiments were performed, revealing the absence of hydrogen in the lattice. The presence of NiO*, rather than NiOOH, is further supported by DFT-calculated spectra. Additionally, we illustrate that a band previously attributed to an OO- species is more likely related to overtones. By varying the pH from alkaline to near-neutral conditions, we examine the impact of pH on the Raman spectra during the OER and discuss these changes in relation to the vibrational Stark effect and possible OER intermediates.

O 97.5 Fri 10:45 TRE/PHYS

Optimizing oxygen vacancies through grain boundary engineering to enhance electrocatalytic nitrogen reduction — •Xiu Zhong[1], Fu Yang[2], and Yong Lei[1] — [1]Institut für Physik & IMN MacroNano (ZIK), Technische Universität Ilmenau, Ilmenau 98693, Germany — [2]School of Environmental and Chemical Engineering, Jiangsu University of Science and Technology, Zhenjiang, Jiangsu 212100, China

This study develops an efficient N2-reduction catalyst by in-situ anchoring ultrafine MoO2 nanograins on N-doped carbon fibers. Optimized thermal treatment generates abundant grain boundaries that increase oxygen-vacancy concentration, enhance electron transfer, and create highly active N2-trapping sites. The optimal MoO2/C700 catalyst delivers superior performance, achieving an NH3 yield of 173.7 μg h-1 mgcat -1 and a Faradaic efficiency of 27.6% at -0.7 V vs. RHE in 1 M KOH. In-situ XPS and DFT confirm the electronic-structure modulation and strong N2-oxygen-vacancy interaction, revealing electron transfer between adsorbed nitrogen and Mo(IV). Correlating activity with interfacial effects further clarifies the origin of enhancement. The catalyst also shows stable operation for 60 h, demonstrating the promise of grain-boundary engineering to boost oxygen vacancies for efficient and sustainable electrochemical ammonia synthesis.

O 97.6 Fri 11:00 TRE/PHYS

Investigating the Role of Nuclear Quantum Effects at Zinc Oxide-Water Interfaces with High-Dimensional Neural Network Potentials — •Jan Elsner[1,2] and Jörg Behler[1,2] — [1]Theoretische Chemie II, Ruhr-Universität Bochum, Germany — [2]Research Center Chemical Sciences and Sustainability, Research Alliance Ruhr, Germany

Zinc oxide is a promising material for sustainable hydrogen production via catalytic water splitting. The interface of ZnO with water exhibits complex dynamical behaviour, including water dissociation and recombination, as well as long-range proton transport. Previous studies [1] have elucidated these mechanisms using High-Dimensional Neural Network Potentials (HDNNPs), which enable simulations at the system sizes and timescales needed for statistically converged interfacial properties. However, the validity of the classical approximation for atomic nuclei in such systems, particularly for describing interfacial proton transfer (PT), remains poorly understood. Here, we employ a new efficient parallel implementation of path-integral molecular dynamics with HDNNPs [2] to investigate the role of nuclear quantum effects (NQEs) at the ZnO-water interface. We show that NQEs significantly lower free energy barriers for PT, and discuss the resulting implications for the interfacial dynamics of the system.

Linking Water Structure to Proton-Coupled Electron Transfer at Metal Interfaces — •Julius Lonnes[1,2], Nicolas G. Hörmann[1], and Karsten Reuter[1] — [1]Fritz-Haber-Institut der MPG — [2]Technische Universität München

Understanding the kinetics of interfacial electrochemical reactions is essential for optimizing technologies such as fuel cells and batteries. To this end, the interfacial water structure plays a key role in determining the effects of pH and electrolyte cations on reaction rates, yet the mechanistic link between water arrangement and reaction barriers remains unclear. By examining the acidic Volmer step on Pt(111) and tuning the hydrogen-bond network surrounding the proton, we uncover how interfacial solvation modulates electrochemical activation barriers. We find that proton stability at the metal-water interface strongly influences the barrier height, a relationship that can be rationalized with Hammond's postulate:[1] variation in electrochemical potential shifts the transition state position along the reaction coordinate, altering its sensitivity to local solvation structure. We establish that interfacial solvation is a decisive factor in determining electrochemical activation energies, advancing fundamental understanding of proton-coupled electron transfer at charged interfaces.

O 97.8 Fri 11:30 TRE/PHYS

Understanding of degradation of catalyst/semiconductor interfaces — Sergej Levashov[1], Tim Rieth[1,2], Ian D. Sharp[1,2], and •Johanna Eichhorn[1] — [1]TUM School of Natural Sciences, TU Munich — [2]Walter Schottky Institute, TU Munich

The performance of photoelectrochemical (PEC) materials are governed by interfacial processes where atomic structure, electronic states, and chemical reactions meet. Local defects and dynamic surface transformations at the nanoscale can dominate charge transfer and often trigger degradation under operating conditions. Accessing such mechanisms requires in-situ/operando techniques that probe interfacial structure and dynamics with nanoscale resolution. We employ in situ scanning probe microscopy to study the interfacial stability of TiO2/Pt photocathodes by monitoring local surface transformations and detachment events during operation. Pt catalysts are deposited on conformal TiO2 coatings either by sputtering, yielding continuous films, or by atomic layer deposition (ALD), forming discrete nanoislands and enabling atom-efficient utilization of precious metals. Under PEC conditions, both architectures show comparable onset potentials and saturation current densities, yet chronoamperometry reveals an enhanced long-term stability for the nanostructured ALD-Pt electrodes. We attribute this contrasting behavior to different bubble formation and detachment dynamics at the catalyst-semiconductor interface. These nanoscale insights highlight the importance of interfacial and morphological engineering, as well as the necessity of controlling reaction processes, to achieve durable and efficient PEC material systems.

O 97.9 Fri 11:45 TRE/PHYS

An Analytical Description for Atomic Diffusion involved Peaks in Cyclic Voltammograms: the Reversible Place-Exchange on Pt(111) — Jon Bjarke Valbaek Mygind[1], Francesc Valls Mascaró[2], Gerard J. Verbiest[3], and •Marcel J. Rost[4] — [1]Catalan Institute of Nanoscience and Nanotechnology, Campus UAB, Barcelona, Spain — [2]Faculty of Physical Chemistry, University of Innsbruck, Innsbruck, Austria — [3]Department of Precision and Microsystems Engineering, Delft University, Delft, The Netherlands — [4]Huygens-Kamerlingh Onnes Laboratory, Leiden University, Leiden, The Netherlands

Cyclic voltammetry (CV) is one of the most powerful tools for the experimental investigation and characterization of electron transfer processes in electrochemistry. As the unique electrochemical fingerprint of a particular system is given by specific (current) peaks in the cyclic voltammogram, it is not surprising that great effort is done to understand, describe, and model these peaks. However, the underlying thermodynamic and kinetic processes make this a difficult task, especially when features in the fingerprint change with the applied CV sweep rate. Here we show, on the example of the reversible Place-Exchange peak, a precursor in the electrochemical oxidation of the Pt(111) surface, that a combination of a Frumkin isotherm followed by an Arrhenius (atomic) diffusion process delivers a rather good description. We present an analytical theory that fits all peaks of all CVs, measured with different sweep rates, with only six fit variables. These variables deliver hard quantitative thermodynamic values.

Machine Learning the Energetics of Electrified Solid-Liquid Interfaces — •Nicolas Bergmann[1], Nicéphore Bonnet[2], Nicola Marzari[2], Karsten Reuter[1], and Nicolas G. Hörmann[1] — [1]Fritz-Haber-Institut der MPG, Berlin — [2]Theory and Simulation of Materials, EPFL, Lausanne

Machine learning interatomic potentials (MLIPs) accelerate many aspects of computational chemistry. However, MLIPs fail to describe the biases introduced at applied potential conditions for typical electrocatalytic systems, where effects of the inner double layer play a critical role [1]. Here, we present the "Response Analysis in z-ORientation" (RAZOR) model [2], which machine-learns the work function, the first-order energy change to bias charges q. RAZOR is stabilized by additionally learning the atomic force derivative to q, equivalent to Born effective charges. The approach extends MLIPs to the variable charge case, by adding bias-induced energy and force changes to traditional zero-bias MLIPs. This enables large-scale molecular dynamics simulations at finite bias. We demonstrate RAZOR's capabilities by investigating OH adsorption on Cu(100) and explicit Pt(111)-H_2O interfaces, faithfully recreating *ab initio* and experimental results.

Entropy-Enthalpy Relationships in Heterogeneous Electrocatalysis: A Case Study of the Hydrogen Evolution Reaction — •Andrew J. Wong, Barbara Sumić, Elias Diesen, Nicolas G. Hörmann, Hendrik H. Heenen, Karsten Reuter, and Vanessa J. Bukas — Fritz-Haber-Institut der MPG, Berlin

Temperature is a key parameter in industrial electrolyzers. And yet, the vast majority of mechanistic lab-scale studies ignores temperature variations by operating at room temperature. This is surprising since existing experimental evidence has shown that even modest heating can significantly affect the rate and selectivity of electrocatalytic reactions. Understanding the origin of such effects is crucial for advancing fundamental electrocatalysis and exploiting temperature as a control parameter. Here, we explore temperature effects on the hydrogen evolution reaction (HER) by developing a simple mean-field microkinetic model based on first-principles energetics. An Arrhenius analysis on the HER rates across different metal catalysts reveals distinct entropy-enthalpy correlations, reflected in the apparent activation enthalpy and entropy-dependent prefactor. Despite the simplicity of our model, these trends are in remarkable qualitative agreement with experiments. A degree of rate control analysis explains the kinetic fingerprints in terms of a change in the rate-determining step, inducing a shift in kinetic regime. We thus conclude that the enthalpy-entropy compensation effect is explained, at least to a first approximation, by the surface kinetics. Our work overall highlights the subtle interplay between temperature, applied potential, and catalyst reactivity.

Electron-phonon interactions in the time domain: from non-equilibrium phonon dynamics to theoretical spectroscopy — •Fabio Caruso — University of Kiel, Germany

First-principles simulations of electron-phonon interactions (EPI) are key to clarifying the microscopic origin of the ultrafast electron and phonon dynamics revealed by pump-probe experiments in crystalline solids [1]. In this talk, I will discuss recent advances in ab-initio simulations of the EPI and their application to light-driven electron and lattice dynamics. Building on recent progress in many-body theory and software, predictive atomistic simulations of complex non-equilibrium phenomena have now become feasible. I will highlight, in particular, non-thermal phonon populations [2], coherent phonons [3], and ultrafast polaron formation as representative examples. This progress forms the basis for a strong synergy between ab-initio theory and experimental ultrafast science.

Coherent phonon control beyond amplitude saturation in a sliding ferroelectric — •Jan Gerrit Horstmann[1,2], Christoph Emeis[3], Andrin Caviezel[1], Quintin Meier[4], Nicolas Wyler[1], Thomas Lottermoser[1], Fabio Caruso[3], and Manfred Fiebig[1] — [1]Department of Materials, ETH Zurich, Vladimir-Prelog-Weg 4, Zurich, 8093, Switzerland — [2]University of Würzburg, Institute of Physical and Theoretical Chemistry, Am Hubland, 97074 Würzburg, Germany — [3]Institute of Theoretical Physics and Astrophysics, Kiel University, Leibnizstraße 15, Kiel, 24118, Germany — [4]Institut Néel, C.N.R.S-Université Grenoble Alpes, BP 166, Grenoble, 38042, France

Intense optical excitation can drive quantum materials into regimes where the usual linear relation between photo-excited carriers and lattice-driving forces no longer applies. Using time-resolved second-harmonic generation, we observe that the interlayer sliding phonon governing sliding ferroelectricity in WTe_2 saturates and even decreases at high single-pulse fluence. Density functional theory traces this nonlinearity to band-specific electron-phonon coupling that produces competing lattice forces. By dividing the same total fluence into two well-timed pulses, we avoid populating counteracting electronic states and achieve significantly larger coherent phonon amplitudes. The resulting enhanced sliding motion reveals anharmonic phonon coupling far from equilibrium and shows that nonlinear limits in driven solids can be overcome through temporal shaping of the optical excitation.

O 98.3 Fri 10:15 TRE/MATH

Ultrafast x-ray sonography: A novel technique to spatially resolve phase heterogeneity on picosecond timescales — •Maximilian Mattern[1], Angel Rodriguez-Fernandez[2], Roman Shayduk[2], Wonhyuk Jo[2], Vojtech Uhlir[3], Jon Ander Arregi[3], Anders Madsen[2], Daniel Schick[1], and Jan-Etienne Pudell[2] — [1]Max-Born-Institut, Germany — [2]European XFEL, Germany — [3]CEITEC BUT, Czech Republic

Laser-induced heterogeneities play an important role for ultrafast dynamics especially of first-order phase transitions due to the phase co-existence during nucleation. However, their probing on picosecond time and nanometer length scales is challenging.

To address this challenge, we introduce ultrafast X-ray sonography. It combines well-established ultrafast hard-X-ray diffraction with a propagating strain pulse as a universal and non-invasive structural marker. The signatures of the strain pulse in the phase-specific lattice dynamics localizes the different phases in both space and time. This non-invasive pump-probe technique can follow the coherent growth and stochastic nucleation of structural domains on picosecond timescales with almost no requirements for sample preparation and is broadly applicable to a broad class of materials, provided that the coexisting phases exhibit distinguishable diffraction signatures. As a benchmark, we apply this approach to the antiferromagnetic-to-ferromagnetic magneto-structural phase transition in FeRh and identify the ferromagnetic phase to nucleate at the surface as columnar domains of approximately 30nm diameter.

O 98.4 Fri 10:30 TRE/MATH

Ultrafast energy flow among electrons and phonons in a Pb/Si nanoscale heterosystem — •Christian Brand[1], Mohammad Tajik[1], Tobias Witte[1], Laurenz Rettig[2], Birk Finke[1], Björn Sothmann[1], Uwe Bovensiepen[1], and Michael Horn-von Hoegen[1] — [1]Department of Physics, University of Duisburg-Essen, Germany — [2]Department of Physical Chemistry, Fritz Haber Institute, Germany

Microscopic excitations in condensed matter interact on ultrafast time scales. In this study, we employed time-resolved photoelectron spectroscopy and ultrafast electron diffraction to probe the spatially confined dynamics of electrons and phonons in ultrathin epitaxial Pb films on Si(111) subsequent to fs-laser excitation. Spatial confinement is crucial here, as without it, the energy flow into the unexcited bulk would obscure the transient dynamics and prevent targeted investigation. Electrons dissipate their excess energy within 400 fs, while lattice vibrations gradually build up over 3-8 ps. During this time gap, energy is transiently stored in high-frequency phonon modes, as captured by a three-temperature model. The transient electron temperature provides direct experimental access to the occupation of these phonons after equilibration at ≈ 3 ps. Subsequent excitation of low-frequency phonons and full lattice thermalization at ≈ 20 ps are governed by anharmonic phonon-phonon coupling within the Pb film.

O 98.5 Fri 10:45 TRE/MATH

Ultrafast manipulation of topological transport properties in Td-MoTe2 via coherent phonon excitation — •Huimin Wang[1], Matthew Day[2,3], Juan Aranzadi[1], James McIver[2,3], and Michael Sentef[1] — [1]Institute for Theoretical Physics and Bremen Center for Computational Materials Science, University of Bremen, Bremen, Germany — [2]Department of Physics, Columbia University, New York, NY, USA. — [3]Max Planck Institute for the Structure and Dynamics of Matter, CFEL, Hamburg, Germany

Ultrafast control of topological properties in quantum materials has emerged as a promising route toward dissipative-free and fast optoelectronic functionalities. In type-II Weyl semimetals such as Td-MoTe*, selective photoexcitation of coherent phonons offers an efficient non-thermal pathway to drive topological phase transitions by modifying lattice symmetry. Yet the microscopic origin of the laser-induced interlayer shear mode*central to this process*remains unclear, with both electron*phonon coupling (EPC) and strong phonon anharmonicity expected to contribute. Here, using real-time TDDFT combined with non-adiabatic molecular dynamics, we map out the excitation pathways of this

shear mode under varying photon energies, polarizations, and field strengths. We reveal cooperative EPC and phonon*phonon mechanisms that enable control of the phonon phase and amplitude. The resulting lattice dynamics induce shifts of Weyl node positions and associated nonlinear photocurrents, providing insight into observed ultrafast Hall responses.[1]Nature 565, 61*66 (2019). [2]Nat. Commun., vol. 12, p. 1885, 2021.[3]Phys. Rev. X, vol. 9, no. 2, p. 021036, 2019.

O 98.6 Fri 11:00 TRE/MATH

Competition of electron-electron and electron-phonon scattering in thermalization of laser-excited electrons — •Christopher Seibel, Tobias Held, Markus Uehlein, Sebastian T. Weber, and Baerbel Rethfeld — Department of Physics and Research Center OPTIMAS, RPTU University Kaiserslautern-Landau, 67663 Kaiserslautern, Germany

When an ultrashort laser pulse irradiates a metal, electrons are excited to a state of strong nonequilibrium. According to the common picture, they thermalize subsequently towards a hot Fermi distribution on a femtosecond timescale and transfer energy to the still cold lattice on a picosecond timescale. Often these two processes are considered to be independet and driven by different interactions. Electron-electron scattering is considered responsible for the thermalization, whereas electron-phonon scattering is considered responsible for the energy transfer to the lattice. However, there are indications that these two processes influence each other and can act on similar timescales.

We use a kinetic description based on full Boltzmann collision integrals to trace the dynamics of the electron distribution during the thermalization after ultrashort laser excitation. We show that electron-electron and electron-phonon scattering have different effects on the distribution, which both lead to thermalization. Comparing various excitation fluences, we find that the thermalization times of the two processes exhibit an opposite fluence dependence and can become comparable for weak excitations.

O 98.7 Fri 11:15 TRE/MATH

Interfacial charge dynamics in hybrid plasmonic-excitonic nanostructures — •Tommaso Pincelli[1], Alessandro De Vita[1], Gian Marco Pierantozzi[2], Manuel Izquierdo[3], Pavel Trofimov[4], Trideep Kadwe[4], Hélène Seiler[4], Niclas S. Müller[4], Caterina Cocchi[5], Laurenz Rettig[6], Martin Wolf[6], Ralph Ernstorfer[1], and Giancarlo Panaccione[2] — [1]Technische Univ. Berlin — [2]IOM - CNR — [3]EuXFEL — [4]Freie Univ. Berlin — [5]Fredrich Schiller Univ. Jena — [6]Fritz Haber Inst. - MPG

Hybrid interfaces that merge plasmonic surfaces with 2D semiconductors are pivotal in energy materials research, allowing to tailor local fields and functionalize charge-transfer excitations. In this work, we exfoliate few-layer WSe_2 on a plasmonic lattice of nanostructured Au in UHV. Angle-resolved reflectivity reveals a rich photonic band structure matching finite-element calculations. Using time and angle resolved photoemission spectroscopy (trARPES), we observe an ultrafast quench of excitonic signatures and hints of rapid interfacial charge transfer. Angle-integrated trPES at higher photon energies allows access to the buried interface by tracking shallow core levels. Notably, the plasmonic lattice induces a pronounced slowing of Au 4f peak shifting dynamics compared with unpatterned Au, suggesting a bottleneck in the interfacial charge transfer. These results highlight the potential of hybrid interfaces as flexible platforms for engineering optoelectronic responses at ultrafast timescales. We acknowledge the Energy Materials community proposal collaboration, the teams of SXP@EuXFEL and HEXTOF@FLASH.

O 98.8 Fri 11:30 TRE/MATH

Non-equilibrium electron dynamics in antenna-reactor plasmonic photocatalysts — •Henry T. Snowden[1] and Reinhard J. Maurer[1,2] — [1]University of Warwick, UK — [2]University of Vienna, AT

Antenna-reactor nanoparticles are a promising form of plasmonic photocatalyst, combining strong light absorption and high catalytic activity. A key materials design question is the correct nanoparticle geometry with proposals ranging from core-shell structures to nanoalloys. Optimal photocatalysts combine strong light absorption, effective carrier transport, and long carrier lifetime. Here, we study the non-equilibrium electron dynamics after pulsed laser excitation using the Athermal Electron Model (AthEM), which explicitly considers thermal and non-thermal electrons in contact with a phonon bath, and a laser source term. Electron-electron scattering effects are considered at the level of the relaxation time approximation. We investigate how athermal electron-hole pair distributions evolve in different classes of promising materials according to the interplay of electron-electron and electron-phonon scattering. Based on our findings, we propose optimal materials compositions and photocatalyst geometries.

O 98.9 Fri 11:45 TRE/MATH

Influence of sulphur vacancies on ultrafast charge separation in WS2-graphene heterostructures — •Johannes Gradl[1], Niklas Hofmann[1], Leonard Weigl[1], Camilla Coletti[2], Raül Perea-Causín[3], Ermin Malic[4], and Isabella Gierz[1] — [1]University of Regensburg, Regensburg, Germany — [2]Istituto Italiano di Tecnologia, Pisa, Italy — [3]AlbaNova University Center, Stockholm, Sweden — [4]University of Marburg, Marburg, Germany

Ultrafast charge separation following photoexcitation, commonly observed in van der Waals heterostructures, is a key process for future optoelectronic devices that rely on the conversion of light into electricity. While electron and hole transfer rates are largely determined by band alignment and interlayer hybridization, recent experiments have revealed that defects critically affect the lifetime of the charge-separated state [1][2]. A microscopic understanding of defect-assisted charge transfer, however, remains elusive. We disentangle the role of sulphur vacancies on ultrafast charge separation and recombination in WS2-graphene heterostructures by (i) systematically increasing the defect density and (ii) switching the defect-assisted charge transfer channel on and off. Using time-resolved ARPES, we probe the resulting charge-transfer dynamics on ultrafast time scales directly in the band structure.

O 98.10 Fri 12:00 TRE/MATH

Formation and thermalization of non-equilibrium excitonic occupations — •Paul Werner[1], Wiebke Bennecke[1], Jan Philipp Bange[1], Giuseppe Meneghini[2], David Schmitt[1], Marco Merboldt[1], Anna Seiler[1], AbdulAziz AlMutairi[3], G. S. Matthijs Jansen[1], Junde Liu[1], Daniel Steil[1], Stephan Hofmann[3], R. Thomas Weitz[1], Ermin Malic[2], Stefan Mathias[1], and Marcel Reutzel[3] — [1]I. Physikalisches Institut, Georg-August Universität Göttingen, Germany — [2]Fachbereich Physik, Philipps-Universität Marburg, Germany — [3]Department of Engineering, University of Cambridge, United Kingdom

Upon optical excitation, bright excitons can scatter into lower energy, potentially dark, exciton states. In these formation and relaxation processes, non-equillibrium exciton populations play a major role, but remain largely elusive because they are inaccessible by most spectroscopic methods. In this work we provide direct access to the formation and thermalization of non-equilibrium exciton states in 2H-homobilayer MoS_2. Using time-resolved momentum microscopy and microscopic many-particle calculations, we reveal the fingerprint of non-equillibrium exciton distributions and quantify their formation and relaxation timescale [1].

[1] Werner *et al.*, arXiv:2505.06074 (2025).

O 99: Spins on surfaces at the atomic scale III

Time: Friday 9:30–12:30 Location: WILL/A317

O 99.1 Fri 9:30 WILL/A317

Measuring magnetic exchange forces of individual quantum spins — •Nicolaj Betz[1,2], Lukas M. Veldman[1,2], Milton Aguliar[3], Eric Lutz[3], Susanne Baumann[1], and Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany. — [2]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart, Stuttgart, Germany. — [3]University of Stuttgart, Institute for Theoretical Physics, Stuttgart, Germany

Dynamics of single atomic spins are governed by interactions with the spins immediate, i.e. atomic scale environment. In that, spin-polarized scanning tunnelling microscopy (STM) can give access to some of these interactions, e.g. those between coupled spins, and it can also be used to detect the dynamics in form of individual spin switches. Atomic force microscopy (AFM) on the other hand, gives access to atomic-scale forces, for example the magnetic exchange interaction [1,2]. Here, we show magnetic exchange force detection on a dynamically switching single Fe atom on MgO/Ag(100). We can tune this spin to undergo a ground state reversal as a function of exchange interaction with the tip. We find that the switching spin interacts strongly with the AFM cantilever. Thus, access to these forces provides a new avenue to study dynamically switching single atomic quantum spins revealing information about the interplay between an atom's interactions and the dynamics of the spin.

O 99.2 Fri 9:45 WILL/A317

Tip induced f-π interaction of $YbPc_2$ Molecules utilizing STM — •Jonas Arnold[1], Kwan Ho Au-Yeung[1], Wantong Huang[1], Eufemio Moreno Pineda[1], Christoph Sürgers[1], Wolfgang Wernsdorfer[1], Mario Ruben[2], and Philip Willke[1] — [1]Physikalisches Institut, Karlsruhe Institute of Technology, Karlsruhe, Germany — [2]Institute of Nanotechnology, Karlsruhe Institute of Technology, Karlsruhe, Germany

Individual molecules constitute excellent building blocks for quantum technologies thanks to their small size, reproducibility and the benefit of self assembly. A promising class are rare-earth bis-phthalocyanine complexes (1). In this work, we investigate $YbPc_2$ molecules using a mK- scanning tunneling microscope (STM) to identify potential indicators of a magnetic signature. In the gas phase, the $YbPc_2$ molecule is expected to exhibit a radical spin localized at its ligands, an f-shell electron spin S = 1/2 as well as a nuclear spin (I = 1/2 and 5/2) for certain isotopes. Thus, this system is a potential candidate for a spin cascade (1). We perform measurements on self-assembled multi-layer islands of $YbPc_2$ on Ag(001) and MgO/Ag(001). We find that the proximity of the STM tip changes the spin state of the molecule by tuning states close to the Fermi level (2). We identify the emerging spectral features close to zero bias as inelastic electron tunneling excitations that result from the combined f-π system. This mechanism can be found for the first, second and third molecular layer on Ag(001) as well as MgO/Ag(001).

Quantifying the interplay between atomic-scale magnetism and Josephson transport atom-by-atom — •Zhengyuan Liu, Sebastian Scherb, Manuel Steinbrecher, Nadine Hauptmann, and Alexander Khajetoorians — IMM, Radboud University Nijmegen, the Netherlands

Josephson transport can locally be affected by the presence of magnetic moments in the junction. For example, it was shown that the individual magnetic impurity, and the Yu-Shiba-Rusinov (YSR) excitations they induce in the superconductor can be used to induce a superconducting diode effect [1]. Furthermore, an intrinsic phase shift of π in its ground state can exhibit when a ferromagnetic layer with certain thickness is introduced in the Josephson junction, known as the π-junction [2]. Here, we study the effect of individual and coupled magnetic atoms on the Josephson transport between a superconducting tip and superconducting surface, using scanning tunneling microscopy. We study the evolution of the YSR states going from an individual impurity to a magnetic nanostructure. We correlate this evolution to changes in the Josephson junction properties locally, by using spatially-dependent I-V spectroscopy. We also review the local diode effect induces in these structures. [1] Trahms, M et al. Nature 615, 628*633 (2023). [2]Ryazanov et al. Phys. Rev. Lett. 86, 2427 (2001)

O 99.4 Fri 10:15 WILL/A317

Exchange-field model for electron spin resonance scanning tunneling microscopy — •Christoph Wolf[1,2], Jose Reina-Galvez[3], Xue Zhang[4], Jan Martinek[5], and Nicolas Lorente[6] — [1]Center for Quantum Nanoscience, Institute for Basic Science (IBS), Seoul 03760, Republic of Korea — [2]Ewha Womans University, Seoul 03760, Republic of Korea — [3]Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — [4]Institute of Molecular Physics, Polish Academy of Science, Smoluchowskiego 17, 60-179 Poznan, Poland — [5]Spin-X Institute, China University of Technology, Guangzhou, China — [6]Centro de Fisica de Materiales, CFM/MPC (CSIC-UPV/EHU), Spain

Since the first experimental demonstration of electron spin resonance in a scanning tunneling microscope the understanding of how spin transitions are driven by oscillating electric fields has gone through several evolutions. In this talk, I will show how an exchange-field model can explain the magnetoelectric coupling between the electric field and a spin impurity. This model is based on an Anderson impurity model and non-equilibrium transport using magnetic electrodes. When the hopping between a magnetic electrode and the impurity is modulated on resonance with the Zeeman splitting one obtains an effective magnetic field that can coherently drive the spin. The sign and magnitude of the exchange field depends on the applied DC bias which gives full control over the position of the resonance and potentially can be used for DC-based quantum-logic operations.

O 99.5 Fri 10:30 WILL/A317

Revealing spatial inhomogeneities in superconducting 2H-NbS_2 using magnetic sensor atoms — •Werner M.J. van Weerdenburg, Margarete Huisinga, Constantin Flommersfeld, Lisa M. Rütten, and Katharina J. Franke — FachbereichPhysik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany

Transition metal dichalcogenides (TMDCs) are an interesting material class in which multiple quantum phases such as charge-density-wave (CDW) order, superconductivity and pair-density-wave order may coexist [1]. Within the family of superconducting TMDCs, 2H-NbS_2 stands out as the only material that does not develop a CDW phase, but this interpretation is challenged in the presence of defects, since the material is very close to a lattice instability [2,3].

Here, we present how magnetic adatoms on a superconducting TMDC substrate can be used to investigate spatial inhomogeneities of 2H-NbS_2. By manipulating an individual Fe atom between binding sites with the tip of a scanning tunneling microscope, we probe the Yu-Shiba-Rusinov (YSR) states and their response to surface variations with high energy resolution. The sensitivity of YSR states to the crystal field, density of states and disorder allows us to analyze the relation between the YSR energies and the properties of the substrate, and to find indications of local charge-density-wave nucleation around intrinsic defects.

Magnetic quantum corrals on a proximity-superconducting Rashba surface alloy — •Jinkyung Kim, Harim Jang, Jens Wiebe, and Roland Wiesendanger — Department of Physics, University of Hamburg, Hamburg, D-20355, Germany

Quantum corrals can confine and resonate surface-state electrons at discrete eigenenergies. When coupled to superconducting substrates, quantum corrals can be used to sculpture Yu-Shiba-Rusinov (YSR) in-gap states as well as spin-degenerate Andreev bound states, referred to as Machida-Shibata (MS) states, due to proximity-induced Cooper pairing [1,2]. Here, we investigated quantum corrals crafted from Fe atoms on a proximity-superconducting BiAg2/Ag/Nb(110) heterostructure. Multiple in-gap states emerge with similar numbers of antinodes as in the eigenmode closest to the Fermi energy. They show an almost perfect spatial antiphasing between the particle- and hole-like components, reminiscent of long-range YSR states of individual magnetic atoms [3]. By further studying how these in-gap states evolve with corral size and the 3d metal atom species, our work characterizes the interplay between YSR and MS states within the quantum corral. [1] L. Spin and Charge States of Open-Shell Nanographenes over Functional Substrates — •Francisco Romero-Lara, Trisha Sai, Katerina Vaxevani, Dongfei Wang, Jon Ortuzar, Leonard Edens, Stefano Trivini, Fabian Schulz, and Jose Ignacio Pascual — CIC nanoGUNE, 20018 San Sebastián, Spain

Atomically precise open-shell nanographenes are platforms hosting spin states, which can be manipulated by local probes and by tuning their local environment. Here, we present the fabrication of aza-triangulenes-based nanostructures over two novel substrates with potential control over their charge and spin state: a rare-earth-gold alloy monolayer and a superconducting surface. The aza-triangulene platforms can host several weakly interacting spin states and a doublet ground state sensitive to Jahn-Teller distortion. We use scanning tunnelling microscopy to resolve their Kondo and spin excitation spectrum. We also resolve the presence of Yu-Shiba-Rusinov (YSR) states inside the proximity gap on the superconducting surface. Owing to an inhomogeneous local contact potential difference, the nanographenes on rare-earth-gold alloy surfaces appear with varying charge states depending on their adsorption site, which is also translated into variations of the spin ground state. Over a superconducting substrate, sub-gap spectral maps reveal with high precision their YSR excitations. They are interpreted based on a model theory as reflecting, in some cases, Jahn-Teller distortions. Overall, our results highlight the potential of unconventional substrates for on-surface nanographene synthesis and for tailoring and probing their intrinsic spin states.

Extracting mechanical work from quantum spin switching of a single atom — Nicolaj Betz[1,2], Lukas M. Veldman[1,2], Milton Aguilar[3], Eric Lutz[3], Susanne Baumann[1], and •Sebastian Loth[1,2] — [1]University of Stuttgart, Institute for Functional Matter and Quantum Technologies — [2]Center for Integrated Quantum Science and Technology (IQST), University of Stuttgart — [3]University of Stuttgart, Institute for Theoretical Physics

Stochastic dynamics are ubiquitous in atomic-scale systems, often arising from dissipative processes through which energy is lost to the environment. Harnessing such dynamics to perform work is at the heart of molecular motors and quantum heat engines. Here, we demonstrate that a single magnetic atom can function as an electric motor that converts spin excitations into mechanical oscillations of a macroscopic cantilever. We couple an Fe atom on MgO/Ag(100) via magnetic exchange interaction to the tip of a combined atomic force (AFM) and scanning tunneling microscope (STM) at milli-Kelvin temperatures. Current-induced inelastic electron tunneling induces cyclic spin switching, creating an alternating exchange force that transfers energy between the quantum spin and the AFM cantilever with a power output sufficient for free-running operation. This single-atom electric motor bridges the quantum-classical divide and provides a platform for studying energy transfer in hybrid quantum-classical systems.

O 99.9 Fri 11:30 WILL/A317

Tuning the magnetic excitation of a single atom by local gating — •Anna M. H. Krieg, Hermann Osterhage, Julian H. Strik, Niels P. E. van Mullekom, Ben Verlhac, and Alexander A. Khajetoorians — Institute for Molecules and Materials, Radboud University, Nijmegen, the Netherlands

The description of single-atom magnetism depends on the interplay of various degrees of freedom and the balance of different interactions. This includes the interplay between the orbital, spin and charge degrees of freedom, as well as the balance between spin-orbit coupling, hybridization, and different exchange interactions, such as Hund's and Kondo exchange. To date, the strategy to change the magnetic behavior of a single atom is to explore different atom/surface combinations. However, in this way, nearly all these parameters are fixed by the material system and when changing the material system, the entire set of parameters changes. Here, we tune the local electrostatic potential in order to modify the magnetic excitations and tunneling transport of individual Fe atoms. We start with Fe atoms on the surface of InSb(110), and characterize its magnetic excitations as a function of magnetic field. We then harness a newly developed quantum simulator platform, based on patterning Cs atoms on the surface of InSb. We show that by varying the local density of Cs on InSb, we can tune the magnetic excitation of an individual Fe atom. These results serve as a starting point to develop quantum simulation to study magnetic models in which the spin, charge, and orbital degree of freedom can be tuned.

Spin dynamics of atomic defects in monolayer MoS_2 — •Johanna Matusche[1,2], Kwan Ho Au-Yeung[1,2], Wantong Huang[1,2], Paul Greule[1,2], Jonas Arnold[1,2], Lovis Hardeweg[1,2], Máté Stark[1,2], Luise Renz[1,2], Affan Safeer[3], Daniel Jansen[3], Jeison Fischer[3], Thomas Michely[3], Wolfgang Wernsdorfer[1,2], Christoph Sürgers[1,2], Johannes Schwenk[1,2], Wouter Jolie[3], and Philip Willke[1,2] — [1]Physikalisches Institut (PHI), Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — [2]Center for Integrated Quantum Science and Technology (IQST), Karlsruhe Institute of Technology, Karlsruhe, Germany — [3]II. Physikalisches Institut, Universität zu Köln, Köln, Germany

Scanning tunneling microscopy (STM) combined with electron spin resonance (ESR) has enabled coherent control of single ad-atoms and single molecules on surfaces [1]. Additionally, recent studies have revealed that defects in monolayer MoS_2 exhibit well-defined spin signatures [2]. In this talk, we combine these two advances for individual point-like defect spins in monolayer MoS_2 on graphene/Ir(111): First, we focus on stochastic resonance spectroscopy (SRS) [3] to periodically drive rapid transitions between spin states. This allows to identify the main relaxation mechanisms and to determine the T_1 relaxation times. Second, pulsed ESR enables coherent control of the defect spins via Rabi and Ramsey sequences, which provides direct access to their T_2 coherence times.

Following Spin Interactions into a Chemical Bond Formation — •Dmitriy Borodin[1], Merve Ercelik[1], Andres Pinar Sole[1], Shadi Fatayer[2], Harald Brune[3], Christoph Wolf[1], Franz J. Giessibl[4], Fabio Donati[1], and Andreas Heinrich[1] — [1]IBS Center for Quantum Nanoscience, Seoul, South Korea — [2]KAUST, Thuwal, Saudi Arabia — [3]EPFL, Lausanne, Switzerland — [4]University of Regensburg, Regensburg, Germany

Exchange interactions are essential for the formation of chemical bonds between atoms and dictate the electronic structure of molecules. In a condensed-matter system, a manifold of exchange mechanisms coexist, ultimately defining the local magnetic structure and phase stability. A particularly interesting interaction occurs between transition metal atoms and rare earth elements, where the nature of magnetic coupling in their alloys remains not fully understood. In this work, we use low-temperature scanning probe microscopy to follow the spin interactions between a tip and an adatom on a surface into a chemical bond. By controlling atom-tip separations on the picometer scale, we continuously tune interaction energies and observe spin pairing between the adatom and the magnetic tip, a situation that is reminiscent of covalent bond formation.

Dark state formation in a zero-field split molecular triplet — •Maria Steiner and Andrea Donarini — Institute of Theoretical Physics, Regensburg University, Regensburg, Germany

In analogy to atomic physics [1], we propose a protocol to prepare and probe a dark state in a single molecule. To this end, we coherently manipulate with a multifrequency magnetic field a three-level system in the V-configuration. Thus, within a density-matrix formalism for open systems, we extend existing protocols developed to probe Rabi oscillations in ESR-AFM on pentacene [2]. The dissipative dynamics of the reduced density matrix are interpreted in terms of multipole expansion and visualized using three intertwined Bloch spheres. We consider a molecule with a zero-field splitting of the first excited triplet. This splitting typically arises from the spatial anisotropy of the frontier orbitals and the spin dipole-dipole interaction between the unpaired electrons. Pentacene is an archetypal example, which, in addition to these properties, also exhibits anisotropic decay to the ground state singlet [3] and thus enables experimental readout of the occupied state [2]. We consider both ideal scenarios and realistic parameterization for ESR-AFM on pentacene to model the expected dark state signature.

Ionic Liquid Surface Science — •Hans-Peter Steinrück — Friedrich-Alexander-Universität Erlangen-Nürnberg

Traditional surface science is often limited to solids, due to the high vapor pressure of conventional liquids or solvents. Quite recently, low-vapor-pressure liquids such as ionic liquids (ILs) or liquid metal alloys have received significant attention as they offer new concepts in catalysis. This contribution focuses on ILs, which are liquid salts with melting points below 100 °C, often even below room temperature. Since their physical and chemical properties can be tailored over a wide range, they represent a fascinating class of liquid materials with interesting applications. Two important concepts in catalysis are the Supported Ionic Liquid Phase (SILP) and Solid Catalyst with Ionic Liquid Layer (SCILL) concepts. In both, a high surface area solid substrate is covered with a thin IL film. In SILP, the film contains a homogeneously dissolved transition metal complex; in SCILL, the film modifies catalytically active surface sites at the catalyst. The interfaces of the IL are thus of critical importance. Due to their extremely low vapor pressure, ILs can be investigated in great detail under well-defined ultrahigh vacuum conditions using surface science methods like angle-resolved XPS, STM, AFM and molecular beam techniques. In this presentation, both the IL/vacuum and the IL/support interfaces are addressed. In the first example, the buoy concept will be introduced, that is, the tailored enrichment of metal complexes at the liquid/vacuum interface. The second example addresses the modification of the properties of single crystal surfaces by an ultrathin IL film.
